Reuter (H.B. 5961b). – 4.5 km W of Seixal, 2.5 km S of Ribeira da Janela, 885 m, branch of *Laurus novocanariensis*, on wood, 13.X.2009, J.P. Priou (J.P.P. 29180, doc. vid.). — **CANADA**: **British Columbia**, 10 km W of Vancouver, University of British Columbia, west side of Walter Gage building, 90 m, branch of *Mahonia dictyota*, on wood, 20.VIII.1994, G. Marson (H.B. 5236). – 11 km NNW of Victoria, Observatory Hill, NW of planetarium, 218 m, twigs and branches of *Arbutus menziesii*, on wood, 28.I.2017, O. & A. Ceska (O.C. 2170126, doc. vid.). — **USA**: **Arizona**, Mogollon Rim, 37 km SSW of Flagstaff, NE of Sedona, 1320 m, branch of *Arctostaphylos patula*, on wood, 8.V.1995, G. Marson (ex H.B. 5733c, M-0276606, **holotype**, anam. substr.).

Orbilia graminis Baral & G. Marson, **sp. nov.**, MB 813537 — Pls 372–373, Map 64

Etymology: referring to the substrate, leaves of *Poaceae*.

Typification: Luxembourg, Koedange, leaves of *Phragmites australis*, 23.V.1994, G. Marson (ex H.B. 5084a, M-0276489, holotype).

Latin diagnosis: *Similis* Orbiliae vibrioidi *sed ascosporae leniter angustiores, corpusculum refringens bacilliforme vel subulatum, cellulae terminales paraphysium leniter longiores. Habitat ad culmos vel folios putridos siccos* Poacearum, *plerumque* Phragmitis australis, *in zona temperata atlantica vel subcontinentali Europae.*

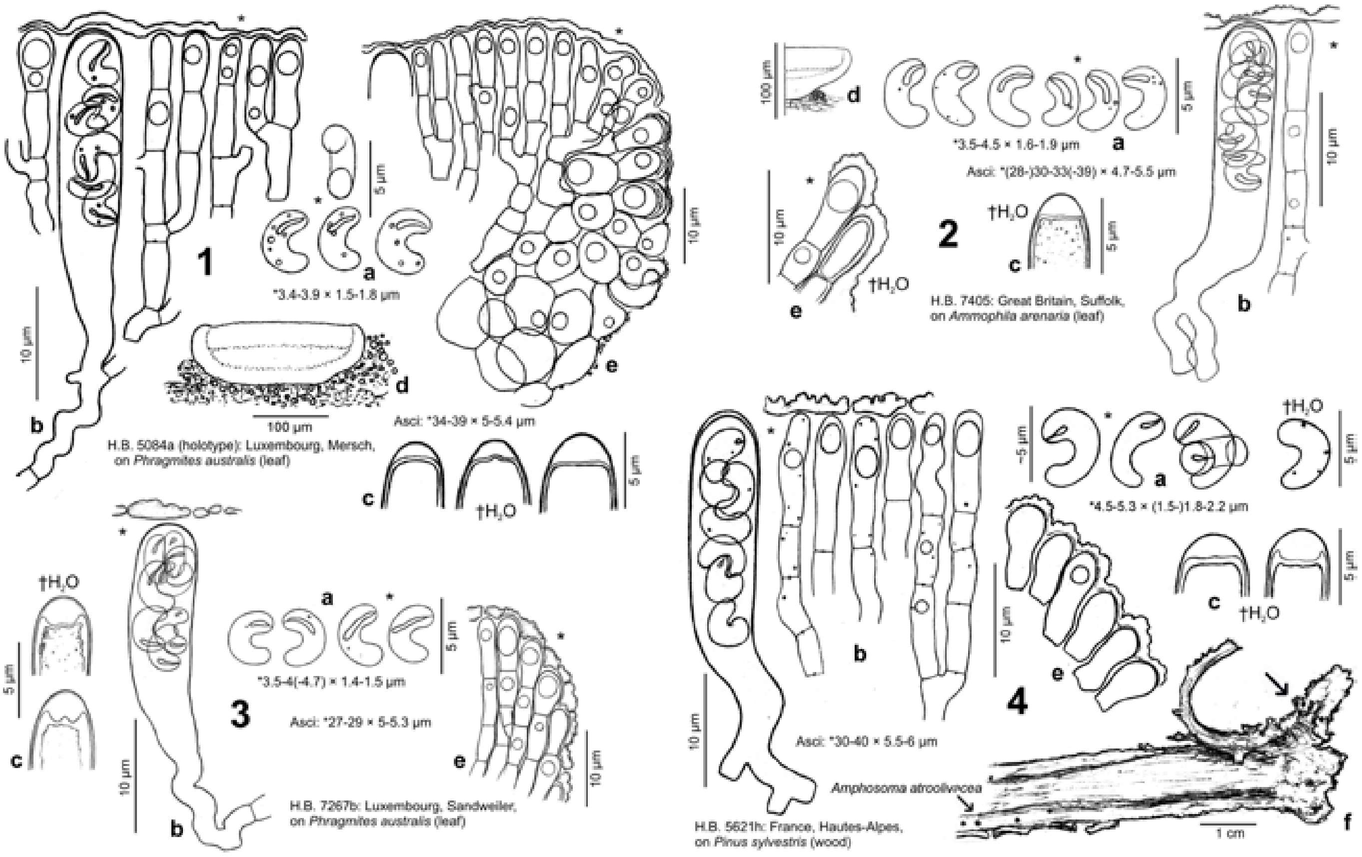

Plate 372. **1–3**: *Orbilia graminis*; **4**: *O.* cf. *graminis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., marginal ectal excipulum; **f**. partially decorticated xeric branch of *Pinus*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.1–0.3(–0.4) mm diam., 0.06–0.1 mm high, pale to light cream or usually pure rose(-orange), round or very slightly lobate, scattered to gregarious; disc flat, margin indistinct or distinct, 0–5 µm rising above disc, smooth; broadly sessile or with ill-defined stipe, superficial or immersed in algal layer; dry pale to bright orange-rose-red. **Asci** *27–39 × (4.7–)5–5.5 µm {3}, †(21–)24–35 × 3.8–4.5(–4.8) µm {4}, (6–)8-spored, spores ± 2–3-seriate, ~3–4 lower spores inversely oriented (upper spores partly crosswise), pars sporifera *13–17 µm long; **apex** (†) hemispherical to slightly conical(-truncate), dome †1.5–2.3 → 1–1.5(–2) µm thick {5}, with or without small apical chamber; **base** with short to long, ± thin, flexuous stalk, L- or h-shaped. **Ascospores** *3.4–4.2(–4.7) × (1.4–)1.5–1.8(–1.9) µm {4}, cashew-shaped, both ends rounded, very strongly curved by (100–)140–180°; **SBs** apically attached to spore wall, *1.8–2.8(–3) × (0.2–)0.3–0.4(–0.5) µm {4}, rod-shaped to vermiform-subulate {5}, straight to medium flexuous, apically narrowed to a ± small point, overmature *1.5 × 0.8 µm, tear-shaped. **Paraphyses** apically uninflated to slightly (to medium) clavate (sometimes spathulate to sublageniform), terminal cells *4–9.5 × 1.5–2.7(–3.2) µm {2}, †1.3–2 µm wide, lower cells *(1.7–)4–7.5 × 1.8–2.5 µm {2}; sometimes branched near apex. **Medullary excipulum** very pale rose, 10–30 µm thick, of dense textura angularis-intricata, medium sharply delimited. **Ectal excipulum** hyaline to very pale rose, of thin-walled († slightly gelatinized) t. globulosa-angularis from base to mid flanks or margin, 20–30 µm thick near base, cells *(5–)7–13(–15) × 5–12 µm {4}, irregularly vertically oriented; 10–20 µm thick near margin, marginal cortical cells *6–10 × 2.5–5.2 µm {4}, thin or firm walls without {2} or with very thin (0.3–1 µm thick) glassy caps {1}, oriented at 20–80°. **Anchoring hyphae** medium abundant, */†(1.7–)2–2.5(–3) µm wide, walls 0.2(–0.4) µm thick {3}. **SCBs** globose, in paraphyses 1–2 per cell, large; in excipulum 1.5–3.5 µm diam. **Exudate** over paraphyses 0.3–1.7 µm thick, continuous to cloddy, rough, ± loosely attached; over margin 0.5–2.5 µm thick, hyaline. **— ANAMORPH**: unknown (but see below).

Habitat: collected 0.1–0.8 m above the ground, on standing, ~1–2 year old leaves or leaf sheaths of *Ammophila arenaria* {1}, *Phragmites australis* {8}, leaf sheaths ± attached to culm, on medium to strongly decayed epidermis or in furrows or longitudinal clefts on epidermis-free areas (*Phragmites*), mainly on ribbed upperside of leaf (*Ammophila*), greyed, medium to strongly covered by green algae. **Associated**: *Albotricha acutipila* {1}, ?*Cryptodiscus* sp. {1}, *Orbilia septispora* {2}, '*Pezizella*' *nigrocorticata* {1}, *Unguiculariopsis* sp. {1}, crustose lichens. **Desiccation tolerance**: ± fully viable for at least 4 months. **Altitude**: 7–565 m a.s.l. **Geology**: fluviatile deposits from Keuper (marl & sandstone) and Lower Jurassic sandstone, Quaternary sand, silt & gravel. **Phenology**: IV–VII, XII–I (probably throughout the year, long-lived).

Taxonomic remarks. The ascospores of *O. graminis* strongly resemble those of the lignicolous *O. vibrioides*, but markedly differ in containing narrow, elongated instead of broadly tear-shaped SBs, and in occurring on *Poaceae*. *O. graminis* further differs in slightly narrower spores and slightly shorter terminal cells of paraphyses.

Variation. *O. graminis* apears to be rather constant and easily recognizable. It shows distinct variation in ascus length among the few studied specimens but deviates only slightly in size and shape of spores and spore bodies. However, the SBs turn tear-shaped in overmature spores which obscures the difference to the otherwise very similar *O. vibrioides*.

Not included collections. Two samples on bark and wood of *Pinus sylvestris* from southern France (Pl. 372: 4) deviate from *O. vibrioides* in slightly narrower spores containing subulate SBs ~1.5–2 × 0.3–0.4 µm (one of them was only studied in the dead state). The spores strongly resemble *O. graminis*,

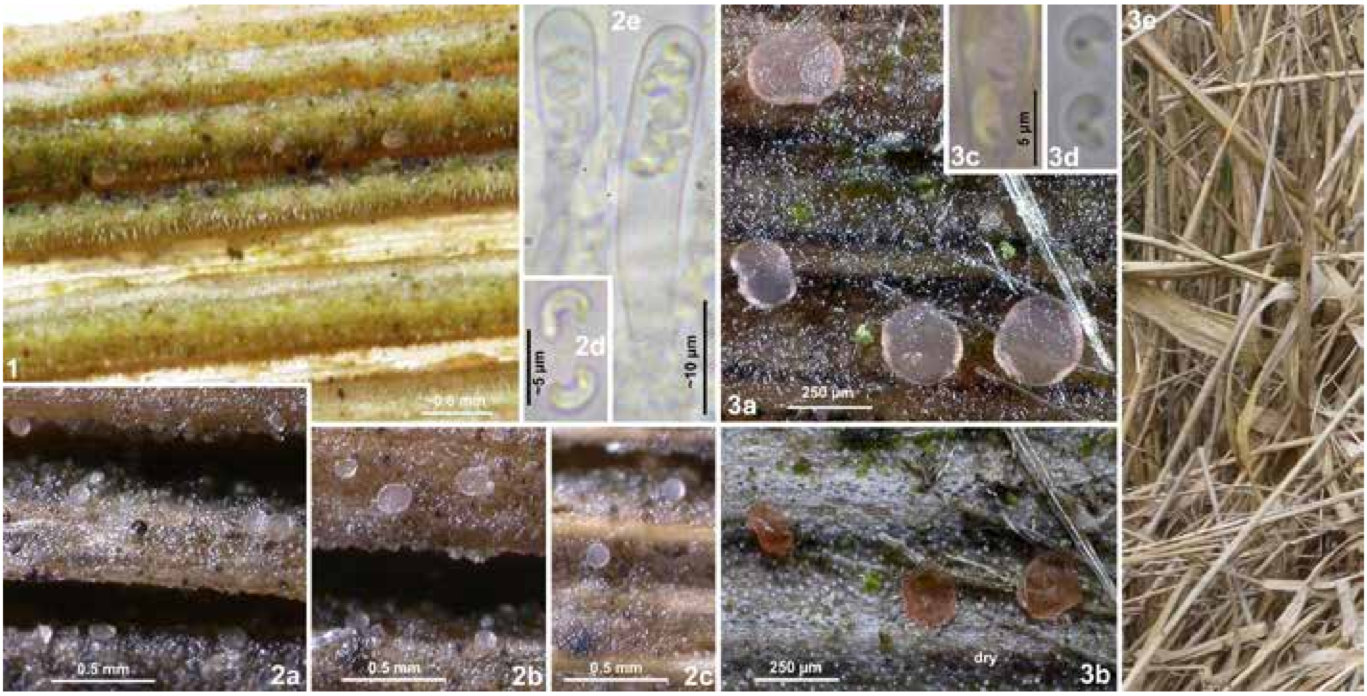

Plate 373. **1–3**: *Orbilia graminis*. – **3e**. *Phragmites* stand; **1**, **2a–c**, **3a**. rehydrated apothecia (**2**: after almost 4 years, originally light rose); **3b**. dry apothecia; **2e**. asci (fully turgescent); **2d**, **3c–d**. ascospores. – Living state. — **1**. H.B. 7405: Great Britain, Suffolk, on *Ammophila*; **2a–e**. H.B. 7267b: Luxembourg, Sandweiler, on *Phragmites*; **3a–e**. G.M. 2017-05-20.1: Luxembourg, Koedange, on *Phragmites*.

but due to the lignicolous habitat they are not included in either description. The apothecia were light rose-pink, and the terminal cells of paraphyses are with *7.5–12 µm slightly longer than in *O. graminis*.

Anamorph. In two collections of *O. graminis* (IVV: H.B. 5087, 7267b) a few 3-armed tridentaria-like conidia were found near the apothecia which resemble those observed in *O. vibrioides*. Yet, in H.B. 7267b *O. septispora* (section *Habrostictis*, IVV: H.B. 7267a) grew in association and the observed conidia might rather belong to this species, for which such an anamorph was obtained in culture.

Phylogeny. A sequence gained from apothecia of a specimen from Koedange comprises ITS (with S1506 intron) and LSU. *O. graminis* clustered with *O. vibrioides*, *O. myrioobliqua*, and *O. helicoobliqua* in a highly or medium supported clade, but with a very high distance (see under *O. vibrioides*, p. 750, and series *Vibrioides*, p. 746).

Map 64. Known distribution of *O. graminis* in Europe.

Ecology. *O. graminis* was collected on ± rotten, still standing xeric culms (leaf sheaths), mainly of *Phragmites*, in cold-temperate subcontinental humid areas of Europe, including a small hemiboreal area in Denmark, but also in atlantic mesotemperate humid southeastern Europe. A single record on *Ammophila* in the atlantic lowlands of Suffolk (Great Britain) indicates that *O. graminis* has a wider amplitude. The *Phragmites* stands in Luxembourg were rather undisturbed swampy areas with *Salix*, that in Suffolk a treeless dyke at the sea shore close to a large *Phragmitetum*. Olariaga et al. (2015: 7) reported *O. graminis* in their study of *Phragmitetum* formations in Gipuzkoa (País Vasco). The two not included collections on *Pinus* are on Middle Jurassic calcareous marl from orosubmediterranean humid Southern French Prealps.

Specimens included. **GREAT BRITAIN**: **East England**, **Suffolk**, 10 km SSW of Southwold, 5 km NNE of Leiston, Minsmere Haven, 5 m, leaves of *Ammophila arenaria*, 5.VII.2003, S.M. Francis (E.B. 4431, K(M) 145649, H.B. 7405). — **DENMARK**: **Midtjylland**, 8 km SW of Viborg, 1 km SE of Hald Hovedgard, Hald Sø, Niels Bugges Kro, 10 m, culm of *Phragmites australis*, 15.V.2005, H.O. Baral (ø). — **LUXEMBOURG**: **Gutland**, **Mersch**, Luxembourg Plateau, 4.3 km S of Larochette, 1.2 km N of Koedange, below Folkend, Mäschpesch, 300 m, leaf sheaths of *P. australis*, 23.V.1994, G. Marson (ex H.B. 5084a, M-0276489, **holotype**; G.M. 5176, **isotype**). – ibid., leaf sheaths of *P. australis*, 25.IV.1994, G. Marson (H.B. 5087, G.M. 5162). – ibid., 0.5 km NNE of Koedange, 297 m, 1.XII.2016, G. Marson (G.M. 2016-12-01.1). – ibid., 20.V.2017 (G.M. 2017-05-20.1; sq.: MH221061). – **Luxembourg**, 7.5 km E of Luxembourg, 1.2 km ENE of Sandweiler, Neimillen, 305 m, culms & leaf sheaths of *P. australis*, 1.XII.2002, G. Marson (H.B. 7267b). — **GERMANY**: **Baden-Württemberg**, Oberschwäbisches Hügelland, 13 km NNW of Ravensburg, 4.8 km SSE of Altshausen, Schreckensee, 565 m, leaf sheaths of *P. australis*, 26.VI.1994, G. Marson (H.B. 5128, G.M. 5199). — **SPAIN**: **País Vasco**, **Gipuzkoa**, 10.5 km WSW of San Sebastián, 6 km E of Zarautz, Itzao, 7 m, culms of *P. australis*, 7.I.2013, I. Olariaga (ARAN-F A3025083, doc. vid.).

Not included. **FRANCE**: **Provence-Alpes-Côte d'Azur**, **Hautes-Alpes**, Alpes de Provence, 24 km SE of Gap, 5 km E of Turriers, 0.6 km SW of Col des Garcinets, 1147 m, branch of *Pinus sylvestris*, on bark, 25.VIII.1996, G.

Marson (H.B. 5621h ø). – 17 km NE of Digne-les-Bains, 5 km SSW of Prads-Haute-Bléone, WSW of Blégier, 970 m, branch of *Pinus sylvestris*, on wood, 24.VIII.1996, G. Marson (ø)

Orbilia myrioobliqua Baral & G. Marson, **sp. nov.**, MB 813510 — Pls 374–375, Map 65

Etymology: referring to the 64-spored asci and obliquely inserted spore bodies. **Typification**: Western Australia, Pithara, twigs of *Acacia*, 24.XI.2001, G. Marson (ex H.B. 7208a, MEL 2389226, holotype).

Latin diagnosis: *Apothecia 0.15–0.33 mm diam., sessilia, erumpentia, aurantio-ochracea, margine albido- vel pallide luteo-pulveracea. Asci 64-spori, apice in statu emortuo rotundati, fortiter crassitunicati. Ascosporae *4.3–7 × 2–3.2 µm, subcylindricae vel clavatae, in statu vivo corpusculum refringens cylindricum vel subclavatum, obliquum vel geniculatum, ad subapicem affixum continentes. Paraphyses ad apicem leniter clavato-capitatae. Excipulum et paraphyses exsudato valido aspero sulphureo tectae. Habitat ad corticem, etiam lignum putridum ramulorum et ramorum in aere prominentium fruticum vel arborum angiospermarum* (Fabales, Myrtales, Santalales), *etiam in petiolis* Macrozamiae, *in zona tropica et subtropica arida ad semihumida Australiae occidentalis et meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.33(–0.4) mm diam., 0.1–0.15 mm high, pale to bright (dirty) ochre- to brick-orange, non-translucent, round, rarely elliptical, scattered; disc slightly concave to flat, with whitish to yellowish pruina or warts, margin thick, 0–20 µm protruding, often distinctly whitish to pale or light yellow pruinose, finely crenulate or with ± prominent radial ribs; broadly sessile, slightly to strongly immersed in cracks, partly almost superficial; dry with small cupulate disc, bright yellow to (ochre-)orange. **Asci** *(46–)60–75(–90) {6} × 8.5–9.5 {2} or 9.5–10.3 {2} or 10.7–12(–12.5) {3}, †(47–)55–75(–82) {6} or (60–)75–100(–118) {1} × (7–)8–8.5 {2} or (9–)9.5–11.5(–13) {4}, 64-spored [~(38–)48–64 spores counted], spores multiseriate, lower spores often inverted (strongly mixed), pars sporifera *39–55 µm long; **apex** (†) hemispherical, dome *1–1.7 µm thick, †3–4(–5) → 1.5–3.7 µm {5} [KOH 3.5–5.5 → 1–3.5(–4.5) µm], mostly with apical chamber, KOH+MLZ negative or pale reddish; **base** unstalked or with short to medium, rarely very long, ± thick, flexuous stalk, L-, T- or Y-shaped. **Ascospores** *(4.3–)4.5–6.5(–7)((–8.5)) {8} × (1.8–)2–2.7 {7} or 2.7–3.2 {2} µm, †(4–)4.5–6.5(–7.3) × 2–2.5((–3)) µm {6}, (sub)cylindrical(-ellipsoid) or slightly to medium clavate (cuneate), both ends rounded, straight, exceptionally slightly curved; **SBs** subapically to laterally attached to spore wall, *(1.8–)2.4–3(–3.3) × (0.7–)0.9–1.1(–1.3) µm {3}, rod- to narrowly pear-shaped, apically narrowed to a wide point, always obliquely oriented within spore, straight or ± geniculate. **Paraphyses** apically uninflated to slightly (rarely medium) clavate-capitate, terminal cells *(5.5–)9–13(–15) × 2–3.5 µm {3}, †2.5–4.2 µm wide {H.B. 8684}, protruding 4–10 µm beyond living asci (5–15 µm beyond dead asci), lower cells *(3.5–)8–15 × 1.5–2.8 µm {2}; unbranched near apex. **Medullary excipulum** hyaline to very pale rose, 10–25(–40) µm thick, of dense textura globulosa-intricata, very indistinctly to sharply delimited. **Ectal excipulum** hyaline to very pale rose, of (†) thin-walled (rarely slightly gelatinized), irregularly or indistinctly horizontally oriented t. globulosa-angularis from base to mid flanks, 15–30 µm thick near base, cells */†6–12(–16) × 5–10(–15) µm {4}; 15–25 µm thick near margin, of t. angularis-prismatica or t. prismatica-porrecta oriented at a 10–50° angle to the surface, marginal cortical cells *5–12 × 3–5.3 µm {3}. **Anchoring hyphae** sparse to abundant, */†1.8–3.3 µm wide, walls 0.2 µm thick {3}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 0.8–1.7 µm diam. **Exudate** light to bright sulphur-yellow (very pale yellow in KOH), over paraphyses 0.2–2(–3) µm thick, coarsely granular-cloddy, ± firmly attached; over margin and flanks 1–4 µm thick. — **ANAMORPH**: unknown.

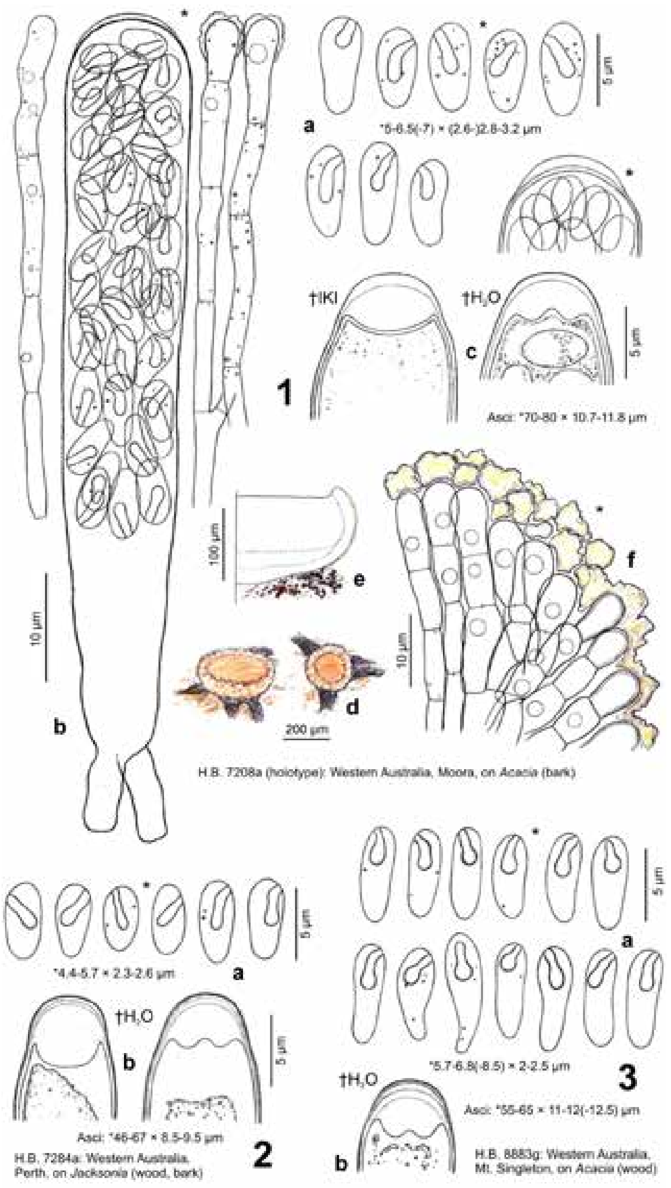

Plate 374. **1–3**: *Orbilia myrioobliqua*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., marginal ectal excipulum.

Habitat: collected 0.2–2.5 m above the ground, corticated or partially to entirely decorticated, 1.5–13(–50) mm thick twigs and branches, rarely fruits, of *Acacia* sp. {7}, *Calothamnus* sp. {1}, *Calytrix* sp. {1}, *Hakea* sp. {1}, *Jacksonia* sp. {2}, *Nuytsia floribunda* {1}, on slightly to strongly decayed bark (periderm or bast, outer surface) {13} and wood {6}, often in small holes or larger cracks in periderm, sometimes in ?beetle gallery; on petioles of *Macrozamia riedlei* {1}; ± strongly greyed, green and orange algae sparse to abundant. **Associated**: *Amandinea* sp. {1}, *Caloplaca* sp. {2}, *Claussenomyces* spp. {4}, *Durella* sp. {1}, *D.* aff. *connivens* {1}, *Gloniopsis praelonga* {4}, *Hysterium angustatum* {1}, *Hysterobrevium mori* {1}, ?*Lecidea* sp. {1}, *Orbilia albidorosea* {1}, *O. amberina* {1}, *O. anguliobliqua* {2}, *O. australiensis* {10}, *O. austroobtusispora* {1}, *O. aviflagellata* {1}, *O. curvatiobliqua* {1}, *O. curvativitalbae* {2}, *O. eucalypti* {5}, *O. helicoobliqua* {2}, *O. hesperidea* {3}, *O. kingsiana* {1}, *O. macrocarpa* {1}, *O. macrotrapeziformis* {1}, *O. microserpens* {3}, *O. multiserpens* {1/1}, *O.* ?*multivirgula* {1}, *O. myrioeuonymi* {1}, *O. myriofusiclava* {5}, *O. myriolilacina* {2}, *O. myriomuscula* {1}, *O.* ?*navajoana* {1}, *O. nothovinosa* {4/1}, *O. paraobliqua* {2}, *O. pleioaustraliensis* {2}, *O. pleioaustrocylindrica* {1}, *Patellaria* ?*andina* {1}, *P. atrata* {1}, *Proliferodiscus griseoviolaceus* {1}, *Symbiotaphrina desertorum* {1}, ?*Triblidium* sp. {3}. **Desiccation tolerance**: fully viable for at least 14 months. **Altitude**: 11–380 m a.s.l. **Geology**: Precambrian and Cretaceous sedimentary rock; granite, granitic gneiss (red-brown to whitish soil). **Phenology**: long-lived.

H.B. 8883g: Mt. Singleton, on *Acacia*; **6**. H.B. 8611a: Perth, on *Jacksonia*; **7**. H.B. 8923a: Moora, on *Acacia*; **8a–b**. H.B. 8966b: ibid., on *Calothamnus*; **9a–b**. H.B. 7204s: Mt. Singleton, on *Acacia*.

Taxonomic remarks. *Orbilia myrioobliqua* is easily identified by its 64-spored asci containing small, subcylindrical to clavate ascospores with obliquely oriented SBs which are consistently subapically to almost laterally attached and often geniculate. Of course, this characteristic feature of the SBs is only visible in profile view. The similar *O. paraobliqua* differs in 128-spored asci that contain much narrower spores with apically attached SBs, whereas *O. pleistoobliqua* hardly differs in features other than spore number.

Variation. Some variation was noted among the collections, especially in ascus and spore size. Particularly in H.B. 8684 (on *Calytrix*, tropical-arid site) the asci were distinctly larger [†75–103(–118) × 11–13 µm] than in the other records. Nevertheless, the spore number never exceeded 64, and the ascus size did not depend on apothecial size which was sometimes extraordinary (up to 0.4 mm diam. and 0.15 mm thick, Pl. 375: 4). Also the spores were larger here, but this was also the case in one of the two samples near Mt. Singleton (H.B. 8883g, Pl. 374: 3). However, ascus and spore size varied between apothecia in these records. In one apothecium of the latter sparse collection the spores tend to form a tail-like base (Pl. 374: 3a) which was not seen in all the other samples, including H.B. 8684. The coexistence of the similar species *O. paraobliqua* (H.B. 8883a) and *O. anguliobliqua* (H.B. 8883i) on the same plant individuum complicated a clear identification of the populations.

In most collections the spore number seemed to lie quite consistently at ca. 64, but in some it appeared to range more around 40 (H.B. 8923a, 8966b, 8478a), at least in some asci. A few observations (e.g., in H.B. 8391a) suggest that also 32-spored asci sometimes occur.

Phylogeny. Two sequences of *O. myrioobliqua* (H.B. 7204s H.B. 8391a, both on *Acacia*) were obtained, comprising S1506 intron (badly sequenced in the latter strain), ITS, and LSU. From *O. helicoobliqua* they differ in possessing the intron, besides a 1.3–1.5 % ITS distance (3–4 nt in ITS1, 4 nt and 1 gap in ITS2) and 1–2 nt in the LSU D2 (pos. 579: G**C**CCC, 600; TT**C**TG or TT**T**TG). However, also the two *O. myrioobliqua* sequences differ by ~5 % in the intron, 1 % in the ITS (5 nt in ITS1), and by 1 nt (pos. 600) in the LSU D2 (in the D1 and D3 the three sequences are identical).

Ecology. *O. myrioobliqua* grew on ± rotten bark (rarely wood) of mostly corticated, xeric twigs and branches of trees, mainly of the order *Fabales*, but also *Myrtales*, *Proteales*, and *Santalales*. Two collection sites are located in Western Australia, in tropical arid to subtropical semiarid acacia shrublands and hummock grasslands (Pilbara, Carnarvon and Yalgoo ecoregion), the remaining are in southwestern Australia at the northern end of Darling Range, in subtropical semihumid (banksia-)eucalypt (open) woodlands (Geraldton Sandplains, Avon Wheatbelt, Jarrah Forest and Swan Coastal Plain ecoregions).

Specimens included. **AUSTRALIA**: **Western Australia**, Pilbara, 84 km SE of Onslow, 25 km N of Nanutarra Roadhouse, 120 m, branch of *Calytrix*, on bark, 5.XII.2001, G. Marson (H.B. 8684). – Yalgoo, W of Toolonga, 200 km N of Geraldton, 15 km SSE of Wannoo Billabong Roadhouse, 157 m, twig of *Acacia*, on bark, 8.XII.2001, G. Marson (H.B. 9033e). – Geraldton Sandplains, 67 km N of Geraldton, 19 km N of Northampton, 273 m, bark and fruit of *Hakea*, 9.XI.2007, G. Marson (ø). – 54 km N of Moora, 16.5 km N of Watheroo, Midlands Road, 292 m, branch of *Calothamnus*, on wood & bark, 25.X.2007, G. Marson (H.B. 8966b ø). – Avon Wheatbelt, 68 km NE of Moora, 14 km S of Dalwallinu, 1.5 km S of Pithara, 327 m, twigs of *Acacia*, on bark, 24.XI.2001, G. Marson (ex H.B. 7208a, MEL 2389226, **holotype**). – 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, branch of *Acacia*, on bark & wood, 24.XI.2001, G. Marson (H.B. 7204s ø; sq.: MK473438). – ibid., twig of *Acacia*, on wood & bark, 26.X.2007, G. Marson (H.B. 8883g). – Swan Coastal Plain, 150 km N of Perth, 13 km WNW of Moora, Dandaragan Road, 235 m, branch of *Acacia*, on bark, 24.X.2007, G. Marson (H.B. 8923a ø). – border to Jarrah Forest, 30 km NE of Perth, 4 km NE of Upper Swan, W of Walyunga, 76 m, branch of *Acacia*, on bark, 2.IX.2006, G. Marson (H.B. 8478a). – ibid., 37 m, twig of *Jacksonia*, on wood & bark, 23.XI.2001, G. Marson (H.B. 7284a). – ibid., twig of *Jacksonia*, on wood & bark, 2.IX.2006, G. Marson (H.B. 8611a ø). – 15 km SE of Mandurah, SW of Pinjarra Road, NE of Sir Ross McLarty Park, 11 m, branches of *Nuytsia floribunda*, on wood & bark, 17.XII.2001, G. Marson (H.B. 7087b ø). – Jarrah Forest, 25 km NNE of Bindoon, 12 km ESE of Wannamal, 271 m, petioles of *Macrozamia riedlei*, 3.IX.2006, G. Marson (ø). – ibid., branch of *Acacia*, on bark, 4.IX.2006, G. Marson (H.B. 8391a, sq.: MK473439).

Orbilia pleistoobliqua Baral & G. Marson, **sp. nov.**, MB 813511 — Pls 376–377

Etymology: named after the 128-spored asci and the obliquely inserted spore bodies.

Typification: Western Australia, Hamelin Pool, branch of *Acacia*, 6.XI.2007, G. Marson (ex H.B. 8727c, MEL.2389252, holotype).

Latin diagnosis: *Similis* Orbiliae myrioobliquae *sed asci 128-spori, latiores, ascosporae paulo minores. Habitat ad corticem putridum ramulorum in aere prominentium* Acaciae *in zona subtropica arida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.14–0.23 mm diam., 0.09–0.12 mm high, light to bright brick-orange, non-translucent, ± round, scattered; disc flat, usually ± pruinose, margin thick, 0–12 µm protruding, usually distinctly whitish to yellowish pruinose, often with prominent radial ribs; broadly sessile, slightly to strongly immersed in cracks, partly almost superficial. **Asci** *64–86 × 12.5–15.7 µm, †58–81 × 11–15 µm, 128-spored (~83 spores counted), spores multiseriate, lower spores often inverted (strongly mixed), pars sporifera *54–55 µm long; **apex** (†) hemispherical, dome *1.5–1.7 → 1–1.2 µm thick, †2–2.8 → 1.5–2.5 µm (in H_2O or KOH), with distinct apical chamber, endotunica light red in CR_{SDS}; **base** with short to medium long, thick, ± flexuous stalk, Y-shaped. **Ascospores** *4.3–5.8 × 2–2.3, (sub)cylindrical or mostly only very slightly clavate or obclavate, both ends rounded, straight or very slightly inequilateral; **SBs** always subapically to laterally attached to spore wall, *2.3–3 × 0.7–0.9(–1) µm, rod-shaped to slightly subulate, apically narrowed to a ± wide point, either straight (then obliquely oriented) or distinctly geniculate in the upper part. **Paraphyses** apically uninflated to slightly clavate,

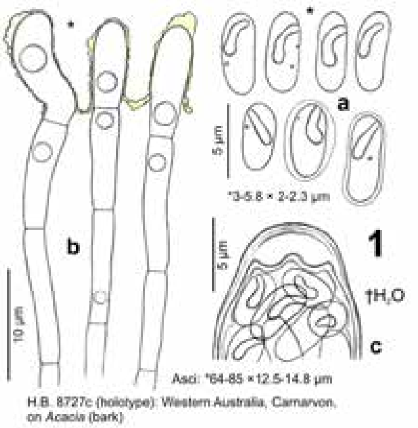

Plate 376. **1**: *Orbilia pleistoobliqua*. – **a**. ascospores (2 spores inside dead ascus seemingly ensheathed); **b**. paraphyses; **c**. ascus apex.

terminal cells *(5.5–)7–12(–18) × (2–)3–3.5(–4) µm, protruding 4–10 µm beyond dead asci, lower cells *(3.5–)7–12(–13.5) × 1.8–2.8 µm, subterminal cells *3–3.7 µm wide, unbranched near apex. **Medullary excipulum** hyaline, 20 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** hyaline, of (†) slightly gelatinized, irregularly oriented t. globulosa-angularis from base to mid flanks, 20 µm thick near base, cells *7–10 × 5.5–9 µm; 10–15 µm thick near margin, submargin of t. angularis-prismatica oriented at a 60–90° angle to the surface, upper margin of t. prismatica-porrecta oriented at 0–10°, marginal cortical cells *6–13 × 3–4 µm. **Anchoring hyphae** sparse, */†1.8–3 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.3–2.7 µm diam. **Exudate** light sulphur-yellow, over paraphyses 0.2–1(–2) µm thick, granular-cloddy, firmly attached; over margin and flanks 1–2.5 µm thick. — **ANAMORPH**: unknown.

Habitat: collected 0.5–2 m above the ground, corticated, 4–7 mm thick twigs of *Acacia* sp., on strongly decayed bark (bast), on cross clefts of periderm or bark, strongly greyed, no algae. **Associated**: *Coccomycetella* sp., *Hyalorbilia ?erythrostigma*, *Hysterobrevium mori*, *Orbilia curvatimyriella*, *O. myriella*, *O. myrioauris*, *O. myrionamibica*, *O. pleioaustraliensis*, *O. ?saguarina*, *Ostropales*, *Tryblidaria* sp. **Desiccation tolerance**: fully viable for at least 2 months, a few mature asci still alive after 40 months. **Altitude**: 67 m a.s.l. **Geology**: Cretaceous sedimentary rock (red-brown gravel). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleistoobliqua* is easily confused with *O. myrioobliqua*, as its main difference lies in a higher spore number. There are, however, some other characteristics which need confirmation by further collections: the spores are slightly shorter and particularly narrower, and never of distinctly clavate shape, also the SBs are slightly narrower, the asci are wider, and the apical domes not as thick as in *O. myrioobliqua*.

Ecology. *O. pleistoobliqua* is so far only known from a single collection, on rotten bark of xeric twigs of *Acacia* in Western Australia in a subtropical semiarid (almost arid) acacia shrubland (Carnarvon ecoregion).

Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, Denham-Hamelin Road, 67 m, branch of *Acacia*, on bark, 6.XI.2007, G. Marson (ex H.B. 8727c, MEL 2389252, **holotype**).

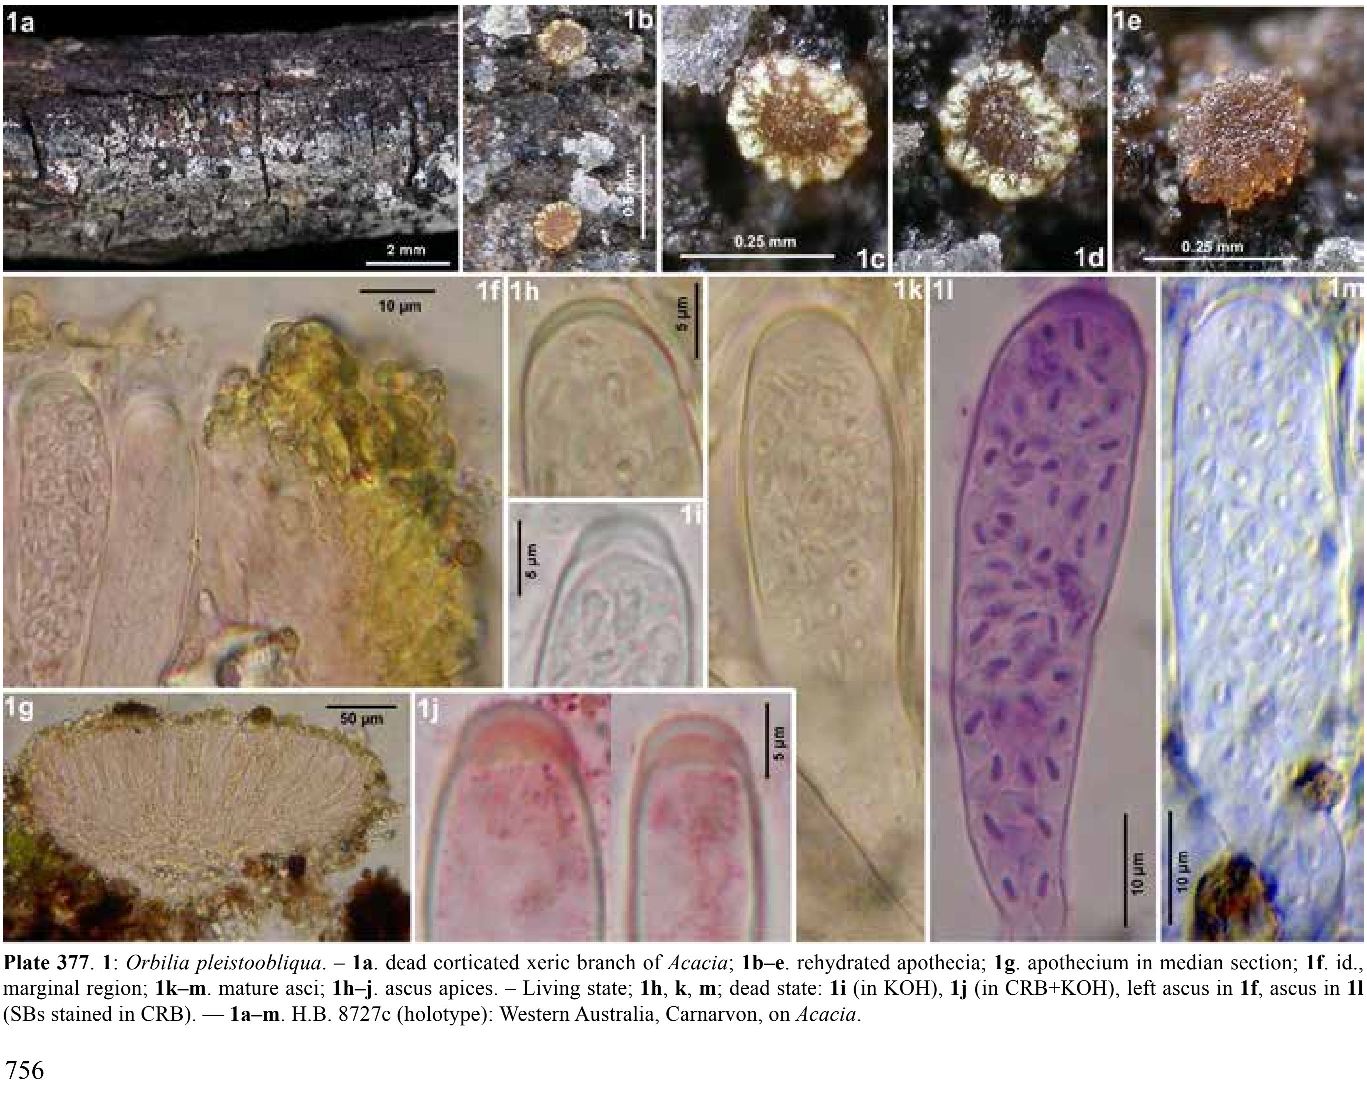

Plate 377. **1**: *Orbilia pleistoobliqua*. – **1a**. dead corticated xeric branch of *Acacia*; **1b–e**. rehydrated apothecia; **1g**. apothecium in median section; **1f**. id., marginal region; **1k–m**. mature asci; **1h–j**. ascus apices. – Living state; **1h**, **k**, **m**; dead state: **1i** (in KOH), **1j** (in CRB+KOH), left ascus in **1f**, ascus in **1l** (SBs stained in CRB). — **1a–m**. H.B. 8727c (holotype): Western Australia, Carnarvon, on *Acacia*.

Orbilia paraobliqua Baral & G. Marson, **sp. nov.**, MB 813512 — Pls 378–379

Etymology: referring to the similarity with *O. myrioobliqua* (but lacking the obliquely attached spore bodies).

Typification: Western Australia, Wubin, twig of *Acacia*, 24.XI.2001, G. Marson (ex H.B. 7204a, MEL 2389222, holotype).

Latin diagnosis: *Similis* Orbiliae myrioobliquae *sed asci 128-spori, ascosporae angustiores, corpusculum refringens ad apicem affixum. Habitat ad corticem putridum ramulorum in aere prominentium* Acaciae *in zona subtropica semiarida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.33 mm diam., 0.11–0.13 mm high, pale to bright orange-ochraceous, non-translucent, round, ± scattered; disc flat, yellowish warted-pruinose, margin thick, not protruding, whitish to yellowish pruinose, sometimes ribbed; broadly sessile, superficial. **Asci** *65–85(–92) × 10.5–13(–14) µm {2}, †60–80 × 9.3–12 µm {2}, 128-spored (75–107 spores counted), spores (*) multiseriate, lower spores somewhat more often inverted than upper spores (strongly mixed), pars sporifera *45–55 µm long; **apex** (†) hemispherical, dome *1.5 → 1 µm thick, †3–4.5(–5.5) → 1.8–2.5 (KOH 2.5–5.5) µm {2}, with or without distinct small apical chamber, KOH+IKI negative, rarely very faintly reddish; **base** with short, ± thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(5–)5.5–7(–8) × (1.6–)1.7–1.9(–2.2) µm {2}, (sub) cylindrical, rarely fusoid, dumbbell-shaped or slightly tapered below, ends rounded, rarely obtuse, straight to (very) slightly curved; **SBs** consistently apically attached to spore wall, *1.7–2.5(–3) × 0.6–1.1 µm {2}, tear- to pear-shaped, also rod-shaped to ampulliform, apically narrowed to a wide to small point. **Paraphyses** apically uninflated or very slightly clavate, terminal cells *7–15.5 × 2–3(–4) µm {1}, protruding 0–10 µm beyond living asci, lower cells *(4–)7–15(–18.5) × 1.8–3(–3.5) µm {2}; rarely or often branched at upper septum. **Medullary excipulum** pale rose, 10–20 µm thick, medium dense textura intricata with many small inflated cells, not sharply delimited. **Ectal excipulum** hyaline to pale rose, of (†) thin-walled, irregularly vertically oriented t. angularis-globulosa from base to mid flanks or submargin, 15–35 µm thick near base, cells *6–12(–16) × 5–8(–10) µm {2}; 15–20 µm thick near margin, (upper) margin of t. prismatica(-porrecta) oriented at a 10–40° angle to the surface, marginal cortical cells *6–10 × 2.8–5 µm {2}. **Anchoring hyphae** sparse, †2–3 µm wide, walls 0.2(–0.4) µm thick {2}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 0.7–2 µm diam. **Exudate** over paraphyses, margin and flanks (1–)2–6(–8) µm thick, cloddy, light to bright sulphur-yellow, loosely attached. **— ANAMORPH**: unknown.

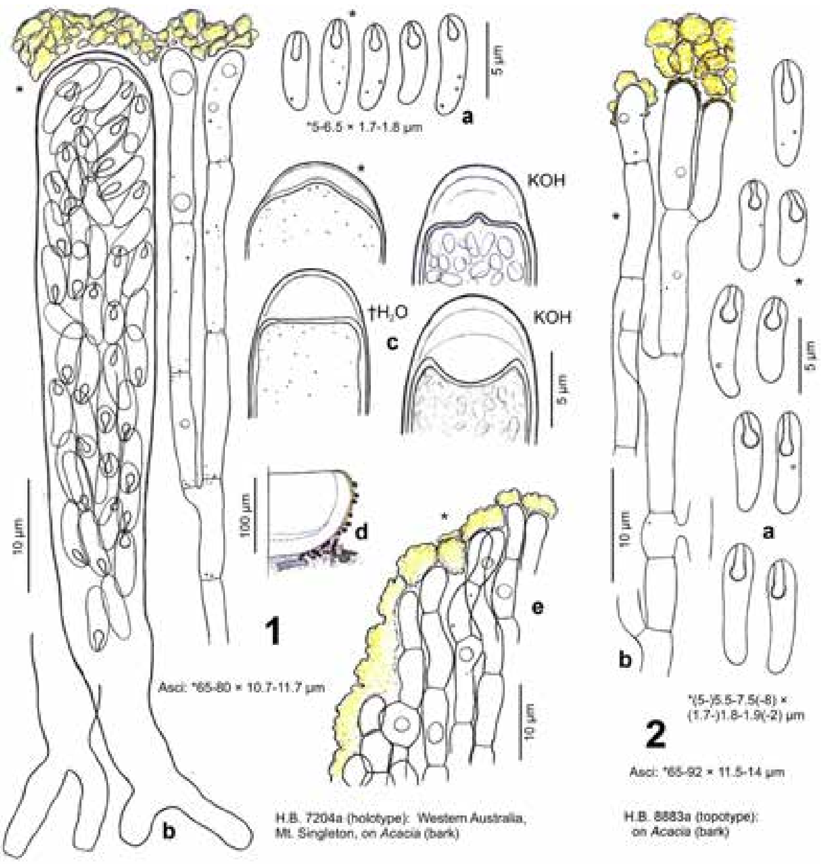

Plate 378. **1–2**: *Orbilia paraobliqua*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

Habitat: collected 1–2 m above the ground, partially to nearly entirely decorticated, 1.5–3 mm thick twigs of *Acacia* sp. {2}, on medium to very decayed bark (bast) {2}, greyed, no algae. **Associated**: *Amandinea* sp. {1}, *Caloplaca* sp. {1}, *Orbilia amberina* {1}, *O. anguliobliqua* {1}, *O. australiensis* {2}, *O. austroobtusispora* {1}, *O. aviflagellata* {1}, *O. curvatiobliqua* {1}, *O. helicoobliqua* {2}, *O. hesperidea* {2}, *O. microserpens* {1}, *O. multiserpens* {1}, *O. myriofusiclava* {1}, *O. myriolilacina* {2}, *O. myriomuscula* {1}, *O. myrioobliqua* {2}, *O. nothovinosa* {1}, *O. pleioaustraliensis* {2}, *O. pleioaustrocylindrica* {1}, *Ostropales* {1}, *Patellaria* ?*andina* {1}, ?*Triblidium* sp. {2}. **Desiccation tolerance**: submature asci still viable after 10 months. **Altitude**: 380 m a.s.l. **Geology**: Archean sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia paraobliqua* is characterized by 128-spored asci and small, cylindrical, not or only slightly allantoid ascospores. Contrary to *O. myrioobliqua*, the SBs are consistently inserted in the spore apex. The spore number of 128 was calculated from the volume of the pars sporifera, but also by counting of spores or SBs which clearly led to values much over 64. Yet, a few asci of an apothecium possibly contained only 64 spores. *O. pleistoobliqua* differs in somewhat shorter and wider spores with subapically to laterally inserted SBs, also in slightly wider asci. *O. anguliobliqua* frequently showed a similar SB-attachment but differs in curved spores and 64-spored asci.

Variation. The topotype (Pl. 378: 2) deviates in a few details from the holotype, though both originate from the same site and substrate. Its spores are larger and their SBs much more broadly attached, also the asci are wider, the paraphyses often branched at the apex (in the holotype branched only below the middle part), and the apothecia have a rougher surface.

A deviating apothecium in the topotype (Pl. 379: 2) shows an apparently reduced spore number of 64 and wider spores [*5.8–7.8(–8.5) × 2.2–2.4 µm] with longer SBs [(2.3–)2.6–3.4(–3.8) × 0.9–1.1 µm] suggesting a position intermediate to *O. myrioobliqua* but also to *O. allantoobliqua*. It cannot safely be included in *O. myrioobliqua* because of somewhat too long spores with more or less apically attached SBs, and not in *O. paraobliqua* because of too wide spores. *O. allantoobliqua* differs from this in distinctly curved spores, but some of its asci contained many inequilateral or even straight spores which do not differ from those of the deviating apothecium.

Ecology. *O. paraobliqua* grew on ± rotten bark of xeric twigs of *Acacia* sp. It is only known from a single collection site in southwestern Australia (Darling Plateau) in a subtropical semiarid eucalypt woodland (border between Yalgoo and Avon Wheatbelt ecoregion).

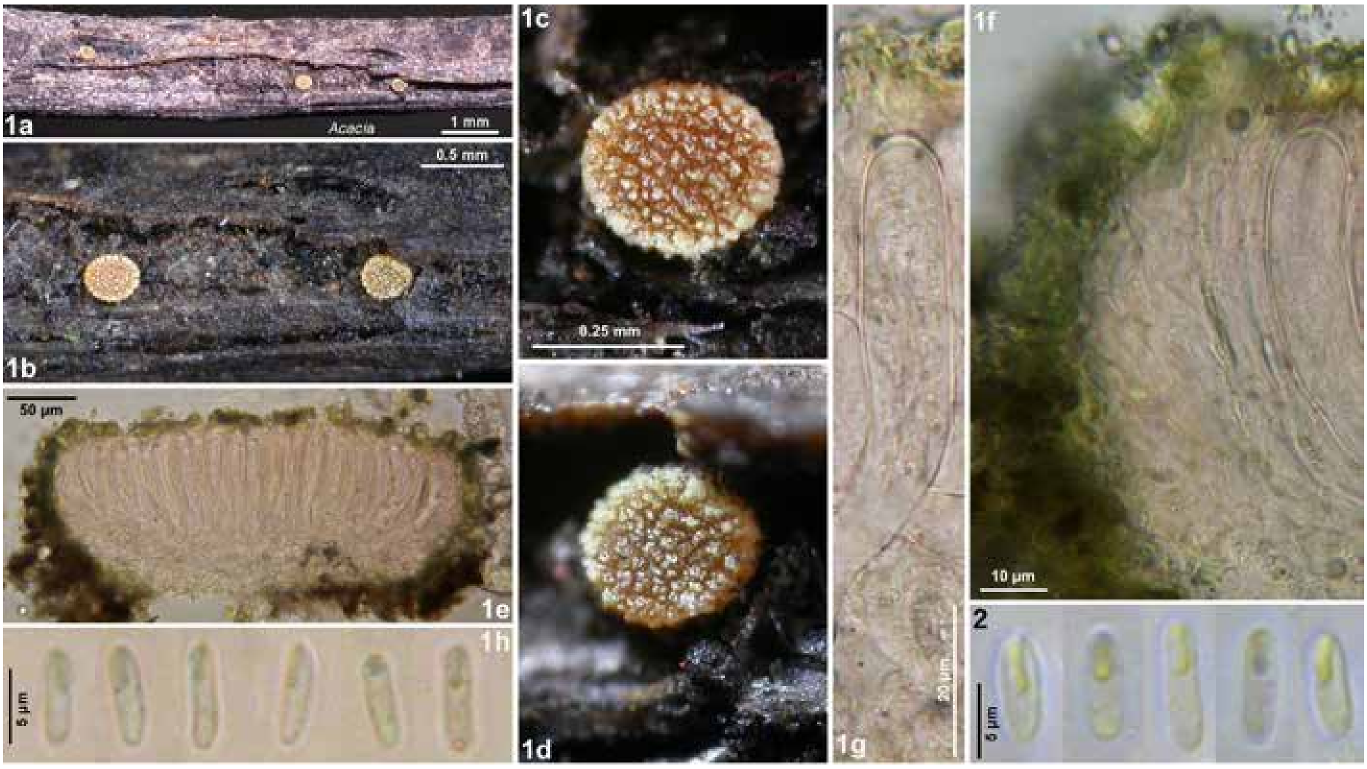

Plate 379. **1**: *Orbilia paraobliqua* (topotype); **2**. *O.* cf. *paraobliqua*. – **1a**. dead corticated xeric twig of *Acacia*; **1b–d**. rehydrated apothecia; **1e**. apothecium in median section; **1f**. id., marginal ectal excipulum; **1g**. mature ascus; **1h**, **2**. ascospores. – Living state. — **1a–h**. porrecta oriented at a 0–40° angle to the surface, marginal cortical cells *6–8 × 2–3 µm {1}. **Anchoring hyphae** sparse, †1.5–2.5 µm wide, walls 0.2 µm thick {1}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2.5 µm diam. **Exudate** over paraphyses and margin 0.2–3 µm thick, coarsely cloddy, light sulphur-yellow, firmly attached but also with loose clods. — **ANAMORPH**: unknown.

Habitat: collected 0.5–2 m above the ground, corticated to partially decorticated, 1.5–5.5 mm thick twigs of *Acacia* sp. {3}, medium to strongly decayed bark {3} (bast & periderm), also on wood {2} (close to bark), partly in cracks of bark, rarely on thallus of *Amandinea*, strongly greyed, with some green algae. **Associated**: *Amandinea* sp. {1}, *Caloplaca* sp. {1}, *Orbilia angustoobliqua* {1}, *O. ?atriplicis* {1}, *O. australiensis* {1}, *O. curvatiobliqua* {1}, *O. helicoobliqua* {1}, *O. helicovinosa* {1}, *O. hesperidea* {1}, *O. macrocarpa* {1}, *O. microserpens* {1}, *O. ?multiserpens* {1}, *O. ?multivirgula* {1}, *O. myriella* {1}, *O. myriofusiclava* {1}, *O. myriolilacina* {1}, *O. myriomuscula* {1}, *O. myrioobliqua* {2}, *O. ?navajoana* {1}, *O. paraobliqua* {1}, *O. pleioaustraliensis* {1}, *O. ?saguarina* {1}, *?Triblidium* sp. {2}. **Desiccation tolerance**: fully viable for at least 18 months. **Altitude**: 157–380 m a.s.l. **Geology**: Archean and Cretaceous sedimentary rock (ochre to red-brown sand). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia anguliobliqua* is very similar to *O. myrioobliqua* and *O. paraobliqua*, which both grew in association though on different twig fragments. The species differs from these mainly in the ascospores which are frequently basally bent (L-shaped). *O. myrioobliqua* also differs in somewhat shorter and wider spores, and *O. paraobliqua* in 128-spored asci. On different twig fragments of this collection grew also the curved-spored *O. helicoobliqua* and *O. curvatiobliqua* (for the differences see under these species).

O. angustoobliqua (Pls 387–388) is sharply separated from *O. anguliobliqua* by much longer and narrower spores with strictly apically inserted SBs. Also *O. allantoobliqua* (Pl. 386) deviates in consistently apically attached SBs, and here the spores tend to be longer and are often only slightly curved, usually allantoid (falcate) but also sometimes bent near the base. Macroscopically, no clear difference could be observed between the Australian taxa of series *Vibrioides*.

Variation. The rather small populations of *O. anguliobliqua* varied somewhat in spore size and curvature, also in ascus size, even within an apothecium. Spore shape was quite regularly L- or comma-shaped in the holotype (Pl. 380: 1a) as well as in the paratype (Pl. 381: 2c). With *6–7 × 1.7–2 µm the paratype possesses rather small spores. In a further sample (H.B. 9033f, unillustrated) the spores varied between slightly and strongly falcate and L-shaped within the single detected apothecium (spores †7–9.5 × 1.8–2.2 µm, asci ?32-spored).

Ecology. *O. anguliobliqua* grew on rotten bark (also wood) of xeric twigs of *Acacia* sp. The species is known from three subtropical semiarid sites in southwestern Australia (Darling Plateau), where it occurred in acacia open shrublands (Yalgoo coregion at border to Carnarvon) and in a eucalypt woodland (Avon Wheatbelt at border to Yalgoo).

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, twig of *Acacia*, on bark, 8.XI.2007, G. Marson (H.B. 9050f ø). – 200 km N of Geraldton, 15 km SSE of Wannoo Billabong Roadhouse, W of Toolonga, 157 m, twig of *Acacia*, on bark, 8.XII.2001, G. Marson (H.B. 9033f ø). – Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, twigs of *Acacia*, on bark, 26.X.2007, G. Marson (ex H.B. 8883i, MEL 2389264, **holotype**).

Orbilia helicoobliqua Baral & G. Marson, **sp. nov.**, MB 813514 — Pls 382–383

Etymology: named after the usually helicoid ascospores and a close relationship to *O. myrioobliqua*.

Typification: Western Australia, Wubin, twigs of *Acacia*, 26.X.2007, G. Marson (ex H.B. 8883f, MEL 2389263, holotype).

Latin diagnosis: *Similis* Orbiliae myrioobliquae *et* O. anguliobliquae *sed ascosporae partim longiores, plerumque distincte helicoideae et basi attenuatae, corpuscula refringentia longiora, ad apicem affixa. Habitat ad corticem* et *lignum putridum, ramulorum et ramorum* Acaciae *in aere prominentium in zona subtropica semiarida Australiae occidentalis.*

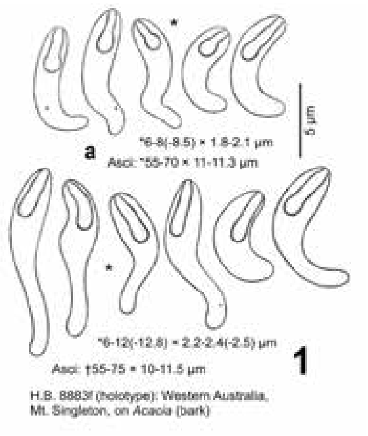

Plate 382. **1**: *Orbilia helicoobliqua*. – **a**. ascospores (2 rows from 2 different apothecia).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.3(–0.75) × 0.2–0.38 mm diam., 0.09–0.11 mm high, disc light brick-orange, non-translucent, ± round, sometimes strongly compressed when in cracks, scattered to subgregarious in small groups; disc flat, often strongly pruinose to warted by pale sulphur-yellow exudate, margin thick, 5 µm protruding, rough, partly ribbed, pale to light sulphur-yellow; broadly sessile, superficial to slightly erumpent; dry contracted, cupulate. **Asci** *55–70 × 11–11.3 µm {T}, †55–75 × (8.5–)9.5–11.5 µm {2}, 64-spored (48–60 spores

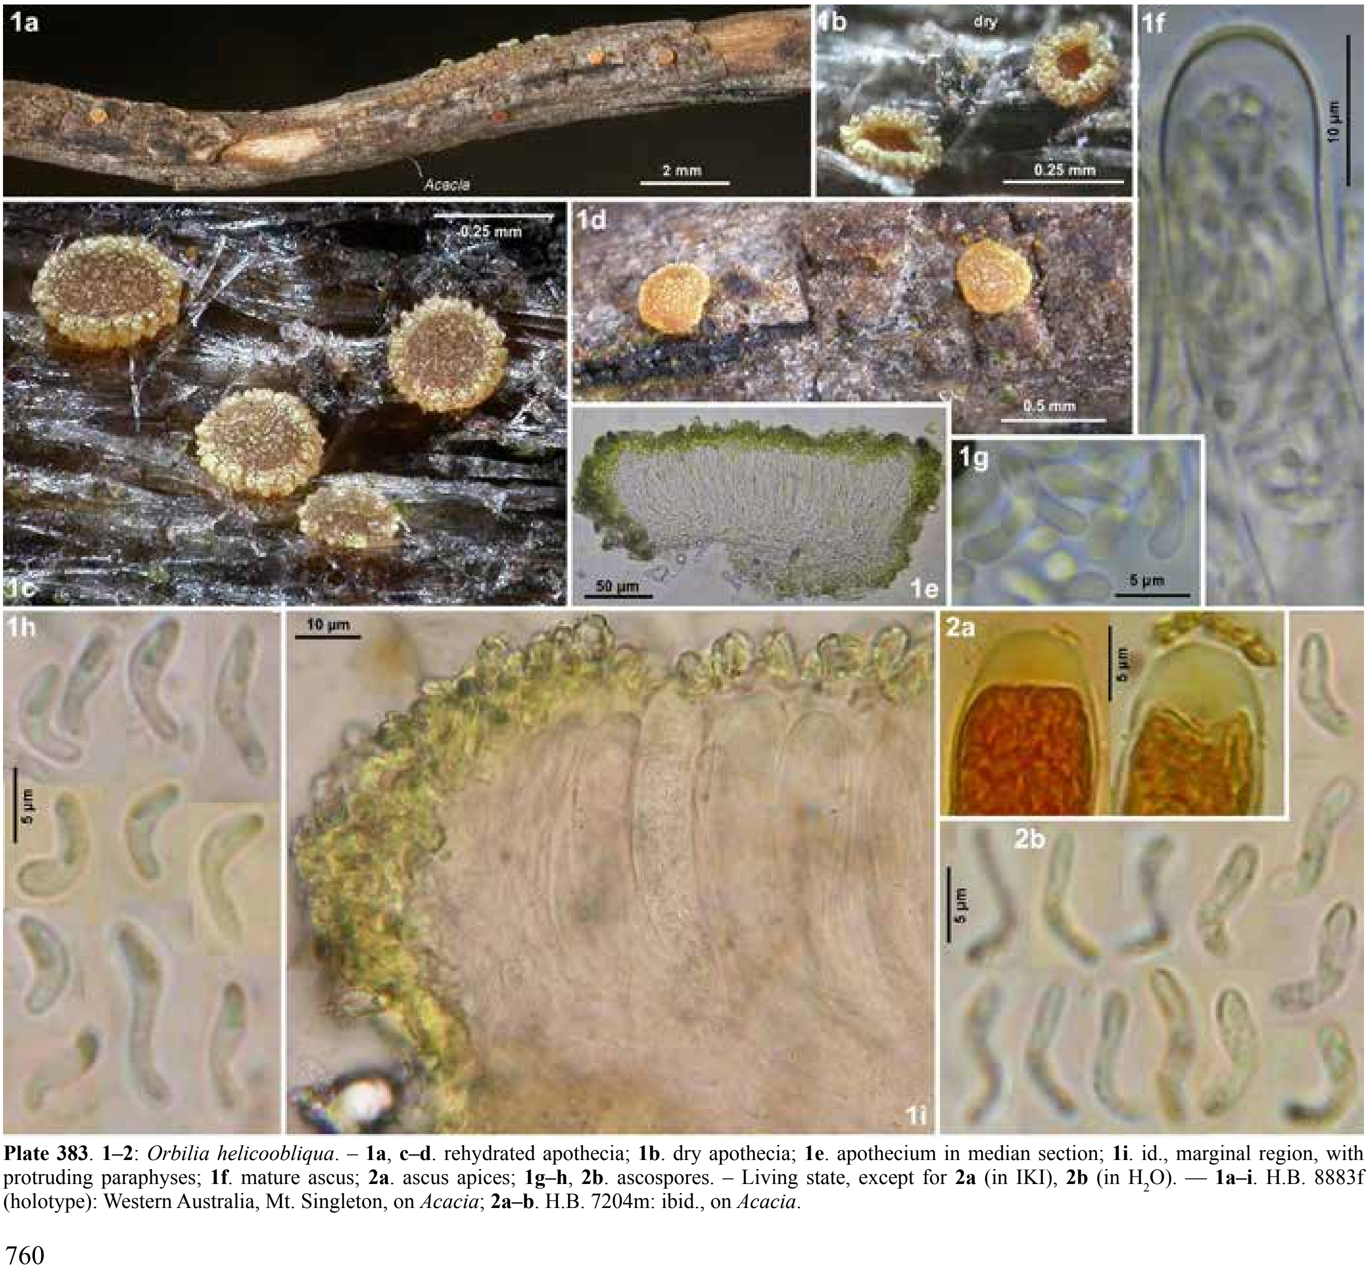

Plate 383. **1–2**: *Orbilia helicoobliqua*. – **1a**, **c–d**. rehydrated apothecia; **1b**. dry apothecia; **1e**. apothecium in median section; **1i**. id., marginal region, with protruding paraphyses; **1f**. mature ascus; **2a**. ascus apices; **1g–h**, **2b**. ascospores. – Living state, except for **2a** (in IKI), **2b** (in H_2O). — **1a–i**. H.B. 8883f (holotype): Western Australia, Mt. Singleton, on *Acacia*; **2a–b**. H.B. 7204m: ibid., on *Acacia*.

counted), spores (*) multiseriate, lower spores inverted (strongly mixed); **apex** (†) hemispherical, dome †3–4.5 → 2–2.5 µm thick, with or without distinct apical chamber, inner layer bright pink in CR_{SDS}, MLZ–; **base** with short to long, ± thick and flexuous stalk, L-shaped. **Ascospores** *(6–)6.5–10.5(–12.8) × (1.8–)2–2.3(–2.5) µm [actual length ~(6–)8–12(–14) µm] {T}, †(6.5–)7–10(–12) × (1.5–)1.8–2.1(–2.2) µm {1}, subcylindrical to clavate, apex rounded to obtuse, base slightly or usually medium attenuated, often with a distinct, sometimes very slightly swollen tail of *3–5 × 1–1.3 µm, always strongly curved, mostly distinctly helicoid (like a left-hand thread) but also falcate; **SBs** consistently apically attached to spore wall, *3–4(–4.3) × (0.9–)1–1.2 µm {T}, ± rod-shaped, partly slightly inflated at the base, apically narrowed to a wide or small point. **Paraphyses** apically slightly clavate, terminal cells *9–12.5 × 2.5–3 µm {T}, 8–15 µm longer than dead asci, lower cells *(6.5–)7.5–12 × 1.5–2 µm {T}. **Medullary excipulum** hyaline, 20 µm thick, of dense textura intricata with indistinctly inflated cells, ± sharply delimited. **Ectal excipulum** hyaline, of (†) thin-walled, indistinctly horizontally oriented t. angularis from base to mid flanks, 25 µm thick near base, cells †8–14 × 6–9 µm; 15 µm thick near margin. **Anchoring hyphae** not examined. **SCBs** in paraphyses globose, 1 µm diam. **Exudate** over paraphyses and margin 0.2–3 µm thick, coarsely cloddy, light sulphur-yellow, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 0.5–2 m above the ground, corticated to partially decorticated, 1–11 mm thick twigs and branches of *Acacia* sp. {2}, medium to strongly decayed bark {2} (bast & periderm) or wood {2}, in small cracks or holes of bark, also at edge of deep cleft in wood, strongly greyed, no algae. Associated: *Amandinea* sp. {1}, *Caloplaca* sp. {1}, *Orbilia amberina* {1}, *O. anguliobliqua* {1}, *O. australiensis* {2}, *O. austroobtusispora* {1}, *O. aviflagellata* {1}, *O. curvatiobliqua* {1}, *O. hesperidea* {2}, *O. microserpens* {1}, *O. multiserpens* {1}, *O. myriofusiclava* {1}, *O. myriolilacina* {2}, *O. myriomuscula* {1}, *O. myrioobliqua* {2}, *O. nothovinosa* {1}, *O. paraobliqua* {2}, *O. pleioaustraliensis* {2}, *O. pleioaustrocylindrica* {1}, *Ostropales* {1}, *Patellaria ?andina* {1}, ?*Triblidium* sp. {2}. **Desiccation tolerance**: fully viable for at least 18 months. **Altitude**: 380 m a.s.l. **Geology**: Archean sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia helicoobliqua* is tentatively separated from *O. anguliobliqua* by having predominantly clavate-tailed, distinctly helicoid ascospores which attain a larger length, also by longer SBs which are consistently apically attached. For the similar *O. curvatiobliqua* see below.

Variation. Within a given apothecium the sparse holotype of *O. helicoobliqua* showed a rather great variability in spore size and curvature (helicoid vs. falcate), whereas SB size was quite constant. Yet, spores from different apothecia on apparently different twig fragments of the holotype differed also markedly in spore width and SB length (Pl. 382: 1), and we consider those apothecia with larger spores (lower row in Fig. 1, Pl. 383: 1h) as typical. Also in the few apothecia of the paratype the spores varied in size (Pl. 383: 2b), being narrower and slightly longer in one apothecium (left 6 spores) compared to another (right).

Phylogeny. A sequence of H.B. 7204m comprises ITS and LSU (the S1506 intron is absent). For the differences to *O. myrioobliqua* see p. 755. One of the two *O. myrioobliqua* sequences (H.B. 7204s) was gained from the same collection, in which a total of three multispored species of series *Vibrioides* occurred, including *O. paraobliqua*. Despite a low distance between the two species, their sequences appear to be trustworthy since the morphological identity of the small group of apothecia from which each sequence was gained was tested beforehand.

Ecology. *O. helicoobliqua* grew on rotten bark and wood of xeric twigs and branches of *Acacia* sp. The species is only known from one collection site in a subtropical semiarid eucalypt woodland (border between Yalgoo and Avon Wheatbelt ecoregion) in southwestern Australia (Darling Plateau).

Specimens included. **AUSTRALIA**: **Western Australia**, Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, branch of *Acacia*, on bark & wood, 24.XI.2001, G. Marson (H.B. 7204m, sq.: MK473437). – ibid., twigs of *Acacia*, on bark & wood, 26.X.2007, G. Marson (ex H.B. 8883f, MEL 2389263, **holotype**).

Orbilia curvatiobliqua Baral, **sp. nov.**, MB 813515 — Pls 384–385

Etymology: named after the falcate ascospores and a close relationship to *O. myrioobliqua*.

Typification: Western Australia, Wubin, twig of *Acacia*, 26.X.2007, G. Marson (ex H.B. 8883j, MEL 2389265, holotype).

Latin diagnosis: *Similis* Orbiliae helicoobliquae *sed ascosporae breviores et angustiores, valde falcatae vel helicoideae, basi non vel leniter attenuatae, corpuscula refringentia breviora. Habitat ad corticem putridum, ramulorum* Acaciae *in aere prominentium in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.27–0.37 mm diam., 0.11 mm high, disc light orange, non-translucent, round to elliptical, scattered; disc flat, strongly pruinose to warted by yellow exudate, margin thin, not protruding, rough; broadly sessile, superficial or in cracks of periderm. **Asci** *60–70 × 9.7–10.7 µm, †55–67(–74) × 8.5–9.5(–10) µm, 64-spored (~50 counted spores counted); **apex** (†) hemispherical, dome †3–3.5 → 1.5–2.5 µm thick, with or without apical chamber, inner layer bright pink in CR_{SDS}; **base** sessile ot with short, thick stalk, L-, Y- or h-shaped. **Ascospores** *(4–)4.5–5.5 × 1.7–1.9(–2.1) µm [actual length ~5–7(–8) µm], †4–5(–5.5)((–7)) × (1.4–)1.5–1.8 µm, cylindrical, apex rounded (to obtuse), base not or sometimes slightly attenuated, always strongly curved, falcate or often helicoid (like a left-hand thread); **SBs** consistently apically attached to spore wall, *2.2–2.8 × 0.6–0.9 µm, tear- to pear-shaped, apically narrowed to a ± small point. **Paraphyses** apically uninflated or slightly clavate, terminal cells †11–15 × 3–4 µm, 6–12 µm longer than dead asci, lower cells *10–22 × 1.5–2(–2.5) µm. **Medullary excipulum** ~20 µm thick, not examined. **Ectal excipulum** hyaline, of (†) thin-walled, indistinctly horizontally oriented t. globulosa-angularis from base to mid flanks, 20 µm thick near base, cells †8–10(–15) × 6–10(–11) µm; 10–15 µm thick near margin. **Anchoring hyphae** not examined. **SCBs** not examined. **Exudate** over paraphyses and margin 0.5–2(–3) µm thick, coarsely cloddy, light to bright sulphur-yellow, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 0.5–2 m above the ground, corticated on 1 side, 1.8 mm thick twig of *Acacia* sp., medium to strongly decayed bark (periderm), in cracks of bark, strongly greyed, no algae. **Associated**: *Amandinea* sp., *Caloplaca* sp., *Orbilia anguliobliqua*, *O. australiensis*, *O. helicoobliqua*, *O. hesperidea*, *O. myriofusiclava*, *O. myriolilacina*, *O. myriomuscula*, *O. myrioobliqua*, *O. paraobliqua*, *O. pleioaustraliensis*, ?*Triblidium* sp. **Desiccation tolerance**: fully viable for at least 18 months. **Altitude**: 380 m a.s.l. **Geology**: Archean sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia curvatiobliqua* is only known from a few apothecia growing in close vicinity of *O.*

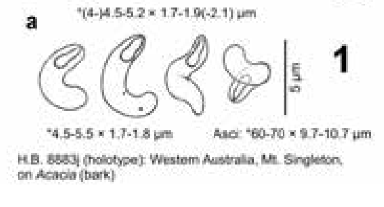

Plate 384. **1**: *Orbilia curvatiobliqua*. – **a**. ascospores.

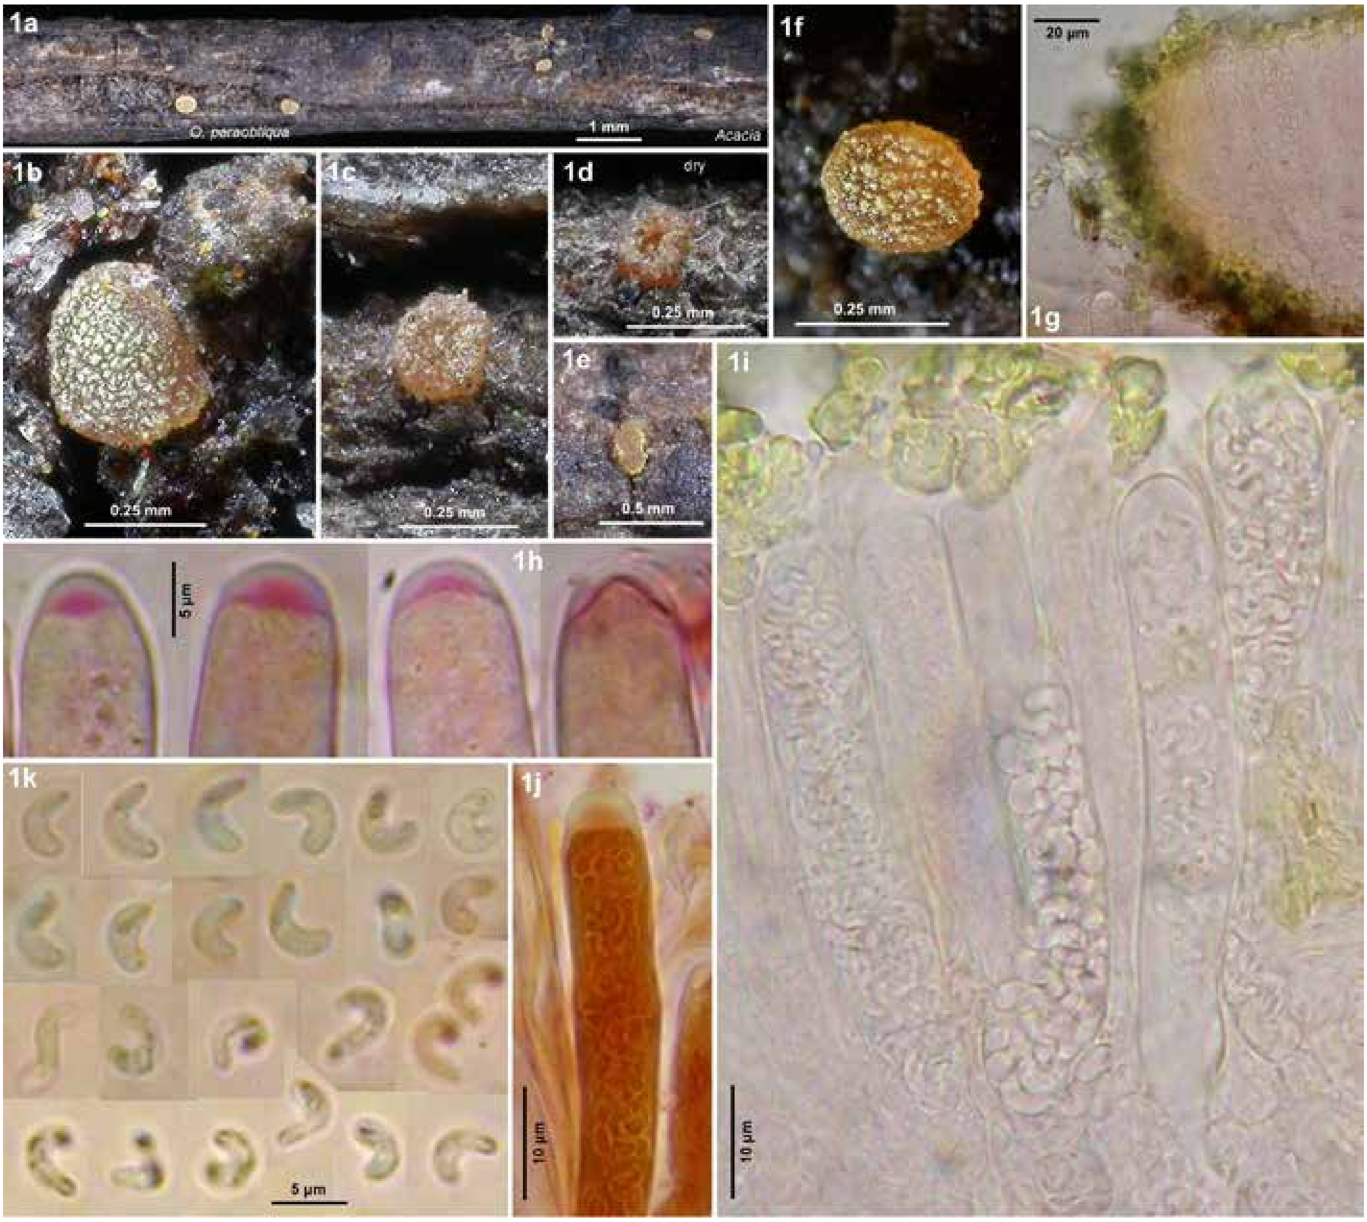

Plate 385. **1**: *Orbilia curvatiobliqua*. – **1a–c**, **e–f**. rehydrated apothecia; **1d**. dry apothecium; **1g**. apothecium in median section; **1i**. mature and immature asci; **1j–h**. ascus apices; **1k**. ascospores. – Living state, except for **1h** (in CR_{SDS}), **1k** below and right 14 spores (in H_2O, 3 right in KOH+CR), **1j** (in KOH+CR+IKI). — **1a–k**. H.B. 8883j (holotype): Western Australia, Mt. Singleton, on *Acacia*.

paraobliqua a few millimetres from each other. On different twigs of the same sample occurred the similar *O. anguliobliqua* and *O. helicoobliqua*. *O. curvatiobliqua* differs from the latter two species in smaller, especially shorter ascospores, and in SBs being usually narrowed apically to a small point, also in narrower asci. From *O. anguliobliqua* it further differs in consistently apically attached SBs and in often helicoid spores, from *O. helicoobliqua* in shorter SBs and predominantly unattenuated spore bases.

Variation. Within each of the examined apothecia the spores varied between falcate and helicoid, whereas the size of spores and SBs was rather constant.

Ecology. *O. curvatiobliqua* grew on rotten bark of a xeric twig of *Acacia* sp. in a subtropical semiarid eucalypt woodland (border between Yalgoo and Avon Wheatbelt ecoregion) in southwestern Australia (Darling Plateau).

Specimens included. **AUSTRALIA**: **Western Australia**, Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, twig of *Acacia*, on bark, 26.X.2007, G. Marson (ex H.B. 8883j, MEL 2389265, **holotype**).

Orbilia allantoobliqua Baral & G. Marson, **sp**. **nov**., MB 813516 — Pl. 386, Map 65

Etymology: named after the slightly allantoid spores and the relationship with the Australian species of series *Vibrioides*.

Typification: Western Australia, Kumarina Roadhouse, branch of *Acacia cyperophylla*, 28.X.2007, G. Marson (ex H.B. 9695c, MEL 2389279A, holotype).

Latin diagnosis: *Similis* Orbiliae anguliobliquae *sed ascosporae leniter majores, plus minusve arcuatae, basi non distincte geniculatae, supra numquam constrictae, corpuscula refringentia longiora, semper recta et ad apicem affixa. Habitat ad lignum putridum ramuli sicci* Acaciae *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.23–0.55 mm diam., 0.13–0.23 mm high (receptacle 0.18 mm), bright orange, hardly translucent, round to elliptical, scattered or in small groups; disc flat, margin ± distinct, 0–10 µm protruding, disc and margin whitish to yellowish pruinose; broadly sessile, slightly to strongly immersed in cracks; dry rather contracted, dirty orange-red. **Asci** *78–105 × (10.5–)11.5–12.5(–13) µm, †73–85 × 10–10.5(–11.5) µm, 64-spored (~50 spores counted), spores multiseriate, lower spores inverted (strongly mixed), pars sporifera *52–70 µm long; **apex** (†) hemispherical, dome †2–5 → 1.8–4.5 µm thick, with distinct apical chamber; **base** with short, thick, flexuous stalk, Y- or

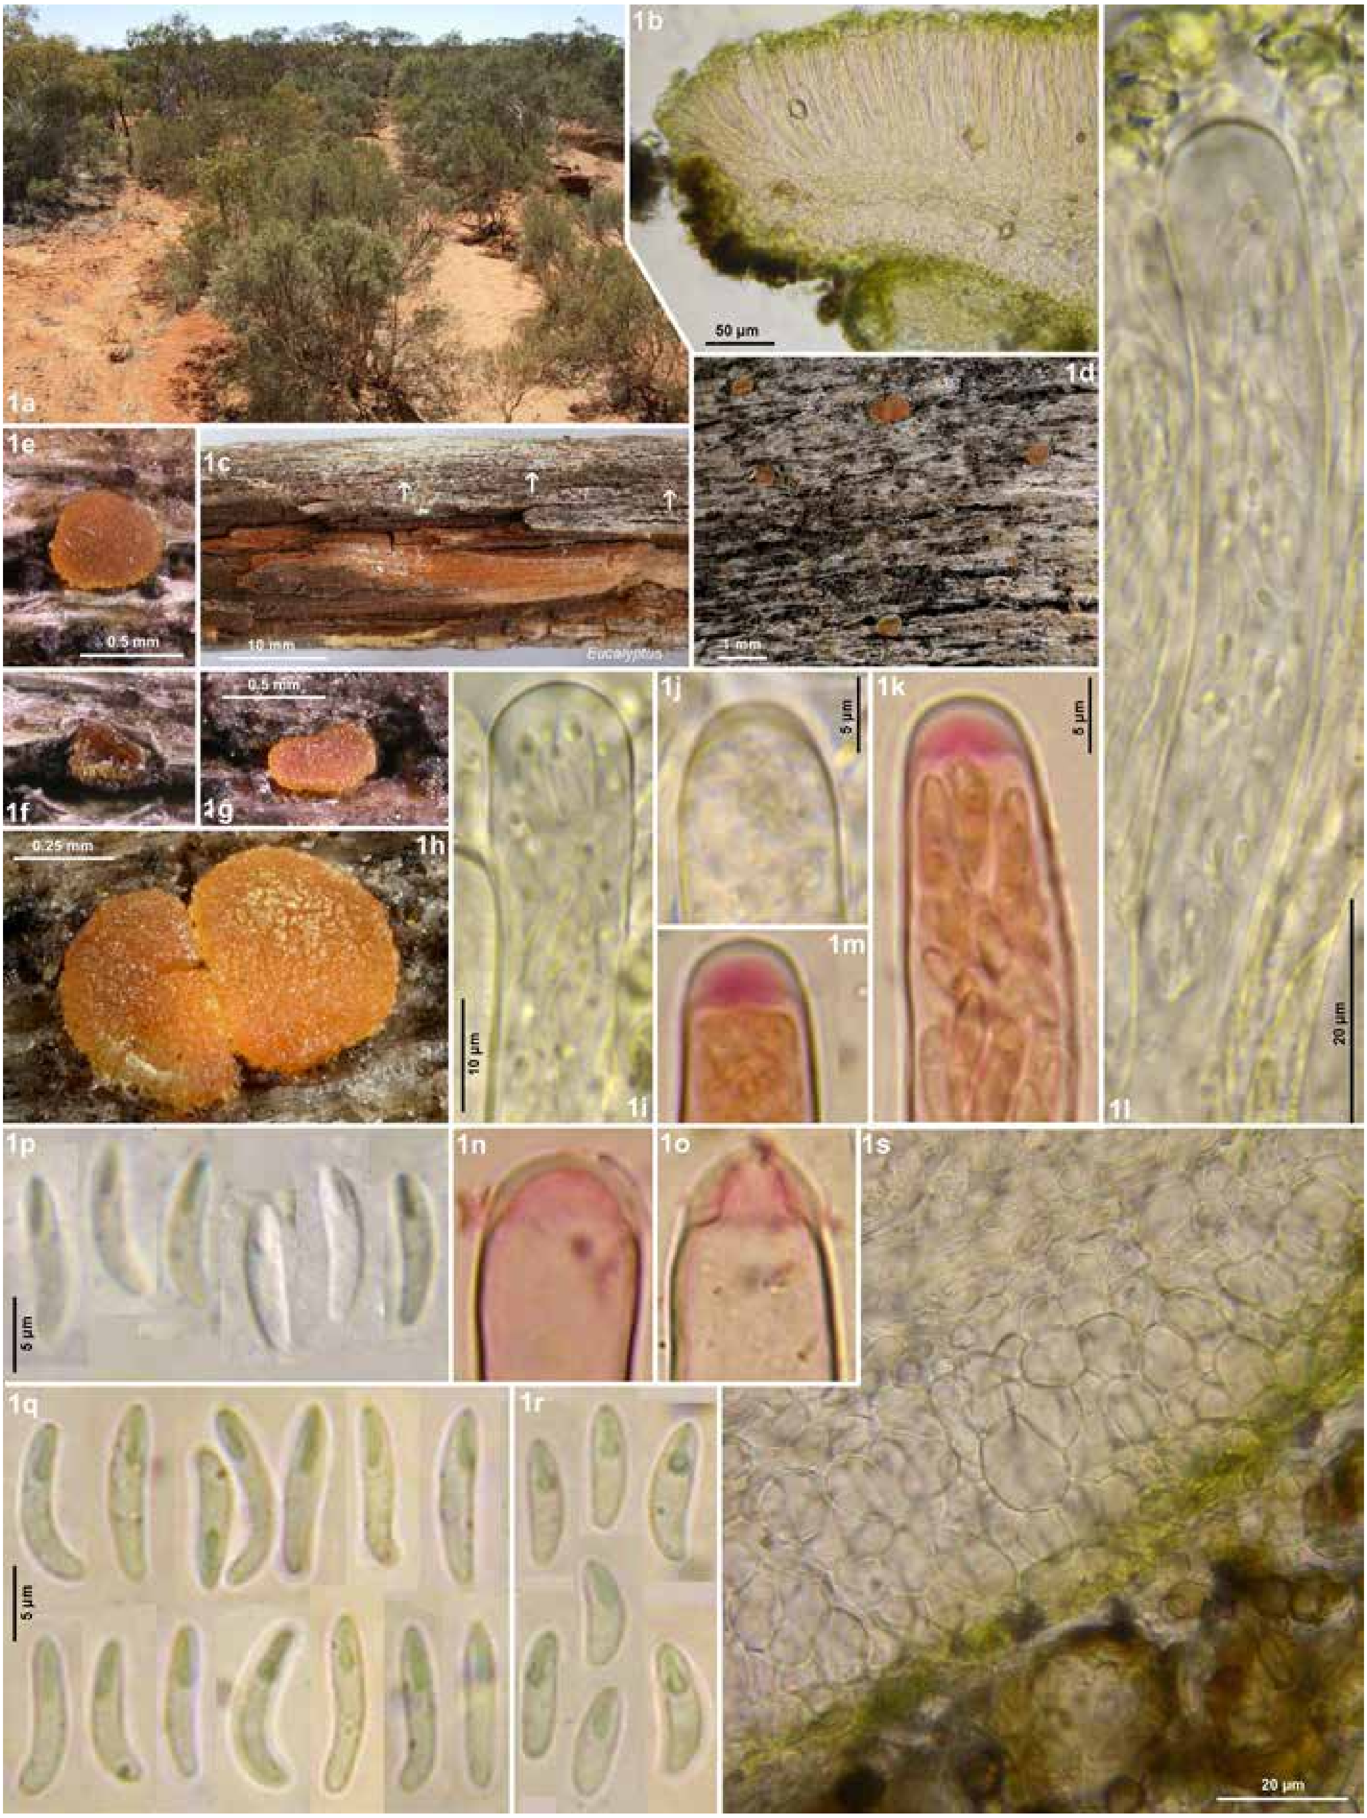

Plate 386. **1**: *Orbilia allantoobliqua*. – **1a**. subtropical arid acacia open woodland; **1b**. apothecium in median section; **1c**. decorticated xeric branch of *Eucalyptus*; **1d–e**, **g–h**. rehydrated apothecia; **1f**. dry apothecium; **1s**. ectal excipulum in median section (lower flanks); **1i**, **k–l**. asci; **1j–k**, **m–o**. ascus apices (**n–o**. basally emptied mature asci); **1p–r**. ascospores. – Living state, except for **1k**, **m–o** (CR_{SDS}). — **1a–s**. H.B. 9695c (holotype): Western Australia, Gascoyne River, on *Acacia*.

L-shaped. **Ascospores** *(6.5–)7.5–10(–11.7) × (1.8–)2–2.5(–2.6) µm, cylindrical to very slightly fusoid, ellipsoid, or clavate, never constricted, apex obtuse, base not or sometimes slightly attenuated, usually slightly to strongly curved (mainly in lower part), sometimes only inequilateral or even straight; **SBs** apically attached to spore wall, *3–4 × 0.8–1.1 µm, rod-shaped with a slight basal inflation, apically narrowed to a ± small point, straight; SBs in aged spores 2–3.3 × 1.2–1.3 µm, tear-shaped to ampulliform. **Paraphyses** apically uninflated to slightly clavate, sometimes sublageniform or moniliform, partly flexuous, terminal cells *8–18 × 2–3 µm, lower cells *11–15(–18) × 1.7–2.5 µm, at base or apex up to 3–3.3 µm wide; unbranched near apex hymenium pale orange-rose. **Medullary excipulum** pale orange-rose, 50–60 µm thick, of dense textura intricata-porrecta, horizontally oriented, partly with many inflated cells, sharply delimited. **Ectal excipulum** very pale rose, of (†) thin-walled, indistinctly oriented textura globulosa-angularis from base to mid flanks 15–70 µm thick near base, cells *(7–)9–17 × 6–12 µm; 15–20 µm thick near margin, cells, of. t. prismatica-porrecta oriented at a 10–30° angle to the surface, marginal cortical cells *4.5–10 × 2.5–4 µm. **Anchoring hyphae** very sparse, *2–2.5 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–1.5(–2) µm diam. **Exudate** over paraphyses, margin and lower flanks 1–4 µm thick, cloddy-resinous, bright sulphur-yellow, firmly attached. — **ANAMORPH**: unknown.

Habitat: collected 2.5–3 m above the ground, decorticated, 16–17 mm thick branch of *Acacia cyperophylla*, on 0.2 mm deep very decayed wood, strongly greyed, no algae. **Associated**: *Coccomycetella* spp. {2}, *Hysterobrevium mori*, *Orbilia australiensis, O. multiaustraliensis*, *O. pleioaustraliensis*, *O. pleiocoronohesperidea, O. pleiovinosa*, *Ostropales*. **Desiccation tolerance**: fully viable after 34 months (57 months when including occasional rehydration). **Altitude**: 540 m a.s.l. **Geology**: Mesoproterozoic sedimentary rock (red-brown sand & gravel). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia allantoobliqua* differs from *O. anguliobliqua* in slightly larger ascospores which are similarly curved though not distinctly bent below and never constricted in the middle, also in longer, always straight and apically attached SBs. Moreover, asci and pars sporifera are distinctly longer in *O. allantoobliqua*, though the spore number is the same.

Variation. Shape and curvature of the spores varied among the ca. six apothecia examined. In one of them which grew in a small group at 6–8 cm distance from the main group, the spores tend to be shorter and wider, and often rather straight (Pl. 386: 1r), reminiscent of the deviating 64-spored apothecium observed in *O. paraobliqua* (Pl. 379: 2), while in the others they were mainly of the typical size. However, such short and wide, hardly curved spores occasionally occurred also in apothecia with typical spores, which indicates that these spore variants belong to a single species. SBs were quite constant in size and shape, but get shorter and wider with age.

Ecology. *O. allantoobliqua* was found on rotten wood of a decorticated xeric branch of *Acacia* in a subtropical semiarid acacia open woodland with *Eucalyptus* in a most of the time dry riverbed in the Gascoyne ecoregion in western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Gascoyne, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW of Plutonic Gold Mine, 540 m, branch of *Acacia cyperophylla*, on wood, 28.X.2007, G. Marson (ex H.B. 9695c, MEL 2389279A, **holotype**).

Orbilia angustoobliqua Baral & G. Marson, **sp. nov.**, MB 813517 — Pls 387–388, Map 65

Etymology: named after the long and narrow ascospores and the similarity with *O. anguliobliqua*.

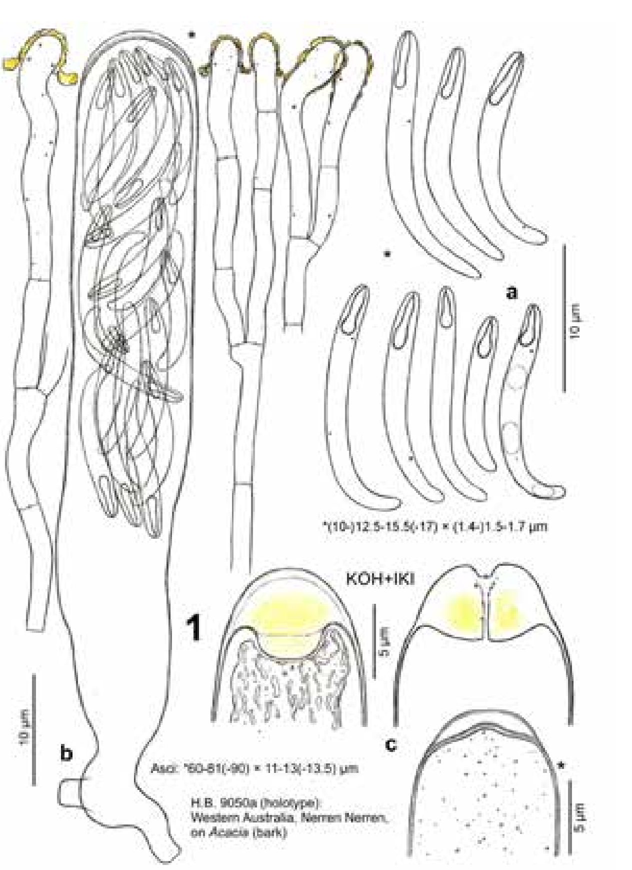

Plate 387. **1**: *Orbilia angustoobliqua*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.22–0.55(–0.65) mm diam., 0.1–0.16 mm high, light to bright orange, with partly distinct whitish-yellowish pruina, non-translucent, round to ± elliptical, scattered to subgregarious; disc flat, margin 0–10 µm protruding, ± distinctly whitish-yellowish crenulate or ribbed; broadly sessile, superficial or ± immersed in cracks; dry strongly contracted with raised margin covering most of the disc, disc bright orange-ochraceous to purplish-brown, margin whitish-yellowish powdered. **Asci** *60–81(–90) × 11–13(–13.5) µm, †54–65 × 8.5–10.5 µm, 64-spored (~50 spores counted), spores (*) multiseriate, lower spores inverted (strongly mixed), pars sporifera *(36–)40–53(–60) µm long; **apex** (†) hemispherical, dome *1.4–1.8 → 1.2–1.3 µm thick, †3.5–4.5 → 2–3 µm (KOH 4–6 → 2–4.5 µm), with or without small apical chamber, endotunica pale yellow-orange in IKI (KOH-pretreated), bright red in $\mathrm{CR}_{\mathrm{SDS}}$; **base** with short, thick stalk, T- or L-shaped. **Ascospores** *10.5–13 or mostly *(10–)13–16(–17) × (1.4–)1.5–1.7 µm, †11–15.5 × 1.4–1.7 µm, cylindric-fusoid, apex obtuse, base slightly (to medium) attenuated, medium to strongly curved near base; **SBs** apically attached to spore wall, *2.8–4(–4.5) × (0.5–)0.6–0.8(–1) µm, subulate to narrowly tear- or pear-shaped, apically narrowed to a ± small point, straight to slightly curved. **Paraphyses** apically uninflated to slightly clavate, terminal cells *(5–)10–18 × 1.8–3 µm, exceeding the hymenial surface by 2–5 µm, lower cells *7–14 × 1.7–2.2(–2.5) µm; sometimes branched at upper septum, hymenium pale rose. **Medullary excipulum** very pale rose, 20–40 µm thick, of dense textura intricata-globulosa, medium to sharply delimited. **Ectal excipulum** hyaline to very pale rose, of (†) thin-walled to slightly gelatinized, indistinctly vertically or horizontally oriented t. globulosa-angularis from base to mid flanks, 15–60 µm thick near base, cells *8–17 × 5–13 µm; 15–20 µm thick near margin, of t.

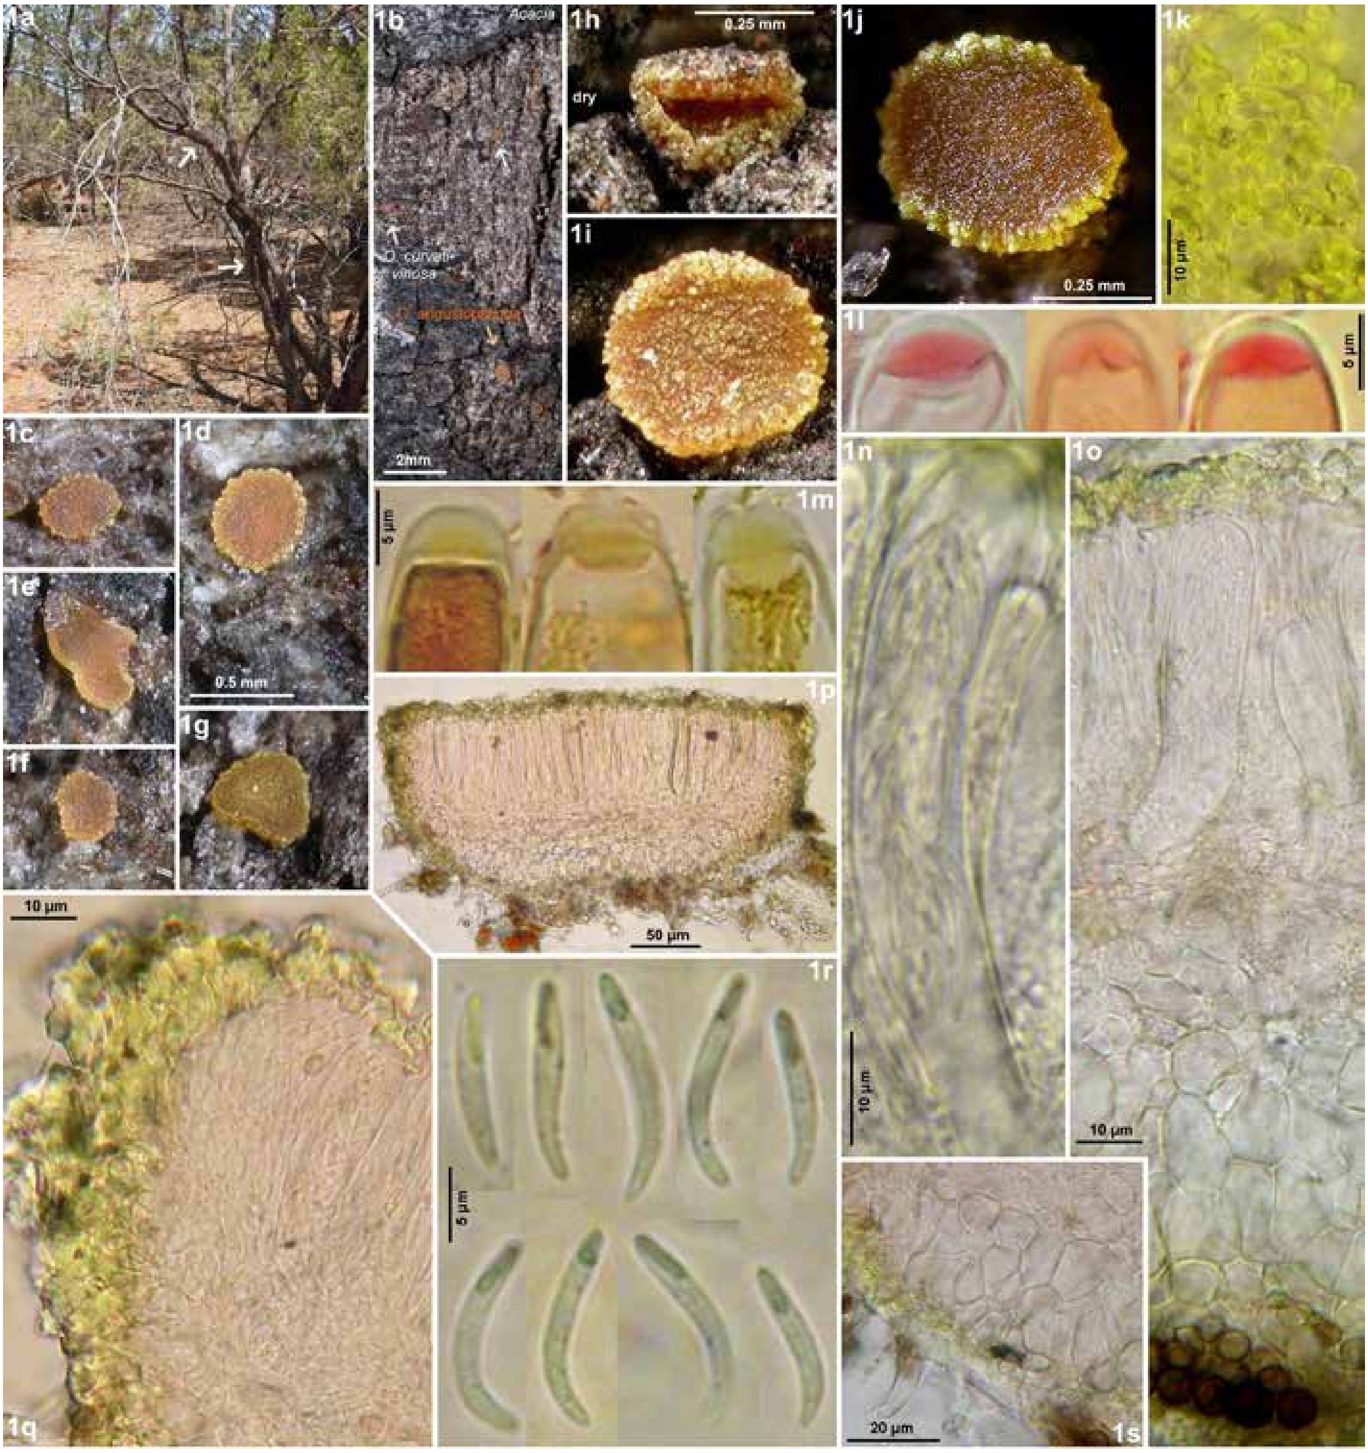

Plate 388. **1**: *Orbilia angustoobliqua*. – **1a**. acacia shrubland; **1b**. xeric bark of a dead *Acacia* shrub; **1b–g**, **i–j**. rehydrated apothecia; **1h**. dry apothecium; **1p**. apothecium in median section; **1q**. id., marginal region; **1o**. id., central part of apothecium; **1s**. id., basal ectal excipulum; **1k**. exudate on margin (external view); **1n**. mature ascus; **1l–m**. ascus apices; **1r**. ascospores. **1j–k**: illuminated by Luxeon-LED. – Living state, except for **1l** (in CR), **1m** (in KOH+IKI). — **1a–s**. H.B 9050a (holotype): Western Australia, Nerren Nerren, on *Acacia* (bark).

porrecta oriented at a 10–30° angle to the surface, marginal cortical cells *8–10 × 2.7–4 µm. **Anchoring hyphae** medium abundant, *2–3 µm wide, walls 0.2–0.4(–0.6) µm thick. **SCBs** in paraphyses absent, in ectal excipulum sparse, globose, 1.5–2 µm diam. **Exudate** over paraphyses and margin 0.3–1.5 µm thick, granular-cloddy, very rough, pale to bright sulphur-yellow, firmly attached. — **ANAMORPH**: unknown.

Habitat: collected 0.5–1.5 m above the ground, corticated, ~4 cm thick trunk of *Acacia* sp., on exterior of detached, very decayed bark (bast), partly in cracks, strongly greyed, no algae. **Associated**: *Orbilia anguliobliqua*, *O.* ?*atriplicis*, *O. helicovinosa*, *O. myriella*, *O.* ?*saguarina*. **Desiccation tolerance**: fully viable for at least 18 months. **Altitude**: 190 m a.s.l. **Geology**: Cretaceous sedimentary rock, Cenozoic regolith (red-brown sand). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia angustoobliqua* is well characterized by comparatively long and narrow, basally tapered, distinctly curved ascospores. *O. anguliobliqua* differs in much shorter, wider spores with slightly shorter and wider, partly subapically attached SBs.

Variation. In a small part of the scattered population the spores were distinctly shorter (*10.5–13 × 1.5–1.7 µm) though the other features fully concurred.

Ecology. *O. angustoobliqua* was found on rotten xeric bark detaching from the main trunk of a ca. 3 m tall *Acacia* tree in a subtropical semiarid acacia shrubland of western Australia (Yalgoo ecoregion). Some lower parts of the *Acacia* showed distinct traces of fire influence, and possibly therefore the shrub looked partially dead. *O. helicovinosa* grew intermingled with *O. angustoobliqua* but was easily recognizable by its lilaceous colour. The other associated *Orbilia* species mentioned above grew on much thinner branches and twigs (3–10 mm) of the same plant individual.

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, branch of *Acacia*, on bark, 8.XI.2007, G. Marson (ex H.B. 9050a, MEL 2389278A, **holotype**; MEL 2389277, **isotype**).

= *Dwayaangam junci* Kohlm., Baral & Volkm.-Kohlm., Mycologia 90(2): 304, fig. 15 (1998)

Etymology: named after the host plant, *Juncus roemerianus*.

Typification: USA, North Carolina, New Port, leaves of *Juncus roemerianus*, 20.XI.1995, J. Kohlmeyer & B. Volkmann-Kohlmeyer (IMS, holotype of teleomorph); ibid., 26.I.1997 (IMS, holotype of anamorph).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.07–0.35 mm diam., 0.06–0.1 mm high, pale to light orange-rose, translucent, round, scattered to subgregarious; disc flat or slightly convex, margin smooth, not rising above disc; broadly sessile, slightly to strongly erumpent, with an immersed obconical stipe up to 0.03 × 0.05 mm, slightly immersed in host tissue when mature; dry light orange. **Asci** *40–45 × 9–10.5 µm {1}, †35–55 × 6.8–9.3 µm {3}, 16-spored (but frequently only 8–14 spores viable) {4}, ~7–12 lower spores inversely oriented (± mixed) {4}; **apex** (†) hemispherical to broadly conico-subtruncate, dome †2.5–3.5(–4.8) → (1–)1.5–2(–2.5) µm thick {3}, with or without small apical chamber, endotunica sometimes slightly dextrinoid in MLZ (diffusely pale red), especially when pretreated by heated KOH, light rose-red in CR; **base** with short- to medium long, flexuous, thick stalk, T-, L- or Y-shaped. **Ascospores** *(6–)7–9(–10.2) × (2.3–)2.5–3.5(–4) µm {4}, †5.5–8 × 2.2–3.2 µm {2}, ± ellipsoid(-fusoid) to somewhat clavate, apex rounded to obtuse, straight, rarely distinctly curved at base; **SBs** apically attached to spore wall, 2–3 × 1–1.2(–1.5) µm {4}, tear-shaped to pyriform or ampulliform, apically narrowed to a small to wide point; with a few minute LBs. **Paraphyses** apically cylindrical or slightly clavate, sometimes curved, terminal cells *9–11 × 2–2.2 µm {1}, †4.5–8 × 1.5–2.8 µm {2}, lower cells *6.5–12 × 1.5–2.2(–3) µm {1}, †4–10 × 1.2–1.7 µm {2}, sometimes branched at upper septum. **Medullary excipulum** 15–20 µm thick, mainly present in centre, of dense t. intricata, slightly to medium sharply delimited. **Ectal excipulum** hyaline, of thin-walled, indistinctly to horizontally oriented textura angularis-prismatica from base to mid flanks, ~12–30 µm thick near base, cells *6–14 × 4.5–13 µm {2}, †6–10 × 5–6 µm {1}; 10–15 µm thick at margin, oriented at 30–70°, marginal cortical cells */†5–11 × 2.5–6 µm {3}, **glassy processes** absent. **Anchoring hyphae** very sparse, †1.5–2 µm wide, wall 0.2 µm thick. **SCBs** globose, in terminal cells of paraphyses 1–2 µm diam., in ectal excipulum 1.5–3 µm. **Exudate** over paraphyses continuous, hyaline, (0.3–)0.5–2(–3) µm thick, externally often coarsely rough, loosely attached; over margin and flanks 1–2.5 µm thick, rough. — **ANAMORPH**: dwayaangam-like (from ascospore isolate {3} and natural substrate {2}). **Conidiophores** short, *4–8.5 × 1.7–3.3 µm. **Conidia** total size *(21.5–)27–44(–50) × 18.5–26 µm; stipe *9–12 × 3–3.5 µm (main axis 10–14 µm long), 0–1-septate; twice dichotomously branched: two arms pointing upwards, two downwards, arms slightly to strongly tapered, medium to strongly curved outwards (upper arms sometimes straight), *16–24 × 2.8–3.2(–3.5) µm in situ, (1–)2(–3)-septate {2}.

Habitat: collected 0.5–1.5 m above low water level (~0.1–1 m above high tides), on dry, standing, dead since min. 1–2 years, 1.5–3 mm thick leaves of *Juncus roemerianus* {6}, very decayed, slightly greyed, green algae sparse. **Associated**: *Loratospora aestuarii*, ?*Phoma* sp., *Physalospora*

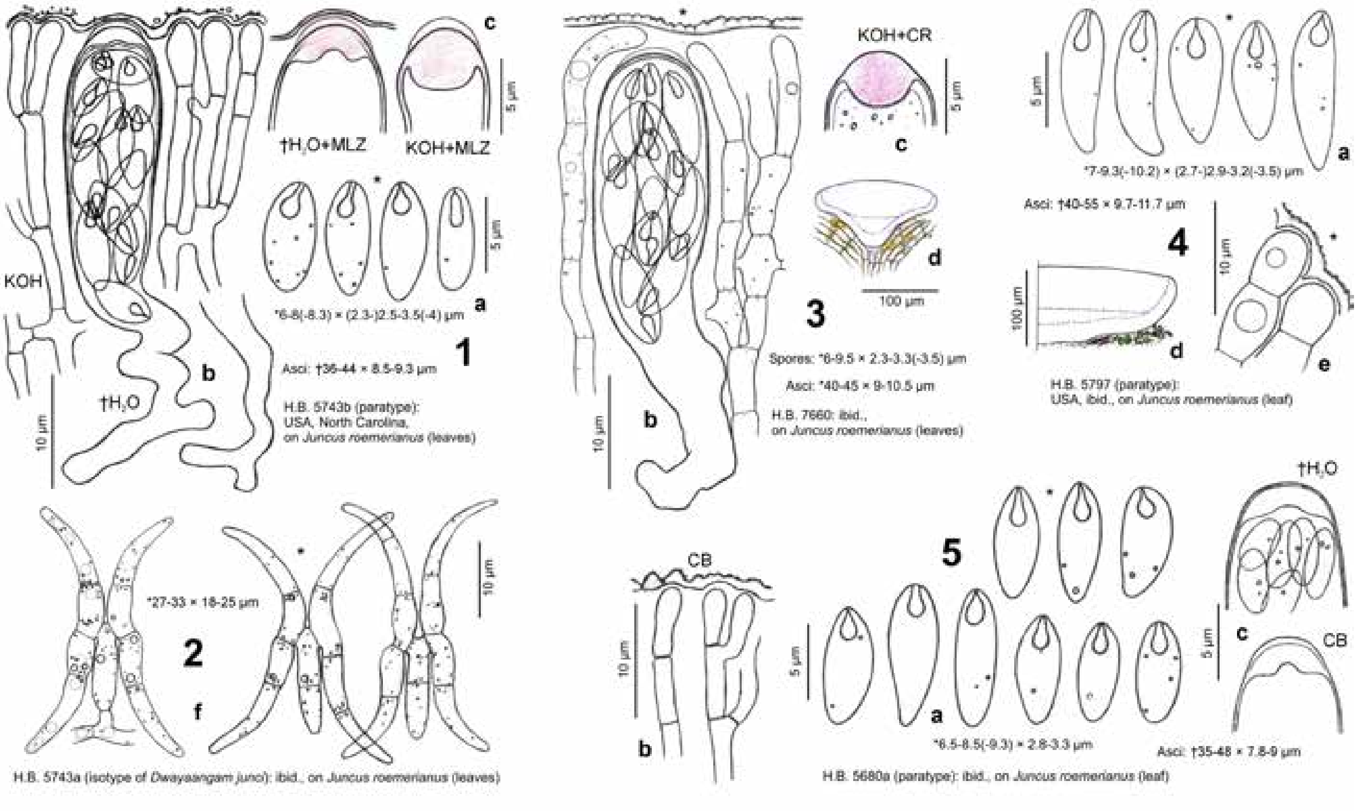

Plate 389. **1–5**: *Orbilia junci*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., marginal cortical cells; **f**. conidia from culture.

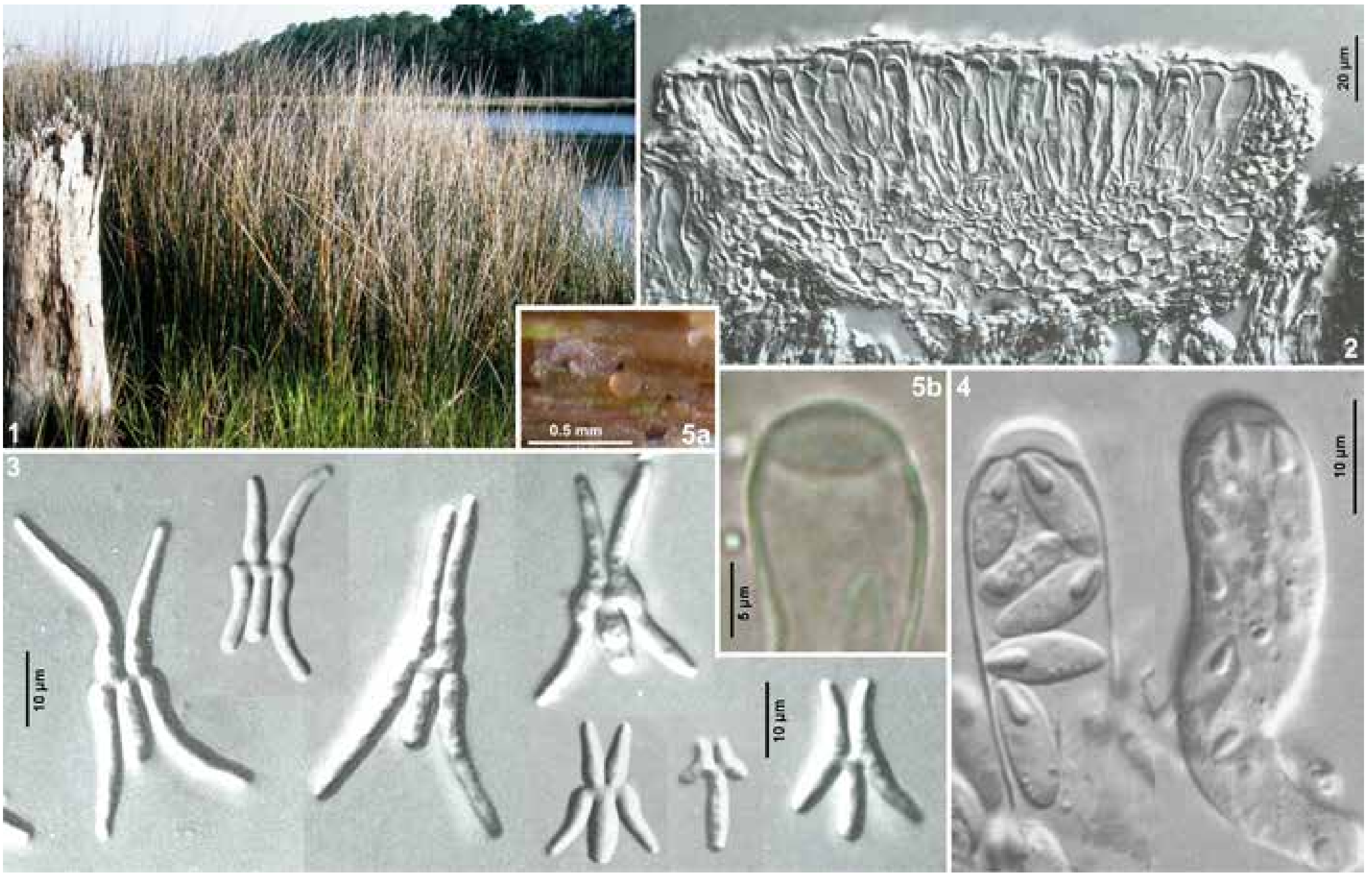

Plate 390. **1–5**: *Orbilia junci*. – **1**. type location, *Juncus roemerianus* stand, with *Spartina alterniflora* below (green); **5a**. rehydrated apothecia; **2**. apothecium in median section; **4**. asci with mature ascospores; **5b**. ascus apex; **3**. conidia from culture. – Living state, except for **2** (cryostat microtome, in ?H_2O), **5b** (in H_2O), asci in **4**. – **1–4**: phot. Kohlmeyer et al. 1998 (DIC). —**1**. USA, North Carolina, Broad Creek, VI.1999; **2**. J.K. 5568 (holotype): ibid.; **3**. J.K. 5604: ibid.; **4**. J.K. 5574: ibid.; **5a–b**. H.B. 7660: ibid. (all on *Juncus roemerianus*).

citogerminans, *Scirrhia annulata*. **Desiccation tolerance**: submature asci still viable after 6 days, excipular cells after 3 weeks, ascospores after 8 months, conidia after min. 1 week (but dead after 4 months). The species is probably also halotolerant since the upper halves of the leaves are exposed to occasional spray from the surrounding estuarine water. **Altitude**: 1 m a.s.l. **Geology**: Quaternary sedimentary deposits. **Phenology**: I, III–VI, XI (possibly throughout the year).

Taxonomic remarks. *Orbilia junci* is characterized by ± ellipsoid ascospores with tear-shaped to ampulliform spore bodies, and by 16-spored asci with strong apical thickenings. The species might have a somewhat isolated position within section *Hemiorbilia*. With series *Vibrioides* it shares the thick apical dome. The shape of ascospores and SBs resembles species of series *Hesperideae* (like *O. palmicola* and *O. australiensis*), species in which the apical domes are always much thinner and the apothecia often much larger.

Variation. Hardly any variation was noted among the collections which all originate from the type locality. Often only 8–14 of the 16 spores were viable within the asci, a phenomenon that in earlier studies misled to consider the asci as 8-spored. Dead spores are easily overlooked among the living spores (Pl. 390: 4), whereas when mounted in MLZ or CB_L always 12–16 spores could be seen.

Anamorph. *O. junci* possesses an extraordinary anamorph with staurosporous, dwayaangam-like conidia having 4 outwards curved arms. The conidia resemble, e.g., those of *Dwayaangam cornuta* in shape, but are distinctly smaller and their arms tend to be more curved, moreover, *D. cornuta* tends to higher-branched conidia. Matsushima (1993: 16, fig. 739) reported under the name *D. cornuta* a species from angiosperm leaves (Ecuador) which is quite similar to *D. junci*. The conidia are slightly longer (40–57 × 13–25 µm according to scale) and have more septa, and the proximal part of the 4 arms is more incurved, resulting in strongly protruding hips at the centre of the conidia (see p. 233–234).

Ecology. According to Kohlmeyer et al. (1998) and Kohlmeyer & Volkmann-Kohlmeyer (2001), *O. junci* has so far only been collected at the type locality, a warm-temperate humid coastal salt marsh of eastern North America, and there exclusively on dead xeric leaves of *Juncus roemerianus*. On that host it appears to be ‘the most frequent species among the 10 tiny discomycetes found so far’. *J. roemerianus* is a common halophyte forming monoculture-like stands, though in association with *Spartina alterniflora*, on salt marshes along estuaries of the United States’ east and Gulf coasts. The leaves very slowly die back from the tip and here bear the first settlers, whereas the basal parts of the leaves are flooded during high tides. The leaves may remain standing for several years in the dead state. *O. junci* is among the last species to appear, and its desiccation-tolerant apothecia occur exclusively on the brittle tips of the senesced standing leaves after the cuticle has been shed. Despite the closeness to seawater, mycelia did not grow on seawater medium in pure cultures, therefore, apothecial growth appears to be supported by rain or dew.

Apothecia of *O. junci* have been collected mainly in winter and spring, but were not found during July–September, the hottest summer months. During severe hurricanes which broke off the oldest leaves, apothecia of *O. junci* vanished, but conidia of the anamorph were discovered to occur abundantly on recently senesced leaves, though exclusively in small holes having been eaten by grasshoppers into the living tissue. Here, the species appears to survive as anamorph until enough senescent, well weathered leaf tips occur.

Specimens included. **USA**: **North Carolina**, Carteret, 43 km E of Jacksonville, 11 km SW of New Port, Broad Creek, 1 m, leaves of *Juncus roemerianus*, 19.IV.1996, J. Kohlmeyer & B. Volkmann-Kohlmeyer (J.K. 5584, H.B. 5680a). – ibid., 20.XI.1995 (ex J.K. 5568, anam. cult., IMS, **holotype of teleomorph**; UME, **isotype**; H.B. 5680b, **isotype** [slide]). – ibid., 21.V.1996 (J.K. 5586, anam. cult.). – ibid., 27.IV.1997 (J.K. 5611, H.B. 5797). – 26.I.1997 (ex J.K. 5604, IMS, anam. cult., **holotype of anamorph**; H.B. 5743a, **isotype**). – ibid., 2.III.1997, (J.K. 5606, H.B. 5743b). – ibid., 6. & 13.VI.2000 (ex J.K. 5652, 5653, IMS, anam. substr.). – ibid., 13.I.2005, J. Subgenus *Habrostictis*

Orbilia subgenus ***Habrostictis*** (Fuckel) Baral & E. Weber, **comb. & stat. nov.**, MB 815006 – Lectotype species: *Habrostictis rubra* Fuckel [= *O. carpoboloides* (P. & H. Crouan) Baral], designated by Höhnel (1917: 330)

Basionym: *Habrostictis* Fuckel, Jahrb. Nassau. Ver. Naturkd. 23–24: 249 (1870)

Description: — **TELEOMORPH**: **Apothecia** hydrated whitish, yellowish, rose, orange, lilaceous, margin glabrous or dentate to hairy, sessile or short-stipitate, superficial to erumpent. **Ascus apex** (†) slightly to mostly medium to strongly truncate, not or slightly to distinctly indented and laterally inflated, hemispherical in profile view, thin-walled; **base** T-, L-, Y- or h-shaped, only exceptionally H-shaped. **Ascospores** variously shaped; **SBs** apically affixed to spore wall, rarely subapically in some taxa in series *Ellipsospermae*, often filiform to vermiform or subulate, usually flexuous, also tear-shaped to globose, apically narrowed to a small point, filum absent or very short (to short to sometimes long). **— ANAMORPH**: anguillospora-like, dicranidion-like, dwayaangam-like, helicoon-like, pseudotripoconidium-like, trinacrium-like, tridentaria-like, vermispora-like. **Trapping organs**: unknown.

Habitat: on xeric or sometimes hygric to semiaquatic wood and bark of gymno- and angiosperms, also caulicolous, foliicolous, or fungicolous, from boreal to tropical, humid to arid climates.

Recognized sections: *Aurantiorubrae*, *Habrostictis*, *Helicoon*, with 173 recognized species plus 3 with a provisional name, and 31 unnamed species ('affinis').

General remarks. The present circumscription of subgenus *Habrostictis*, which comprises three sections (*Habrostictis*, *Aurantiorubrae*, *Helicoon*), is mainly based on molecular phylogenetic data. A morphological feature common to all its members is the thin-walled, truncate ascus apex which is, however, characteristic also of subgenus *Orbilia* and series *Ovales* of subgenus *Hemiorbilia*. The paraphyses are frequently inflated at the apex, but this feature is likewise also found in the two mentioned and some other groups. The predominant absence of H-shaped ascus bases is in contrast to their frequent presence in subgenus *Orbilia*. Many taxa of the three included sections possess characteristic, vermiform to filiform or subulate, often flexuous SBs in the mature ascospores, but section *Aurantiorubrae* includes also taxa with globose SBs, while some taxa of section *Hemiorbilia* feature similar vermiform SBs.

Section delimitation. Sections *Habrostictis* and *Helicoon* are rather well characterized by comparatively long and narrow, often ± flexuous to helicoid, sometimes uncinate SBs, though a few taxa have rather short and wide SBs. Within section *Aurantiorubrae*, subulate to filiform, ± flexuous SBs occur in some species of series *Abutilones*, *Piliferae*, and *Poitevinicae,* whereas in the other included series SBs are always straight (or follow the curvature of the spores), either rod-shaped or usually narrowly tear-shaped to globose. Further distinguishing features between the sections concern, e. g., length/width ratio of ascospores, spore numbers, length of terminal cell of paraphyses in relation to lower cells, glassy processes, and crystalloid SCBs.

The two large sections *Habrostictis* and *Aurantiorubrae* contain almost exclusively desiccation-tolerant species with yellow-orange to rose-red apothecia. Apothecia of section *Helicoon*, on the contrary, are desiccation-sensitive or at best slightly tolerant, and are often whitish to pale rose-lilaceous but also yellow-orange.

Anamorphs. Members of sections *Habrostictis* and *Aurantiorubrae* form two very different types of conidia: stauroconidia (mainly trinacrium-like, also tridentaria- or dwayaangam-like) or curved phragmoconidia (vermispora-like, rarely anguillospora- or dactylella-like). Also in section *Helicoon* two very different types of conidia occur: phragmoconidia (anguillospora- to vermispora- or dactylella-like), and inversely pyramidal ameroconidia with small protuberances (pseudotripoconidium-like). Taxa with predatory capabilities are unknown within subgenus *Habrostictis*.

Phylogeny. In the phylogenetic analysis of SSU+ITS+LSU rDNA in Baral et al. (2017b), subgenus *Habrostictis* formed an unsupported paraphyletic clade which contains also section *Lentiformes* of subgenus *Hemiorbilia*. Sections *Helicoon* and *Habrostictis* formed two strongly supported independent clades, whereas section *Aurantiorubrae* clustered in no less than six independent, strongly supported clades with more or less distant kinship and unsupported nodes. Paraphyly of section *Aurantiorubrae* is also obvious in Phyl. 7.

The present phylogenetic analyses do not allow to elucidate the evolutionary pathways of the different types of spore bodies within subgenus *Habrostictis*. The phenomenon that SBs of the elongate type change in overmature spores to shorter and wider and finally globose could be interpreted as a regression to a plesiomorphic character, by considering vermiform to filiform SBs as an apomorphy within the genus *Orbilia*, i. e., a higher step in evolution compared to taxa with globose SBs. However, the largest clade within section *Aurantiorubrae*, which includes series *Aurantiorubrae*, *Commatoideae*, *Regales*, and *Rubellae*, comprises globose, tear-shaped, and subulate but never filiform SBs, and it would seem logical that, within this clade, SB shape developed from globose over tear-shaped to subulate. Moreover, the general occurrence of long and narrow SBs in sections *Habrostictis* and *Helicoon* does not seem to trace back to a common ancestor with elongate SBs, since these two sections are placed in our analyses in two rather distant clades. If the hypothesis of SB development holds true, we may conclude that elongation of SBs within *Orbilia* occurred by convergence in different lineages.

Similar as in subgenus *Orbilia*, the frequently observed desiccation-sensitivity in section *Helicoon* is thought to be an apomorphy, which would mean that the common ancestor of this section was a desiccation-tolerant fungus (see also p. 160).

Specific nucleotide positions. No molecular motifs being characteristic of the entire subgenus *Habrostictis* have been discovered in any of the frequently recorded regions of nuclear rDNA. However, some of the included sections or series show a few rather consistent nucleotides by which they can be distinguished (see there).

Section *Aurantiorubrae*

Orbilia subgenus ***Habrostictis*** section ***Aurantiorubrae*** Baral & E. Weber, **sect. nov.**, MB 815007 – Type species: *Orbilia aurantiorubra* Boud.

Latin diagnosis: *Apothecia plerumque tolerantia ad siccitatem, flavida, ochracea, aurantia, rosacea vel rubra, raro hyalina, ad marginem partim pilis septatis vel processis vitreis, vacuolae refringentae plerumque absentes, ascosporae saepe angustae et falcatae vel helicoideae, conidia plerumque elongatae, multiseptatae, falcatae, raro rectae vel ramosae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.3–1.5(–3) mm diam., whitish, pale to bright rose, red, orange or yellow to ochraceous, ± smooth to whitish fimbriate or toothed, sessile or with a short stipe. **Asci** *(23–)30–70(–82) × (3–)3.5–6(–7.5) µm, 8-, rarely 16(–32-)spored, lower (rarely upper) (0–)3–5(–7) spores inverted (if 8-spored); **apex** (†) slightly to strongly truncate, not or partly distinctly indented and laterally inflated; **base** T-, L-, Y-, or h-, exceptionally H-shaped. **Ascospores** *(4–)5–15(–19) × 0.6–2.8(–3) µm, broadly to usually narrowly subcylindric- to ellipsoid- or fusiform-clavate, apex rounded to acuminate, base attenuated or not, partly tail-like or sometimes with a distinct tail or a subbasal constriction, straight or slightly to strongly curved or geniculate near base or as a whole (falcate or helicoid); **SBs** attached to spore apex, globose, tear-shaped, ampulliform, subulate or filiform, apically narrowed to a small, more rarely to a wide point, mostly with a very short filum. **Paraphyses** not or slightly to strongly clavate-capitate or spathulate to mammiform at the apex, rarely lageniform or lanceolate, terminal cells (0.8–)1–3(–5)× longer than lower cells, usually unbranched at upper septum. **Ectal excipulum** at flanks of textura (globulosa-) angularis(-prismatica), cells isodiametric or vertically to irregularly elongated, (†) thin-walled to medium gelatinized (common walls †0.2–1.7 µm thick), cells near base *(6–)9–25(–38) × (5–)7–18(–25) µm (on ± xeric substrate), */†(9–)15–50(–70) × (7–)12–45(–60) µm (on hygric substrate); **glassy processes** absent or 1–10 µm up to 20–80(–200) µm long, **hairs** absent or (10–)20–65(–93) µm long, thin- or thick-walled, septate. **SCBs** globose and/or crystalloid, or absent; **VBs** rarely present, medium refractive; **carotenoids** in **LBs** observed in many species. — **ANAMORPH**: anguillospora-like, dactylella-like, dicranidion-like, dwayaangam-like, trinacrium-like, vermispora-like. **Conidiophores** unbranched or branched, short to long, 2–200 µm long. **Conidiogenous cells** monoblastic or sympodial. **Conidia** mainly unbranched (phragmo- to scolecosporous), straight or often ± curved, more rarely branched (staurosporous), with 2–4 straight or curved arms, with or without stipe; conidial dimorphism not observed. **Trapping organs**: none observed.

Habitat: mainly desiccation-tolerant, also desiccation-sensitive.

Recognized series: *Abutilones*, *Albovinosae*, *Aurantiorubrae*, *Commatoideae*, *Hyalinia*, *Piliferae*, *Poitevinicae*, *Regales*, *Rubellae*, and *Xanthoguttulatae*, with 67 recognized species plus 1 with a provisional name and 10 unnamed species ('affinis').

Taxonomic remarks. Section *Aurantiorubrae* includes taxa with predominantly narrow ascospores which are frequently curved, either at the base (geniculate), or entirely (falcate or helicoid). The spore apices vary from rounded to acuminate, and the bases from slightly to strongly tapered, sometimes with a prominent tail or basal constriction. Spore body shape varies from globose to tear-shaped or filiform. Spathulate to mammiform paraphysis apices are frequent, but capitate ones also often occur. Short to very long, septate marginal hairs and/or glassy processes are typical of a majority of the species.

Most of the included species are desiccation-tolerant and lack VBs in the paraphyses. VBs were exceptionally observed in *O. caulicola*, *O. neocomma*, *O. milinana*, *O. nemaspora*, and *O. pilifera*, though never in the often studied desiccation-sensitive *O. crenatomarginata*. The asci are always 8-spored, except for some species of series *Albovinosae* which are 16–32-spored.

Series delimitation. Ten series are tentatively recognized within section *Aurantiorubrae*: series *Regales*, *Commatoideae*, *Rubellae*, *Aurantiorubrae*, *Xanthoguttulatae*, *Hyalinia*, *Abutilones*, *Poitevinicae*, *Piliferae*, *Albovinosae*. Some series (*Xanthoguttulatae*, *Abutilones*) were mainly based on molecular data. Series *Commatoideae* and *Rubellae* are difficult to maintain against series *Aurantiorubrae* and *Regales*. Questionable is also the relationship between *O. caulicola* (*Commatoideae*) and the unsequenced *O. rosella* which we tentatively placed in series *Abutilones*.

Anamorph. The predominant anamorph of section *Aurantiorubrae* is represented by rather uniform phragmosporous, vermispora-like conidia, which occur throughout the first four here recognized series, as far as the anamorph is known, but also in series *Poitevinicae*. The conidial ends are usually slightly to strongly curved (C-like, or resembling a square bracket). Many of these conidial states resemble *Lecophagus navicularis*, from which they differ in the lack of ampulliform conidiogenous cells, as far as conidiophores were studied, in consistently much narrower conidia, and especially in the lack of cubical SCBs in the centre of the conidial cells. '*Chionomyces*' *ponapensis* has quite similar conidia, and this species also fits section *Aurantiorubrae* in conidial size. *O. caulicola* of series *Commatoideae* possesses the longest conidia, which can be classified as anguillospora-like and which are partly ± straight as a whole.

Three series of section *Aurantiorubrae* include species with stauroconidia. Dicranidion-like conidia with parallel arms without a stipe are verified for *O. xanthoguttulata*, and strongly resemble those of the rather unrelated *O. eucalypti* and *O. tremulae* (series *Orbilia*). Likewise, the 2–4-armed, stipitate dicranidion-like conidia of *O. siculispora* resemble those of *O. fissilis* of series *Orbilia*. Trinacrium-like conidia are found in two series, and have always curved-down arms: in series *Piliferae* they resemble *Trinacrium incurvum* and serve as a key character of the group, whilst in series *Albovinosae* they are much more slender and are only known in two species (*O. albovinosa*, *O. pseudoaristata*). Series *Albovinosae* comprises also dwayaangam-like conidia (*O. albidorosea*, exceptionally also in *O. albovinosa*) with either straight or curved arms. Series *Hyalinia* and series *Xanthoguttulatae* p.p. are extraordinary in forming straight, dactylella-like conidia. The conidiophores in section *Aurantiorubrae* are short to medium long, but in series *Hyalinia* and *Xanthoguttulatae* partly very long.

Phylogeny. As already stated under subgenus *Habrostictis*, in the analysis in Baral et al. (2017b) section *Aurantiorubrae* formed six independent but strongly supported clades with unclear relationship to each other. Two unsupported main clades were formed which each comprises three of these six clades but also one or two clades of other sections by making section *Aurantiorubrae* paraphyletic: (1) series *Piliferae*, *Abutilones*, and *Hyalinia* loosely group with section *Helicoon*; (2) series *Xanthoguttulatae* and *Albovinosae* loosely group with the large and strongly supported core clade of section *Aurantiorubrae*, which includes series *Aurantiorubrae*, *Commatoideae*, *Regales*, and *Rubellae*, but also with sections *Habrostictis* and *Lentiformes.* However, all nodes outside the six supported clades remained unsupported.

The most unexpected results within this group include the high molecular distance between *O. aurantiorubra* and *O. xanthoguttulata*, and between *O. crenatomarginata* and *O.*

Table 68. Characteristic motifs in the nuclear 5.8S, ITS2, and LSU rDNA within the 3 sections of subgenus *Habrostictis*. Position numbers starting with AAAACTTT (5.8S), after GAGCGTC (ITS2), and with TGACCT (LSU, herr by omitting predominant gaps in alignment of all groups of *Orbiliomycetes*). The number of species within each group for each gene region is given in brackets. Species which deviate from their group are listed separately.

- *O. carpoboloides*	TCCGAA	ATTT	TTACTTC	ATCGGTT

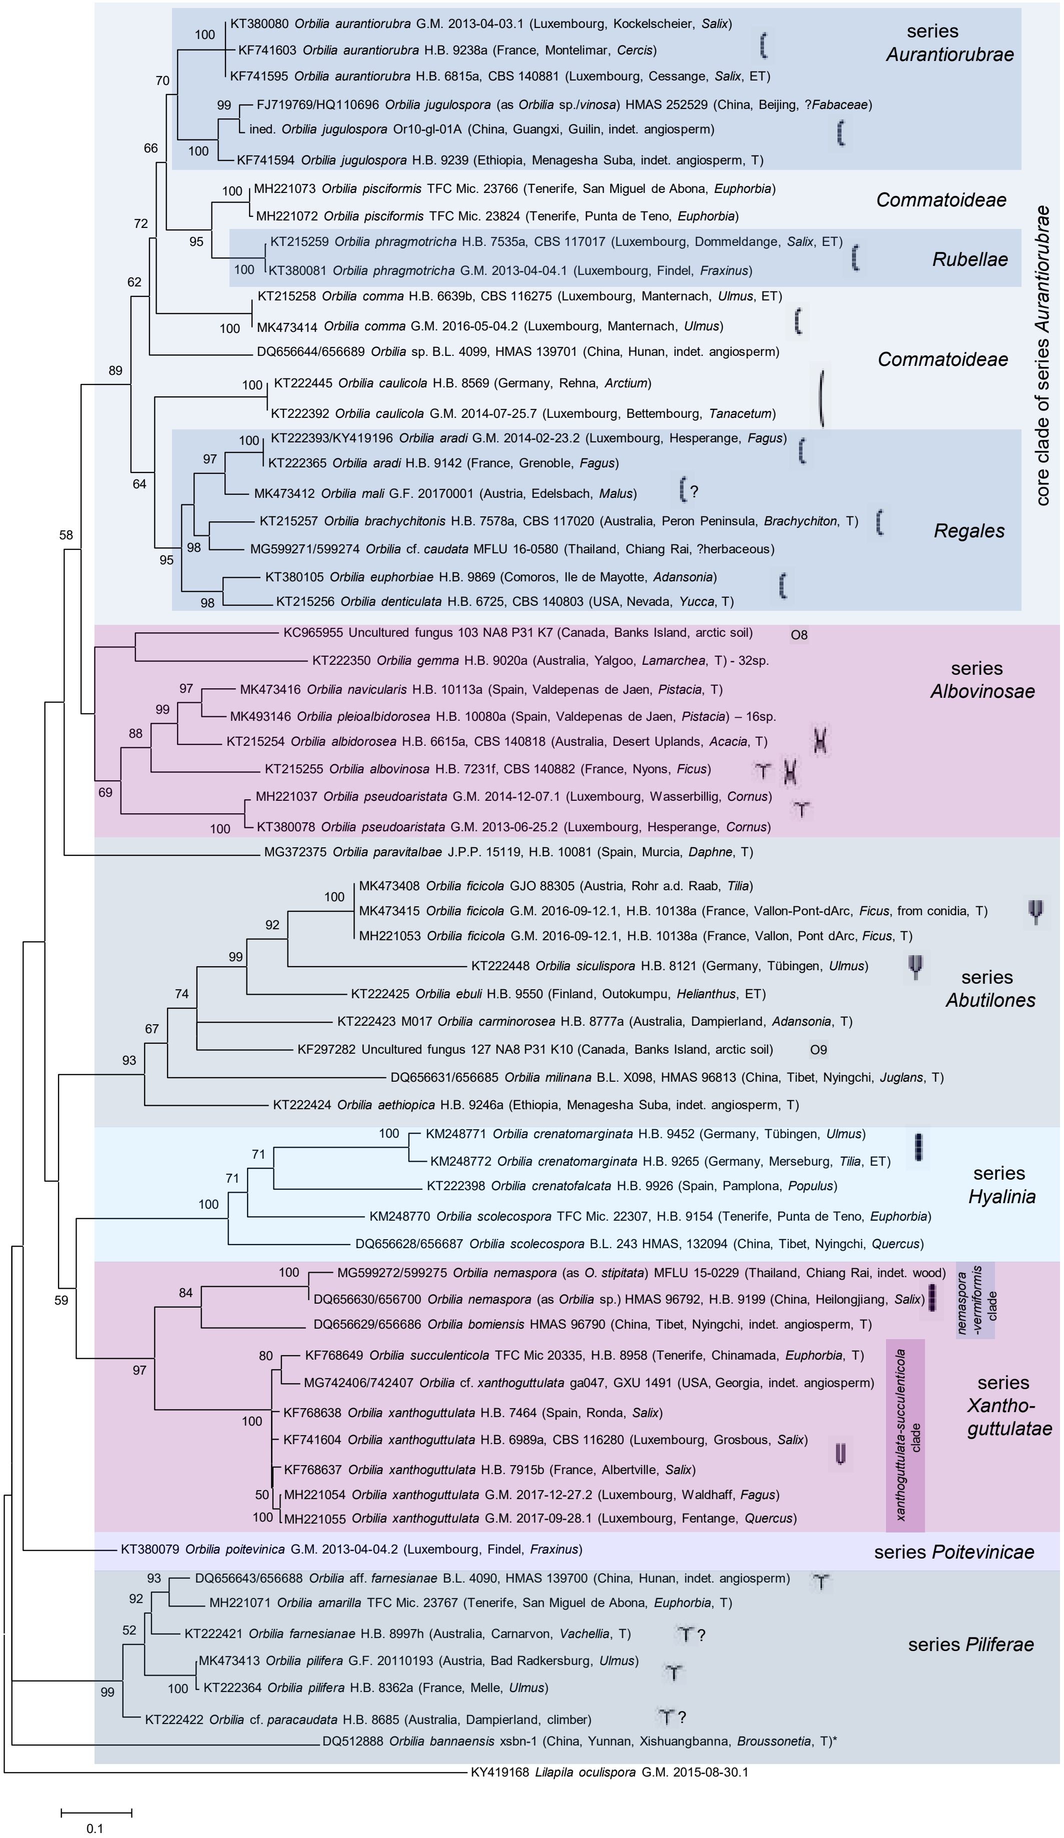
vermiformis, and the low distance between *O. xanthoguttulata* and *O. vermiformis* (Phyls 13, S15–S16). Within the core clade of section *Aurantiorubrae*, series *Regales* formed with medium or high support a sister clade of the three remaining core series *Commatoideae*, *Rubellae*, and *Aurantiorubrae*, whereby *O. caulicola* clustered with low or medium support with series *Regales* (Phyls 13, S15). Separation between the three remaining core series is not supported by our molecular data but we maintained these series because of striking morphological differences.

Specific nucleotide positions. No molecular motifs being characteristic of section *Aurantiorubrae* have been discovered. Three motifs in the rDNA are informative regarding relationships within section *Aurantiorubrae* (Tab. 68). At pos. 129–134 of the 5.8S region the motif TCC**TTT** is characteristic of series *Aurantiorubrae*, *Rubellae*, and *Commatoideae*, whereas other members of subgenus *Habrostictis* have TCC**GAA**, TCC**GAT**, TCC**GGA**, or rarely TCC**GTA** or TCC**GTT** (Tab. 68). *O. caulicola* has TCC**GAA**, which would suggest that it does not belong in either of the three series mentioned. Another motif is found at the 5'-end of ITS2 (pos. 1–4 after GAGCGTC): a majority of section *Aurantiorubrae* has AT**TT**, which is also characteristic of section *Helicoon*, whereas a minority have AT**TA** (series *Xanthoguttulatae*, *Regales* p.p., *Albovinosae*), and series *Hyalinia* AT**GT** or AT**CT** (see also Tab. 20). The motif AT**TA** occurs in combination with TCC**GAT** (rarely TCC**GTT**), and both are exclusive for the three groups within section *Aurantiorubrae*.

Another motif is located at pos. 239–245 in the D1 domain of LSU (Tab. 68). This is characteristic of series *Regales* (TT**T**C**AAT** or TT**T**C**AAC**) and to some extent of series *Hyalinia* (YT**G**CDHY), whereas the current motif within section *Aurantiorubrae* is TT**A**C**TTC** (but some deviations from this occur). Also pos. 500 of LSU D2 is informative, being consistently ATC**A**GTT in series *Aurantiorubrae*, *Rubellae*, *Commatoideae*, *Poitevinicae*, *Piliferae*, and *Albovinosae*, but G in series *Regales*, *Xanthoguttulatae*, and *Hyalinia*. Yet, it is G in the disputable *O. gemma*, and it varies between A and G in series *Abutilones*. In section *Helicoon* it is mostly A and in section *Habrostictis* mostly G.

In the SSU (V8–V9) little variation is observed, and the different series cannot be recognized because some taxa of different groups share exactly the same sequence.

Ecology. Members of section *Aurantiorubrae* have been recorded worldwide. A majority of species are desiccation-tolerant and grow on exposed (xeric), woody or herbaceous substrates. In contrast, members of series *Hyalinia* and some of series *Xanthoguttulatae* occur on permanently moist (hygric) substrate. Various species are found in temperate to montane or (sub)alpine-boreal, more or less humid areas, whereas others appear to be adapted to (sub)tropical (sub)



Phylogenetic analysis 13. Phylogram of section *Aurantiorubrae* (and *Helicoon*) inferred from combined ML analysis of ITS1-5.8S-ITS2+LSU (D1–D2) rDNA dataset (64 sequences, 1456 positions, aligned with MUSCLE) using the GTR+G+I model in MEGA6 (500 replicates). Two environmental strains from GenBank are included representing unidentified species (O8, O9). The tree is rooted with *Lilapila oculispora*. Asci 8-spored except when otherwise stated; T = type, ET = epitype, * = only ITS available.

Key to series and species of section *Aurantiorubrae*

1. Spore apex rounded to obtuse or subacute, spores never strongly helicoid; SBs globose to ellipsoid or broadly tear- to pear- or rod-shaped, sometimes with a vermiform to subulate upper part, (0.7–)1–3(–4.7) µm long (if spore apex acute then SBs globose) 2
1. Spore apex subacute to acuminate, if rounded to subacute then spores strongly helicoid; SBs broadly to narrowly tear-shaped or subulate to filiform, (1.7–)2–4.5(–5.5) µm long 14

2. SBs 1.5–4.7 µm long, rod-shaped or divided into an ellipsoid to tear-shaped lower and a vermiform to subulate upper part.............3
2. SBs (0.7–)1–2.3(–2.7) µm long, globose to broadly tear- or pear-shaped 5

3. SBs ± rod-shaped, ascospores often with tails or tail-like bases; paraphyses often spathulate to mammiform............. **series *Piliferae*** (p.p.), p. 915
3. SBs divided into an ellipsoid to tear-shaped lower and a vermiform to subulate upper part, ascospores without a tail.............4

4. Spores with rounded apex, subcylindric- to fusoid-clavate, *(6–)7–8(–9) × 2.2–2.8 µm; paraphyses uninflated or capitate-clavate .... **series *Poitevinicae*** (*O. poitevinica*, p. 913)
4. Spores with broadly subacute apex (forming a > 90° angle), cylindric-clavate, *4.8–6.3 × (1.8–)2–2.3(–2.5) µm; paraphyses often sublanceolate to lanceolate .... **series *Abutilones*** (*O. aethiopica*, p. 912)

5. Spores ± cylindrical, base not or only slightly tapered, ± straight, *5.5–8.7 × 1.7–2.3 µm, SBs 1.3–1.9 × 0.4–0.7 µm............. **series *Regales*** (*O. pseudocylindrospora*, p. 798)
5. Spores medium to strongly tapered at base and/or ± curved (especially at base) 6

6. Apothecial margin ± smooth, without distinct hairs or glassy processes 7
6. Apothecial margin usually ± distinctly crenulate, dentate or hairy, at least with short glassy processes and/or septate projecting hairs ...10
A sample on *Urtica* with ± smooth apothecia and spores similar to *O. phragmotricha* is mentioned under that species (p. 830).

7. Paraphyses apically capitate-clavate, rarely uninflated .... **series *Commatoideae***, p. 802
If spores ± straight and *1–1.2 µm wide see **series *Piliferae*** (*O. bannaensis*, p. 930).
7. Paraphyses apically ellipsoid-clavate, spathulate to lageniform, or uninflated 8

8. Paraphyses covered by 1–3 µm thick glassy caps; apothecia rose-lilaceous or yellowish; SBs globose to tear-shaped, with short filum .... **series *Regales*** (*O. kingsiana*, p. 793, *O. aradi*, p. 777)
8. Paraphyses without glassy caps; apothecia rose-orange or orange 9

9. Spores with rounded to obtuse apex; SBs ± ampulliform .... **section *Hemiorbilia*** (*O. concoloris*, p. 672)
9. Spores with subacute apex; SBs ?broadly tear-shaped............. **series *Piliferae*** (*O.* aff. *farnesianae*, p. 925)

10. Marginal hairs consisting of short to long glassy processes which emerge directly from thin-walled marginal cortical cells of the compact excipular texture, free septate hairs absent .... **series *Regales*** (p.p.), p. 773
If paraphyses capitate and spore apex subacute compare *O. neocomma* (series *Commatoideae*, p. 817).
10. Marginal hairs septate, thin- or thick-walled, with or without terminal glassy processes 11

11. Paraphyses clavate-capitate; spores fusoid, †(7–)7.5–9(–9.8) × (1.5–)1.6–1.8(–2) µm; SBs ?tear-shaped; apothecial margin finely crenulate; caulicolous (*Atropa*)............. series ***Abutilones*** (*O. rosella*, p. 908)
11. Paraphyses spathulate to lageniform or mammiform.............12

12. Marginal hairs with †(0.3–)0.5–1.5(–2.7) µm thick walls, (10–)30–60(–93) µm long, 1–3- up to 3–10-septate, with or without terminal glassy processes; spores *1–1.9 µm wide .... series ***Rubellae***, p. 820
12. Marginal hairs with †0.2–0.5(–0.8) µm thick walls, usually without terminal glassy processes 13

13. Spores *5–9.2 × 2–2.7 µm, ellipsoid-clavate; SBs broadly tear-shaped to subglobose, 1–1.3 µm wide; marginal hairs 35–55 µm long, 2–6-septate; apothecia ochre-orange, 0.3–1.8 mm diam.; bark of *Ulmus* .... **series *Piliferae*** (*O. pilifera*, p. 918)
13. Spores *(6.5–)8–11(–11.5) × (1.5–)1.6–1.8(–2) µm cylindric(-clavate); SBs ± ampulliform, 0.7–1 µm wide; marginal hairs 7–20 µm long, 0–1-septate; apothecia rose-orange, 0.2–0.7 mm diam.; wood of *Abies*, *Lonicera*........ **section *Hemiorbilia*** (*O. concoloris*, p. 672)

14. Margin ± crenulate by coherent, indistinct, < 20 µm long hair-like projections, glassy processes absent or < 5 µm long; spores ± straight, *(8–)9–11(–12) × 1.3–1.7 µm, narrowly fusoid; SBs with a tear-shaped lower and a filiform upper part; apothecia pale rose-cream, caulicolous .... **series *Abutilones*** (*O. ebuli*, p. 900)
14. Margin with glassy processes or long hairs, if smooth then spores distinctly curved 15

15. Spores min. *(1.3–)1.5 µm wide, straight to slightly curved; apothecial margin with 1–7 up to 10–120 µm long glassy processes .... **series *Albovinosae***, p. 932
15. Spores max. *1.4–1.7 µm wide, usually medium to strongly curved, or with a basal constriction 16

16. Apothecia whitish (but yellow-orange in *O. bomiensis*), often desiccation-sensitive; margin smooth or often with small to large triangular teeth of agglutinated glassy processes; spores generally distinctly helicoid, rarely falcate .... **series *Hyalinia*** (including link to ***nemaspora-vermiformis*** **clade** of **series *Xanthoguttulatae***), p. 868
16. Apothecia orange to yellow, rarely whitish, always desiccation-tolerant; margin smooth or with long, septate hairs or short (up to 18 µm) glassy processes; spores straight to falcate, also helicoid or basally bent.............17

17. Paraphyses mainly ellipsoid-spathulate or lageniform; apothecial margin smooth or crenulate to hairy.............18
17. Paraphyses uninflated or clavate-capitate; apothecial margin smooth.............20

18. Margin with 15–65 µm long, septate, thin-walled hairs without glassy processes; spores *6.5–10.5 µm long, slightly to strongly curved (sickle-shaped) but usually not distinctly helicoid, base partly constricted or strongly geniculate; SBs filiform to subulate or narrowly tear-shaped, (1.7–)2–4(–4.5) × 0.2–0.7(–0.9) µm .... **series *Abutilones***, p. 885
18. Margin hairless or with short glassy processes (9–18 µm) or hair-like projections; SBs subulate to tear-shaped, 1.7–3 × 0.6–1.3 µm 19

19. Spores *(9–)10–14(–16) × (1–)1.2–1.5(–1.7) µm, falcate to helicoid, with often strongly curved base; apothecia yellow(-ochraceous), sometimes turning orange-red with age, rarely whitish.. series ***Xanthoguttulatae*** (*O. xanthoguttulata*, p. 848, *O. succulenticola*, p. 853)
19. Spores †6.5–7.5(–8) × (0.9–)1–1.3(–1.4) µm, fusiform, with a thin, curved, tail-like base; apothecia cream red to bright pink .... series ***Abutilones*** (*O. carminorosea*, p. 906 & *O. rehmii*, p. 904)

20. Spores *(9–)10–14(–17.2) × 1–1.6 µm, ± helicoid (S-shaped in profile view), with strongly curved base .ser**ies *Aurantiorubrae***, p. 833
20. Spores *7–10 µm long, slightly to strongly falcate but usually not distinctly helicoid, spore base partly constricted, strongly geniculate to reflexed .... **series *Abutilones*** (*O. milinana*, p. 897 & *O. lobeliae*, p. 899)

humid regions. In semihumid to arid areas the observed species diversity is not significantly higher as it was observed within section *Habrostictis*.

Core clade of section *Aurantiorubrae*
(series *Regales*, *Commatoideae*, *Rubellae*, *Aurantiorubrae*)

Series *Regales*

Orbilia subgenus ***Habrostictis*** section ***Aurantiorubrae*** series ***Regales*** Baral & E. Weber, **ser. nov.**, MB 815010 – Type species: *Orbilia regalis* (Cooke & Ellis) Baral

Etymology: named after the type species, *O. regalis*.

Latin diagnosis: *Seriei* Rubellae *similis sed pili solum ex processis vitreis compositi sunt, absque hyphis septatis, cellulae excipuli corpusculis crystalloides carentes.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–1.8(–3) mm diam., pale to bright cream-rose, yellow-ochraceous to orange-red, rarely rose-lilaceous, margin smooth or usually finely rough to fimbriate, crenulate, or with prominent whitish teeth, sessile or with a short stipe **Asci** *40–66(–74) × 4–5.5 µm, 8-spored, (1–)2–5(–7) lower spores inverted; **apex** (†) slightly to strongly truncate, not or slightly, rarely strongly indented and/or laterally inflated; **base** T-, L-, Y- or h-, rarely H-shaped. **Ascospores** *(5.8–)6.5–12(–14.5) × (1.1–)1.3–2.3(–2.6) µm, cylindric-ellipsoid or mostly cylindric- to fusoid-clavate, apex rounded to obtuse (exceptionally subacute), base partly tail-like, straight or usually slightly to strongly curved or geniculate near base (sometimes slightly helicoid), **SBs** (0.8–)1–2(–2.3) × 0.3–1(–1.2) µm, globose to tear-shaped or ampulliform, also plug-shaped, apically narrowed to a small to wide point, very short filum often present. **Paraphyses** very slightly to strongly inflated at the apex, often spathulate(-mammiform) but also clavate-capitate, terminal cells (1–)1.5–3(–5)× longer than lower cells. **Ectal excipulum** cells near base *(7–)10–20(–25)((–38)) × (5–)7–15(–20)((–25)) µm, near margin of textura prismatica-angularis-globulosa to textura prismatica-porrecta oriented at a medium to high angle (rarely under a low angle: *O. peudocylindrospora*); **glassy processes** absent or (1–)5–20(–60)((–100)) µm long, **hairs** absent. **SCBs** absent or globose; **VBs** consistently absent. **Exudate** (0.2–)0.5–2(–4) µm thick, cloddy-granular or cap-like, firmly attached over protruding part of paraphyses, hyaline to pale yellowish. — **ANAMORPH**: vermispora-like. **Conidiophores** short (9–25 µm). **Conidiogenous cells** monoblastic or sympodial. **Conidia** phragmosporous, *20–62 × 3–7.5 µm (in situ), 3–12(–15)-septate, slightly to strongly curved at both ends, rarely straight.

Habitat: wood and bark of angiosperms (rarely gymnosperms), also on branches of *Cactaceae* or caulicolous on small to large monocots, exceptionally on liverworts (*Radula*, *O. mali*), all species desiccation-tolerant, temperate to subtropical or ?boreal, humid to arid, always desiccation-tolerant.

Recognized species: 11, plus 1 unnamed species (‘affinis’).

Taxonomic remarks. Series *Regales* in the present circumscription is characterized by more or less narrow, somewhat comma-shaped ascospores with rounded to obtuse apices, rather short, usually globose to broadly tear-shaped SBs, and the frequent presence of glassy processes. *O. kingsiana*, *O. pseudocylindrospora*, and partly *O. mali* deviate from the more typical members of the group in lacking glassy processes, *O. pseudocylindrospora* also in mainly straight, basally only slightly attenuated spores. *O. denticulata* has the broadest spores of the series.

Typical members of series *Regales* resemble those of series *Microsomates* (section *Orbilia*, e.g., *O. microsoma*, *O. microlentiformis*). The latter mainly differ in more broadly attached, plug-shaped SBs, although similar SBs occur in *O. denticulata*. Moreover, a species placed in series *Microsomates* of section *Orbilia* (*O. myriopseudoregalis*) shows SBs very similar to typical members of series *Regales*. However, the very different anamorphs, the frequency of polysporous asci in series *Microsomates*, and the available DNA-data indicate that the two series are not closely related. For the similar series *Rubellae* see p. 821. Series *Aurantiorubrae* differs from series *Regales* in acute spore apices containing narrowly tear-shaped to subulate SBs.

Species delimitation. The included species are partly very similar and only tentatively separated by morphological markers. Six of them were repeatedly collected and found to be morphologically either quite constant (*O. aradi*, *O. euphorbiae*, *O. kingsiana*) or showed some variation between the collections, perhaps because different species were included (*O. brachychitonis*, *O. denticulata*, *O. mali*).

Anamorph. Very similar vermispora-like anamorphs were obtained in pure culture in four species of series *Regales*, while in three further species they were only seen on the natural substrate.

Phylogeny. Sequences of the ITS region were available for five species (*O. aradi*, *O. brachychitonis*, *O. denticulata*, *O. euphorbiae*, *O. mali*), LSU for three of them (*O. aradi*, *O. brachychitonis*, *O. denticulata*), and SSU for the latter three. The S1506 intron exists in *O. euphorbiae* (from Comoros) and *O. brachychitonis* but is absent in *O. euphorbiae* from Australia and the other three species. In our analyses of ITS+LSU and ITS series *Regales* forms a strongly (Phyl. 13), or medium (S15) supported clade, to which *O. caulicola* is associated as a sister clade. In the combined analyses (Baral et al. 2017b, Phyl. 13), series *Regales* clustered highly or medium supported in the core clade of section *Aurantiorubrae*. When analysing the S1506 intron, *O. euphorbiae* and *O. brachychitonis* clustered in a highly supported clade with unresolved position (S14).

Specific nucleotide positions. Series *Regales* shows a highly conserved motif near the 5’-end of the ITS2 region (CTGYACCAGTTAATTTTGGT), by which it distinctly deviates from all other series of section *Aurantiorubrae* which are much more variable here. In the LSU D1 domain, series *Regales* deviates at position 242–245 (CAAT or CAAC) from most other groups of subgenus *Habrostictis* which have CTTC, except for *O. gemma* and *O. crenatomarginata* which concur with *O. denticulata* (CAAC, see Tab. 68). The SSU V8–V9 region does not show any unique motifs but includes at pos. 248–271 combinations of nucleotides that are shared with other series.

Ecology. All included species are desiccation-tolerant. They occur on wood and bark, mainly of angiosperms, but also on herbaceous stems. Records derive from various climatic regions: the majority of species grew in semihumid to arid area and are known from Northern and Middle America, southern Europe, Africa, and Australia. Collections are also known from alpine subhumid South America (*O. puyae*) and tropical humid Australia (*O.* cf. *puyae*). Only two species are known from cold-temperate humid Europe (*O. aradi*, *O. mali*), one from orotemperate southern Europe (*O. pseudocylindrospora*), and one from warm-temperate humid eastern North America (*O. regalis*).

Key to species of series *Regales*

1. Glassy processes at margin absent 2
1. Glassy processes at margin present (sometimes only 1–5 µm long) 4

2. Spores *(6.5–)8–11.5(–12.3) × (1.5–)1.6–2 µm; SBs 1.5–2.7 × 0.7–1 µm, ± ampulliform; paraphyses spathulate to lageniform, not covered by glassy caps; apothecia rose-orange, margin with 7–19 µm long hair-like, ± freely protruding cortical cells; wood of *Abies*, *Lonicera*, montane-subalpine humid western North America, central Asia .... ***O. concoloris*** (section *Hemiorbilia*), p. 672
If apothecia yellow and SBs ± globose, on bark of *Fagus*: see under 17 (*O. aradi*)
2. Spores *5.5–8.8 µm long; SBs 1.3–1.9 µm long; paraphyses partly or consistently capitate-clavate; apothecia pinkish-rose to lilaceous, exceptionally orange 3

3. Paraphyses covered by 1–3 µm thick glassy caps, terminal cells 1–5× longer than lower cells; spores *(1.4–)1.5–1.7(–1.8) µm wide, slightly to medium curved at the mostly strongly tapered base; SBs 0.8–1.1 µm wide; apothecial margin 0–10 µm protruding; herbaceous stems or bark of *Fabaceae* & *Myrtaceae*, subtropical semihumid to semiarid western Australia .... ***O. kingsiana***, p. 793
3. Paraphyses covered by 0.2–0.5 µm thick exudate, terminal cells 1–3× longer than lower cells; spores *1.7–2.3 µm wide, ± straight, never strongly tapered below; SBs 0.4–0.7 µm wide; apothecial margin 10–25 µm protruding; bark of *Salix*, orotemperate humid Europe .... ***O. pseudocylindrospora***, p. 798
If exudate 0.2–2 µm, spores strongly tapering, SBs 0,7–1.2 µm wide, temperate to submediterranean Europe: see *O. mali* (p. 781)

4. Asci 16–64-spored; in semihumid to arid regions .... see **series *Microsomates*** (section *Orbilia*), p. 1295
4. Asci 8-spored 5

5. Spores *1.2–1.6(–1.7) µm wide 6
5. Spores predominantly > *1.6 µm wide; paraphyses often covered by thick glassy caps 14

6. Spores *(8–)9–12(–14.5) × 1.3–1.5 µm; SBs 0.4–0.7 µm wide; paraphyses ± spathulate to lageniform; branches of *Carnegiea gigantea*, subtropical semiarid western North America .... ***O. carnegieae***, p. 792
6. Spores max. *9.5(–10.5) µm long 7

7. Paraphyses consistently slightly to strongly spathulate or lageniform 8
7. Paraphyses uninflated, capitate or only sometimes slightly spathulate, often covered by glassy caps 10

8. Spores *(6–)7–9(–10.5) × 1.3–1.6 µm, slightly to medium tapered and curved below; SBs 0.8–1.3 × 0.3–0.5(–0.6) µm; apothecia yellowish-orange, with denticulate margin; branches of *Acacia*, *Adansonia*, *Euphorbia*, *Ipomoea*, stems of *Solanecio*, warm-temperate to tropical, humid to arid Macaronesia, Africa, Australia .... ***O. euphorbiae***, p. 787
If apothecia cream-ochre-brownish, SBs *1.2–1.8 × 0.5–1 µm, see ***O. pseudeuphorbiae*** (section *Arthrobotrys*, p. 1476).
8. Spores *5.5–7.3 × 1.4-1.7 µm, ± strongly tapered 9

9. Spore bases strongly tapered, partly tail-like, geniculate; glassy processes ± straight; apothecial margin rough; bark of *Malus*, warm-temperate humid eastern North America .... ***O. regalis***, p. 775
9. Spore bases medium to strongly tapered, spores partly entirely curved (C-shaped); glassy processes curved downwards; apothecial margin crenulate-dentate; bark of *Acacia*, *Eucalyptus*, subtropical semihumid western Australia .... ***O. austroregalis***, p. 776

10. Glassy processes 1–4 µm long; apothecia rose-lilaceous .... see under 3 (*O. kingsiana*)
10. Glassy processes min. 5–14 µm long; apothecia ± orange 11

11. Spores *5.7–8 µm long; glassy processes 5–14 µm long 12
11. Spores *8–9.5(–10) µm long; glassy processes 5–60 µm long; paraphyses ± capitate 13

12. Spores *5.7–8 × (1.3–)1.4–1.5(–1.7) µm; paraphyses ± uninflated; tropical Middle America .... ***O. cocois*** (section *Arthrobotrys*), p. 1474
12. Spores *6–7 × 1.2–1.4 µm; paraphyses ellipsoid-capitate; culms of *Phragmites*, tropical humid northeastern Australia .... ***O.* cf. *puyae***, p. 796

13. Spores ± strongly tapered below; SBs 0.8–1 µm wide; inflorescence stem of *Puya*, high-montane subtropical subhumid South America .... ***O. puyae***, p. 796
If paraphyses ± uninflated, compare *O. pseudeuphorbiae* (section *Arthrobotrys*, p. 1476).
13. Spores not or only slightly tapered below; SBs ~0.3–0.6 µm wide; branch of *Cylindropuntia*, subtropical semiarid western North America .... ***O.* cf. *carnegieae***, p. 793

14. Apothecia orange-rose without distinct yellow component 15

14. Apothecia yellow-orange, rarely with rose component (cells often with abundant yellow LBs, especially in paraphyses and marginal ectal excipulum) 16

15. Spores *(6–)7–12(–13.5) × 1.6–2.2 µm; SBs tear-shaped to globose; bark & wood of *Brachychiton*, *Nuytsia*, *Adansonia*, (sub)tropical subhumid to semiarid Australia .... ***O*. *brachychitonis***, p. 784

15. Spores *(6–)7–9(–10) × 1.8–2.2 µm; SBs tear- to pear-shaped; bark of angiosperms, temperate humid to mediterranean (semi)humid Europe..***O*. *mali***, p. 781

16. Apothecial margin usually with distinct prominent teeth; anchoring hyphae 2.5–5 µm wide; SBs tear- to plug-shaped; spores *6–10(–12) × 1.8–2.6 µm; paraphyses apically medium to strongly capitate-clavate or spathulate; branches of *Myrtillocactus* and *Yucca*, warm-temperate to subtropical (semi)arid Northern and Middle America .... ***O*. *denticulata***, p. 798

16. Apothecial margin crenulate but without distinct teeth; anchoring hyphae 1.8–3.5 µm wide; SBs ± globose..17

17. Spores *(6–)7–9.5(–11) × (1.6–)1.7–2 µm; SBs ± globose; paraphyses uninflated to slightly clavate, rarely subspathulate; ascus base never H-shaped; bark of *Fagus*, cold- to orotemperate humid western & central Europe .... ***O*. *aradi***, p. 777

17. Spores †8–11.8 × 1.6–2 µm; SBs unknown; paraphyses consistently spathulate; ascus base partly H-shaped; wood of *Cistus*, mesomediterranean semihumid southern Europe..***O*. aff. *aradi***, p. 781

Orbilia regalis (Cooke & Ellis) Baral, **comb. nov.**, MB 814377 — Pl. 391

Basionym: *Peziza regalis* Cooke & Ellis, Grevillea 6: 91 (1878)
≡ *Pezizella regalis* (Cooke & Ellis) Sacc., Syll. Fung. 8: 284 (1889)
≡ *Hymenoscyphus regalis* (Cooke & Ellis) Kuntze, Revis. Gen. Pl. 3: 486 (1898)

Etymology: apparently because the apothecia had a crenulate margin similar as a crown.

Typification: USA, New Jersey, Newfield, unlocalized, branch of *Malus domestica*, undated, J.B. Ellis (M.C. Cooke 2778, K(M) 35323, apothecia on inner surface of bark, lectotype, designated here, MBT202653).

Misapplied name: Nannfeldt (1932: 252), as ?*Hyalinia rubella*.

Misinterpretation of *O*. *regalis*: J.B. Ellis (N. Amer. F. 438), = *Orbilia occulta*.

Description: — **TELEOMORPH**: **Apothecia** superficial, ± gregarious, rehydrated 0.35–0.8 mm diam., in total 0.11 mm high, light cream-ochraceous throughout, turning orange-brownish (Cooke & Ellis: 'miniate' = saturn-red), round, somewhat lobate when large, disc flat or slightly concave, margin rough, scarcely protruding; broadly sessile. **Asci** †40–49 × 3.3–3.6 µm, cylindrical, 8-spored, spores biseriate in upper part, ~4 lower spores inversely oriented, pars sporifera †20–31 µm; **apex** (†) slightly to medium truncate; **base** with long, thin, flexuous stalk, L- to h-shaped. **Ascospores** frequently seen within asci (especially in CB_L), †6–7.3 × 1.4(–1.5) µm, cylindric- to fusoid-clavate, apex (rounded to) obtuse, base strongly attenuated to form a tail-like end, here distinctly geniculate (slightly helicoid), **SBs** not seen. **Paraphyses** apically medium to strongly spathulate to lageniform-mammiform, rarely lanceolate, terminal cells †14–25 × 2.3–3.5 µm, exceeding the asci by 3–6 µm, lower cells †7–10 × 1–1.5(–1.8) µm, branched only near base. **Medullary excipulum** 40 µm thick, of ± dense, horizontally oriented textura intricata with rather numerous inflated cells, sharply delimited. **Ectal excipulum** of thin-walled, vertically oriented t. angularis from base to flanks, 40 µm thick at lower flanks, cells †8–14 × 6–10 µm, margin not clearly seen, probably of t. angularis, cortical cells with **glassy processes** 8–15 × 3.5–5 µm, ± straight, strongly stratified, abundantly present from lower flanks to margin. **Anchoring hyphae** abundant at base, hyphae †1.5–2.7(–3.5) µm wide, walls 0.2–0.4(–0.7) µm thick, forming as a loose t. intricata up to 50 µm thick. **Exudate** over paraphyses strongly refractive, pale yellowish, 0.3–1.4(–1.8) µm thick, firmly attached, cap-like. **— ANAMORPH**: unknown.

Habitat: on slightly rotten bark (bast) of a branch of *Malus domestica*, on inner surface, no algae. **Associated**: *Orbilia occulta*, brown hyphae of *Sporidesmium* sp. among anchoring hyphae, crustose and fruticose lichen. **Desiccation tolerance**: certainly tolerant, according to the associated lichens and *O. occulta*. **Altitude**: ~35 m a.s.l. **Geology**: Miocene sedimentary rock. **Phenology**: unknown.

Taxonomic remarks. *Orbilia regalis* is characterized by rather small, cylindric-fusoid ascospores with strongly attenuated, short, geniculate tail-like bases, distinctly spathulate to mammiform paraphysis apices, and short, not clearly curved glassy processes at the margin. The species is very close to the European *O. aradi*, which is confined to bark of *Fagus* and rather sharply delimited by consistently less inflated, never lageniform paraphysis apices, slightly larger spores, and usually more yellow apothecia. For the very similar *O. austroregalis* see below.

O. euphorbiae and *O. puyae* are distinguished by longer spores with a less tapered base, the latter also by never lageniform or mammiform paraphyses. In spore shape *O. regalis* also somewhat resembles *O. mali* and *O. comma* (series *Commatoideae*), but these species sharply differ in capitate paraphyses, partly also in the absence of glassy processes.

Type studies. Cooke & Ellis (1878) considered *Peziza regalis* to be close to *P. lasia* (= *O. carpoboloides*). A specimen of *P. regalis* (M.C. Cooke 2778, K), which contains two small pieces of *Malus* bark, was reexamined and found to be a mixture of two very different species of *Orbilia*. One grew on the rather undecayed inner surface of both pieces of bark, with ~30 mature, rehydrated 0.35–0.8 mm large apothecia, and on this the above description is based (Pl. 391). The apothecia of the other species measured rehydrated only 0.15–0.3 mm and grew abundantly on the rather decayed outer surface of one of the two pieces (IVV: H.B. 5344). These have a more distinctly crenulate margin made up of glassy processes (3–)10–30(–35) µm long. The asci measured 37–43 × 4–4.3 µm and were apically hemispherical, but no distinct apical thickening could be seen, and the paraphyses were apically not inflated, but heavily covered by exudate. No spores could be found, even within the asci, but these features suggest that the fungus belongs to section *Hemiorbilia*. Very probably it represents *O. occulta* (see p. 731), mature material of which was collected by J. B. Ellis in Newfield on bark of *Vitis* and *Malus*.

The brief original description by Cooke & Ellis does not allow to decide on which of the two species it was based. Indeed it seems likely that both influenced the protologue. The apothecia were described as 0.1 mm diam., with raised, white-crenulate margin, the paraphyses as globose-clavate, and the spores as linear, straight, 0.007 mm. Obviously the apothecial size stated by Cooke & Ellis is erroneous. The crenulate margin, on which the name *regalis* was undoubtedly based, was probably taken from the population of immature apothecia, but the reported

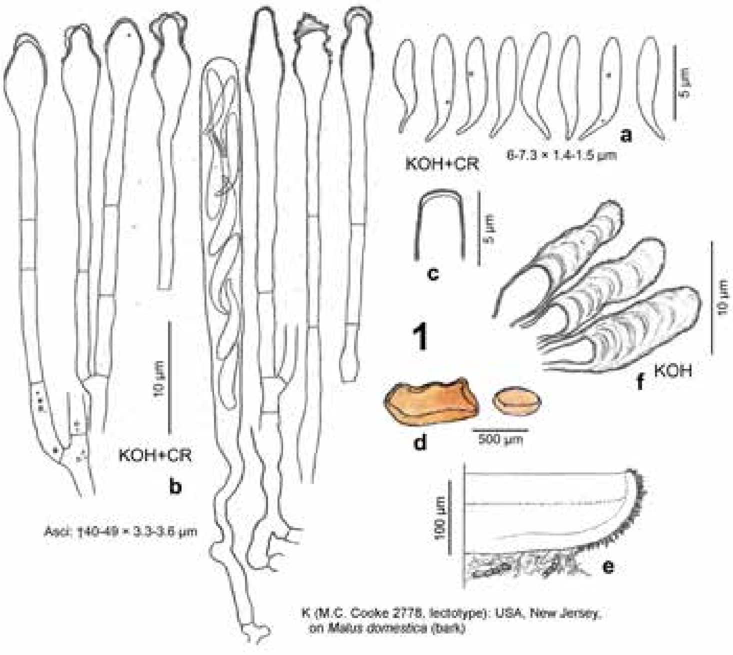


Plate 391. **1**: *Orbilia regalis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., marginal cortical cells with glassy processes.

spores exclude *O. occulta*, while apically inflated paraphyses occur in both species. In order to settle the identity of *O. regalis*, we here designate the mature apothecia growing on the inner surface of bark in M.C. Cooke, Fungi – New Jersey, U.S.A., No. 2778, K(M) 35323 as the **lectotype** of *Peziza regalis* (Pl. 391). This choice results in a clear identity of the name *P. regalis*, but has the disadvantage that the rough apothecial margin does not match the etymology of the name. On the other hand, apothecia of the very similar *O. austroregalis* described below look like a crown, but vary between populations in the length of the glassy processes, the paratype showing partly an almost smooth margin.

Massee (1894b: 100) considered *P. regalis* to be a synonym of *P. cruenta*. Nannfeldt (1932: 252) believed that these two taxa were possible synonyms of *Hyalinia rubella* (s. Nannfeldt, = *Orbilia phragmotricha*). Massee examined another specimen under the name *P. regalis* in K (J.B. Ellis, N. Amer. F. 438, unlocalized, 'on loose hanging bark of old apple trees, summer and autumn', published in 1880) which might be a topo- or even isotype of Cooke 2778). Its reexamination revealed identity with *O. occulta*, which supports that the above immature population also represents this species (see also under *O. occulta*, p. 731, and under *O. cruenta*, p. 1668). Dennis (1964: 61) studied the type at K and stated that he could not find ripe ascospores, but it is unclear which of the two populations he had examined.

Ecology. *O. regalis* grew on rather undecayed bark of a probably xeric branch of *Malus domestica* in the warm-temperate humid lowlands of eastern North America.

Specimens included. **USA**: **New Jersey**, Newfield, unlocalized, ~35 m, branch of *Malus domestica*, on bark, undated, J.B. Ellis (M.C. Cooke, 2778, K(M) 35323, **lectotype**, H.B. 5343 ø).

Orbilia austroregalis Baral, **sp. nov.**, MB 813750 — Pl. 392–393

Etymology: named after the similarity with *Orbilia regalis*.

Typification: Western Australia, Wannamal, twig of *Eucalyptus*, 3.IX.2006, G. Marson (ex H.B. 8662b, MEL 2389247, holotype).

Latin diagnosis: Orbiliae regali *persimilis sed ascosporae partim arcuatae, margo excipuli processis vitreis partim curvatis praeditus. Habitat ad corticem putridum ramorum siccorum* Acaciae *vel* Eucalypti *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.35–0.55 × 0.2–0.4 mm diam., 0.15–0.2 mm high (receptacle 0.12 → 0.08–0.11 mm), light orange- to brick-red, hardly translucent, ellipsoid, ± scattered; disc slightly to medium concave, margin 5–30 µm protruding (incl. glassy processes), distinctly whitish crenulate-dentate; sessile on a broad base, superficial or immersed in cracks. **Asci** *40–45 × 3.5–3.8 {T} or 55–57 × 4–4.3 µm {1}, 8-spored, spores *biseriate, (2–)3–4(–5) lower spores inverted {2} (not or ± mixed); **apex** (†) strongly truncate (slightly indented, laterally distinctly inflated), hemispherical in side view, thin-walled; **base** not studied. **Ascospores** *(5.3–)5.7–6.5(–7) × 1.4–1.6(–1.7) µm {2} (~7–8 µm actual length), †5–6 × 1.4–1.5 µm {T}, cylindric-clavate, apex rounded to obtuse, gradually tapered towards partly tail-like base, medium to strongly curved; **SBs** *1.3–1.6 × (0.7–)0.8–0.9 µm {2}, globose to broadly tear-shaped, apically abruptly narrowed to a very short filum. **Paraphyses** apically slightly or strongly lageniform to mammiform, terminal cells †21–23 × (3–)3.5–4.2 µm {T}, *2.5–3.5 µm wide {1} (†2.3–2.7 µm), beak 2–4(–5) × 1.5–2 µm {T}, exceeding the dead asci by 5–7 µm, lower cells *9–11 × 1.8–2 µm {T}; unbranched at upper septum, hymenium pale orange. **Medullary excipulum** hyaline, 30–40 µm thick, of dense textura intricata with many inflated cells, indistinctly or sharply delimited by a t. porrecta at flanks. **Ectal excipulum** hyaline, of (†) thin-walled, indistinctly vertically oriented textura globulosa-angularis from base to mid flanks, 60–100 µm thick near base, cells *10–15(–19) × 8–10(–14) µm {2}; 15–25 µm thick at flanks, of vertically oriented t. angularis(-prismatica), cells at mid flanks *8–9 × 3–3.5 µm, oriented at a 70–80° angle to the surface, 15–20 µm thick at margin, of t. prismatica-porrecta oriented at 30–70°, marginal cortical cells *9–11 × 2–2.5 {1} or *8–10 × 4–5 µm {T}; **glassy processes** 10–25 {1} or 30–70 {T} × 2.5–4 µm {2}, high-refractive, not stratified, hyaline to light orange-yellow, outwards curved, coherent to form teeth. **Anchoring hyphae** rather sparse and only at base, †2–3(–4) µm wide, walls 0.2 µm thick {1}. **SCBs** in paraphyses and ectal excipulum apparently absent {2}; **LBs** in lower ectal excipulum 1–2.7 µm diam., very pale orange (carotenoids). **Exudate** over paraphyses and margin 0.1–0.8 µm thick, finely rough to granular, firmly attached. **— ANAMORPH**: unknown.

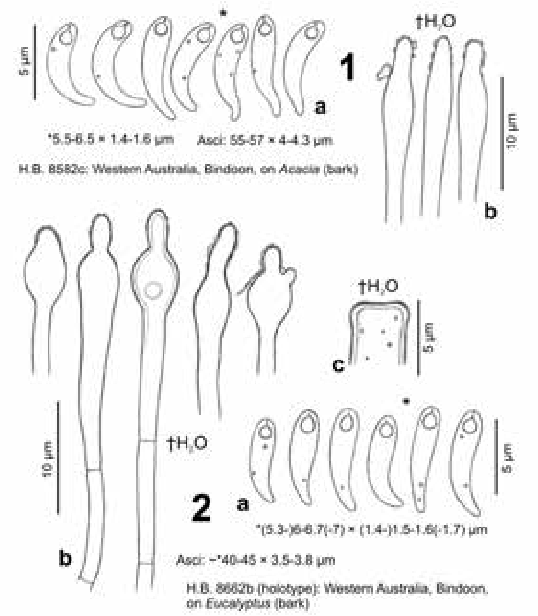

Plate 392. **1–2**: *Orbilia austroregalis*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex.

Plate 393. **1–2**: *Orbilia austroregalis*. – **2a**. semihumid Eucalypt open forest with *Macrozamia*; **1a–b**, **d–f**. rehydrated apothecia; **1c**. dry apothecium; **2b**. apothecium in median section; **1g**, **2f**. id., marginal region with glassy processes; **2c–e**. asci and paraphyses. – Living state, except for ascus in **2d**. — **1a–g**. H.B. 8662b (holotype): Western Australia, Bindoon, on *Eucalyptus*; **2a–f**. H.B. 8582c: ibid., on *Acacia*.

Habitat: collected 0.5–1.5 m above the ground, corticated, 6–11 mm thick branches of *Acacia* sp. {1}, *Eucalyptus* sp. {T}, on strongly decayed bark {2} (bast), partly on inner surface of detached bark, partly blackened, no algae. **Associated**: *Orbilia albidorosea* {1}, *O. austroocculta* {1}, *O. pleiocrescens* {1}, *Tryblidaria* sp. {1}. **Desiccation tolerance**: ectal excipulum and a few mature asci still viable after 14 months. **Altitude**: 272 m a.s.l. **Geology**: Archean granulite with granitic gneiss (red-brown soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia austroregalis* is very similar to *O. regalis*. It is tentatively separated here by thicker apothecia, slightly shorter spores with a partly more curved (sickle-shaped) upper part and less attenuated base (but these differences could be due to the living vs. dead state), and in downwards curved, longer glassy processes in the holotype. Together with a different climate (subtropical semihumid vs. warm-temperate humid), we suspect that the Australian specimens belong to a different species.

Variation. In the sparse paratype the asci are much larger, the paraphyses narrower and less mammiform, the marginal cortical cells much narrower, and the glassy processes much shorter compared to the holotype.

Ecology. *O. austroregalis* is only known from two sparse collections made at a single site, where it grew on rotten bark of xeric twigs and branches of *Acacia* and *Eucalyptus* in a subtropical semihumid eucalypt woodland with *Macrozamia* located in the Jarrah Forest ecoregion of southwestern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Jarrah Forest, 25 km NNE of Bindoon, 12 km ESE of Wannamal, 272 m, branch of *Acacia*, on bark, 4.IX.2006, G. Marson (ex H.B. 8582c, mixture in MEL 2389242 [type of *O. pleiocrescens*]). – ibid., twig of *Eucalyptus*, on bark, 3.IX.2006, G. Marson (ex H.B. 8662b, MEL 2389247, **holotype**).

Orbilia aradi Baral & G. Marson, **sp**. **nov**., MB 813751 — Pls 394–395, Map 66

Etymology: named after *Aradus conspicuus*, a mycophagous flatbug repeatedly encountered under *Fagus* bark together with the *Orbilia*.

Typification: Luxembourg, Senningerberg, trunk of *Fagus sylvatica*, 27.XI.2004, G. Marson (ex H.B. 7628c, M-0276433, holotype).

medium abundant. **Associated**: *Coniochaeta subcorticalis* {1}, *Fomes fomentarius* {1}, *Hyalorbilia juliae* {1}, *Lasiosphaeria* aff. *sorbina* {1}, *Orbilia aristata* {5}, *O. xanthoguttulata* {2}, *Orthotrichum* sp. {1}, *Parmelia sulcata* {1}, *Pyrenopeziza* sp. {1}, *P.* ?*caespiticia* {1}, ?*Teichospora* sp. {2}. **Desiccation tolerance**: fully viable for at least 8 weeks, about 50% of spores still viable after 10 months. **Altitude**: 270–460 m a.s.l. (central Europe), 1240 m (southern Europe). **Geology**: Keuper (marl & sandstone), Lower Jurassic sand- & limestone, Minette, Cretaceous siliceous shale, Pleistocene loess. **Phenology**: II–III, V, VII–XII (throughout the year).

Taxonomic remarks. *Orbilia aradi* is characterized by yellow(-orange) apothecia and fusoid-clavate, basally geniculate ascospores. The short glassy processes evoke a finely crenulate margin, and the paraphyses are apically only slightly inflated and tipped by glassy caps of exudate, but do not show any trace of beaks. The very similar North American *O. regalis* (p. 775) and Australian *O. austroregalis* (p. 776) differ particularly in paraphysis shape but also in apothecial colour. An Australian collection mentioned under *O. puyae* (on *Phragmites*, Pl. 408: 2) has paraphyses very similar to *O. aradi* but differs in smaller spores and a tropical origin. For the mediterranean *O.* aff. *aradi* on *Cistus* see below.

Variation. Although the typical colour of *O. aradi* is light (ochraceous-)yellow, populations with yellow-orange or almost hyaline apothecia were occasionally seen. In their microscopical features the 17 samples studied showed only very little variation.

Anamorph. The observed vermispora-like conidia are very similar as in other species of series *Regales* and also of, e. g., *O. comma* (series *Commatoideae*) or *O. phragmotricha* (series *Rubellae*). The conidia obtained in culture (at the lid of a Petri dish) were distinctly longer (*43–45 µm, Pl. 394: 1f) than those on the natural substrate (*29–40.5 µm, Pls 394: 3–4; 395: 3d), but were also less curved at the ends, so that their actual length is less divergent. The number of septa did not vary noticeably.

Phylogeny. Sequences of *O. aradi* were taken from apothecia of a sample from French Alps and from pure culture of a sample from Luxembourg, comprising ITS and partial LSU. From the culture also complete SSU and almost complete LSU were gained. All three sequences lack the large S1506 intron and completely concur in their overlapping parts. *O. aradi* shows a minimum ITS distance of 7.5% to *O. mali* and 8% to *O. brachychitonis*, and 2.5% in the LSU D1–D2 to *O. brachychitonis*. *O. aradi* formed with *O. mali* a supported clade (see under *O. mali*, p. 784).

Ecology. *O. aradi* grows very hidden on the inner surface and edges of detaching, ± undecayed xeric bark of large, mostly standing, damaged living or recently dead *Fagus* trees. As an exception (26.X.2010, Graulinster) the tree was lying on the ground, thrown by a storm about 3 years earlier. At three sites the species was instead collected on attached branches. *O. aradi* appears to be restricted to *Fagus* and was so far only collected in subcontinental central cold-temperate and a single time in orotemperate humid southern Europe. Very probably the species has a much wider distribution within the area of European beech, being overlooked due to its unusual habitat.

When occurring on the main trunk, the trees are either in the process of dying or recently dead: the bark detaches by splitting into large, ± rectangular pieces (Pl.395: 5a). Apothecia are formed during the initial stage of bark decay; at later stages the *Orbilia* becomes more sparse and soon vanishes. A bark beetle (*Taphrorhychus bicolor*) often has its galleries in the bast close to the apothecia and is possibly involved in the death of the trees, but in those collections on very undecayed bark the beetle was not present yet. Apothecia have never been found on bark being internally strongly destroyed by the bark beetle, and are usually absent on trunks or branches fallen to the ground.

Map 66. Known distribution of *O. aradi* in Europe.

Some associated ascomycetes, particularly *O. aristata* and an unidentified *Pyrenopeziza*, inhabit the same or closely adjacent pieces of bark, which are usually smaller and more strongly detached from the trunk by curling outwards. The inhabited trees were either half-shaded or fully sun-exposed, standing near edges of forests or in clearings caused by storms or wood-logging. Due to sunburn effects, bark damage and occurrence of *O. aradi* are usually limited to the sun-exposed side of the trunk. The inhabited trees might have died due to water stress caused by a rapid increase of sun exposition when the trees around were removed. Local wounds with detaching small bark pieces might also be induced mechanically during cutting of adjacent trees, perhaps also by deer, accompanied by *Fomes fomentarius* fruitbody formation. The associated flatbug *Aradus conspicuus* was repeatedly observed under the bark, partly in association with the *Orbilia*.

Specimens included (all on bark of *Fagus sylvatica*). **LUXEMBOURG**: **Gutland**, **Diekirch**, 3.5 km W of Beaufort, 1.3 km SSW of Eppeldorf, Süddig, 400 m, trunk, 15.III.2006, G. Marson (ø). – **Capellen**, 11.5 km NW of Luxembourg, 0.8 km SW of Dondelange, S of Telpeschholz, Uesbach 305 m, trunk, 12.III.2007, G. Plate 396. **1**: *Orbilia* aff. *aradi*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. cortical cells with glassy processes.

Orbilia aff. *aradi* — Pl. 396

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.7 × 0.25–0.5 mm diam., 0.14 mm high, pale orange-ochre (light yellow-amber with a rose tint when fresh), round to often elliptical, ± scattered; disc flat, margin thick, 5 µm protruding, finely rough; broadly sessile, partly ± immersed in clefts; dry orange-yellow. **Asci** †(40–)45–60 × 4–5 µm, 8-spored, spores †2–3-seriate, lower spores inverted, pars sporifera †30 µm long; **apex** (†) slightly to medium truncate (not indented, laterally not inflated), hemispherical in side view, thin-walled; **base** with medium long stalk, partly H-shaped. **Ascospores** †(8–)9–10(–11.8) × (1.6–)1.8–1.9(–2) µm, narrowly fusoid(-clavate), apex obtuse (rarely subacute), base medium tu rather strongly attenuated, sometimes tail-like, slightly to medium curved; **SBs** not observed (?globose), with several minute LBs in each half. **Paraphyses** apically slightly to medium inflated, consistently spathulate, terminal cells †16–22 × 2.4–3.2(–3.7) µm, lower cells †6.5–12.5 × 1.2–1.7 µm; unbranched at upper septum. **Medullary excipulum** 55 µm thick, of t. intricata. **Ectal excipulum** of vertically oriented textura angularis from base to mid flanks, 40–50 µm thick near base, cells †10–20 × 8–14 µm; 15–20 µm thick at flanks, cells †4–9 × 4–6 µm, 30 µm thick at margin, of t. porrecta oriented at a 30–60° angle to the surface, marginal cortical cells †6–13 × 2.5–3.2 µm; **glassy processes** 2–10 × 3–5 µm, high-refractive, yellowish, stratified. **Anchoring hyphae** sparse at base, †1.7–2.7 µm wide, walls 0.2–0.7 µm thick. **SCBs** and **VBs** unknown; **LBs** in paraphyses minute, scattered. **Exudate** over paraphyses (0.3–)1–2.5 µm thick, forming conical caps, pale yellowish, firmly attached, 1 or often several on each apex, over glassy processes absent. **— ANAMORPH**: unknown.

Habitat: decorticated, xeric, ?15 mm thick branch of *Cistus ladanifer*, on slightly decayed wood, greyed, with a few green algae. **Associated**: '*Helotium*' aff. *uvidulum*, *Orbilia vinosa*. **Desiccation tolerance**: unknown (certainly desiccation-tolerant). **Altitude**: ~650 m a.s.l. **Geology**: Quaternary clay and sand. **Phenology**: XII (but probably long-lived).

Taxonomic remarks. This taxon was only studied in the dead state from a single collection 10 years after it was collected. It differs from *O. aradi* in the paraphyses being more distinctly inflated (spathulate) at the apex and covered by often more than one glassy cap on each tip. The ascospores are slightly longer and more fusoid, and a H-shaped ascus base was drawn which has never been seen in *O. aradi*. The other characters are quite similar, but in combination with a different ecology this collection appears to represent a separate species. From *O. denticulata* it differs especially in shorter glassy processes and consequently absent marginal teeth, and in narrower anchoring hyphae. *O. regalis* differs in distinctly smaller spores.

The presence of a H-shaped ascus base might point to a relationship with section *Orbilia* or *Arthrobotrys*. Series *Microsomates* could be the right place for the taxon. Particularly *O. microlentiformis* looks similar but has more subcylindric-ellipsoid spores, and the indistinctly observed globose SB remote from the spore apex seen in a single spore (see Pl. 396: 1a) questions identity with this species.

Ecology. *O.* aff. *aradi* grew on slightly rotten wood of a xeric branch of *Cistus ladanifer* in the mesomediterranean semihumid subcontinental Meseta of Castile of the Iberian Peninsula in southeastern Europe.

Specimens included. **SPAIN**: **Madrid**, 14 km NNW of Madrid, El Pardo, ~650 m, branch of *Cistus ladanifer*, on wood, 5.XII.1984, G. Moreno, R. Galán & J.T. Palmer (AH 6402-1, as *O. ?luteorubella*, H.B. 5093 ø).

Orbilia mali Baral, **sp. nov.**, MB 813745 — Pls 397–398, Map 67

Etymology: named after the substrate in the type, bark of *Malus*.

Typification: France, Ariège, Rimont, branch of *Malus sylvestris*, 23.V.2007, J. Fournier (ex H.B. 8502a, M-0276508, holotype; sq.: KT222353).

Latin diagnosis: *Similis* Orbiliae commae *sed ascosporae multo minus curvatae, cellulae excipuli in statu vivo absque corpusculis crystalloideis, cellulae marginales partim processis vitreis praeditae. Habitat ad corticem leniter putridum ramorum vel truncorum siccorum angiospermarum in zona supratemperata humida ad submediterranea Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.6 {4} or 0.6–1.2 {2} mm diam., (0.1–)0.12–0.14(–0.16) mm high (receptacle 0.1–0.14 → 0.08 mm), light (to bright) orange-rose, ± translucent, ± round, scattered to subgregarious; disc flat, margin thin, 0–15 µm protruding, smooth to very finely crenulate; broadly sessile or with a short hidden stipe ~0.05 × 0.12 mm, superficial; dry bright orange(-rose). **Asci** *47–58(–63) × 4–5 µm {3}, †35–50(–56) × 3.5–4.5(–5) µm {4}, 8-spored, spores *2–3-seriate, (2–)3–5(–6) lower spores inverted {5} (sometimes mixed), pars sporifera *(21–)23–28(–35) µm long; **apex** (†) strongly truncate (not or slightly indented, laterally sometimes slightly inflated); **base** with medium to very long, slender, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(6–)7–9(–10) × 1.8–2.2((–2.5)) µm {6}, †(5–)6–8(–9) × 1.8–2(–2.4) µm {2}, ellipsoid- to fusoid-clavate, apex obtuse (rarely rounded or subacute), base medium to strongly attenuated in an often tail-like base or sometimes short tail, mostly slightly (to medium) curved especially near base; **SBs** *(1.5–)1.7–2(–2.3) × (0.7–)0.8–1(–1.2) µm {5}, tear- to pear-shaped or ampulliform, with a very short filum. **Paraphyses** apically (slightly to) medium to (very) strongly capitate(-clavate), terminal cells *(12–)17–23(–29) × (2.2–)2.8–4.2(–4.8) µm {4}, lower cells *(5–)7–11(–15) × 1.5–2.5(–3) µm {4}; never branched at upper septum. **Medullary excipulum** hyaline to very pale rose, 30–50(–70) µm thick, of medium dense textura intricata with many inflated cells, indistinctly to sharply delimited from ectal excipulum by a t. porrecta at flanks. **Ectal excipulum** subhyaline to very pale rose-orange, of (†) thin-walled (externally slightly gelatinized), (indistinctly) vertically oriented t. globulosa-angularis-prismatica from base to mid flanks or margin, (20–)30–50 µm thick near base, cells *(7–)9–20(–25) × (5–)7–12(–16) µm {4}; 20–40 µm thick at lower flanks, 15–25 µm near margin, of t. prismatica(-globulosa) oriented at 70–

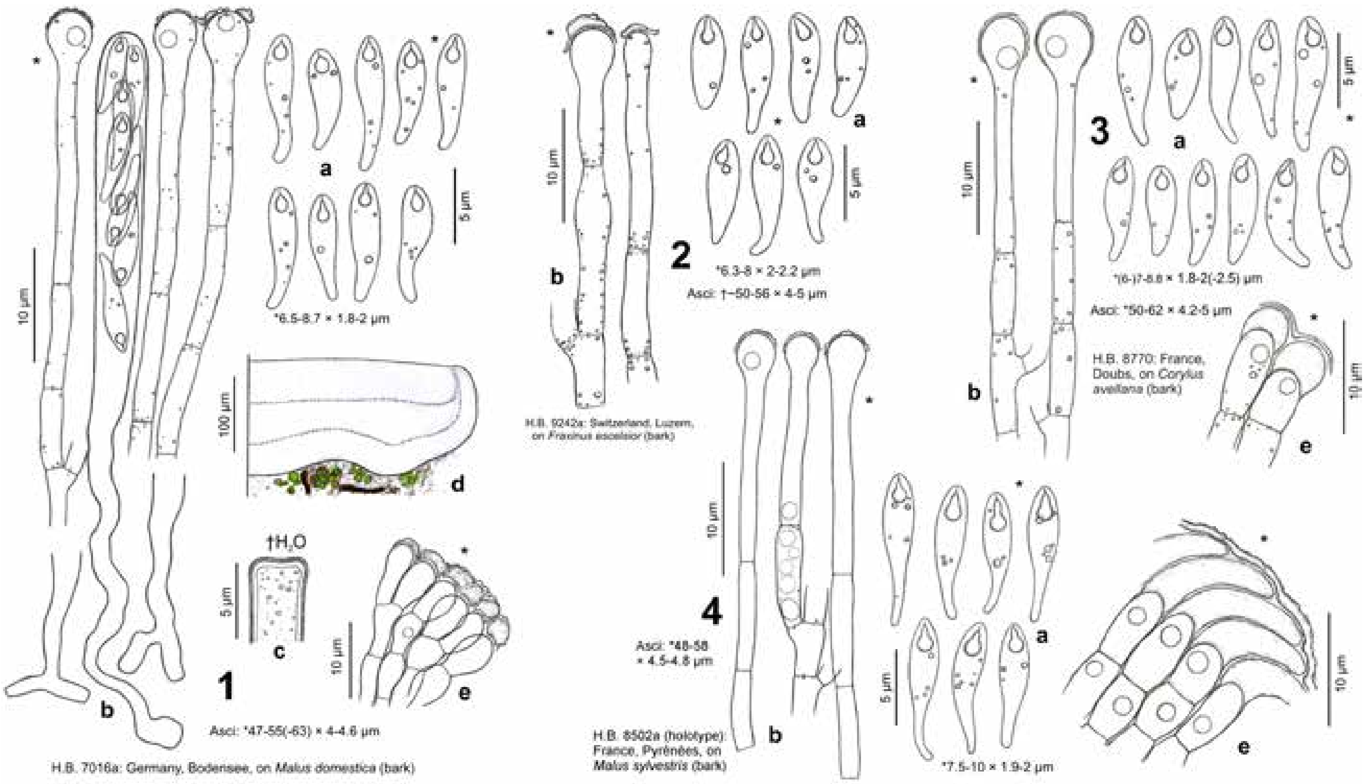

Plate 397. **1–4**: *Orbilia mali*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum with or without glassy processes.

90°, marginal cortical cells *5–10 × 3–5 µm {4}, **glassy processes** absent {3} or present, 2–6 × 3–4(–5) {4} or 8–14 × 2.5–3.3 µm {T}, medium to high-refractive, not or indistinctly stratified, outwards curved {T}. **Anchoring hyphae** sparse to abundant, *1.7–3.5(–4.5) µm wide, walls 0.2 µm thick {3}, or *3–6(–7) µm wide, walls 0.2–0.5 µm thick {*Radula*}, with a gel sheath, forming a loose t. intricata. **LBs** in lower part of hymenium and in excipulum towards margin with yellow-orange carotenoids {2}. **SCBs** globose, in paraphysis apices 1–1.8 µm diam., in marginal cells of ectal excipulum 1.3–2 µm diam., crystalloid SCBs absent {4}. **Exudate** over paraphyses 0.2–1(–2) µm thick, granular to cloddy, firmly attached; over margin and flanks 0.3–1 or 2–5 µm thick, cloddy to continuous, hyaline. — **ANAMORPH**: vermispora-like (presumed, from natural substrate {2}). **Conidiophores** not seen. **Conidia** unbranched, slightly (to medium) curved, *50–69 × 3–3.5 µm, †41 × 3.5 µm, 7–8-septate {2}.

Habitat: collected 0.5–1.5 m above the ground, corticated, ~20 cm thick living trunks or 5–20 mm thick, still-attached, dead branches of *Corylus avellana* {1}, *Fraxinus excelsior* {1}, *Malus domestica* {3}, *M. sylvestris* {1}, *Punica granatum* {1}, *Salix* sp. {1}, on outer surface of bark {7}, on periderm {3} or bast {6} (either in cracks of periderm or on inner surface of detaching bark), on black mould of *Helicoma muelleri* (anamorph of *Thaxteriella pezizula*) {T}, slightly to medium decayed, slightly to strongly greyed, with a few to many green algae; on partly bleached leaves of *Radula* {1}. **Associated**: *Arthonia cinnabarina* {1}, *Cosmospora* sp. {1}, *Graphis scripta* {1}, *Hyalorbilia orbiliicola* (parasitic on *O. mali*) {1}, *Karstenia idaei* {1}, *Metzgeria* sp. {1}, *Mollisia ligni* {1}, *Orbilia aristata* {2}, *O. aurantiorubra* {1}, *O. clavuliformis* {1}, *O. eucalypti* {1}, *O. ?flagellispora* {1}, *O. gambelii* {1}, *O. subaristata* {1}, *O. xanthoguttulata* {1}, *Orthotrichum* sp. {1}, *Radula complanata* {1}, *Thaxteriella pezizula* {1}, *Tympanis alnea* {1}, *Unguiculariopsis* sp. {1}, indet. lichen and pleurocarpous moss. **Desiccation tolerance**: some mature asci and paraphyses still viable after 8 days, a single spore after almost 6 months. **Altitude**: 210–540 m a.s.l. **Geology**: Middle & Upper Jurassic limestone, Cretaceous marl-, sand- & limestone, Tertiary molasse & flysch, Pleistocene till & sand. **Phenology**: I–II, V, IX–X (probably throughout the year, long-lived).

Taxonomic remarks. *Orbilia mali* shows a certain similarity to *O. brachychitonis* and *O. aradi*, from which it differs in more fusoid-clavate ascospores and never spathulate paraphyses, *O. aradi* also differs in the yellow apothecial colour and occurrence on *Fagus* bark, also in shorter, more globose SBs and much less inflated paraphyses. In gross morphology *O. mali* also resembles members of series *Commatoideae*, e. g., *O. comma*, from which it differs in much less curved, scarcely helicoid spores, also in the living excipular cells lacking crystalloid SCBs, and in the predominant presence of glassy processes. *O. caulicola* and *O. cookei* differ in more straight spores without a tail, shorter SBs due to a shorter and less distinct attachment, and in the consistent absence of glassy processes, *O. caulicola* also in less inflated paraphyses. For the similar *O. pisciformis* see p. 808. *O. caudata* (series *Piliferae*) differs from *O. mali* in wider spores with much more broadly attached SBs.

Variation. Although four of the included collections grew on the same host genus (bark of *Malus*), they differ from each other in several respects. In the holotype (Pl. 398: 1) and the sample from Austria (IVV: 18.II.2017) the apothecia are larger than in the other collections. The holotype has medium long glassy processes at the margin (Pl. 397: 4e), which are absent or very short in the other collections studied, or the margin is covered by exudate or a hyphal layer (Pl. 397: 1, IVV: H.B. 8770, 9242a, 1.V.2016 etc.). The spores in the holotype are slightly longer, with more distinct tails and somewhat longer, more pear-shaped SBs compared to all the remaining samples. Nevertheless, the collections on *Fraxinus*, *Salix*, and *Radula* (on *Corylus*) fit well some of those on *Malus*.

Anamorph. Only a few conidia of the presumed vermispora-like anamorph were seen in the two *Malus* collections (Pl. 398: 1j, IVV: H.B. 7016a) resembling those of *O. comma*. In both collections a few similar but larger conidia with many more

Plate 398. **1–6**: *Orbilia mali*. – **1a**. clearing in mixed *Acer-Fraxinus* forest with *Malus sylvestris*; **1d–e**. fresh apothecia; **1b–c**, **2a–d**, **3a–d**, **5a–b**, **6a**. rehydrated apothecia; **1f**. apothecium in median section; **1h**, **2e**, **5c**. id., marginal region; **1g**. id., basal excipulum; **1i**, **6b**. ascospores, in **1i** attached to air bubble; **1j**, **4**, **5d**. 3 types of conidia from substrate. – Living state, except for **4** (in H_2O). – **1a**: phot. J. Fournier, **3d**: phot. G. Moyne, **5** & **6**: phot. B. Perić. — **1a–k**. H.B. 8502a (holotype): France, Pyrénées, on *Malus*; **2a–e**. H.B. 9242a: Switzerland, Luzern, on *Fraxinus*; **3a–d**. H.B. 8770: France, Doubs, on *Radula* (on *Corylus*); **4**. H.B. 7016a: Germany, Bodensee, on *Malus*; **5a–d**. B.P. Dgf/C7D-01-05-16b: Montenegro, Podgorica, on *Punica*; **6a–b**. ibid.

septa were found (*/†62–92 × 6–7 µm, with 13–17 septa, Pl. 398: 4, IVV: H.B. 8502a), which might as well represent the anamorph of *O. mali*. In the sample on *Punica* similar but much shorter 3-septate conidia occurred on the natural substrate (*20–27 × 3 µm, Pl. 398: 5d).

Phylogeny. Sequences were gained from apothecia of the holotype (ITS) and the sample from Austria (ITS+LSU D1–D2) (both on *Malus* and without S1506 intron). The ITS distance is 1.1 % (6 nt and 1 gap) between them, and 7 % to *O. aradi*, 10 % to *O. brachychitonis*, 13.5–14 % to *O. caulicola* and 14.5–15 % to *O. comma*. The lowest LSU distance is 1.8 % (11 nt) to *O. aradi*. In our analyses of ITS+LSU or LSU (Phyls 13, S16) *O. mali* clustered with *O. aradi* in a strongly supported clade.

Ecology. *O. mali* was collected on ± decaying bark of living or dead xeric trunks or branches of different angiosperm trees, also on ± living leaves of a liverwort (*Radula*). Although four times recorded on *Malus*, the other collections disprove a strict host specificity. Most of the apothecia of the *Radula* collection (on *Corylus*) grew on the liverwort and only a few on bark. The eight known collections are from cold-temperate, subatlantic to subcontinental central Europe (Bodensee, Bayerischer Wald, Luzern, Côte d'Or, Doubs), also from atlantic (Pyrénées) and submediterranean southern Europe (Dinaric Alps). The vegetation includes a cold-temperate humid orchards with apple trees (Germany), a warm-temperate humid deciduous forest with *Fraxinus*, *Corylus*, *Acer campestre*, *Prunus avium*, *Malus sylvestris* etc. (Pyrénées), and a mesosubmediterranean (semi)humid orchard with *Punica granatum* and *Vitis vinifera* (Dinaric Alps).

Specimens included. **GERMANY**: **Baden-Württemberg**, Bodensee, 6.5 km NW of Überlingen, NW of Sipplingen, 430 m, trunk of *Malus domestica*, on bark, 1.IX.2001, H.O. Baral (H.B. 7016a, anam. substr.). – **Bayern**, **Oberbayern**, 17 km NE of Traunstein, 2 km NNW of Tittmoning, Schlichten, 407 m, branch of *M. domestica*, on bark, 23.II.2020, P. Karasch (T.R.L., doc. vid.). — **SWITZERLAND**: **Luzern**, 24 km NNW of Luzern, 1.2 km E of Aesch, Gitzitobel, 540 m, branch of *Fraxinus excelsior*, on bark, 9.I.2010, U. Graf (H.B. 9242a). — **AUSTRIA**: **Steiermark**, 5.5 km NW of Feldbach, SW of Edelsbach, 315 m, twig of *Malus domestica*, on bark, 18.II.2017, A. Gallé, vid. G. {1}, *O. carminorosea* {1}, *O. ?eucalypti* {1}, *O. euphorbiae* {1}, *O. gregorii* {1}, *O. mammifera* {1}, *O. ?multigambelii* {1}, *O. neocomma* {1}, *O. ?pleiogambelii* {1}, *O. scandens* {1}, *O. subcryptogena* {1}, *Patellaria ?andina* {1}, various crustose & foliose lichens. **Desiccation tolerance**: fully viable for 34 months, conidia still alive after 4 years. **Altitude**: 12–278 m a.s.l. **Geology**: Australia: Cenozoic regolith (red-brown gravel), granite, granitic gneiss; USA: Tertiary-Quaternary clay & mud. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia brachychitonis* resembles European *O. aradi* and American *O. regalis*, from which it differs in slightly wider ascospores being usually less attenuated at the base, from *O. aradi* also in apically inflated paraphyses, larger SBs, and in an orange-rose apothecial colour. *O. kingsiana* resembles *O. brachychitonis* in the spores and mainly deviates in the more clavate paraphyses, absence of glassy processes, narrower spores, and mostly pinkish apothecia. *O. euphorbiae* mainly differs in narrower spores and SBs.

Variation. The holotype (on *Brachychiton*) and the specimen from Queensland (on indet. climber) differ from the remaining paratypes (including another sample on *Brachychiton* close to the type locality) in slightly wider spores, the latter also in longer, sometimes strongly curved (sickle-shaped), apically more subacute spores (especially in the dead state). Inconspicuous crystalloid SCBs were observed in the few living paraphyses in the other sample on *Brachychiton* and more distinct ones in those on *Nuytsia* and *Baccharis*, but none were seen in the holotype and in the samples on *Adansonia* and indet. climber. The North American collection on *Baccharis* differs in comparatively small SBs (*1.2–1.5 × 0.5 µm), but that on *Adansonia* has also smaller SBs than the remaining specimens. Yet, a sketch from a different apothecium without exact scale (Pl. 399: $6a_2$) questions this difference. Only in this apothecium crystalloid SCBs were seen in paraphyses as well as excipulum. The presence of exudate caps on the paraphyses was inconsistent especially in this sample.

Anamorph. The conidia obtained in pure culture of the holotype (Pls 399: 1; 400: 1f–g) are slightly smaller, especially narrower and with fewer septa compared to those found on the natural substrate in four further collections (Pls 399: 2h, 3h, 5h, 6h; 400: 2e, 3d).

Phylogeny. A sequence was gained from a culture of *O. brachychitonis* (H.B. 7578a, western Australia) which comprises SSU (with S1506 intron), ITS, and LSU. The species shows a minimum ITS distance of 8 % to *O. aradi* and 10 % to *O. mali*. In the LSU D1–D2 the minimum distance is 2.5 % to *O. aradi* and 2.8 % to *O. denticulata*, and in the intron 18 % to *O. euphorbiae* (H.B. 9869). *O. brachychitonis* clustered strongly supported with *O.* cf. *caudata* (Phyls 13, S16).

Ecology. *O. brachychitonis* was collected on ± rotten bark and wood of xeric branches of *Nuytsia* and *Brachychiton* in subtropical semiarid acacia shrublands in (south)western Australia, and of *Adansonia* and unidentified climber in tropical wet and dry eucalypt woodlands (savannah) in subhumid northwestern (edge of Kimberley Mts.) and tropical northeastern Australia (east of Great Dividing Range). The North-American collection was on bark of *Baccharis* in a subtropical subhumid woodland at a dry rivulet in the Coastal Prairies at the southern end of the Great Plains.

Specimens included. **AUSTRALIA**: **Western Australia**, Dampierland, SW-border of Leopold Ranges (Kimberleys), 47 km SSW of Derby, 12 km WNW of Willare Bridge over Fitzroy River, 20 m, branch of *Adansonia gregorii*, on wood, 1.XI.2007, G. Marson (H.B. 8777b). – Carnarvon, 165 km SSE of Carnarvon, Peron Peninsula, 24 km SE of Shell Beach, 41 m, branches of *Brachychiton gregorii*, on bark & wood, 8.XII.2001, G. Marson (ex H.B. 7578a, MEL 2389237, **holotype**, CBS 117020, anam. cult.; sq.: KT215257). – 18 km SE of Shell Beach, 48 m, branches of *B. gregorii*, on bark, 8.XII.2001, G. Marson (H.B. 7572a, anam. substr.). – Geraldton Sandplains, 60 km N of Geraldton, 12 km N of Northampton, 278 m, branch of *Nuytsia floribunda*, on bark, 9.XII.2001, G. Marson (ø, anam. substr.). – **Queensland**, Brigalow Belt North, 49 km SE of Ayr, 4 km ESE of Gumlu, 12 m, branches of indet. climber, on bark & wood, 19.X.1998, G. Marson (H.B. 7276e, anam. substr.). — **USA**: **Texas**, Coastal Prairies, 100 km WNW of Houston, 13 km WNW of Hempstead, W of bridge over Brazos river, 70 m, branch of *Baccharis salicifolia*, on bark, 19.VI.1996, G. Marson (H.B. 5681b, anam. substr.).

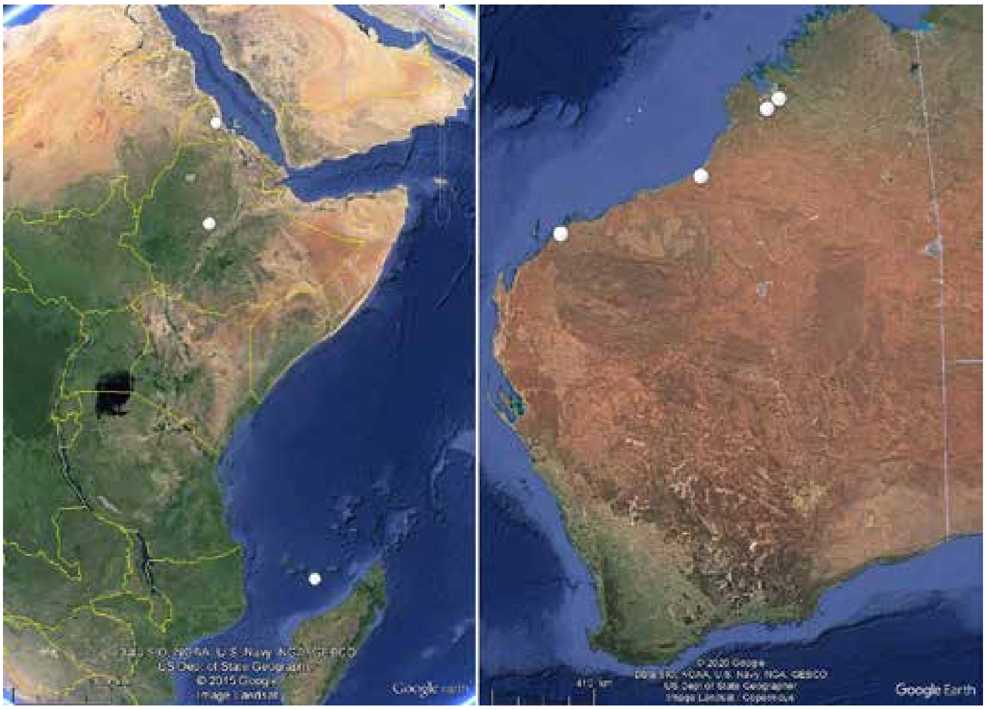
conidia formed terminally or on sparse lateral nodules. **Conidia** unbranched; on natural substrate C-shaped, slightly to often strongly curved at both ends, *26–37.5 × 4.8–5.3 µm, †28–43 × 3.8–4.5 µm, 5–8-septate {1}, with minute LBs at the septa; in pure culture on CMA:4 C-shaped, slightly to strongly curved, *13–23 × 4.2–5 µm, 1–3-septate, containing large LBs when 1-septate; after transfer to CMA:1 *(23–)31–36(–45) × (3.8–)4–4.6 µm, 3–4-septate, straight or slightly to medium curved at the ends only, containing a few minute LBs {1}.

Habitat: collected ± close to the ground or in 0.2–3 m above the ground, corticated, 8–37 mm thick branches of *Acacia aneura* {1}, *Adansonia digitata* {1}, *A. gregorii* {3}, *Euphorbia* sp. {1}, *E. polyacantha* {1}, *Ipomoea costata* {1}, on medium rotten bark (bast) {5} or wood {2}, on outer surface of bark along clefts and on periderm-free areas, or on inner surface of detached bark, 0.3–0.5 mm deep very decayed; herbaceous stem of *Solanecio gigas* {1}, on strongly decayed epidermis or epidermis-free areas; ± greyed, algae absent or very sparse. **Associated**: *Orbilia brachychitonis* {1}, *O. carminorosea* {1}, *O. commarosa* {1}, *O. ?livistonae* {1}, *O. ?menageshae* {1}, *O. ?multiserpens* {1}, *Patellaria ?andina* {1}. **Desiccation tolerance**: fully viable for at least 15 months, some ascospores still alive after more than 4.5 years, conidia after 15 months. **Altitude**: 12–46 m a.s.l. (Australia, Macaronesia, Comoros), 900–2520 m (northeastern Africa). **Geology**: mafic-basaltic volcanic rock and mainly Cenozoic regolith (red-brown gravel). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia euphorbiae* is characterized by spathulate to lageniform paraphyses, narrowly subcylindrical, comma-like ascospores with a small tear-shaped spore body, and comparatively large, ± bright yellow-orange apothecia with a typically denticulate margin due to glassy processes. The very similar *O. carnegieae* differs in longer ascospores and conidia, also in the terminal cells of paraphyses that are partly not longer than the lower cells, apically only sometimes lageniform, containing globose SCBs. Also *O. regalis* is very similar to *O. euphorbiae*. It is tentatively separated by slightly shorter spores with a consistently strongly attenuated and geniculate base, in combination with the occurrence in a temperate humid region. *O. brachychitonis* mainly differs in wider spores and SBs. *O. denticulata* closely matches *O. euphorbiae*, e. g., in macroscopy and in the wide, thick-walled anchoring hyphae, but differs in much wider spores with partly more broadly attached SBs. Species such as *O. puyae* and *O. aradi* differ in the predominant absence of lageniform paraphyses. A North American collection on *Cylindropuntia* mentioned under *O. carnegieae* resembles *O. euphorbiae*, but differs in basally not or only slightly tapered spores and in capitate or only slightly spathulate paraphyses that contain globose SCBs. *O. pseudeuphorbiae* (see Pls 919–920) strikingly resembles *O. euphorbiae* but differs in a number of more or less stable characteristics, including its presumed anamorph (see p. 1476). *O. succulenticola* (series *Aurantiorubrae*) occurs in the same habitat as *O. euphorbiae* but is sufficiently distinct (see Pls 445–446).

Variation. Three of the eight collections of *O. euphorbiae* examined in the present study were studied in the dead state only (Pl. 401: 2–3; IVV: H.B. 8726b), except that a few spores were still alive in one of them (Pl. 401: 3a left), and their conspecificity is somewhat uncertain. Based on a remarkable genetical distance between the two sequenced strains on *Adansonia* (see below), we must conclude that *O. euphorbiae* in the present circumscription is a collective species. However, the morphological differences between these two strains are comparatively low, and similar morphological variation was noted by us in many other species of *Orbilia*.

O. euphorbiae varies considerably in diameter and thickness of the apothecia, which are in the lectotype from Eritrea (on *Euphorbia*, Pls 401: 2; 402: 2) and in the sample from the Comoros (on *Adansonia*, Pl. 403) distinctly larger than in the other collections. Also the paraphyses vary in apical width and



Map 69. Known distribution of *O. euphorbiae* in eastern Africa and western Australia.

in length of the apical beak, partly even within a population. The exudate on the beaks varies from a continuous thin layer (Pl. 401: 3) to thick cloddy caps (Pl. 401: 1, 4). The glassy processes show some variability in length, resulting in a different strength of marginal crenulation. In the lectotype they are partly up to 30–55 µm long, though on the drawing and microphoto only 13–20 µm (Pls 401: 2e; 402: 1d). In the remaining records the processes attain a length of only ~(6–)9–13(–18) µm, and in some apothecia of a population they are even shorter (1–2 or 3–6 µm), resulting in an almost smooth margin (Pl. 402: 5b).

In the lectotype the paraphyses are distinctly lageniform and the SBs could sometimes be seen as a faint, rather large region in the ascospore apex, though their original size remains unclear. In another sample from northeastern Africa (Ethiopia, on *Solanecio*, Pl. 402: 2) the spores are smaller (*7–8.5 × 1.3–1.4 µm), and the SBs (*0.8–1 × 0.4–0.6 µm) and the mammiform paraphyses fit quite well, e. g., those populations from Australia. A collection on wood of *Ipomoea costata* (IVV: H.B. 8726b) deviates from the more typical collections in slightly wider asci (†4–4.5 µm) and spores (†1.5–1.8 µm). Since no vital characters (especially SBs) are known here, the identity of this specimen is uncertain, as it fits also the closely related *O. brachychitonis*.

Only in the specimen from Tenerife an H-shaped ascus base was sometimes seen (Pl. 401: 3b). This collection is thought to belong here rather than to *O. pseudeuphorbiae* (section *Arthrobotrys*) because of its narrow SBs and rehydrated light orange-ochre apothecia. However, the paraphyses are not distinctly lageniform or mammiform in this collection, and *O. pseudeuphorbiae*, which was recorded from various places of Tenerife, occurred also quite close (1 km or less) to the site of this sample at Montaña Roja.

Type studies. The examined syntype specimen in S (Pl. 401: 2, Pl. 402: 1) corresponds quite well to the protologue, except for the spores which Hennings (1891) described as subellipsoid, 3–5 × 2–2.5 µm. The apothecia, reported as 2–9 mm diam. by Hennings, were smaller in the present study (rehydrated 1.5–3 mm) as well as in Svrček's (1974) revision of another syntype (from G, 1–2 mm). Svrček found the asci 40–70 × 3.5–4.5 µm, the spores 9–11 × 1.5–1.8 µm, the paraphysis apices 2.5–4.5 µm wide (present study 1.8–2.6 µm, –3.3 µm incl. exudate), and the excipular cells up to 18 µm diam. (present study 7–13 × 5–9 µm near base). The pruinose exterior and the glassy processes are not mentioned by him. Since the syntype in B, which might have been the basis of Hennings' description, was destroyed during the Second World War, the examined specimen in S (S-F 41427, herb. Sydow) is designated here as **lectotype** of *O. euphorbiae* (Art. 9.11, Turland et al. 2018).

The collection data of the type of *O. euphorbiae* bear some uncertainties. In the region of Gheleb the altitude is around 1700 m, therefore, the statement 'ca. 900 m' in the protologue would point to a valley ENE of Gheleb. However, it could also be a lapsus for 1900 m, since Hennings (1891: 369) mentions another fungus (*Ustilago penniseti*) from near Gheleb at 1900m. The indicated substrate *Euphorbia thii* was newly described from eastern Sudan by the finder G. Schweinfurth, and is today regarded as a synonym of *E. polyacantha*. The collection date of *O. euphorbiae* is noted on the label as 4.V.1891, but in the protologue as 4.IV.1891. The latter must be correct: according to personal plant drawings, Schweinfurth was on the eastern slopes of this mountain range also on the 5th of April (http://www.bgbm.org/de/node/131), and Hennings (1891) stated in his preface that Schweinfurth was in Eritrea from January until April 1891.

Anamorph. In one of the Australian collections on *Adansonia* we observed curved phragmoconidia of the *Vermispora*-type on the substrate near apothecia (Pl. 401: 1f), characteristic of series *Regales*. In that from the Comoros (also on *Adansonia*) conidia developed in pure culture (Pl. 403: 1g–h). These eventually attained a similar size but were much less curved and with fewer septa (1h). The small 1-septate conidia with large LBs observed on CMA:4 are assumed to represent young, untypical conidia which are frequently formed in a young culture (1g).

Misapplication. A Macaronesian collection reported by Korf (1992) under the name *O. occulta* turned out to belong to *O. euphorbiae* (Pl. 401: 3).

Phylogeny. An ITS sequence was gained from apothecia of one of the specimens from Australia (H.B. 8777c, on *Adansonia*), and ITS+LSU from the pure culture from the Comoros (H.B. 9869, on *Adansonia*). In the ITS region a distance of 5% was noted between the two strains. In H.B. 8777c the S1506 intron is absent, whereas in H.B. 9869 it is present. For the time being, we have considered both samples as conspecific (see above).

O. euphorbiae clustered in our phylogenetic analyses of ITS+LSU or ITS with *O. denticulata* in a strongly (Phyls 13–14, S15), with a distance of 8.5–9.5/2.7% in the ITS/LSU D1–D2 (in comparison 13/3.3% to *O. aradi*). In the intron a distance of 18% to *O. brachychitonis* is observed. The morphologically similar *O. pseudeuphorbiae* falls in series *Neodactylella* of section *Arthrobotrys*, with a ~22% ITS distance to *O. euphorbiae*.

Ecology. Collections of *O. euphorbiae* on rotten branches of succulent *Euphorbia* species derive from a inframediterranean hyperarid xerophytic scrub (tabaibal dulce) in Tenerife (Macaronesia) and a subtropical arid steppe of a high plateau in Eritrea. The sample on herbaceous stems of *Solanecio* was from a warm-temperate humid (somewhat winter-dry), evergreen afromontane forest in the central plateau of the Ethiopian highlands. Collections on rotten bark and wood of xeric branches of *Acacia* and *Adansonia* were from a tropical humid (wet & dry) rainforest in the oceanic Comoros and from tropical (to subtropical), arid to semihumid acacia open shrublands (mulga), tussock grasslands, or eucalypt open woodlands (savannah, wet and dry) more or less close to the coastline in northwestern and western Australia south of the Kimberley Mountains adjacent to the Pilbara desert.

Specimens included. **AUSTRALIA**: **Western Australia**, Dampierland, 235 km SW of Broome, 6 km E of Sandfire Roadhouse, 12 m, branch of *Acacia aneura*, on bark, 3.XII.2001, G. Marson (H.B. 7302c). – SW-border of Leopold Ranges (Kimberleys), 47 km SSW of Derby, 12 km WNW of Willare Bridge over Fitzroy river, 20 m, branches of *Adansonia gregorii*, on bark, 30.XI.2001, G. Marson (H.B. 7295, anam. substr.). – ibid., branches of *A. gregorii*, on wood, 1.XI.2007, G. Marson (H.B. 8777c; sq.: KT222351). – S of Kimberley Mts., 35 km ESE of Derby, 5 km W of Meda, 38 m, branches of *A. gregorii*, on bark, 1.XI.2007, G. Marson (G.M. 2007-11-01). – Pilbara, 58 km WSW of Karratha, 37 km NE of Fortescue River Roadhouse, 46 m, branch of *Ipomoea costata*, on wood, 4.XII.2001, G. Marson (H.B. 8726b). — **MACARONESIA**: **Canary Islands**, **Tenerife**, Granadilla de Abona, ~2 km SW of El Médano, Montaña Roja, ~30 m, branch of *Euphorbia*, 15.I.1990, R.P. Korf & J.T. Palmer (CUP-MM-000269, as *O. occulta*, H.B. 5149 ø). — **ERITREA**: **Anseba**, Great Rift Valley, 43 km ENE of Keren, ~8 km ENE of Gheleb, high plateau of Haigett, ~900 m, branch of *Euphorbia polyacantha* (as *E. thii*), on bark, 4.IV.1891, G. Schweinfurth (herb. Sydow, S-F41427, **lectotype**, H.B. 7688 ø). — **ETHIOPIA**: **Oromia**, 22 km WSW of Addis Ababa, 10 km NW of Sebeta, southern part of Menagesha Suba State Forest, ~2520 m, stem of *Solanecio gigas*, 26.III.2010, U. Lindemann (H.B. 9309a, U.L. 0310-23). — **COMOROS**: **Mayotte**, 1.5 km SW of Bandrele, North Bambo Bay, 14 m, on bark of *Adansonia digitata*, 2.II.2014, M. Pélissier (J.P.P. 14030, H.B. 9869, anam. cult., sq.: KT380105).

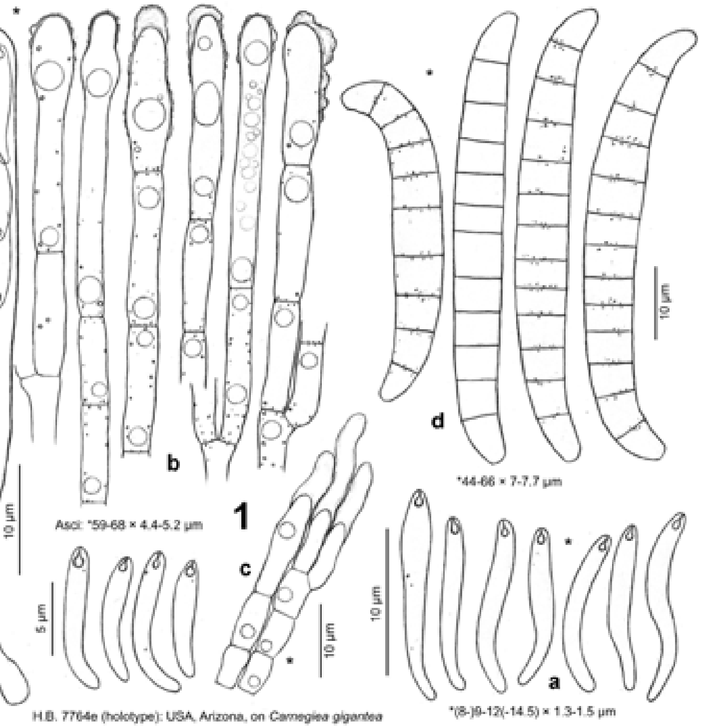


Plate 404. **1**: *Orbilia carnegieae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. marginal ectal excipulum in median section, with glassy processes; **d**. conidia from substrate.

Orbilia carnegieae Baral & G. Marson, **sp. nov.**, MB 813753 — Pls 404–405

Etymology: named after the substrate of the type, *Carnegiea gigantea* (saguaro cactus).

Typification: USA, Arizona, Lukeville, skeleton of *Carnegiea gigantea*, 28.V.2003, G. Marson (ex H.B. 7764e, M-0276449, holotype).

Latin diagnosis: *Similis* Orbiliae euphorbiae *sed ascosporae longiores*, *basi minus attenuatae*, *paraphyses ad apicem plerumque non lageniformes. Habitat ad residuos trunci putridi sicci* Carnegieae giganteae *in zona subtropica semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1.8 mm diam., 0.25–0.3 mm high (receptacle 0.1–0.12 mm), light orange, scarcely translucent, round, subgregarious in small groups; disc slightly concave to flat, margin with distinct whitish teeth 50–70 × 40 µm which project beyond disc; sessile on a very broad obconical stipe, ± superficial. **Asci** *59–68 × 4.4–5.2 µm, 8-spored (mostly only 5–7 spores developed), spores *2–3-seriate, 3–5 lower spores inverted (often mixed), pars sporifera *21–30 µm long; **apex** (†) strongly truncate (not indented, laterally not widened); **base** with medium long, thick, ± flexuous stalk, L-shaped. **Ascospores** *(8–)9–12(–14.5) × 1.3–1.5((–2)) µm, narrowly subcylindric(-clavate) to sometimes fusoid-clavate, apex rounded to obtuse, base not or usually slightly (to medium) attenuated, slightly to mostly medium (to strongly) curved, especially near base, often ± distinctly helicoid; **SBs** *1.1–1.6 × 0.4–0.7 µm, tear-shaped, apically abruptly narrowed to a very short filum. **Paraphyses** apically uninflated or mostly slightly to medium spathulate, sometimes lageniform, also obtusely lanceolate, terminal cells *13–28 × (2.5–)3–4(–4.5) µm, lower cells *7.5–15 × 2–3.2 µm; frequently unbranched at upper septum. **Medullary excipulum** hyaline, 40–70 µm thick, of medium dense textura intricata-globulosa, sharply delimited. **Ectal excipulum** pale rose, of thin-walled, vertically oriented t. globulosa(-prismatica) from base to mid flanks, 100–160 µm thick near base, cells *14–25(–38) × 10–18(–25) µm; 15–30 µm thick at flanks, 30 µm near margin, of t. prismatica-porrecta oriented at an 80° angle to the surface, marginal cortical cells *7.5–15 × 2.5–4(–5.5) µm; **glassy processes** 5–60 × 2.5–3.5 µm, high-refractive, not stratified, coherent to form distinct teeth, curved outwards at margin but upwards at flanks. **Anchoring hyphae** very abundant, †2.7–3.8 µm wide, walls 0.3–0.7 µm thick, forming a loose t. intricata up to 100 µm thick, also covering flanks. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.3–3.3 µm diam; **LBs** pale yellow-orange (carotenoids), peripheral and near septa at base of paraphyses and in marginal excipulum. **Exudate** over paraphyses 0.2–2 µm thick, cloddy, hyaline, firmly attached, cap-like; over margin and flanks sparse. — **ANAMORPH**: vermispora-like (presumed, from natural substrate). **Conidiophores** not seen. **Conidia** phragmosporous, slightly to strongly curved at the ends, ± straight in middle part, *44–62 × 7–7.5 µm, 9–12-septate.

Habitat: lying on ground, 15–20 mm thick branches of *Carnegiea gigantea*, on wood in excavation, strongly decayed, greyed, without algae. **Associated**: *Orbilia cactacearum*, *O. saguarina*, *Teichosporella dura*, ?*Trichopeziza* sp. **Desiccation tolerance**: fully viable for at least 27 months, conidia after 30 months. **Altitude**: 750 m a.s.l. **Geology**: lava tuff with basalt, andesite, dacite, rhyolite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia carnegieae* is tentatively segregated from the Afro-Australian *O. euphorbiae* based mainly on longer spores (for further details see p. 790). The South American *O. puyae* differs in shorter, basally more attenuated

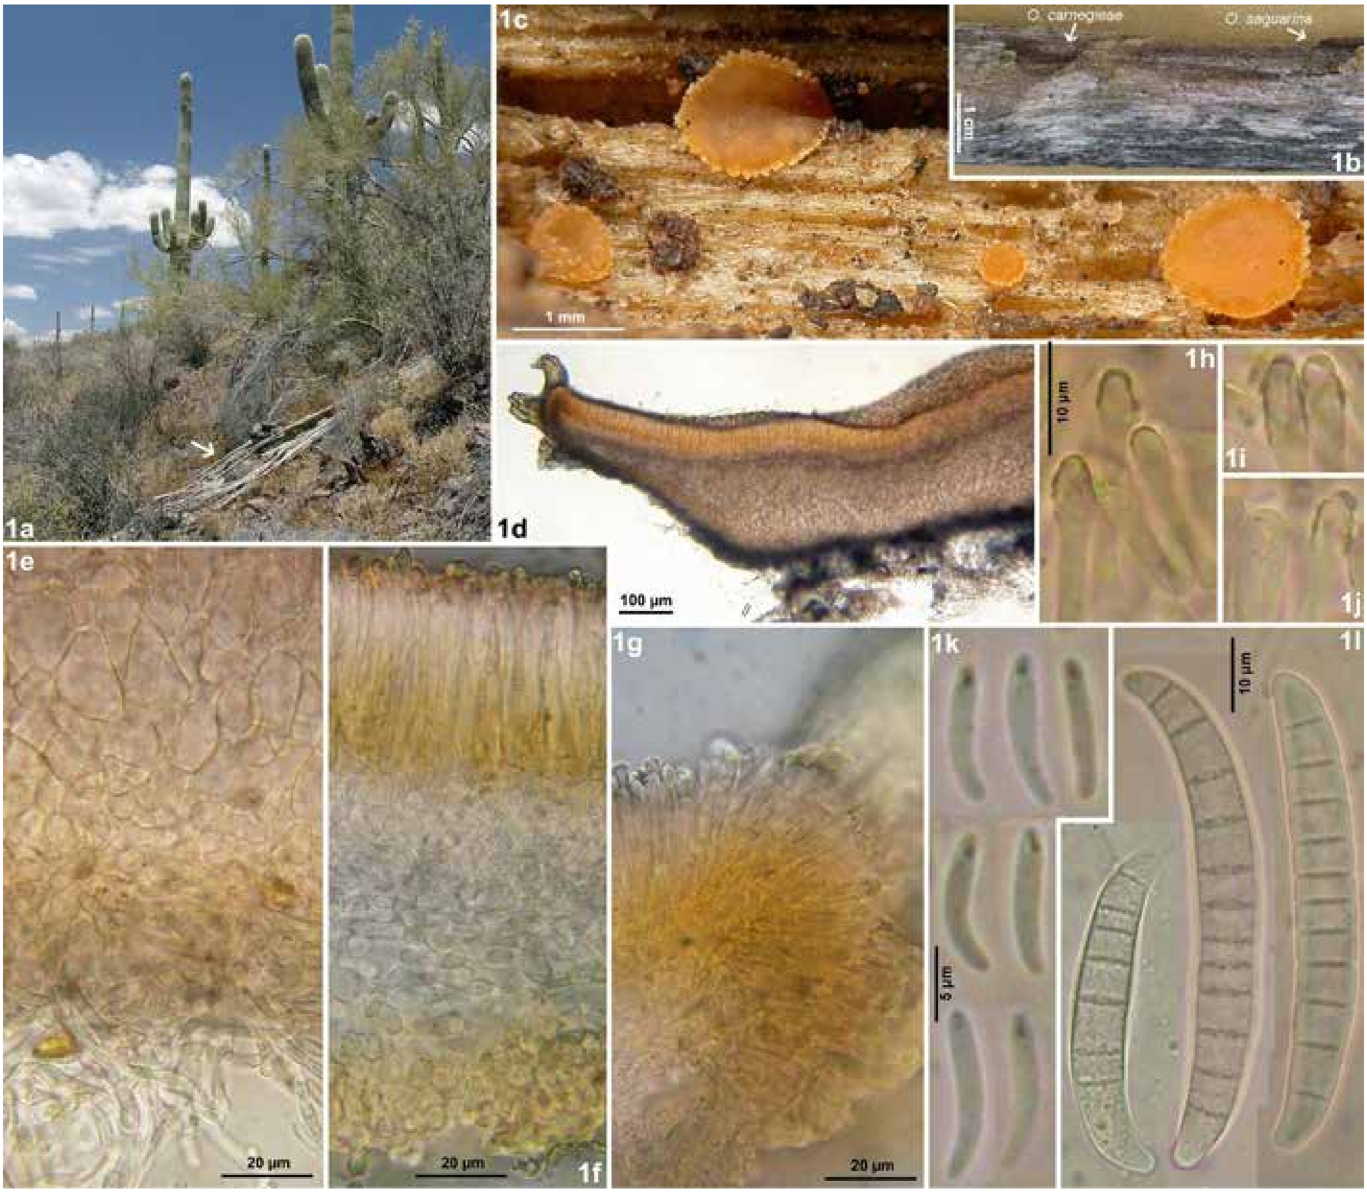

Plate 405. **1**: *Orbilia carnegieae*. – **1a**. semiarid mixed cacti desert scrub with saguaro (*Carnegiea gigantea*), *Parkinsonia microphylla* in foreground, skeleton fragments of *Carnegiea* lying on ground (arrow); **1b**. decayed greyed skeleton fragment; **1c**. rehydrated apothecia; **1d**. apothecium in median section; **1e**. id., basal ectal excipulum and anchoring hyphae; **1f**. id., lower flanks of apothecium; **1g**. id., marginal ectal excipulum; **1h–j**. paraphysis apices; **1k**. ascospores; **1l**. conidia from substrate. – Living state. — **1a–l**. H.B. 7764e (holotype): USA, Arizona, on *Carnegiea*.

spores with distinctly larger SBs, and in capitate paraphyses.

Not included collection. A sparse sample on *Cylindropuntia bigelovii* (Cholla cactus, IVV: H.B. 8355a,) from almost the same collection site as the holotype might be conspecific, but differs in shorter spores (*8–9.2 × 1.2–1.6 µm) and in the paraphyses being never lageniform.

Anamorph. Although *O. carnegieae* is very similar to *O. euphorbiae*, the larger conidia with more septa (Pls 404: 1d; 405: 1l) clearly differ from the more C-shaped conidia on the natural substrate of *O. euphorbiae* (Pl. 401: 1f) or the almost straight, also shorter conidia obtained in culture of *O. euphorbiae* (Pl. 403: 1h).

Ecology. *O. carnegieae* was collected in the Sonoran Desert on rotten, xeric fragments of the vascular skeleton of fallen branches of the saguaro cactus in a subtropical semiarid (almost arid) Sonoran mixed cacti desert scrub in the southwest of Northern America.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 17 km NNE of Lukeville, Ajo Mountain Trail, Organ Pipe, 750 m, branches of *Carnegiea gigantea*, 28.V.2003, G. Marson (ex H.B. 7764e, M-0276449, **holotype**, anam. substr.).

Not included. **USA**: **Arizona**, Sonoran Desert, 17.5 km NNE of Lukeville, Ajo Mountain Trail, Organ Pipe, 710 m, branch of *Cylindropuntia bigelovii*, 5.V.1995, G. Marson (H.B. 8355a).

Orbilia kingsiana Baral & G. Marson, **sp. nov.**,

MB 813754 — Pls 406–407, Map 70

Etymology: named after the type locality, Kings Park (Perth).

Typification: Western Australia, Perth, on stem of an indet. herbaceous dicot, 7.IX.2006, G. Marson (ex H.B. 8459, MEL 2389240, holotype).

Latin diagnosis: *Apothecia rehydratata 0.25–0.65 mm diam., vivide roseo-lilacea, (sub)sessilia, margine glabro. Ascosporae *5.8–8.8 × 1.4–1.8 µm, cylindrico- vel fusoideo-clavatae, apice rotundatae, basi leniter vel valde attenuatae, saepe leniter vel modice curvatae, in statu vivo corpusculum refringens globosum continentes. Paraphyses ad apicem leniter vel valde inflatae, capitatae ad spathulatae, exsudato calyptriforme tectae. Margo excipuli absque processis vitreis distinctis. Habitat ad corticem putridum ramulorum vel ramorum siccorum arborum (*Fabales *et* Myrtales) et *culmos siccos* Anigozanthi *in zona subtropica, semiarida ad semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.65 mm diam., 0.13–0.2 mm high (receptacle 0.11 mm), light to bright pure salmon-rose-lilaceous, exceptionally orange, ± translucent,

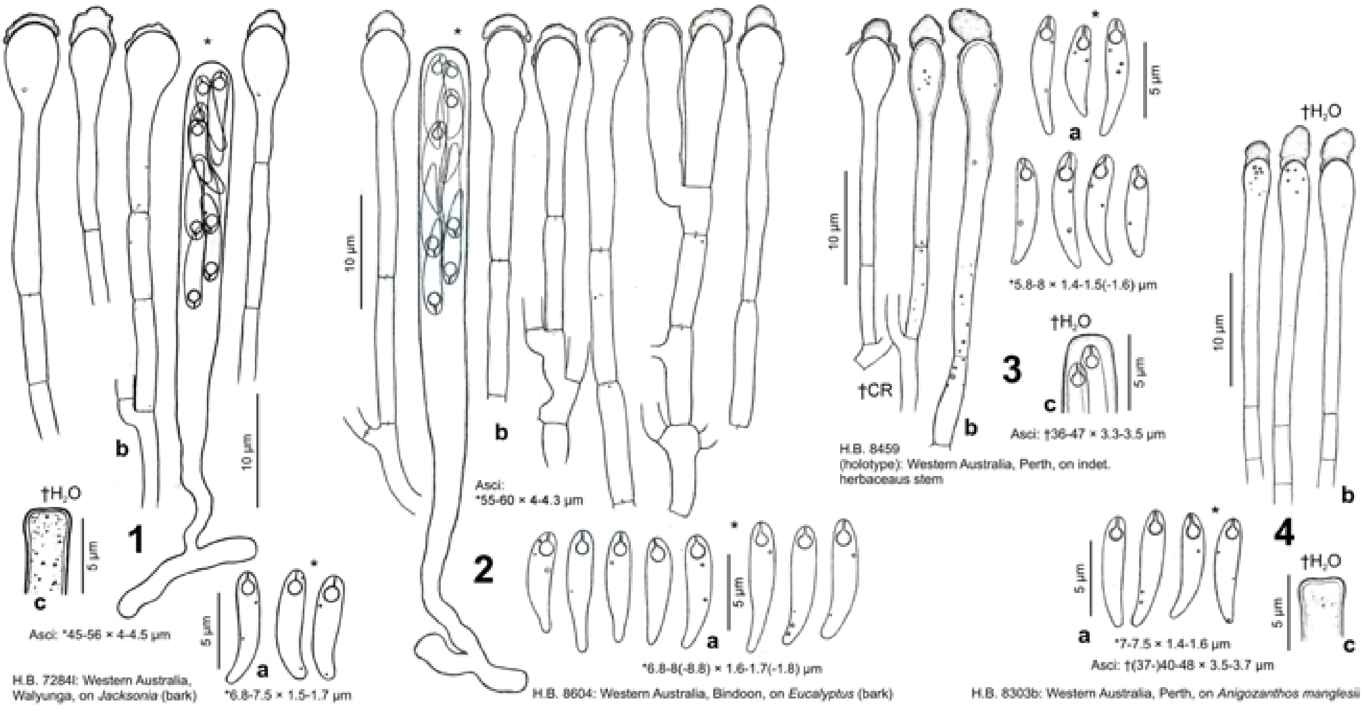

Plate 406. **1–4**: *Orbilia kingsiana*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices.

round, scattered or in small groups; disc flat, margin distinct, thin, 0–10 µm protruding, ± smooth; sessile on an obconical base or ill-defined broad stipe, superficial or slightly immersed in detritus, also erumpent from small cracks; dry bright to deep rose-pink. **Asci** *44–60 {2} × 4–4.5 µm {3}, †(36–)40–53 × 3.2–3.7 µm {3}, 8-spored, spores *2(–3)-seriate, (2–)3–5 lower spores inverted {3} (sometimes mixed), pars sporifera *22–26(–29) µm long; **apex** (†) (medium to) strongly truncate (not or slightly indented, laterally sometimes ± inflated); **base** with medium to long, thin, flexuous stalk, T- to L-shaped. **Ascospores** *(5.8–)6.3–8(–8.8) × (1.4–)1.5–1.7(–1.8) µm {5}, narrowly cylindric- to fusoid-clavate, apex rounded, base slightly to strongly attenuated, ± inequilateral to often slightly to medium curved near base; **SBs** *1.5–1.8 × 0.8–1.1 µm {5}, globose to tear-shaped, apically abruptly narrowed to a very short filum. **Paraphyses** apically slightly to rather strongly clavate(-capitate) to often spathulate, rarely moniliform, terminal cells *(12–)15–25(–33) {2} × (2.7–)3.3–4.3(–4.7) µm {4}, †15–28 × (1.8–)2.2–3.8 µm {2}, lower cells *8–13 × 1.3–2.2 µm {2}, †4–8 × 1.2–2 µm {1}; unbranched at upper septum, hymenium pale rose. **Medullary excipulum** very pale rose, 30–70 µm thick, of medium dense textura intricata-angularis with many inflated cells (especially in lower part), distinctly delimited from ectal excipulum only at flanks by a thin t. porrecta. **Ectal excipulum** hyaline, pale rose towards margin, of (†) thin-walled to slightly gelatinized, indistinctly or vertically oriented t. globulosa-angularis from base to submargin, 40–90 µm thick near base, cells *(8–)10–20(–26) × (6–)8–16(–20) µm {3}; 20–25 µm thick at flanks, 15 µm at submargin, of t. prismatica-angularis oriented at a 70–90° angle to the surface, 10 µm thick at upper margin, of t. prismatica(-angularis) to t. porrecta oriented at 10–50°, marginal cortical cells *6–13(–16) × 3–4(–5) µm {4}, †7–13 × 2.5–3.5 µm {1}; **glassy processes** absent {3} or (0.5–)1–3(–4) × 2.5–3 µm {2}, refractive, not stratified. **Anchoring hyphae** sparse to abundant, */†2–3.5(–4.3) µm wide, walls 0.2–0.5(–1) µm thick {5}, forming a loose, slightly gelatinized t. intricata. **SCBs** in paraphyses sometimes present, globose, ~1–1.3 µm diam. **Exudate** over paraphyses forming 0.5–3(–4) µm tall {5}, hyaline to very pale yellowish, firmly attached, strongly refractive glassy caps, over margin and flanks (0.5–)1–2(–3) µm thick, rough-cloddy, pale to light yellow(-chlorinaceous). — **ANAMORPH**: unknown.

Habitat: collected 1–2 m above the ground, on 3–35 mm thick corticated twigs and 10–18 cm thick trunk of *Eucalyptus* sp. {1}, *Jacksonia* sp. {1}, *Lamarchea hakeifolia* {1}, on very rotten bark {3} (bast), bark sometimes strongly detached, on upper- and underside of bark, also at edges, medium to strongly greyed, without algae; on 4–6 mm thick medium to strongly decayed herbaceous stems of *Anigozanthos manglesii* {1}, indet. angiosperm {1} lying ± close to sandy soil. **Associated**: *Capronia* sp. {2}, *Claussenomyces* spp. {2}, *Durella* sp. {1}, *D.* aff. *connivens* {1}, *Gloniopsis praelonga* {1}, *Hyalorbilia pleioerythrostigma* {1}, *Orbilia albidorosea* {1}, *O. anigozanthi* {1}, *O. australiensis* {1}, *O. austroobtusispora* {1}, *O. curvativitalbae* {1}, *O. eucalypti* {1}, *O. gemma* {1}, *O. lamarcheae* {1}, *O. macrotrapeziformis* {1}, *O. microserpens* {1}, *O. myriofusiclava* {1}, *O. myriolilacina* {1}, *O. myrioobliqua* {1}, *O. ?nothoaprilis* {1}, *O. nothovinosa* {1}, *O. pseudoflagellispora* {1}, *O. ?pubescens* {1}, *Ostropales* {1}, *Symbiotaphrina desertorum* {1}, ?*Xerotrema* sp. {1}. **Desiccation tolerance**: fully viable for at least 11 months, many paraphyses and submature asci after 17 months. **Altitude**: 37–271 m a.s.l. **Geology**: Cretaceous sedimentary rock, Cenozoic regolith, granulite with granitic gneiss. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia kingsiana* is characterized by pure rose-lilaceous apothecia with a smooth margin, rather small, slightly curved, cylindric-fusoid-clavate ascospores, and glassy caps on the paraphyses, though glassy processes on the margin are absent or very short. Several species with similar spores and glassy caps on the paraphyses, such as *O. aradi*, *O. brachychitonis*, or *O. puyae*, differ from *O. kingsiana* in the presence of distinct glassy processes at the margin, and in longer and/or wider spores, also in differently coloured apothecia.

Map 70. Known distribution of *O. kingsiana* in southwestern Australia.

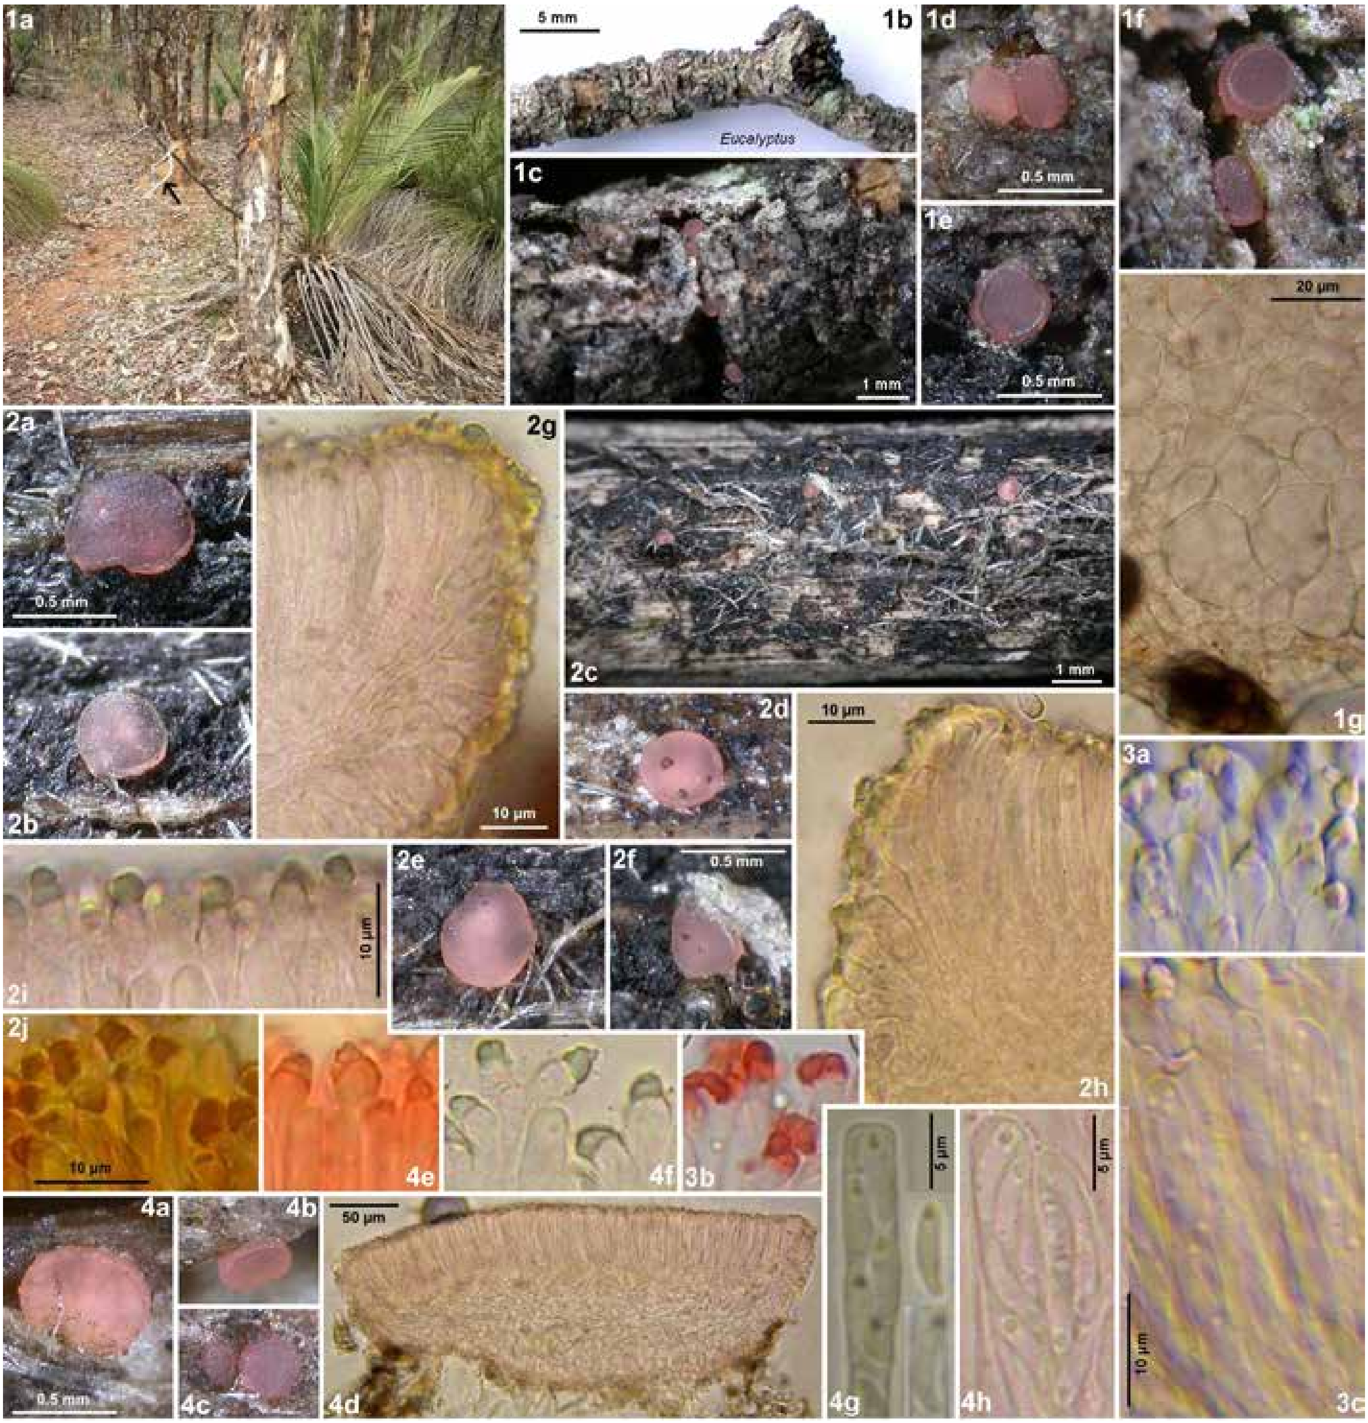

Plate 407. **1–4**: *Orbilia kingsiana*. – **1a**. semihumid Eucalypt open forest with *Macrozamia*, **1b**. dead corticated twig; **2c**. xeric herbaceous stem; **1c–f**, **2a–f**, **4a–c**. rehydrated apothecia; **4d**. apothecium in median section; **2g–h**. id., marginal ectal excipulum; **1g**. id., basal excipular cells; **3c**, **4g–h**. asci with ascospores; **2i–j**, **3a–b**, **4e–f**. paraphysis apices. – Living state, except for **2g–i**, **4f** (in H_2O), **2j** (in IKI), **4e** (in CR), **3b** (in KOH+CR), asci in **4g–h**. — **1a–g**. H.B. 8604: Western Australia, Bindoon, on *Eucalyptus*; **2a–i**. H.B. 8459 (holotype): Perth, on indet. herbaceous dicot; **3a–b**. H.B. 8303b: ibid., on *Anigozanthos*; **4a–i**. H.B. 9020d: Geraldton, on *Lamarchea*.

Variation. The collections on woody substrates deviate from those on herbaceous substrate solely in very slightly wider spores and SBs, and in slightly wider paraphysis apices, with the terminal cells only 1–3 × as long as the lower cells compared to 2–5 ×. In two collections (on *Anigozanthos* and *Lamarchea*) very short (0.5–4 µm) glassy processes could be observed on the marginal cells. These and partly also the caps on the paraphyses did not distinctly stain in IKI and CR (Pl. 407: 4e), therefore, they are assumed to consist of cell wall material covered by a thin layer of exudate. However, in other collections of *O. kingsiana* the caps on the paraphyses stained more distinctly in IKI and CR (Pl. 407: 2j, 3b).

Ecology. *O. kingsiana* was collected on dead, xeric herbaceous stems of *Anigozanthos* (*Commelinales*) and on rotten bark of xeric twigs and branches of *Fabales* and *Myrtales* in subtropical semihumid banksia-eucalypt-acacia open forests and woodlands (partly with *Macrozamia*) in the northern part of the Swan Coastal Plain and adjacent Darling Range of southwestern Australia, and in a semiarid acacia shrubland in the Yalgoo ecoregion of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, twig and trunk of *Lamarchea hakeifolia*, on bark, 8.XI.2007, G. Marson (H.B. 9020d). – Swan Coastal Plain, 30 km NE of Perth, 4 km N of Upper Swan, W of Walyunga, 37 m, branches of

Jacksonia, on bark, 23.XI.2001, G. Marson (H.B. 7284l). – 3 km SW of Perth, NE of Matilda Bay, Kings Park, 50 m, stem (or leaf sheath?) of *Anigozanthos manglesii*, 7.IX.2006, G. Marson (H.B. 8303b ø). – ibid., stem of indet. angiosperm, 7.IX.2006, G. Marson (ex H.B. 8459, MEL 2389240, **holotype**). – Jarrah Forest, 25 km NNE of Bindoon, 12 km ESE of Wannamal, 271 m, twigs of *Eucalyptus*, on bark, 3.IX.2006, G. Marson (H.B. 8604).

Orbilia puyae Baral & Priou, **sp. nov.**, MB 813757 — Pls 408–409

Etymology: named after the host plant, *Puya raimondii*.

Typification: Peru, Catac, inflorescence stem of *Puya raimondii*, 23.X.2005, J.P. Priou (ex H.B. 8043a, M-0276574, holotype).

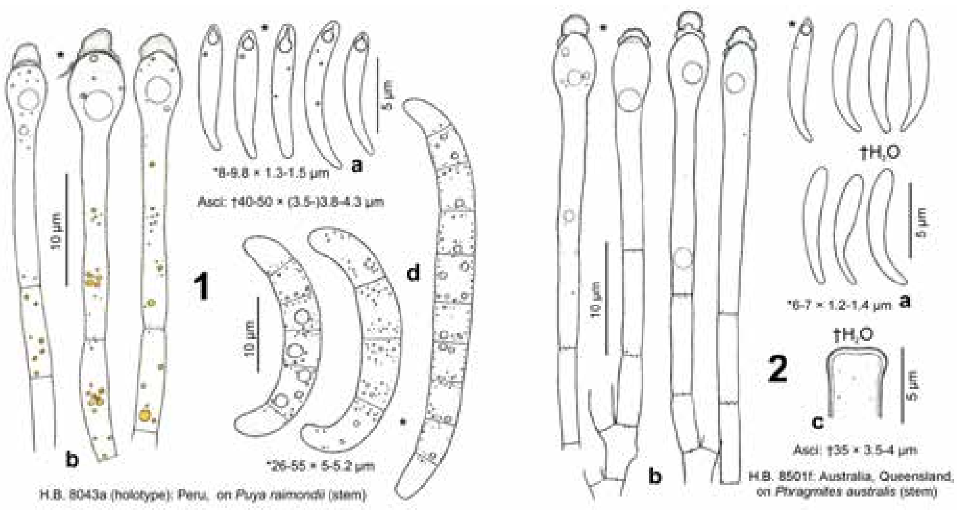

Plate 408. **1**: *Orbilia puyae*; **2**: *O.* cf. *puyae*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex; **d**. conidia from substrate.

Latin diagnosis: *Similis* Orbiliae carnegieae *sed ascosporae breviores, paraphyses ad apicem capitatae, semper pileis vitreis tectae. Habitat ad caulem inflorescentiae putridum semisiccum* Puyae raimondii *in zona alpina subhumida Americae australis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–0.8 mm diam., 0.11–0.25 mm high (receptacle 0.09–0.15 → 0.07–0.1 mm), light rose-orange(-cream), medium translucent, round, (scattered to) gregarious; disc young cupulate then slightly concave to flat, margin distinct, not protruding, very finely crenulate to sometimes distinctly toothed; sessile on a broad, stipe-like base, superficial; dry bright orange-red. **Asci** †40–50 × (3.5–)3.8–4.3 µm, 8-spored, spores (*) biseriate, (1–)3 lower spores inverted (sometimes mixed); **apex** (†) medium to strongly truncate (not indented, laterally not widened); **base** with medium to long, thin, flexuous stalk, T- to L-shaped. **Ascospores** *8–9.5(–10) × 1.3–1.5 µm, †7.3–9.5 × 1.2–1.4 µm, narrowly cylindric- to fusoid-clavate, apex rounded to obtuse, base slightly to medium (rarely strongly) attenuated, slightly to medium curved (entirely or only near base); **SBs** *1.4–1.6(–2) × 0.8–1 µm in situ, globose to broadly tear-shaped, apically abruptly narrowed to a very short filum. **Paraphyses** apically medium to strongly capitate(-clavate) or ellipsoid, terminal cells *19–25 × 3–4(–5) µm, lower cells *5–11 × 2–2.4 µm; unbranched near apex, with or without yellow-orange **LBs** (carotenoids) in lower part, hymenium pale to light orange. **Medullary excipulum** pale orange, 20–35 µm thick, of dense textura intricata-angularis, sharply delimited from ectal excipulum only at flanks by a ± distinct t. porrecta, hyphae with pale orange LBs. **Ectal excipulum** subhyaline, of thin-walled, irregularly oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 25–170 µm thick near base, cells *8–18 × 6–12 µm; 20–30 µm thick at flanks and margin, at margin of t. porrecta oriented at a 70–80° angle to the surface, marginal cortical cells †7–12 × 3–5 µm; **glassy processes** 10–30 × 3.5–4(–5) µm, sometimes only 2–3 µm long, refractive, not stratified, straight to ± outwards curved, sometimes coherent to form distinct teeth. **Anchoring hyphae** abundant, †2–4 µm wide, walls 0.2–0.5 µm thick. **SCBs** in apex of paraphyses globose, 2–2.5 µm diam. **Exudate** over paraphyses forming 1–2 µm thick, hyaline, firmly attached glassy caps. **— ANAMORPH**: vermispora-like (presumed, from natural substrate). **Conidiophores** not seen. **Conidia** phragmosporous, strongly curved (C-shaped), *(25–)29–31 × (5–)5.2–5.5 µm, 4–7-septate.

Habitat: inner surface of 10 cm broad broken piece of hollow inflorescence stem of *Puya raimondii*, lying on ground inside down, very decayed, partly blackened, no algae. **Associated**: *Cistella* sp., *Coniochaeta* sp. **Desiccation tolerance**: cells of ectal excipulum and some paraphyses still viable after 3 months. **Altitude**: 4223 m a.s.l. **Phenology**: rather long-lived.

Taxonomic remarks. *Orbilia puyae* appears to be closely related to European *O. aradi* and North American *O. denticulata*, from which it differs in distinctly narrower ascospores. With *O. denticulata* it shares the apically inflated paraphyses with glassy caps, and with *O. aradi* the more globose spore bodies. *O. euphorbiae* differs from *O. puyae* in narrowly spathulate-lageniform paraphyses. A North American collection mentioned under *O. carnegieae* (on branches of *Cylindropuntia bigelovii*) resembles *O. puyae* in the spores and paraphyses, but the spores are not so much attenuated towards the base, also the SBs are narrower, and the (rehydrated) yellowish-ochraceous, rather small apothecia are distinctly cupulate. *O. kingsiana* differs from *O. puyae* in pinkish apothecia lacking glassy processes, and wider spores.

Not included collection. A sample on *Phragmites* from subtropical Australia (Pl. 409: 2) is not included in the description because of the deviating ecology, although it could well be conspecific with *O. puyae*. The apothecia differ in 10–20 µm protruding margins which are dotted by black-brown conidia of the associated *Arthrinium* that occurs in abundance on the culms. When studied 11 months after it was collected, the paraphyses and excipular cells were still viable in this specimen, but hardly any spores.

Anamorph. In the holotype material we found some typical C-shaped phragmoconidia near the apothecia on the natural substrate (Pls 408: 1d; 409: 1h).

Ecology. *O. puyae* was detected on decayed, mesic parts of an inflorescence stem of *Puya raimondii* (*Bromeliaceae*), a giant rosette plant with the largest spike in the world, growing in the subtropical (orotemperate) subhumid puna ('Puna subhúmeda'), a rather dry grassland vegetation in the highlands of the Peruvian Andes of South America. The not included Australian specimen, in contrast, was found in a floodplain in the tropical (sub)humid lowland of northeastern Australia between savannah and rainforest, on standing, dead, xeric culms of *Phragmites* which are covered over large areas by a black conidial layer of *Arthrinium arundinis*.

Specimens included. **PERU**: **Ancash**, Cordillera Blanca, 47 km SE of Huaraz, 18.5 km ESE of Catac, 4223 m, inflorescence stem of *Puya raimondii*, 23.X.2005, J.P. Priou (ex H.B. 8043a, M-0276574, **holotype**, anam. substr.; J.P.P. 25140, **isotype**).

Not included. **AUSTRALIA**: **Queensland**, Einasleigh Uplands, 22 km SSW of Mossman, 2 km N of Mount Molloy, Mossman Mt. Molloy Rd, 390 m, leaf sheath of *Phragmites australis*, 28.VIII.2006, G. Marson (H.B. 8501f).

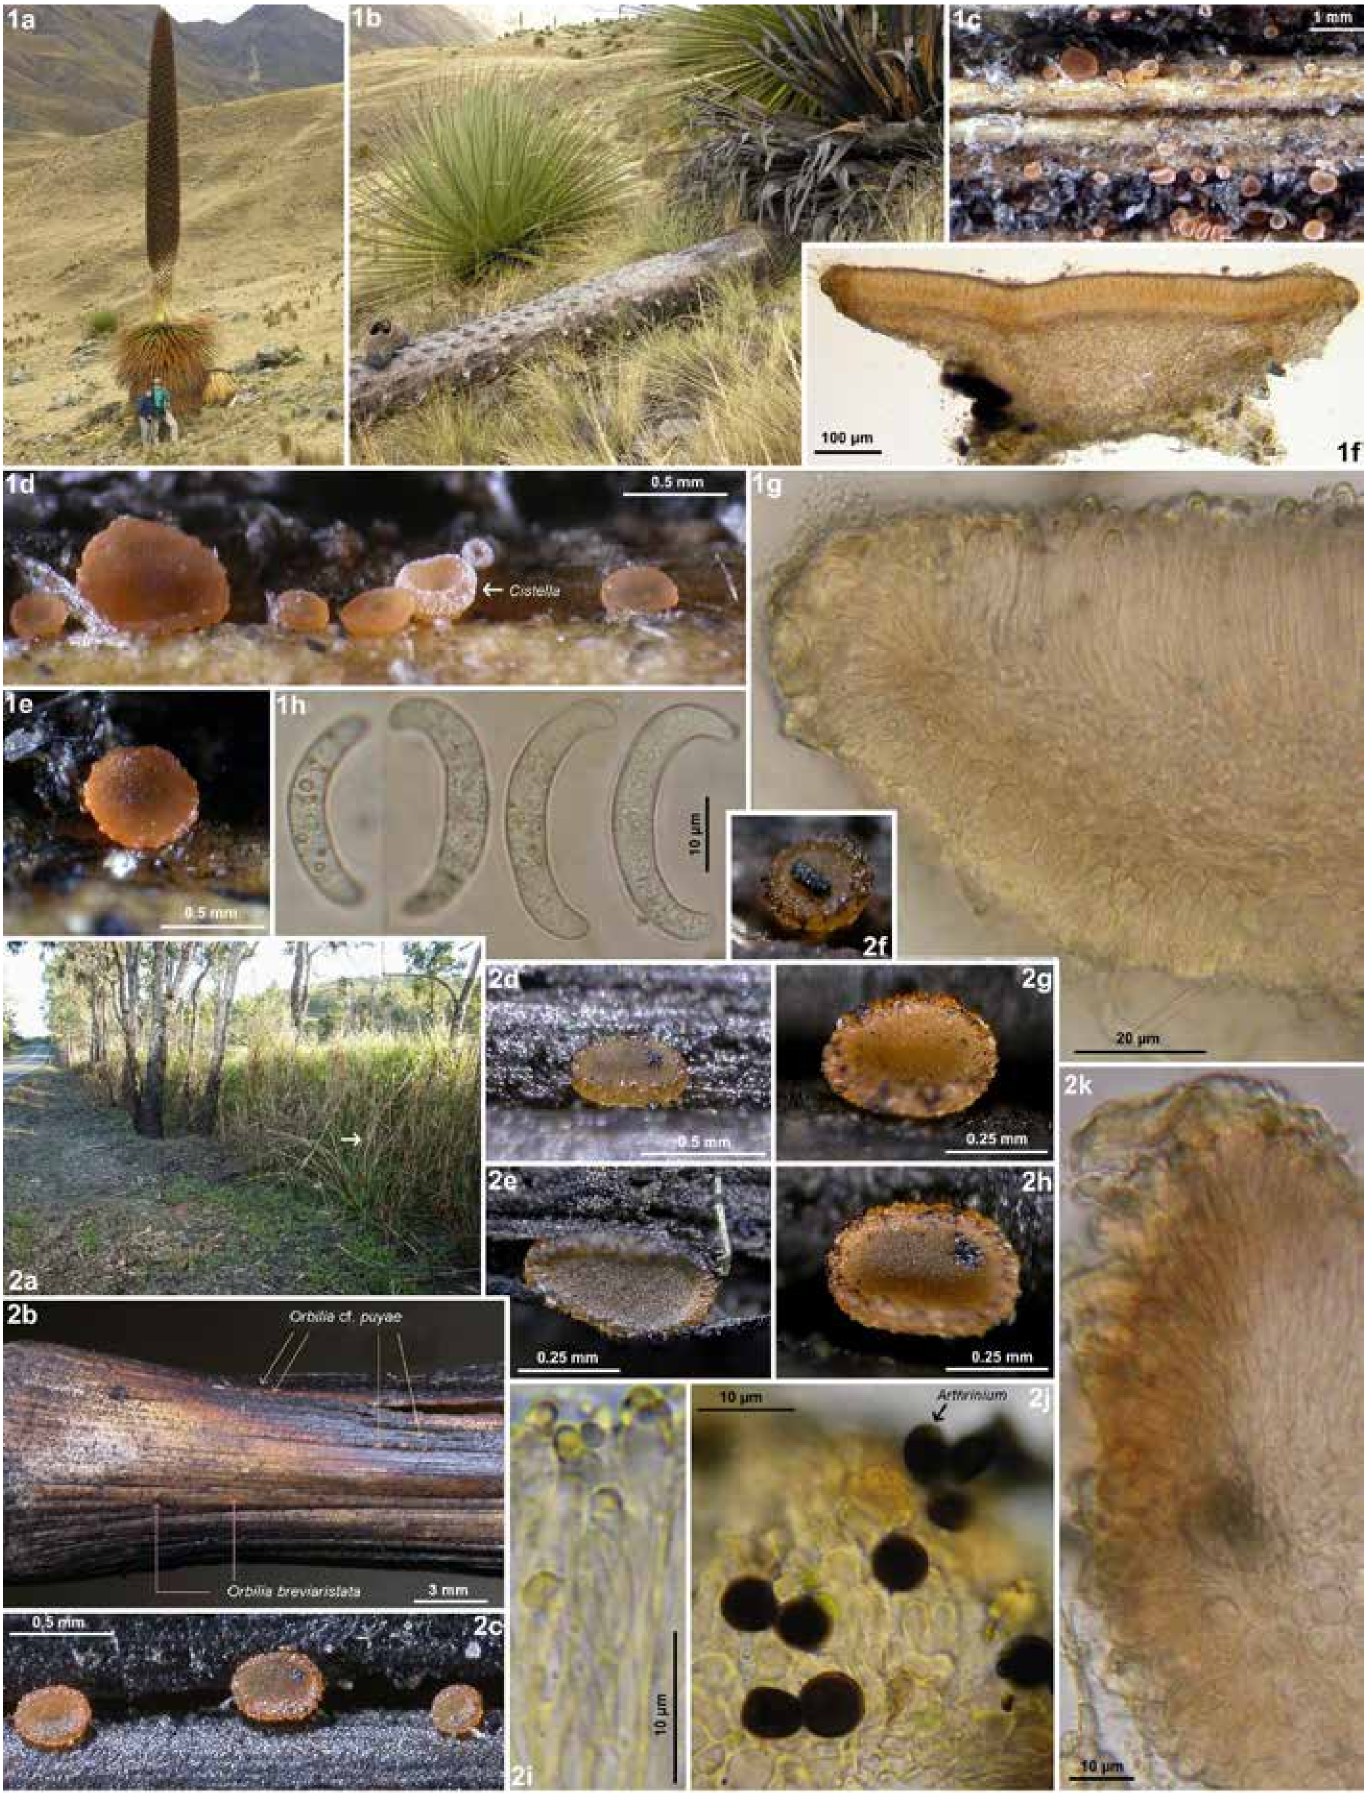

Plate 409. **1**: *Orbilia puyae*; **2**. *O.* cf. *puyae*. – **1a**. alpine subhumid puna grassland with *Puya raimondii* and O. & J.P. Priou; **1b**. young *Puya* and dead fallen stem; **2a**. tropical humid *Phragmitetum*; **2b**. dead culm of *Phragmites* blackened by *Arthrinium arundinis*; **1c–e**, **2c–h**. rehydrated apothecia (**1c–d** associated with *Cistella* sp.); **1f**. apothecium in median section; **1g**, **2k**. id., margin and flanks; **2j**. marginal ectal excipulum in external view, with conidia of *Arthrinium*; **2i**. paraphyses with glassy caps, asci with spores; **1h**. conidia from substrate. – Living state, except for **1f–g** (in H_2O), **2k** (p.p.maj.), asci in **2i**. – **1a–b**: phot. J.P. Priou. — **1a–h**. H.B. 8043a (holotype): Peru, Ancash, on *Puya*; **2a–k**. H.B. 8501f: Australia, Queensland, on *Phragmites*.

Orbilia pseudocylindrospora Baral & G. Marson, **sp. nov.**, MB 813759 — Pls 410–411

Etymology: named after the resemblance to *O. cylindrospora*.

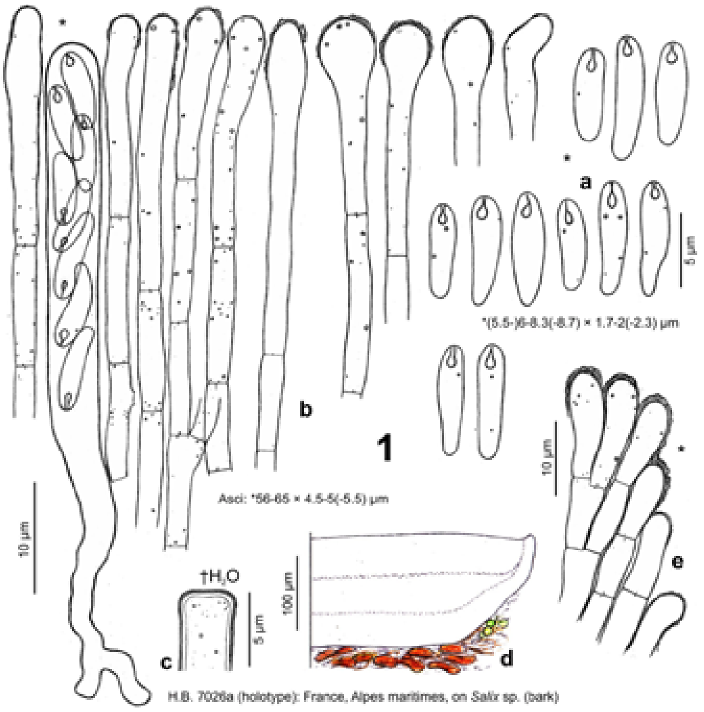
Typification: France, Var, Colmars-les-Alpes, branch of *Salix*, 15.VIII.2001, G. Marson (ex H.B. 7026a, M-0276571, holotype).

Latin diagnosis: Orbiliae concolori s*imilis sed ascosporae breviores*, *minus curvatae*, *corpuscula refringentia minora*, *paraphyses clavato-capitatae vel subspathulatae, apothecia pure rosacea. Habitat ad corticem putridum rami sicci* Salicis *in zona orotemperata Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–0.8 mm diam., 0.15–0.17 mm high, light rose, semitranslucent, ± round, subgregarious in small groups; disc medium concave to flat, margin distinct, 10–25 µm protruding, white, smooth to finely crenulate; broadly sessile, somewhat erumpent from cracks in bast; dry bright apricot-rose. **Asci** *56–65 × 4.5–5(–5.5) µm, †52–67 × 4–4.5 µm, 8-spored, spores *(1–)2(–3)-seriate, 2–6 lower spores inverted (sometimes strongly mixed), pars sporifera *(19–)28–32(–35) µm long; **apex** (†) strongly truncate (sometimes distinctly indented, laterally rarely slightly inflated); **base** with medium to long, thin, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(5.5–)6–8.3(–8.7) × 1.7–2(–2.3) µm, subcylindrical, sometimes slightly fusoid to clavate, apex rounded, base not or slightly (to medium) attenuated, straight to (very) slightly curved near base; **SBs** *1.3–1.9 × 0.4–0.7 µm, tear-shaped to ellipsoid or subglobose, also ampulliform, apically narrowed to a very short, partly thickened filum. **Paraphyses** apically (uninflated to) slightly or medium (rarely strongly) capitate-clavate, also spathulate to sublageniform, terminal cells *13–30 × (2–)2.5–4.5(–5.3) µm, lower cells *8–16 × 1.8–2.3 µm; unbranched at upper septum, hymenium hyaline. **Medullary excipulum** hyaline, 40–55 µm thick, of ± dense, ± horizontally oriented textura intricata with many inflated cells, very sharply delimited. **Ectal excipulum** hyaline, very pale rose only near margin, of (†) distinctly gelatinized, vertically oriented t. angularis from base to mid flanks, 45–55 µm thick near base, cells *10–22(–31) × 8–17 µm; 25–40 µm thick at lower flanks, 15–20 µm near margin, of t. prismatica-porrecta oriented at a 10–30° angle to the surface, marginal cortical cells *10–15 × (3–)3.5–4.5(–6) µm, (†) thin-walled; **glassy processes** absent. **Anchoring hyphae** sparse, 2–3 µm wide, walls 0.2–0.4 µm thick. **SCBs** in paraphyses and ectal excipulum absent. **Exudate** over paraphyses 0.2–0.5 µm thick; over margin and flanks 0.3–1 µm, rough, firmly attached, forming thin caps. — **ANAMORPH**: unknown.

Habitat: collected 2–3 m above the ground, corticated, 10 mm thick branch of *Salix* sp., on periderm-free area (bast) of strongly decayed bark, greyed, with a few green algae. **Associated**: *Orbilia aristata*, *Physcia* sp., crustose lichen. **Desiccation tolerance**: fully viable for at least 1 month. **Altitude**: 1455 m a.s.l. **Geology**: glacial deposits from Upper Jurassic marl (terres noires) and syenite. **Phenology**: VIII (but probably long-lived).

Taxonomic remarks. *Orbilia pseudocylindrospora* is characterized by subcylindrical, more or less straight ascospores with small tear-shaped SBs which are apically narrowed to a small to wide point, also by a thin, rough, firmly attached exudate, and by rose apothecia with a whitish protruding margin. The paraphysis apices are rather variable in shape: cylindric-sublageniform to spathulate in some apothecia but clavate-capitate in others. The spores of *O. subcylindrospora* (section *Ovoideae*) are similar in size and shape but are usually curved, the SBs are closer to the spore apex, and their connection is mostly invisible. The exudate in *O. subcylindrospora* is more detached and cloddy.



H.B. 7026a (holotype): France, Alpes maritimes, on *Salix* sp. (bark)

Plate 410. **1**: *Orbilia pseudocylindrospora*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

The position of *O. pseudocylindrospora* is quite unclear. The species resembles *O. concoloris* of section *Hemiorbilia* in the spores and in the exudate being firmly attached to the paraphyses. *O. concoloris* differs in longer, more curved spores with larger, more ampulliform SBs, and in more distinctly spathulate-lageniform paraphyses. In spore characters *O. pseudocylindrospora* is also similar to the Chinese *O. yuanensis* (section *Helicoon*) and the European *O. cardui* (section *Arthrobotrys*) which both differ in narrower spores and whitish to yellowish, desiccation-sensitive apothecia. Also *O.* aff. *dixiensis* (on *Arctostaphylos*, Pl. 699: 4) resembles *O. pseudocylindrospora* in the spores. It differs in more consistently capitate paraphyses, presence of globose SCBs, smaller apothecia, and especially in a tendency to elongate SBs. For the latter feature we assume that it belongs to section *Habrostictis*.

Ecology. *O. pseudocylindrospora* was collected on rotten bark of a xeric branch of *Salix* at a south-exposed border of a broad-leaved altimontane forest near a rivulet in the orotemperate humid Southern French Alps of southern Europe.

Specimens included. **FRANCE**: **Provence-Alpes-Côte d'Azur**, **Var**, 10 km ENE of Colmars-les-Alpes, 1.3 km N of Entraunes, 6,7 km S of Col de la Cayolle, 1455 m, branch of *Salix*, on bark, 15.VIII.2001, G. Marson (ex H.B. 7026a, M-0276571, **holotype**).

Orbilia denticulata Baral, R. Galán & G. Marson, **sp. nov.**, MB 813760 — Pls 412–413

Etymology: after the denticulate apothecial margin.

Typification: USA, Nevada, Blue Diamond, leaves of *Yucca schidigera*, 22.VI.2000, G. Marson (ex H.B. 6725; M-0276473, holotype; ex-type culture: CBS 140803; sq.: KT215256, MH878178).

Latin diagnosis: *Apothecia rehydratata 0.3–1.8 mm diam., vivide luteo-aurantiaca, sessilia vel subsessilia, margine crenulato vel conspicue albido-dentato. Ascosporae *6–12 × 1.8–2.6 µm, ellipsoideo- ad fusoideo-clavatae, apice rotundatae vel obtusae, basi saepe modice vel valde attenuatae et leniter vel modice curvatae, in statu vivo corpusculum refringens lacrimi- ad obturamentiformem continentes. Paraphyses ad apicem distincte inflatae, capitatae vel spathulatae, calyptra vitrea tectae. Margo excipuli processis vitreis agglutinatis praeditus. Habitat ad ramos putridos siccos* Myrtillocacti *vel folios et caules* Yuccae *in zona mesotemperata ad subtropica semiarida ad arida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–1.1(–1.8) mm diam., 0.14–0.22(–0.4) mm high (receptacle 0.12–0.17 mm), light to bright yellow-orange (to rose-orange), round, scattered to subgregarious; disc slightly concave to flat, margin crenulate {1} or typically with prominent whitish teeth 25–100 × 50–200 µm {2}; broadly or narrowly sessile or with a stalk ~0.2 × 0.3 mm, ± superficial; dry deep orange-red. **Asci** *47–65(–72) × 4.4–5.3 µm {2}, †(40–)48–60 × 3.7–4.8 µm {3}, 8-spored, spores *2(–3)-seriate, 2–5(–7) lower spores inverted {2} (often mixed), pars sporifera *23–39 µm long; **apex** (†) (medium to) strongly truncate (not or very slightly indented, laterally not widened); **base** with long, thin, flexuous stalk, T- to L-shaped (exceptionally ± H-shaped). **Ascospores** *6–10(–12) × (1.8–)2–2.4(–2.6) µm {3}, †6–9.5 × 1.8–1.9 µm {1}, ellipsoid- to fusoid-clavate, sometimes narrowly ellipsoid, apex rounded to obtuse, rarely subacute, base often medium to strongly attenuated (partly tail-like), straight or basally often slightly to medium curved; **SBs** *1–1.6 × 0.4–0.8 µm {3}, tear- to pear-, also plug-shaped, apically narrowed to a small to often wide point. **Paraphyses** apically slightly to strongly (clavate-)capitate {2}, also spathulate to sublageniform {T}, terminal cells *(14–)17–27 × (3–)4–5(–5.5) µm {2}, †11–23 × 2.6–3.7 µm {1}, lower cells *6–12.5 × 1.8–3 µm {2}; unbranched at upper septum, hymenium light orange. **Medullary excipulum** hyaline or pale yellow-orange, 40–80(–150) µm thick, of loose to dense textura intricata with sparse to abundant inflated cells, sharply delimited. **Ectal excipulum** hyaline to very pale orange (bright orange near margin), of thin-walled († slightly to medium gelatinized), vertically (or indistinctly) oriented t. globulosa-angularis(-prismatica) from base to submargin, 25–50 µm thick near base, cells *10–18(–25) × 7–12(–20) µm {2}, †7–12 × 5–10 µm {1}, cortical cells thick-walled; 20–30 µm thick at lower flanks, cells *7–12 × 5–8 µm; 20–30 µm near margin, of t. prismatica(-porrecta) oriented at a 70–90° angle, marginal cortical cells *7–10 × 2.5–4 µm {1}, †8–15 × 2–4 µm {2}; **glassy processes** at margin 3–10 {1} or 20–50(–100) {2} × (2.5–)3–4(–6) µm {3}, refractive, stratified, coherent to form distinct teeth, on lower and mid flanks much shorter. **Anchoring hyphae** abundant, */†(1.7–)2.5–5(–6) µm wide {3}, walls *(0.3–)0.4–0.8(–1.2) µm {2}, †(0.2–)0.5–1(–2) µm {3}. **SCBs** in paraphyses globose, (1–)2–3 µm diam. {2}; in excipular cells not seen; **LBs** rather abundant in paraphyses and excipular cells, pale to light yellow-orange (carotenoids), 0.5–1.3 µm diam. {2}. **Exudate** on paraphyses forming glassy caps 0.5–1.5(–3.3) µm thick {3}, hyaline, firmly attached; at margin sparse, granular. **— ANAMORPH**: vermispora-like (from ascospore isolate {1} and natural substrate {2}). **Conidiophores** not seen. **Conidia** phragmosporous, slightly curved, *27–38.5 × 5.3–6 µm, 4–6-septate, †41 × 4.5 µm, 10-septate, with low lipid content {T}; †58–60 × 5–6 µm, ~15-septate, with high lipid content {H.B. 5430}.

Habitat: collected 0.2–1.5 m above the ground, branches of *Myrtillocactus cochal* {1}, base of still-attached, hanging leaves of *Yucca schidigera* {1}, 3 cm thick inflorescence stem of *Yucca elata* {1}, on epidermis or on epidermis-free parts, greyed, green algae sparse or absent. **Associated**: *Dothideales* {1}, *Orbilia bicknellensis* {1}, *O. lentiformis* {1}, *O. paradoxoides* {1}, *O. pleiolentiformis* {1}, *Pragmopora* sp. {1}. **Desiccation tolerance**: fully viable for at least 2 months, excipular cells and spores still viable after 26 months. **Altitude**: 500–1510 m a.s.l. **Geology**: Mississippian-Permian sedimentary rock; volcanic rock (basalt, andesite, rhyolite). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia denticulata* is characterized by bright yellow-orange apothecia with a whitish denticulate margin composed of usually long glassy processes, and by capitate to spathulate paraphyses tipped by glassy caps. The European *O. aradi* differs in more globose SBs and much less inflated paraphysis apices. *O. brachychitonis* and *O. concoloris* (the latter in section *Hemiorbilia*) differ in the absence of yellow LBs in the paraphyses and marginal excipulum, *O. brachychitonis* also in wider SBs and *O. concoloris* in lacking glassy processes. *O. euphorbiae* differs in distinctly narrower ascospores and more lageniform paraphyses. A North American collection included in *O. brachychitonis* (on *Baccharis*, Pl. 399: 6) is very similar to *O. denticulata*. However, it lacks, yellow-orange LBs, instead, the cells of paraphyses and ectal excipulum contain globose and crystalloid SCBs. The Australian *O. farnesianae* on branches of

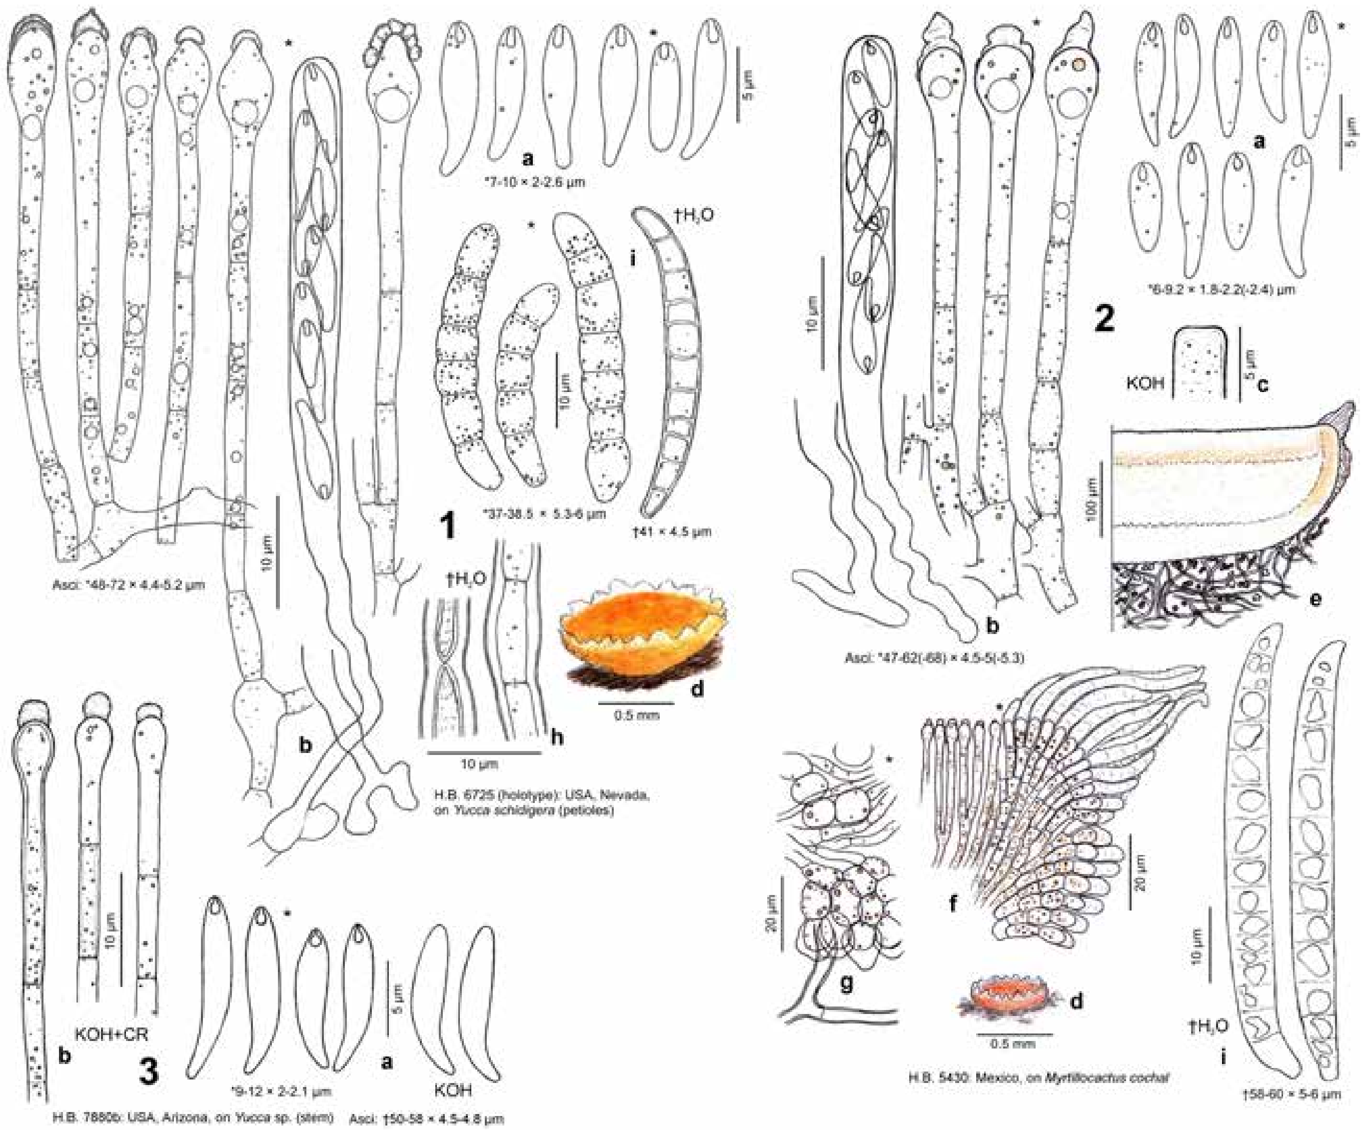

Plate 412. **1–3**: *Orbilia denticulata*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. rehydrated apothecia with dentate margin; **e**. apothecium in median section; **f**. id., marginal ectal excipulum; **g**. id., ectal and medullary excipulum and anchoring hypha at lower flanks; **h**. anchoring hyphae; **i**. conidia from culture (**1**) and substrate (**1** right, **2**).

Vachellia differs in more orange-ochraceous apothecia without yellow LBs, with an only finely rough margin, longer SBs, and thin-walled anchoring hyphae.

Variation. The three collections included in *O. denticulata* are somewhat heterogeneous. The type (on *Yucca schidigera*) differs from the other two in slightly wider spores with more broadly attached SBs, also in spathulate to sublageniform paraphysis apices, and in broader and more thick-walled anchoring hyphae. Only one apothecium was detected on *Yucca elata* (Pl. 413: 2a), which differs from the other two samples in lacking distinct marginal teeth due to very short glassy processes, also in a very thick medullary excipulum.

Anamorph. A few conidia were obtained in pure culture of the holotype, but only after flooding with water (Pl. 412: 1i, three living conidia). Conidia found on the natural substrate in the *Myrtillocactus* sample were much longer and with many more septa, also with a higher lipid content (3i). However, a single conidium on the natural substrate in the holotype (1i right) had distinctly more septa than those in culture.

Phylogeny. A sequence taken from the holotype culture of *O. denticulata* comprises SSU (S1506 intron absent), ITS, and LSU. In our analyses (Phyls 13–14, S15) it clustered in a strongly supported clade with *O. euphorbiae* with an ITS distance of 8.5% (Comoros) or 9.5% (Australia). In the LSU D1–D2 the distance is 2.7–3.5% to other members of series *Regales*, the closest being to *O. euphorbiae*.

Ecology. *O. denticulata* was found on rotten xeric inflorescence stems and leaves of *Yucca* spp. in warm-temperate arid to semiarid desert scrubs (creosotebush and mixed grass-scrubland) of Mojave and Chihuahua in western North America, and on branches of *Myrtillocactus* in subtropical semiarid Baja California.

Specimens included. **USA**: **Nevada**, Mojave Desert, 25.5 km WSW of Las Vegas, 4.5 km SW of Blue Diamond, 1218 m, leaves of *Yucca schidigera*, 22.VI.2000, G. Etymology: named after the type species, *O. comma*.

Latin diagnosis: *Seriei* Aurantiorubrae *similis sed ascosporis plus minusve brevioribus et latioribus, apice plerumque obtuso ad subacuto, corpusculum refringens globosum vel late lacrimiformem continentibus differt.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–1(–1.6) mm diam., whitish to usually pale to bright orange to rose, rarely yellow, margin smooth or sometimes very finely crenulate, sessile or with a short and broad stipe. **Asci** *(25–)30–68(–76) × 3.5–5(–5.8) µm, 8-spored, lower (1–)3–5(–6) spores inverted; **apex** (†) slightly to strongly truncate, not or slightly to strongly indented and/or laterally inflated; **base** T-, L-, Y- or h-, but never H-shaped. **Ascospores** *(5–)6–10(–11.5) × 1.3–2.3(–2.5) µm, cylindric-, ellipsoid- or fusiform-clavate, apex obtuse to subacute (rarely rounded or acute), base often tail-like or with a short to rather long tail, tail sometimes with a bulbous basal inflation, straight or slightly to strongly curved near base (partly distinctly helicoid), **SBs** 0.9–2.3 × 0.7–1.3(–1.5) µm, globose to broadly tear-shaped, rarely ampulliform, apically narrowed to a small point, mostly with a very short filum. **Paraphyses** slightly to strongly clavate-capitate at the apex (rarely not inflated), terminal cells 0.8–3(–4)× longer than lower cells. **Ectal excipulum** cells near base *(8–)10–25(–35) × (5–)8–16(–22) µm; **glassy processes** absent or 1–4(–14) µm long, **hairs** absent. **SCBs** absent or usually globose, also mixed with crystalloid ones; **VBs** absent, rarely low-refractive. **Exudate** 0.2–2(–5) µm thick, continuous to cloddy-granular, loosely to mostly firmly attached, sometimes forming prominent caps, hyaline to light yellow. **— ANAMORPH**: anguillospora-like, vermispora-like. **Conidiophores** 16–25 × 2–4 µm. **Conidiogenous cells** *7–9 × 1.8–2 µm, monoblastic. **Conidia** either phragmosporous (vermispora-like), *22–60 × 2.7–4.8 µm (in situ), 3–8-septate, straight to medium curved, or scolecosporous (anguillospora-like), *90–170 × 3–5 µm (actual length), 7–32-septate, slightly (to medium) curved.

Habitat: on bark and wood of angiosperms, caulicolous on both mono- and dicots, humid, temperate to tropical, always desiccation-tolerant (unclear for *O. disseminata*).

Recognized species: 7.

Taxonomic remarks. Series *Commatoideae* is characterized by comparatively short and wide, ± fusoid-clavate ascospores with obtuse to subacute apices and tapered, partly tailed bases, short and broad, ± globose SBs, and capitate-clavate paraphyses. Delimitation from series *Regales*, based mainly on a different morphology of the paraphysis apices (capitate vs. often spathulate), is not sharp. A close similarity is seen between *O. comma* and *O. aurantiorubra*: both species possess the same type of crystalloid SCBs and similar conidia, and are macroscopically indistinguishable.

Key to the species of series *Commatoideae*

1. Spore tail very thin (†0.1–0.25 µm wide), 1/3–1/2 of total spore length; leaves of large monocots 2
1. Spore tail min. */†0.3–0.4 µm thick, about 1/5–1/3 of total spore length, or absent 3

2. Spores †8–9.3 × 1.2–1.3 µm, sickle-shaped; tropical humid Australasia .... ***O. neglecta*** (section *Arthrobotrys*), p. 1568
2. Spores †9–10 × 1.4–1.6 µm, helicoid; subtropical humid South America .... ***O. disseminata***, p. 818

3. Spores ± strongly curved (helicoid), fusiform-clavate, *(5–)6–8(–9) µm long, with a short, straight or bent, abrupt basal tail; mainly on bark of *Ulmaceae* and *Moraceae* 4
3. Spores straight or only basally distinctly curved, with or without a tail 5

4. Spores * (1.5–)1.7–2.1(–2.4) µm wide, twisted with one turn, tail straight; exudate over paraphyses usually as a continuous to cloddy layer; apothecial margin smooth; bark of *Ulmus* (rarely *Broussonetia* or *Faboideae*), thermoboreal to mesomediterranean Europe .... ***O. comma***, p. 812
4. Spores *(1.3–)1.4–1.5(–1.6) µm wide, twisted with 1–2 turns, tail straight or curved; exudate partly forming individual glassy caps on paraphyses; apothecial margin sometimes very finely crenulate; bark of *Ficus* etc., (sub)tropical (sub)humid Middle and South America, northeastern Australia, southeastern Asia .... ***O. neocomma***, p. 817

5. Asci *6–6.4(–6.7) µm wide (†5.2–5.7 µm); spores *7.3–9.5 × 2–2.3(–2.4) µm, medium to strongly curved at tail-like base, tail base never swollen; bark of *Lonicera*, cold-continental subhumid central Asia .... ***O. basiflexa*** (section *Ovoideae*), p. 1279
5. Asci *3.5–5 µm wide (†3–4.5 µm) 6

6. Spores *(6–)7–9.5(–11) × 1.8–2.3 µm, SBs (1.5–)1.7–2.3 µm long; glassy processes often present, 1–9 µm long 7
6. Spores *(4–)5–8(–9) × 1.3–2 µm, SBs 1–1.8 µm long; glassy processes absent or < 2 µm long 8

7. Crystalloid SCBs present; spores consistently with a short tail with an often slight to distinct basal inflation, spore base straight or only slightly curved; SBs 0.9–1.2(–1.5) µm wide; branches of *Euphorbia*, inframediterranean (semi)arid Macaronesia ..... ***O. pisciformis***, p. 808
7. Crystalloid SCBs absent; spore base attenuated or tail-like, also with a short tail, never inflated at the base, often slightly to medium curved; SBs (0.7–)0.8–1(–1.2) µm wide; bark of angiosperms, also bryicolous, cold-temperate humid to submediterranean (semi)humid Europe .... ***O. mali*** (series *Regales*), p. 781

8. Spores *5.8–7.5(–8.5) × 1.3–1.6 µm, with a 1.3–1.5 µm long tail with a strong globular basal inflation, upper part subcylindrical; culms of *Phragmites*, tropical (sub)humid northeastern Australia .... ***O. stilbospora***, p. 807
A sample on angiosperm bark from southern China merely differs in the predominant absence of a basal inflation of the spore tails (p. 808).
8. Spore base partly tail-like but never or only exceptionally basally inflated 9

9. Paraphyses uninflated to medium capitate, terminal cells mainly 12–18 µm long, often 2 × as long as lower cells; spores *(4–)5–8(–9) × 1.3–1.8 µm; herbaceous stems, rarely wood or bark, cold-temperate to submediterranean (semi)humid Europe .... ***O. caulicola***, p. 803
9. Paraphyses strongly capitate, terminal cells mainly 8–11 µm long, hardly longer than lower cells; spores †5–7 × 1.3–1.9 µm; herbaceous stems of *Conyza*, warm-temperate humid eastern North America .... ***O. cookei***, p. 807

O. cookei seems to be extraordinary in its terminal cells of paraphyses which are hardly longer or partly even shorter than the lower cells, but such short terminal cells are also sometimes seen in *O. stilbospora* and *O. comma*. *O. pisciformis* has the longest SBs of this group, which are broadly tear-shaped to pyriform or ampulliform instead of globose, and the longest glassy processes which, however, vary in length among the collections. *O. disseminata* is exceptional in having yellow apothecia and rather long and thin spore tails.

Anamorph. Merely phragmosporous anamorphs are known, which are ascertained in pure culture only in the former two species: *O. caulicola* is characterized by long anguillospora-like conidia, while *O. comma* and *O. stilbospora* have shorter, vermispora-like conidia.

Phylogeny. Sequences were available for four species of series *Commatoideae* (*O. caulicola*, *O. comma*, *O. pisciformis*, *Orbilia* sp. B.L. 4099). In our analyses of ITS+LSU (Phyl. 13), they clustered in the medium supported core clade of section *Aurantiorubrae*, but did not form a clade of their own. Instead, *O. caulicola*, *O. comma*, and *Orbilia* sp. clustered unresolved, only in the LSU analysis the latter two formed a weakly supported clade (Phyl. S16). *O. caulicola* clustered weakly or medium supported sister to series *Regales* (Phyls 13, S15), whereas *O. pisciformis* clustered strongly (ITS+LSU, ITS) or medium (ITS, Phyl. 14) supported sister to series *Rubellae* (Phyls 13–14, S15). In the phylogenetic analysis in Baral et al. (2017b), the clade containing series *Aurantiorubrae* and *Rubella* and *O. comma* received high support, and here also *O. caulicola* clustered with low support sister to it by rendering series *Commatoideae* paraphyletic. In any case, the two main clades, into which the core clade of section *Aurantiorubrae* is divided, both comprise species with globose and elongate SBs. Which of the two SB types would be the plesiomorphic state cannot be deduced from these analyses. The easier explanation would be that elongate SBs developed from globose ones, so that series *Commatoideae* and *Regales* with predominantly globose SBs would represent the more plesiomorphic groups.

Specific nucleotide positions. No molecular motifs have been found to characterize series *Commatoideae*.

Ecology. Series *Commatoideae* includes only more or less desiccation-tolerant species (no information is available for *O. disseminata*), which occur on wood and predominantly bark of angiosperms but also on herbaceous stems. Records derive from subtropical to tropical humid America and Australia (*O. neocomma*, *O. ?caulicola*, *O. disseminata*, *O. stilbospora*), subtropical semihumid (*O. pisciformis*) or humid (*O. caulicola*) Macaronesia, and temperate humid America (*O. cookei*) and subtropical semihumid to temperate to mountainous humid Europe (*O. comma*, *O. caulicola*, *O. mali*).

Orbilia caulicola Baral & G. Marson, **sp. nov**., MB 813742 — Pls 414–415, Map 71

Etymology: referring to the preference for herbaceous stems.

Typification: France, Vosges, Gérardmer, stem of *Angelica sylvestris*, 2.IX.1996, H.O. Baral (ex H.B. 5561a, M-0276451, holotype).

Latin diagnosis: *Apothecia rehydratata 0.1–0.7 mm diam., aurantiaca, sessilia, margine laevi. Ascosporae *5–9 × 1.3–1.8 μm, fusoideae vel fusiformes, rectae vel basi leniter curvatae, apice obtusae ad acutae, ad basim plerumque valde attenuatae, in statu vivo corpusculum refringens globosum, ad apicem filo brevissime affixum continentes. Paraphyses ad apicem vix vel modice capitato-clavatae. Habitat ad caules putridos siccos herbarum, etiam ad lignum vel corticem putridum ramulorum vel ramorum siccorum fruticum et arborum angiospermarum in zona supratemperata humida et submediterranea semihumida Europae et subtropica humida Macaronesiae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–0.5(–0.7) mm diam., 0.06–0.12 mm high, whitish, greyish-cream or mostly very pale to light rose, also (rose-)orange, ± translucent, round, very scattered or medium to strongly gregarious; disc flat to ± convex, immarginate, smooth; broadly sessile, superficial; dry light to bright cream, ochraceous, rose or orange(-red). **Asci** *(25–)28–40(–43) × 3.8–4.7 μm {9}, †(22–)26–36(–42) × 3.3–4 μm {6}, 8-spored, spores *2–4-seriate, (1–)3–5(–6) lower spores inverted {17} (not or slightly mixed), pars sporifera *15–21 μm long; **apex** (†) medium to strongly truncate (not or slightly indented, laterally not widened); **base** with short to long, flexuous stalk, L-, T- or h-shaped. **Ascospores** *(4–)5–8(–9) × (1.3–)1.4–1.7(–1.8)((–2)) μm {28}, †5–8.5 × 1.2–1.5 μm {3}, fusoid(-clavate) to fusiform(-clavate), apex obtuse to acute, base slightly to mostly strongly attenuated, with or without a tail-like end (exceptionally inflated at base), straight to sometimes slightly curved near base; **SBs** *(1–)1.2–1.6(–1.8) × 0.7–1.3 μm {18}, globose (to broadly tear-shaped), with a very short filum. **Paraphyses** apically uninflated to medium (rarely strongly) clavate-capitate, terminal cells *(7.5–)12–18(–20) × (2.2–)2.5–4.5(–5.2) μm {9}, lower cells *3–8 × 1.8–2.5(–3.2) μm {3}; sometimes branched at upper septum. **Medullary excipulum** very pale rose, 10–30 μm thick, of textura intricata-angularis, not sharply delimited. **Ectal excipulum** of very pale rose, thin-walled, irregularly vertically oriented t. globulosa-angularis from base to margin, 30–40 μm thick near base, cells *8–18 × 5–18 μm {3}; 25 μm thick at lower flanks, cells *8–12 × 7–9.5 μm, 10–20 μm thick near margin, oriented at a 45–80° angle to the surface, marginal cortical cells *(3–)5–8 × 3.5–7 μm at lower margin, 9–12(–14) × 3–6 μm at upper margin {5}, sometimes hyphoid, hair-like, conglutinate to form radial rows; **glassy processes** absent. **SCBs** absent {6}; **VBs** in paraphyses usually absent {7}, rarely present, elongate, sparse, very low-refractive {1}. **Exudate** over paraphyses 0.2–1(–1.5) μm thick, continuous to cloddy, hyaline to light yellowish-amber, loosely to firmly attached; over margin and mid flanks 0.2–2 μm thick, granular(-cloddy). **Anchoring hyphae** sparse, *2–3(–4.8) μm wide, walls 0.2–0.3 μm thick {2}. — **ANAMORPH**: anguillospora-like (from ascospore isolate {1} and natural substrate {3}). **Conidiophores** not seen. **Conidia** filiform, slightly (to medium) curved, gradually tapered towards both ends, *(90–)110–150(–170) × (3–)3.5–5 μm (actual length), (7–)15–26(–32)-septate {4}, with a few to many small LBs in each cell, especially at the septa, sometimes with 1–2 μm large, globose, medium refractive VBs inside roundish vacuoles in many of the central cells, 1 per cell (Pl. 415: 7, not tested with CRB), VBs disappearing and vacuoles getting larger and elongate when overmature.

Habitat: collected 0.1–1.6 m above the ground, also lying ± moist among moss or grass, on 1–2 years old herbaceous, mostly ± standing stems, rarely leaves or culms, of *Angelica sylvestris* {1}, *Anthriscus sylvestris* {1}, indet. *Apiaceae* {1/1}, *Arctium lappa* {1}, *Conyza canadensis* {1}, *Dactylis glomerata* {1}, *Echinops sphaerocephalus* {2}, ?*Echium vulgare* {1}, *Heracleum sphondylium* {2/2}, *Melilotus* sp. {2}, *M. albus* {1}, *Pastinaca sativa* {1/1}, *Phyllostachys* sp. {1}, *Reynoutria japonica* {1}, *R. sachalinensis* {1}, *Sambucus ebulus* {3}, *Saponaria officinalis* {1}, *Scirpoides holoschoenus* {1}, *Tanacetum vulgare* {1}, *Typha latifolia* (1), *Yucca* sp. {2}; inner parts of very old stems of *Rubus fruticosus* {1}, *R. grandifolius* {1}; 3–35 mm thick, corticated to ± decorticated twigs and branches of *Ficus carica* {1}, *Ononis spinosa* {1}, *Salix* (?)*caprea* {1}, *Ulex europaeus* {1}, on medium to strongly decayed wood {3} and bark (bast) {1}, slightly to strongly greyed, with a few to many green algae; also on excrements of an invertebrate. **Associated**: *Arnium apiculatum* {1}, ?*Bacidia* sp. {1}, **?***Calloriopsis* sp. {1}, *Capronia* sp. {1}, *Cistella grevillei* {4}, *Cyathicula cacaliae* {1}, *C. cyathoidea* {3}, ‘*Dasyscyphus*’ *castaneus* {1}, *Diaporthe arctii* {2}, *D. eres* {1}, *Heterosphaeria patella* {1}, *Hydropisphaera arenula* {1}, *Karstenia rhopaloides* {1}, *Lachnella alboviolascens* {2}, *L. villosa* {2}, ?*Laetinaevia* sp. {1}, *Leptospora rubella* {2}, *Lophiostoma* sp. {1}, *Mollisia* sp. {1}, *M. ?coerulans* {1}, *M. revincta* {1}, *Merismodes* sp. {1}, ?*Nectria* sp. {1}, *Olla*

millepunctata {4}, *Ophioceras leptosporum* {1}, *Orbilia albovinosa* {1}, *O. auricolor* {1}, *O. carpoboloides* {1}, *O. cylindrosoma* {4}, *O. flavida* {8}, *O. flavidorosella* {2}, *O. ocellata* {1}, *O. pleiolentiformis* {1}, *O. quaestiformis* {8}, *O. ungulata* {4}, *O. vitalbae* {3/1}, *Patellaria atrata* {2}, *Peroneutypa* ?*scoparia* {1}, *Phragmocephala atra* {1}, *Pirottaea* ?*imbricata* {2}, *Pyrenopeziza* sp. {2}, *P. atrata* {1}, *P.* ?*rubi* {1}, *Ramichloridium* ?*schulzeri* {1}, *Stictis* ?*stellata* {1}, *Trichopeziza* ?*perrotioides* (immature) {1}, *T. lizonii* {1}, *T. mollissima* {1/2}, *Unguiculariopsis ilicincola* {1}, *Urceolella crispula* {2}, *U.* ?*pani* {1}. **Desiccation tolerance**: fully viable for at least 4.5 weeks, after 2 months only excipular cells alive. **Altitude**: 7–643 m a.s.l. **Geology**: Cambrian silt & wacke, Devonian slate, Carboniferous sand-, mud- & siltstone with coal, Keuper (gypsum, marl & sandstone), Lower Jurassic & Miocene sand, sandstone & shale, Quaternary loess & sand; granite, gneiss, rhyolite, gabbro. **Phenology**: II, IV–XI (apparently throughout the year).

Taxonomic remarks. *Orbilia caulicola* is characterized by small, straight, fusoid to fusiform ascospores being often strongly attenuated and partly slightly curved at the base, with a ± globose apical spore body. The North American *O. cookei* is tentatively segregated by strongly capitate paraphyses with rather equally distibuted septa, whereas the apices in *O. caulicola* are usually less inflated and the terminal cells tend to be distinctly longer than the lower cells. The type of *O. rosella* (tentatively placed in series *Abutilones*) differs from these two taxa in a crenulate apothecial margin due to very short hairs with small glassy caps, also in slightly larger asci and spores. *O. ebuli* differs from *O. caulicola* in distinctly longer spores with elongate spore bodies with an inflated ellipsoid to tear-shaped lower part.

Variation. *O. caulicola* varies strongly in spore length among the collections (from *5–6 µm to 7.5–9 µm), also in thickness of paraphysis apices (from uninflated to medium capitate). Variation in shape of spore apices (from obtuse to acute) and bases (partly tail-like) was noted among but also within populations. Collections on woody substrates did not markedly differ from those on herbs. Very low-refractive VBs were seen in the paraphyses of only one collection consisting of one apothecium (Schwäbisch Hall, 31.VII.1992).

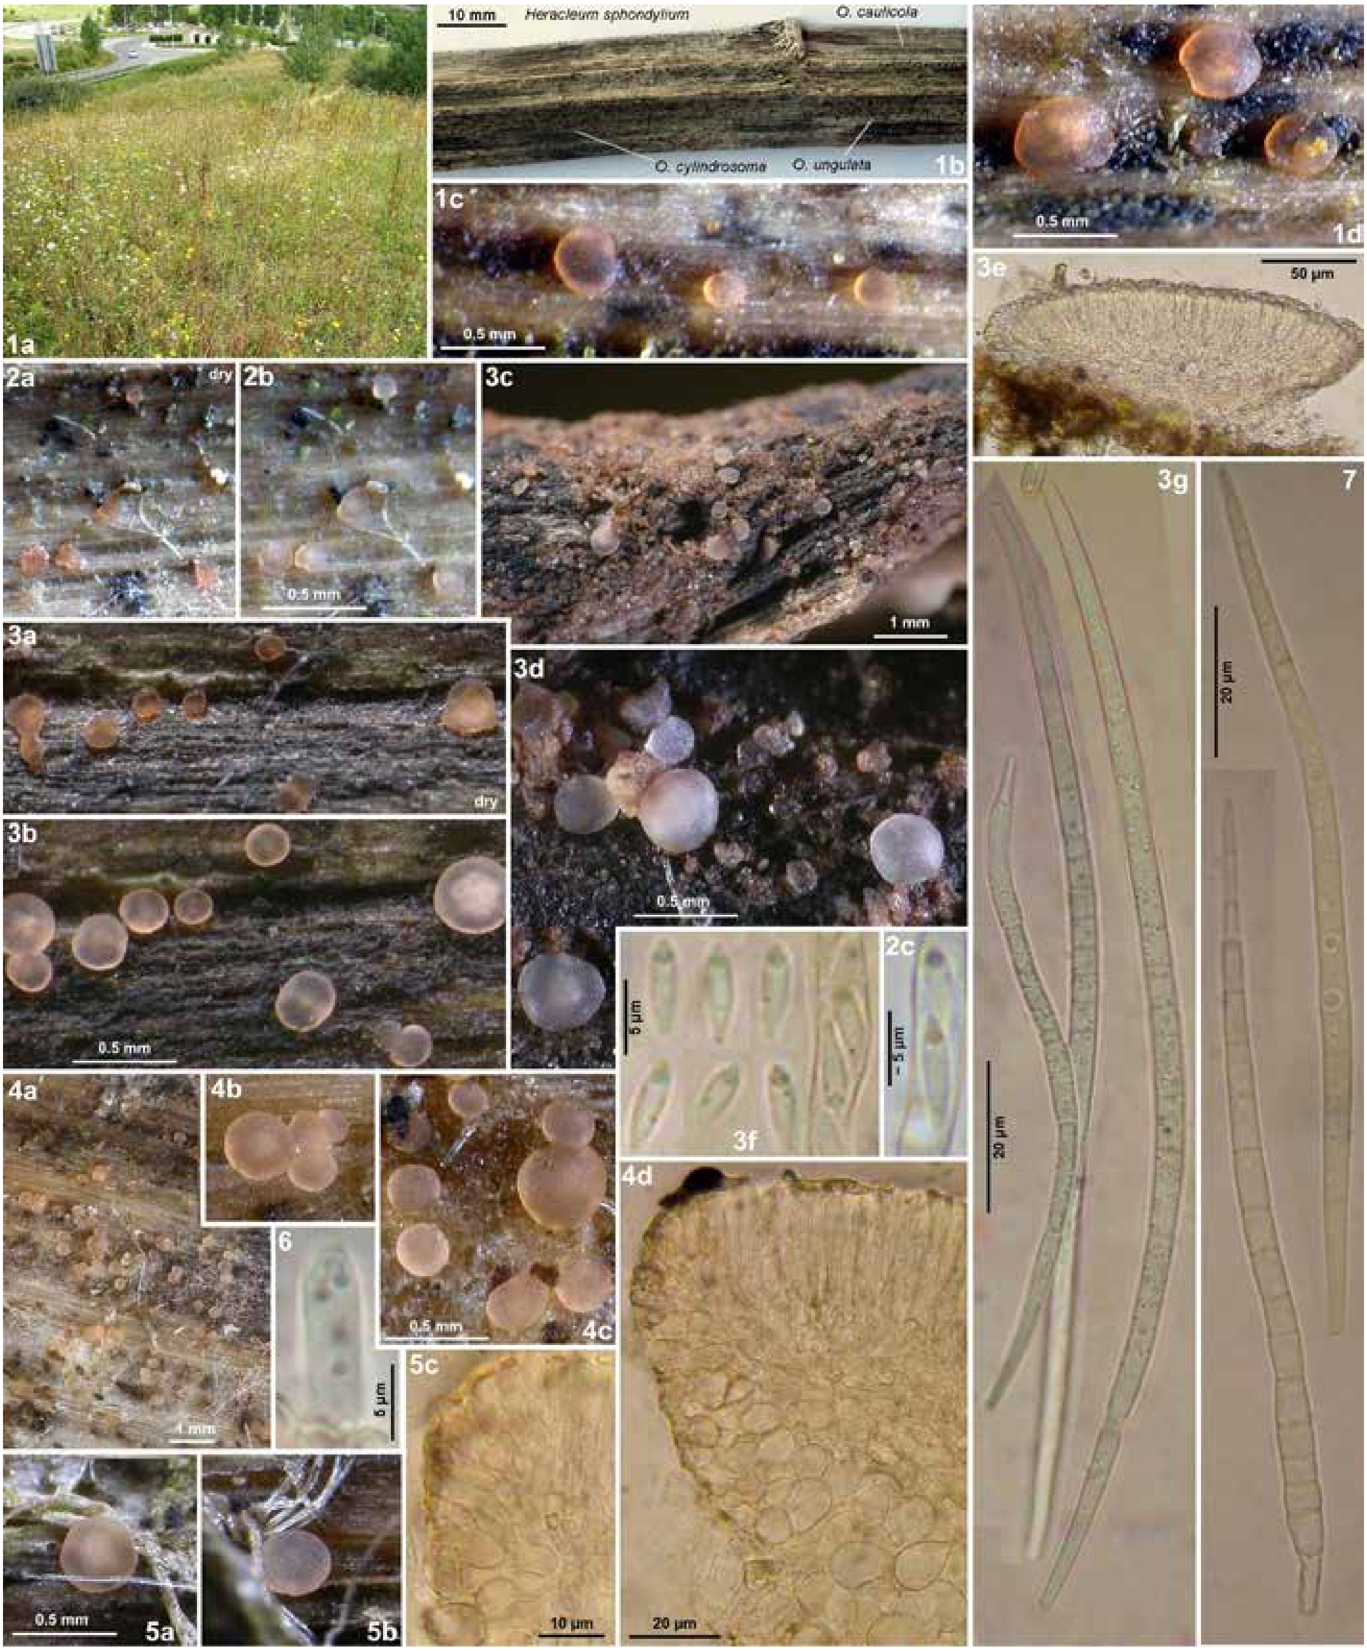

Plate 415. **1–7**: *Orbilia caulicola*. – **1a**. ruderal meadow between railway and road; **1b**. dead xeric stem of *Heracleum sphondylium*; **4a–c**. fresh apothecia; **1c–d**, **2b**, **3b–d**, **5a–b**. rehydrated apothecia; **2a**, **3a**. dry apothecia; **3e**. apothecium in median section; **4d**, **5c**. id., marginal ectal excipulum; **6**. apex of mature ascus; **2c**, **3f**. ascospores; **3g**. conidia from substrate; **7**. conidia from pure culture. – Living state, except for asci in **2c**, **6**. — **1a–d**. H.B. 7869a: Luxembourg, Bonnevoie, on *Heracleum*; **2a–c**. H.B. 7559: ibid., Ettelbruck, on *Heracleum*; **3a–g**. H.B. 8346a: Germany, Tübingen, on indet. ?*Apiaceae*; **4a–d**. H.B. 8569: Germany, Rehna, on *Arctium*; **5a–c**. H.B. 8539c: Luxembourg, Dudelange, on *Melilotus*; **6**. H.B. 7564d: Luxembourg, Junglinster, on *Sambucus ebulus*; **7**. G.M. 2013-07-30.3: Luxembourg, Bettembourg, on *Melilotus*.

Not included collection. A very sparse unillustrated sample from South America differs from *O. caulicola* by thin, filiform to circular crystalloid SCBs in the excipular cells. The fusiform spores (*5.5–7 × 1.7–1.9 µm) with acute ends and broadly tear-shaped SBs of 1.4–1.7 × 0.7–1.1 µm, and the paraphyses with 3 µm wide, slightly to medium clavate apices closely resemble *O. caulicola.*

Anamorph. The anguillospora-like conidia of *O. caulicola* (Pls 414: 8; 415: 3g, 7) resemble those of '*Brachyphoris*' *stenomeces* as described by Drechsler (1963), which has slightly narrower conidia with their widest part more in the lower half (see Pl. 1: b). The anamorph of *O. rosea* (section *Helicoon*), *Anguillospora rosea*, is similar but has much longer conidia and occurs, in contrast, in semiaquatic habitats.

Phylogeny. Sequences were obtained from three collections: on *Arctium* from Mecklenburg (from apothecia), on *Melilotus* and *Tanacetum* from the same site in Luxembourg (from pure culture and apothecia, respectively). They comprise ITS and LSU, the latter two also the S1506 intron, which is not covered by the former. The ITS region is only complete in the *Tanacetum* strain while the *Melilotus* strain lacks IT2 and the *Arctium* strain a part of ITS1. Deviations among the strains concern 4 nt and some gaps in the ITS1, and 2 nt and 2 gaps in the ITS2, resulting in a variation of 0.7–1.3 % (2 nt in the ITS1 differ only between the two strains from Luxembourg). In the LSU D1–D3 domain, 1 nt deviates in the D2 and 1 nt in the D3. In the intron a distance of 1.5 % is observed in the overlapping part.

The closest species in the ITS region was *O. mali* with a distance of 13.5 %, while *O. comma* differs by 16.5 %, and other members of the clade by 15–16 %. In the LSU the distance to other taxa ranges at 4–10 %, whereas in the intron it is generally very high. A close relationship to *O. comma* or *O. pisciformis* is not supported, but for the time being we decided to keep *O. caulicola* for morphological reasons in series *Commatoideae*.

Ecology. *O. caulicola* was collected on both hygric and xeric substrate, predominantly herbaceous stems of various mono- and dicotyledonous biannual or perennial plants, but also on ± rotten wood and bark of twigs and branches of angiosperm trees and shrubs. The vegetation includes thermophilous ruderal places with *Artemisia*, *Conyza*, *Echium*, *Melilotus*, *Pastinaca*, *Reynoutria*, *Sambucus ebulus*, *Solidago* etc., shrublands with *Ulex* and *Yucca*, and wetlands with *Angelica* or *Scirpoides*. The climatic zones comprise planar to submontane, atlantic to subcontinental, cold- to warm-temperate humid, but also suprasub- to mesosub- and supramediterranean semihumid Europe. A single sample was from a suprasubmediterranean humid laurel forest in Madeira (Macaronesia). The not included record from South America was in a subtropical humid forest with planted tropical fruit trees.

Map 71. Known distribution of *O. caulicola* in Europe and Macaronesia.

Specimens included. **GREAT BRITAIN**: **Yorkshire**, **South Yorkshire**, 7.5 km NNW of Sheffield, 1 km NW of Grenoside, Greno Wood, 280 m, stem of *Anthriscus sylvestris*, 18.V.2011, J.H. Orbilia cookei Baral, **nom. nov.**, MB 813743 — Pl. 416

Replaced synonym: *Peziza exigua* Cooke, Bull. Buffalo Soc. Nat. Sci. 2: 296 (1875) [non *Orbilia exigua* Velen., Monogr. Discomyc. Bohem.: 100, 1934, = *Hyalorbilia berberidis*]

≡ *Pezizella exigua* (Cooke) Sacc., Syll. Fung. 8: 283 (1889)

≡ *Mollisia exigua* (Cooke) Seaver, North Amer. Cup Fungi (Inop.) p. 207 (1951)

Etymology: *cookei*: named after the author of the basionym, M.C. Cooke; *exigua*: referring to the minute apothecia.

Typification: USA, New Jersey, Newfield, stem of *Conyza canadensis*, VIII.1873, J.B. Ellis (K(M) 36004, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.13–0.32 mm diam., pale cream-reddish-orange (Cooke: miniate = saturn-red, Dennis: pink), round to slightly elliptical, scattered; disc flat (Cooke: concave, eventually flat to convex), margin smooth, scarcely protruding; sessile on a small base, superficial; dry dirty reddish. **Asci** †28–33 × (2.9–)3.4–4(–4.2) µm, 8-spored, spores †2–3-seriate, ?3 lower spores inverted, pars sporifera †20–23 µm long; **apex** (†) strongly truncate (deeply indented, laterally distinctly inflated); **base** with short stalk, Y-shaped. **Ascospores** †5–7 × 1.3–1.9 µm, fusoid to fusoid-clavate, apex obtuse to subacute, base medium to strongly attenuated in a ± acute end, straight or rarely slightly curved at base; **SBs** unknown (perhaps globose). **Paraphyses** apically (very) strongly capitate, terminal cells †(5–)8–11 × 3–4.8 µm, lower cells †(5–)8–10 × 1–1.6 µm; unbranched at upper septum. **Medullary excipulum** not examined. **Ectal excipulum** of (†) thin-walled textura angularis from base to margin, cells near base †9–20 × 7–15 µm; near margin of t. prismatica-angularis oriented at a high angle to the surface, marginal cortical cells †7–12.5 × 3.5–5 µm; **glassy processes** absent. **Anchoring hyphae** not examined. **SCBs** no data available. **Exudate** over paraphyses and marginal cells 0.2–0.3 µm thick, granular, firmly attached. **— ANAMORPH**: unknown.

Habitat: previous year's stems of *Conyza canadense* {1}, on medium decayed epidermis, slightly greyed, no algae. **Associated**: none observed. **Desiccation tolerance**: unknown. **Altitude**: 35 m a.s.l. **Geology**: Miocene sedimentary rock. **Phenology**: VIII.

Taxonomic remarks. Although mature, the type material is not in very good shape, and the ascospores could only be seen inside the asci. No further collections referable to this species came to our notice. *O. cookei* is probably very closely related to *O. caulicola*. The two species have very similar spores and perhaps also spore bodies, which do not appear to permit species recognition. The shape of the SBs in *O. cookei* was indistinctly seen in a single spore (Pl. 416: 1a right). The difference between the two species lies in the paraphyses, which are strongly capitate in *O. cookei* but uninflated to medium capitate in *O. caulicola*. In addition, the terminal cells of *O. caulicola* are often 2(–4)× as long as the lower cells, whereas those of *O. cookei* are rather equal in length, so that the absolute length of the terminal cells in the two taxa hardly overlaps. *O. cardui* (*section Arthrobotrys*) resembles *O. cookei* in spore size and shape, though the spores are distinctly narrower; the species clearly differs in larger apothecia, longer terminal cells of paraphyses with hardly swollen apex, covered by rather thick exudate, and in glassy processes at the margin.

Naevia canadica Rehm was described with characters similar to *O. cookei*, except for the filiform paraphyses (see p. 1663).

Nomenclature and type studies. Cooke's (1875a, b) very brief diagnosis of *Peziza exigua* includes 'lanceolate' asci and linear, scarcely 5 µm long spores. Saccardo (1889) and Seaver (1951) merely repeated Cooke's description, although Seaver examined the type material. Dennis (1964: 46) provided a rather detailed redescription of the holotype, which he found to represent a genuine *Orbilia*, though feeling unable to compare it with any known taxon of that genus. His measurements of asci (35 × 5 µm) and spores (6–8 × 1.5 µm) are slightly larger than in the present study. Apparently without personal examination, Raitviir (1991: 359) referred *P. exigua* to synonymy with *O. cardui*. Due to the existence of *Orbilia exigua* Velen., a new name is proposed here.

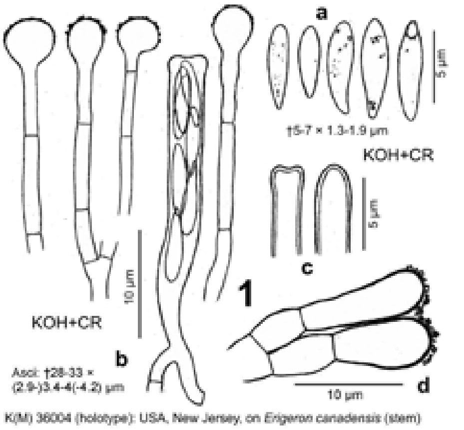

Plate 416. **1**: *Orbilia cookei*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section.

Ecology. *O. cookei* was collected in warm-temperate humid lowlands of New Jersey in eastern North America. According to Seaver (1951), several collections of this species were made by J. B. Ellis (preserved in the New York Botanical Garden), apparently always on stems of *Conyza* (as *Erigeron*).

Specimens included. **USA**: **New Jersey**, ~7 km N of Vineland, Newfield, unlocalized, 35 m, stems of *Conyza canadensis*, VIII.1873, J.B. Ellis (Ellis 1016, K(M) 36004, **holotype**, H.B. 5447 ø)

Orbilia stilbospora Baral, **sp. nov.**, MB 813744 — Pls 417–418

Etymology: named after the stilboid ascospore bases resembling a stalked head.

Typification: Australia, Queensland, Mossman, leaf of *Phragmites australis*, 28.VIII.2006, G. Marson (ex H.B. 8501c, BRI AQ799195, holotype).

Misapplied name: Zhang et al. (2009b: 151), as *O.* aff. *comma* (= *O.* ?*stilbospora*).

Latin diagnosis: *Similis* Orbiliae caulicolae *sed ascosporae basi valde attenuatae et constrictae*, *globulo leniter vel valde inflato terminatae. Habitat ad basim folii sicci*, *leniter putridi* Phragmitis australis *in zona tropica humida Australiae septentrio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.18–0.5 mm diam., 0.09–0.11 mm high, pale orange-rose to cream or light orange, slightly translucent, round, scattered; disc flat, margin distinct, 0–10 µm protruding, ± smooth; broadly sessile, superficial. **Asci** †29–41 × 3.1–3.5 µm, 8-spored, (1–)3–4(–5) lower spores inverted (± mixed or not); **apex** (†) strongly truncate (often distinctly indented, laterally inflated); **base** with medium long, ± thin, flexuous stalk, L-shaped. **Ascospores** *5.8–7.5(–8.5) × 1.3–1.5(–1.6) µm, †6–7.2 × 1.3(–1.4) µm, cylindric(-fusoid), apex (rounded to) obtuse, base abruptly constricted, with a globose to tear-shaped, 0.5–0.9 µm wide appendage-like lower part, straight to slightly inequilateral, tail *1–1.8(–2.2) × 0.6–0.9 µm; **SBs** 1.3–1.5 × 0.8–0.9 µm, globose to broadly tear-shaped, with a very short filum. **Paraphyses** apically (slightly to) medium to strongly (clavate-) capitate, terminal cells *9–20 × 2.8–4.2 µm, †2.8–3.8 µm wide, lower cells *4–8(–11) × 1.8–2.4 µm; unbranched at upper septum. **Medullary excipulum** 20–30 µm thick, of dense textura intricata-globulosa, medium sharply delimited. **Ectal excipulum** pale to light orange, of thin-walled, vertically oriented t. prismatica-globulosa at base, 30–40 µm thick near base, cells *9–16 × 7–12 µm; t. globulosa from flanks to submargin, 15 µm thick near margin, upper margin of t. prismatica-porrecta oriented at a 30–50° angle to the surface, marginal cortical cells

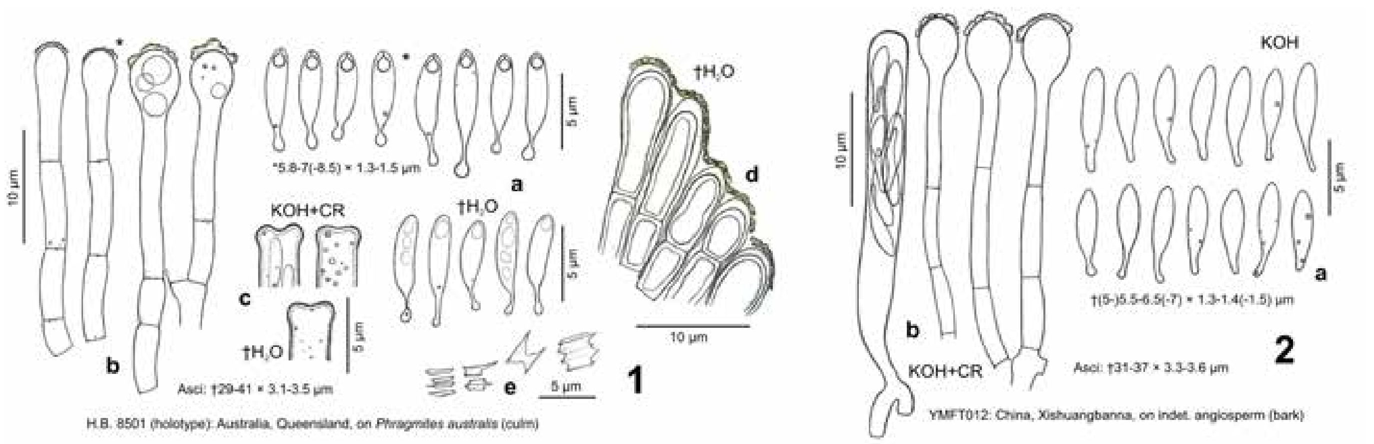

Plate 417. **1**: *Orbilia stilbospora*; **2**. *O.* cf. *stilbospora*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section; **e**. SCBs in ectal excipulum (base and flanks).

†6–10 × 2.7–3.7 µm, covered by indistinct **glassy caps** 1–1.5 × 3–5 µm. **Anchoring hyphae** sparse, †2–3 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses globose, 1.5–2.5 µm diam., in ectal excipulum at base and flanks crystalloid, hyaline to very pale orange. **Exudate** over paraphyses and marginal excipulum 0.2–1.5 µm thick, granular-cloddy, firmly attached, hyaline or yellowish. — **ANAMORPH**: vermispora-like (presumed, from natural substrate {1}). **Conidiophores** not seen. Very few **conidia** seen: †41–47 × 4–4.5 µm (*4.8 µm wide), narrowly fusoid, 5-septate, slightly curved.

Habitat: collected 0.1–0.5 m above the ground, ~10 mm thick standing culms of *Phragmites australis*, at base of leaf sheath on or close to node, slightly rotten, greyed or blackened, no algae. **Associated**: *Arthrinium arundinis*, *Orbilia ?atlantis*, *O. ?breviaristata*, *O. phragmitis*, *O. ?puyae*. **Desiccation tolerance**: many excipular cells and some paraphyses still viable after 11 months. **Altitude**: 390 m a.s.l. **Geology**: Devonian sedimentary rock. **Phenology**: VIII (but long-lived).

Taxonomic remarks. In the ascospores *O. stilbospora* resembles *O. caulicola*, to which it appears to be closely related. The basal globule, which is formed by a constriction of the spore base (similar as in the probably less related *O. abutilonis* and similar species, series *Abutilones*), is easily overlooked inside the asci, especially when these are dead. Like *O. caulicola*, members of series *Regales* differ in the absence of knob-shaped spore bases, partly also in distinctly wider spores, and partly in more spathulate paraphyses with glassy caps and pinkish apothecia.

Not included collection. A specimen on angiosperm bark from China (Pls 417: 2; 418: 2), published as *O.* aff. *comma* by Zhang et al. (2009), resembles *O. stilbospora* in the spore tails which are, however, only sometimes with a small globular inflation (tail size †1–2 × 0.4–0.6 µm). The SBs in this specimen are slightly longer and more tear-shaped than in *O. stilbospora* and more resemble *O. mali* (series *Regales*).

Anamorph. Two slightly curved phragmoconidia (Pl. 418: 1i) were observed near the apothecia. In *O. comma* and many other species of this section, the conidia are more canoe-shaped, i. e. more strongly curved at the ends.

Ecology. *O. stilbospora* was found at the base of the leaf sheath on a standing, dead, xeric culm of *Phragmites* being covered over large areas by the black conidial layer of *Arthrinium arundinis*, in a floodplain at the roadside in a tropical (sub)humid lowland of northeastern Australia between savannah and rainforest. The not included collection was from a tropical humid (winterdry) forest in southern China.

Specimens included. **AUSTRALIA**: **Queensland**, Einasleigh Uplands, 22 km SSW of Mossman, 2 km N of Mount Molloy, Mossman Mt. Molloy Rd, 390 m, leaf sheath of *Phragmites australis*, 28.VIII.2006, G. Marson (ex H.B. 8501c, BRI AQ799195, **holotype**, anam. substr.).

Not included. **CHINA**: **Yunnan**, **Xishuangbanna**, 50 km ESE of Jinghong, 2 km SE of Menglunzhen, Green Stone Forest Park, 600 m, branch of indet. angiosperm, on bark, 3.VIII.2005, M. Qiao (YMFT 012, as *O.* aff. *comma*, H.B. 8731).

Orbilia pisciformis Baral, Quijada & Beltrán-Tej., in Quijada et al., Nova Hedwigia 96: 243 (2012) — Pls 419–420, Map 72

Etymology: named after the ascospores somewhat resembling a fish.
Typification: Macaronesia, Tenerife, Teno Alto, stems of *Euphorbia balsamifera*, 3.V.2009, L. Quijada & R. Castro (TFC Mic. 22122, holotype).
Misapplied name: Korf (1992, p.p. 510: CUP MM 2555), as *O. occulta*.

Latin diagnosis: Orbiliae caudatae *similis sed ascosporae multo longiores, corpuscula refringentia majora, paraphyses apice processis vitreis tectae. Habitat ad lignum siccum* Euphorbiae *in zona subtropica semiarida ad arida Macaronesiae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.35–)0.4–0.8(–0.9) mm diam., (0.13–)0.15–0.23(–0.25) mm high, light to bright orange to rose-orange, not or slightly translucent, ± round, scattered to gregarious; disc flat, margin thin, 0–10 µm protruding, smooth; broadly sessile, superficial to slightly erumpent; dry slightly contracted, bright to deep orange-red. **Asci** *(59–)63–76 × 4.3–5(–5.8) µm {2}, †(45–)52–67 × 3.8–4.8 µm {3}, 8-spored, spores (*) biseriate, 3–5 lower spores inverted {3} (often mixed), pars sporifera *37–43 µm long; **apex** (†) strongly truncate (sometimes slightly indented and laterally inflated); **base** with medium to very long, thin, flexuous stalk, T- to often L-shaped. **Ascospores** *(7–)8–9.5(–11) × 1.9–2.3(–2.5) µm {3}, †(7.5–)8–10(–11.5) × 1.9–2.2(–2.3) µm {2}, fusoid (to fusiform), apex obtuse to subacute, straight, base always provided with a distinct, straight to sometimes slightly, rarely strongly curved, usually basally ± inflated tail *(1.5–)1.8–2.5(–3) × (0.7–)0.9–1.2 µm {1}, †1.5–3(–4) × 0.6–1(–1.2) µm {2}; **SBs** *1.7–2.3 × (0.9–)1–1.2(–1.5) µm in situ {3}, globose to broadly tear-shaped, with a very short filum, usually with 1 large (0.7–1.2 µm) and a few minute LBs. **Paraphyses** apically medium to strongly clavate-capitate, terminal cell *12–22 × (3–)3.5–4.5(–5) µm {1}, †14–23 × 2.2–3.3 µm {1}, lower cells *(7.5–)10–16 × 1.7–2.5 µm {1}, †9–14 × 1.2–2 µm wide {1} (near base *5–9 × 2–3.3 µm); unbranched at upper septum. **Medullary excipulum** hyaline to pale rose-orange, 30–80(–100) µm thick, lower part of ± dense textura intricata-globulosa, sharply delimited from ectal excipulum, sometimes by a distinct parallel 10 µm thick layer of t. porrecta, upper part of dense t. intricata. **Ectal excipulum** hyaline, of (†) slightly to medium gelatinized (common walls †1–1.7 µm thick), vertically oriented t. angularis-prismatica from base to mid flanks, 40–70(–85) µm thick near

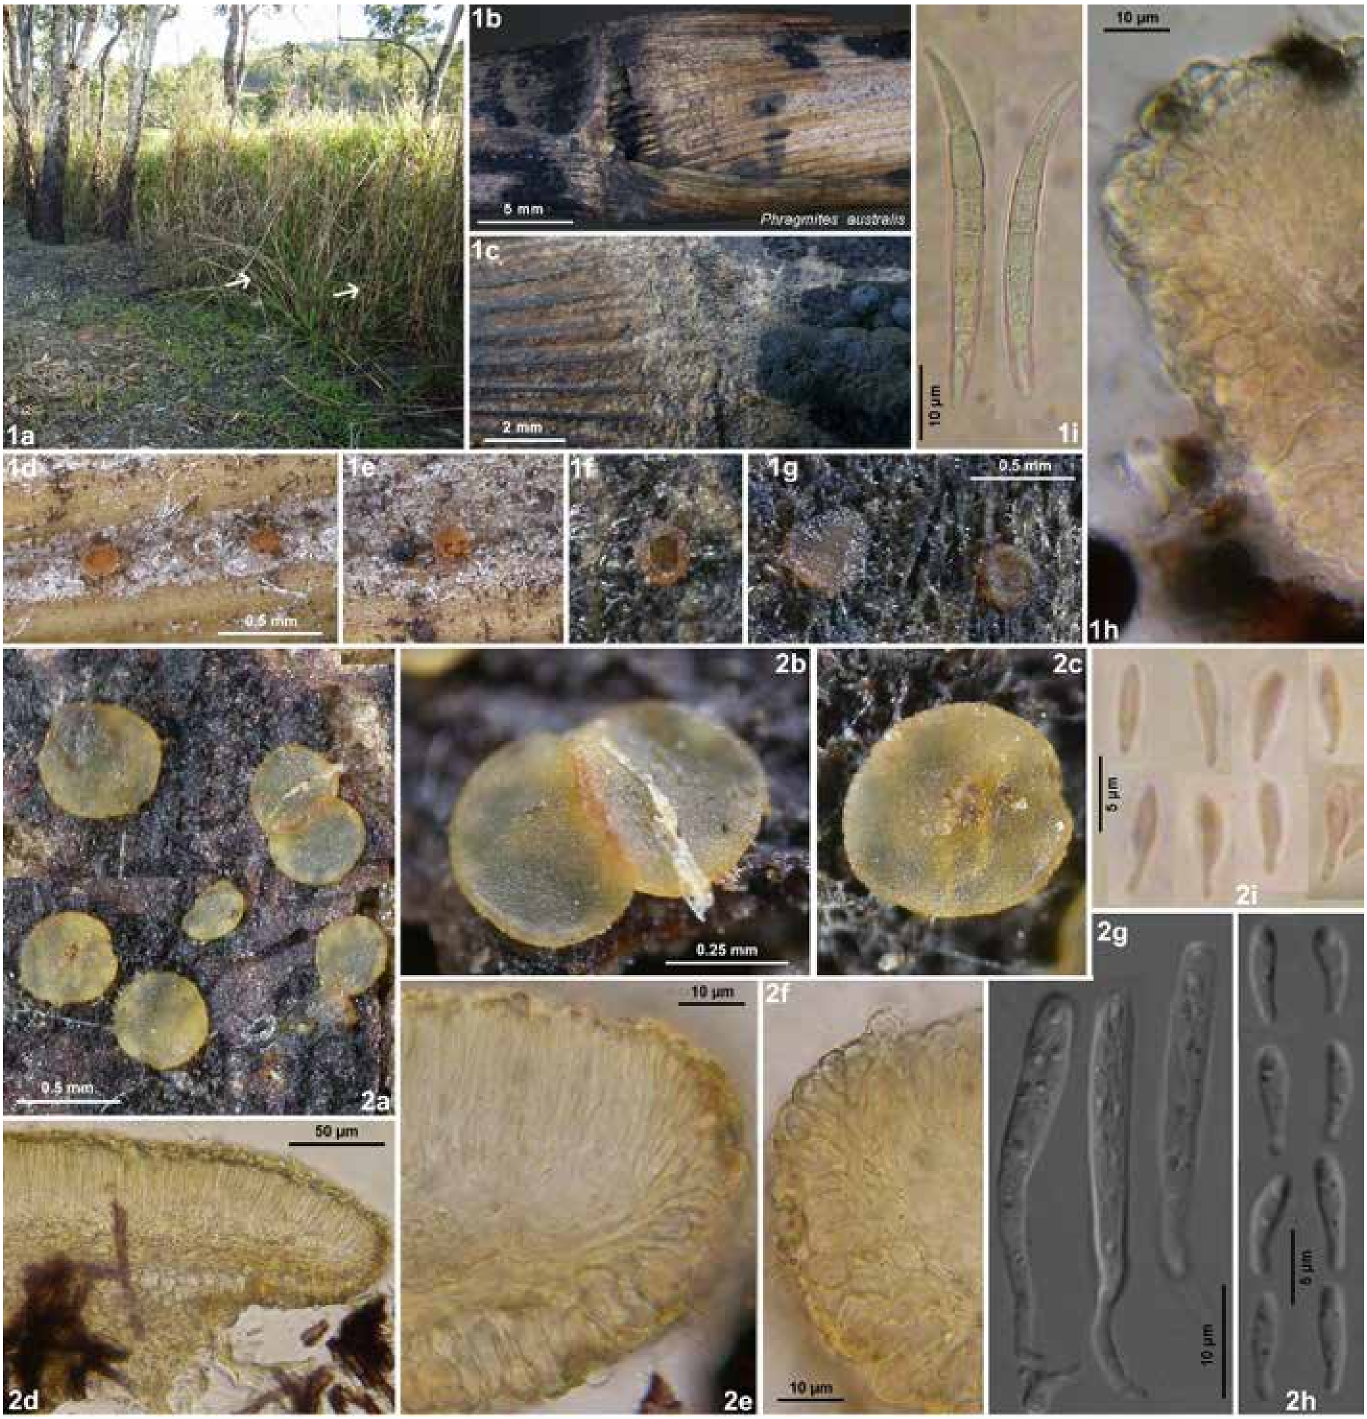

Plate 418. **1**: *Orbilia stilbospora*; **2**: *O.* cf. *stilbospora*. – **1a**. tropical *Phragmitetum* along roadside; **1b–c**. standing culms with black mould (*Arthrinium arundinis*); **1d–g**, **2a–c**. rehydrated apothecia; **2d**. apothecium in median section; **1h**, **2e–f**. id., marginal region; **2g**. asci; **2h–j**. ascospores; **1i**. conidia from substrate. – Dead state (**2d–f** in KOH, **2i–j** in KOH+CR), except for **1h**, spores in **2g–h**, and one conidial cell of **1i**. – **2g–h**: from Zhang et al. base, cells †8–11 × 7–13 µm {1} or */†(12–)15–25(–30) × (8–)9–16(–20) µm {2}; 15–25 µm thick near margin, of t. prismatica oriented at a 40–80° angle to the surface, marginal cortical cells *7–9 × 3.5–6 µm {1}; **glassy processes** 1–9 × 3–4.5 µm {3}, low-refractive, stratified. **Anchoring hyphae** abundant, †2–3(–4) µm wide (at insertion 5–6 µm), walls 0.2–0.5(–0.8) µm thick {3}, slightly gelatinous, forming a very loose t. intricata 40–50 µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2.3 µm diam.; in lowermost cells of paraphyses and in excipular cells at base and flanks also crystalloid, often delicate, in paraphyses as short lines, in ectal excipulum 5–10 µm large, ring- to irregularly lasso-shaped, also C-shaped or as parallel lines {6}, hyaline; light yellow **LBs** (carotenoids) abundant in cells of lower part of paraphyses, singly or scattered in basal ectal excipulum (here 1–2.5 µm diam.) {1} or absent {2}. **Exudate** over paraphyses and margin 1–4 µm thick, cloddy, loosely attached {1}, or cap-like (then perhaps covering glassy processes) and firmly attached {3}, pale yellowish. **— ANAMORPH**: unknown.

Habitat: lying on ground shaded by shrubs and woody debris, decorticated, 30–80 mm thick branches of *Euphorbia atropurpurea* {1}, *E. balsamifera* {1}, *E. canariensis* {10}, *E. lamarckii* {1}, on medium to strongly decayed outer surface of wood (xylem), sometimes in beetle galleries, not or slightly greyed, no algae. **Associated**: *Orbilia amarilla* {1}, *O. asomatica* {1+}, *O. beltraniae* {1}, *O.* aff. *farnesianae* {1}, overmature pyrenomycete {1}. **Desiccation tolerance**: fully tolerant for at least 3 months, ectal and medullary excipular cells, also

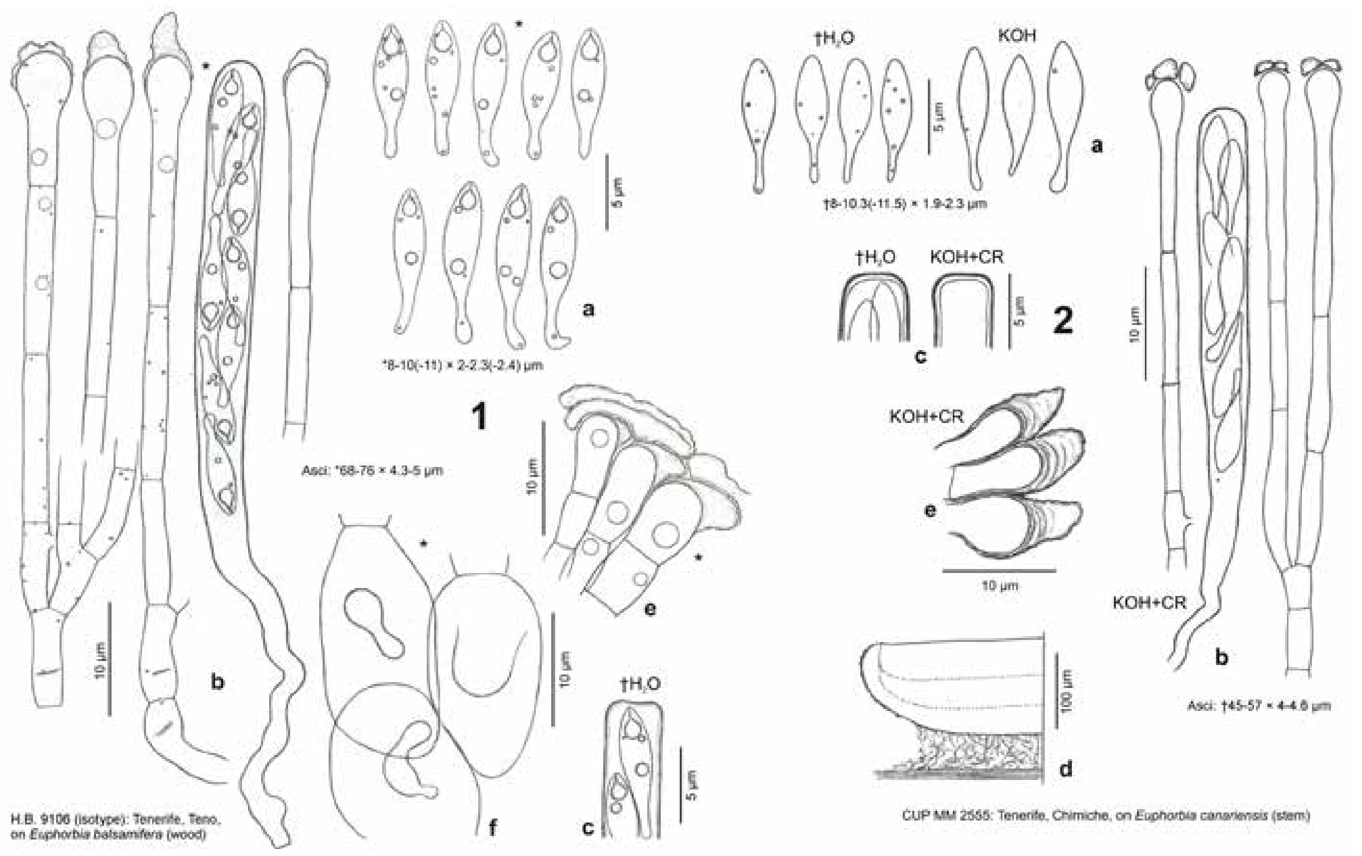

Plate 419. **1–2**: *Orbilia pisciformis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal cortical cells with glassy processes; **f**. lasso-shaped crystalloid SCBs in cells of ectal excipulum at lower flanks.

ascospores partly alive after 13 months. **Altitude**: 25–345 m a.s.l. **Geology**: basaltic and trachybasaltic flows and pyroclasts, ignimbrite. **Phenology**: IX–VI (probably throughout the year).

Taxonomic remarks. *Orbilia pisciformis* is easily recognized by its fusoid, short-tailed ascospores with broadly tear-shaped SBs. It differs from *O. stilbospora* in distinctly larger spores and SBs, and from the temperate *O. mali* (series *Regales*) in slightly longer spores with a more straight upper part, and in often basally inflated spore tails, also in the presence of ring-shaped crystalloid SCBs in the excipulum. *O. comma* possesses very similar SCBs but sharply differs in helicoid spores with basally uninflated tails. *O. pisciformis* has also strong morphological affinities to *O. caudata* (series *Piliferae*), from which it mainly differs in longer spores, larger SBs, and in the paraphyses having glassy caps and longer lower cells.

Although rDNA data of *O. pisciformis* suggest a close relationship to series *Rubellae*, we prefer not to place it there because it lacks the characteristics of that series, namely septate hairs and spathulate to lageniform paraphyses.

Variation. *O. pisciformis* varied only slightly, mainly in length of the spore tails ranging among the collections between 1.5–2 and 2–3(–4) µm, also in the exudate which usually forms cap-like structures (Pl. 419: 1b), but also loosely adhering clods (2b). In the latter collection, the basal excipular cells were much smaller than in the other specimens whenever these cells were examined.

Misapplication. *O. pisciformis* was reported by Korf (1992) under the name *O. occulta*, a taxon of section *Hemiorbilia* that deviates in much longer and thinner spore tails, wider and shorter spore heads, in rather long marginal teeth, and particularly in hemispherical thick-walled ascus apices. The reexamined specimen (CUP MM 2555) consisted merely of some microtome sections.

Phylogeny. Sequences were taken from apothecia of TFC Mic. 23824 and 23766, comprising SSU (without S1506 intron), ITS, and LSU. Between the two strains only 1 nt differed in the ITS region and 1 nt in the LSU (D1–D3), while in the SSU (V8–V9) they are identical. *O. pisciformis* clustered in our analyses of ITS+LSU or ITS with high or medium support sister to series *Rubellae* (Phyls 13–14, S15). The distance in the ITS region lies at 9.5% to *O. phragmotricha*, 11.5% to *O. rubella*, and 13.5–14% to *O. comma*; in the LSU (D1–D2) the lowest distance is 2.2–2.6% to *O. phragmotricha*, but 3.5% to *O. albidorosea*, *O. comma*, *O. aurantiorubra*, and *O. caulicola*. This means that a close relationship to *O. comma* or *O. caulicola* is not supported, but for the time being we decided to keep *O. pisciformis* for morphological reasons in series *Commatoideae*.

Ecology. *O. pisciformis* is so far only known from Tenerife (Macaronesia), where it was recorded at 10 sites in 1977 and between 2009–2011, on rotten wood of xeric branches of different *Euphorbia* species, mainly *E. canariensis*, in inframediterranean, arid to lower semiarid, also hyperarid xerophytic scrublands along the southern, eastern, and western coastline (Korf 1992, Quijada et al. 2012). The species occurred in various associations, mainly tabaibal dulce (*Ceropegio fuscae-Euphorbietum balsamiferae*), but also cardonal (*Periploco laevigatae-Euphorbietum canariensis*), *Artemisio thusculae-Rumicion lunariae*, and *Launaeo arborescentis-Schizogynetum sericeae* (L. Quijada & E. Beltrán-Tejera pers. comm., most of these were earlier subsumed as *Kleinio-Euphorbietea canariensis*). The branches were always lying on the more or less shaded ground, nevertheless they were dry most time of the year.

Orbilia comma Graddon, Trans. Br. Mycol. Soc. 69: 265 (1977) — Pls 421–423, Map 73

Etymology: refers to the spore shape that resembles a comma.

Typification: Great Britain, Warwickshire, Stratford-upon-Avon, branch of *Ulmus*, I.1975, M.C. Clark (K(M) 36048, holotype); Luxembourg, Manternach, branches of *Ulmus*, 4.V.2000, H.O. Baral, G. Marson & L.G. Krieglsteiner (ex H.B. 6639b, M-0291759, epitype, designated here, MBT385117, ex-epitype culture: CBS 116275; sq.: KT215258).

Misapplied names: Breitenbach & Kränzlin [1981, pl. 261 p.p. (colour photo)], as *Habrostictis rubra*; Persoon (1796 p.p.), as *Peziza aurea*.

Misinterpretation of *O. comma*: Baral (1987b: 428), = *O. xanthoguttulata*; Zhang et al. (2009b: 151, as *O.* aff. *comma*), ?= *O. stilbospora* (see p. 808).

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated (0.1–)0.3–1(–1.6) mm diam., 0.13–0.25(–0.3) mm high, light to bright rose-orange(-carneous) to orange, also pale whitish-rose-cream to light amber(-rose), translucent, round, ± strongly undulating when large, medium scattered to mostly (densely) gregarious in often large numbers when on inner surface of bark, fasciculate in small groups when erumpent from holes in periderm; disc young slightly concave, soon flat, rarely slightly convex, margin smooth, at first thick, protruding 0–10 µm, later thin, not protruding; broadly sessile, superficial; dry light to deep (rose-)orange-red to apricot, margin thick, sometimes with sparse white subiculum. **Asci** *(43–)47–65(–68) × (3.7–)4–4.8(–5.3) µm {9}, †38–57(–60) × 3–4.2 µm {5}, 8-spored, spores (*) biseriate, somewhat intertwined, ((1–))(2–)3–5(–6) lower spores inverted {13} (not or slightly mixed), pars sporifera *19–24(–27) µm long (†20–30 µm); **apex** (†) medium to strongly truncate (not indented, laterally sometimes inflated); **base** with medium to very long, slender, flexuous stalk, T-, L- or Y-shaped. **Ascospores** *(5.8–)6.5–7.5(–8) × (1.5–)1.7–2.1(–2.4) µm {21} (~7–9 µm actual length), †(5–)6–8(–8.5) × (1.5–)1.6–1.9(–2) µm {7} (up to 2.3 µm wide if flattened), fusoid- to fusiform-clavate, apex obtuse to subacute (to acute), base strongly attenuated in a tail-like end or distinct tail *1–2.5 × 0.3–0.8 µm, ± strongly helicoid (in profile view appearing 2× geniculate), tail straight; **SBs** *(0.9–)1.1–1.6 × 0.8–1.1(–1.2) µm {7}, (sub)globose to broadly tear-shaped, apically narrowed to a very short filum. **Paraphyses** apically uninflated or slightly (to medium) clavate-capitate, terminal cells *(11–)14–24(–32) × (1.8–)2.5–3.5(–4) µm {6}, †11–20 × (1.5–)2–3.5 µm wide {2}, lower cells *4.5–11 × 1.6–2(–2.5) µm {3}, †6–12.5 × 1.2–1.8 µm {2}; rarely branched at upper septum; hymenium pale to light orange-rose or yellow-orange. **Medullary excipulum** hyaline to very pale rose, 30–90 µm thick in centre, lower or upper part with many inflated cells forming a compact t. globulosa-angularis, otherwise a loose textura intricata, near margin 10–30 µm thick, of a rather loose t. intricata-porrecta, especially here quite sharply delimited. **Ectal excipulum** hyaline to pale orange-rose, of thin-walled or slightly gelatinized, vertically oriented t. globulosa-angularis-prismatica from base to margin, 40–70(–100) µm thick near base, cells *(8–)12–25(–35) × (7–)10–15(–20) µm {6}; 30–50 µm thick at lower flanks, 15–30 µm at mid flanks and margin, oriented at a 70–90° angle to the surface, marginal cortical cells */†(5–)7–15 × (2.5–)4–7(–9) µm {7}, (cylindric-)clavate(-subglobose), **glassy processes** absent. **Anchoring hyphae** abundant, */†1.5–3(–4) µm wide, walls (0.1–)0.2(–0.3) µm thick {7}, forming a dense or loose, hyaline t. intricata(-porrecta) ~10–30 µm thick. **SCBs** in paraphyses absent or globose, 1.5–2 µm diam., sometimes also a few filiform (crystalloid); in ectal excipulum towards margin often globose, 2–4 µm diam., also ring- to C-shaped, also as thin parallel lines, hyaline to pale yellowish-orange, at base and flanks frequently filiform to S- or ring-shaped {15}, 2–5(–8) × 1.5–3.5 µm, sometimes connected to each other; **LBs** in paraphyses sparsely present near septa, small, hyaline, in pigmented apothecia yellow-orange (carotenoids). **Exudate** over paraphyses 0.2–2(–3) µm thick, cloddy, pale to light yellowish-chlorinaceous, often firmly attached, also completely free and continuous; over margin and flanks (1–)2–4(–5) µm thick, rough, continuous or often large-cloddy to granular, subhyaline to light yellowish-chlorinaceous. — **ANAMORPH**: vermispora-like (from ascospore isolate {2} and natural substrate {8}). **Conidiophores** branched, 16–25 × 2–4 µm. **Conidiogenous cells** *7–9 × 1.8–2 µm, conidia formed terminally. **Conidia** unbranched, canoe-shaped, *(22–)30–50(–60) × 2.7–4.2 µm {6}, †21–44 × 2.4–3.2 µm {2} (all in situ), towards ends slightly to strongly curved (by 30–45°, at upper end up to 90°), middle part straight to slightly curved, (3–)7(–8)((–10))-septate; overmature wider [up to 5.5(–7.5) µm], more or less constricted at septa.

Habitat: dead, standing, more rarely fallen, 10–25 cm thick {20} trunks with loosely adhering bark, also on still-attached or fallen corticated twigs and branches, 5–25 mm {20} or 25–100 mm thick {21}, collected 0–4 m above the ground, bark still hanging or fallen in ± large pieces to the ground, of *Broussonetia papyrifera* {1}, *Ficus carica* {2}, *Morus nigra* {1}, *Robinia pseudoacacia* {1}, *Ulmus* sp. {33/8}, *U. glabra* {18/1}, *U. minor* {10/3}, *Wisteria* sp. {1}, on bark {77}, often on inner surface or on edges of bast {> 26}, also on outer surface of bast {15} or periderm {15}, partly over cracks, slightly to medium (to strongly) decayed, sometimes in beetle galleries, ungreyed, usually without but sometimes amidst abundant green algae, especially when on outer surface, then often growing among or on old perithecia or pycnidia {6} in small holes or cracks of periderm provoked by these fungi (*Chaetosphaeria*, *Diaporthe*, *Eutypella*, *Nectria*, *Thyridaria*, ?*Diplodia melaena* and others). **Associated**: *Annulohypoxylon*

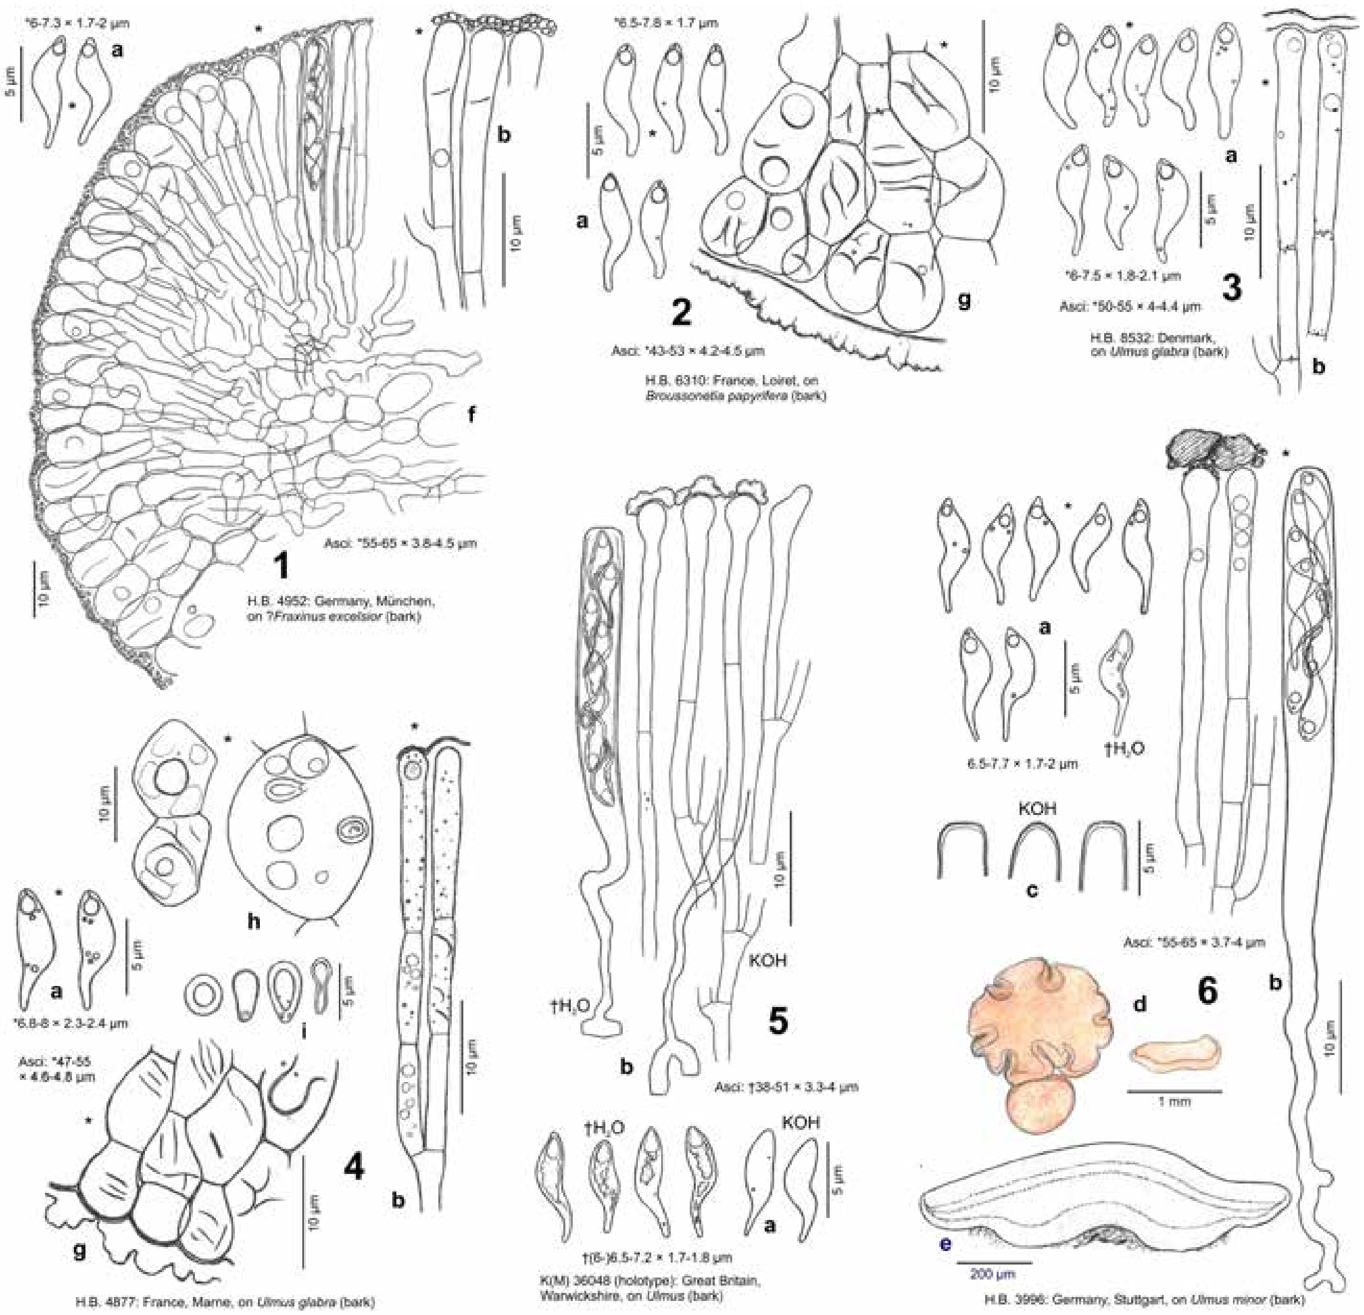

Plate 421. **1–6**: *Orbilia comma*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices (immature); **d**. apothecia (fresh); **e**. apothecium in median section; **f**. id., marginal ectal excipulum; **g**. id., at mid flanks; **g–i**. crystalloid SCBs in cells of ectal excipulum at flanks.

cohaerens {1}, *Auricularia auricula-judae* {1}, *Bionectria ralfsii* {1}, *Chaetosphaeria ovoidea* {1}, *Cistella chlorosticta* {1}, *Crepidotus cesatii* {1}, *Diaporthe* sp. {2}, *D. eres* {1}, *Eutypa* ?*stellulata* {1}, *Helminthosporium velutinum* {2}, *Hyalorbilia erythrostigma* (parasitic on *B. ralfsii*) {1}, *Lachnella alboviolascens* {1}, *Nectria* sp. {2}, *N. pseudopeziza* {2}, *Nitschkia* ?*collapsa* {1}, *Orbilia aurantiorubra* {1}, *O. auricolor* (anamorph) {1}, *O. carpoboloides* {2}, *O. ficicola* {2}, *O. rubella* {2}, *O. subfabacearum* {1}, *O. vitalbae* {1}, *O. xanthoguttulata* {1}, *Parmelia* sp. {1}, *Patellaria atrata* {1}, *Peroneutypa scoparia* {1}, *Pyrenopeziza caespiticia* {1}, *Thyridaria rubronotata* {1}, *Unguiculariopsis rehmii* {1}. **Desiccation tolerance**: Fully viable after 13 months, after 22 months many cells of ectal excipulum alive, after 26.5 months still many spores alive. **Altitude**: 5–900 m a.s.l. **Geology**: Devonian slate, Cambrian greywacke, Permian Zechstein (dolomite), Muschelkalk, Keuper (clay, sandstone), Lower & Upper Jurassic & Cretaceous marl- & limestone, flysch, dolomite, Eocene calcareous marl, Tertiary molasse, Pleistocene loess, sand, silt & till; granite, gneiss, basalt. **Phenology**: throughout the year (long-lived).

Phenology of *O. comma*

Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
4	6	8	8	18	3	3	4	6	6	7	3

Taxonomic remarks. *Orbilia comma* is easily recognized by its curved (helicoid) ascospores consisting of a thick fusoid to fusiform upper part and a ± short tail or tail-like base. Due to the helicoid curvature of about one complete turn, the spores look in profile view ± geniculate near the base and thus provoke a comma-like appearance. In the European *O. mali* (series *Regales*) and the Asian *O. basiflexa* (section *Ovoideae*) the spores are somewhat larger and do not show a helicoid curvature, and no crystalloid SCBs could be observed. The (sub)tropical *O. neocomma* differs from *O. comma* mainly in narrower spores, and the tropical *O. caudata* (series *Piliferae*) in straight spores, elongate SBs, and the partial presence of glassy processes.

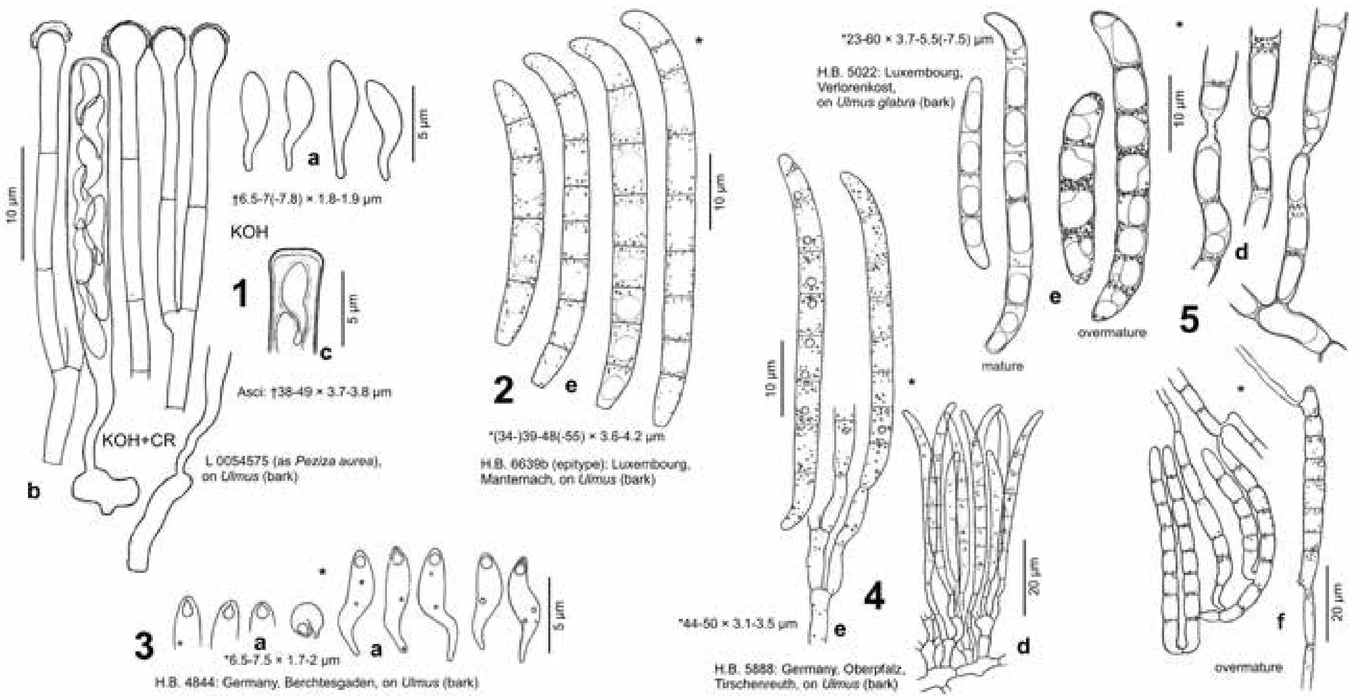

Plate 422. **1–5**: *Orbilia comma*. – **a**. ascospores (one seen from above showing helicoid curvature); **b**. ascus and paraphyses; **c**. ascus apex; **d–f**. conidiophores and conidia (**2** & **5** from culture, 4 from substrate).

Variation. The spores of *O. comma* vary somewhat in the shape of their apex (from obtuse to subacute), also in width (from *1.5–1.8 µm to *1.9–2.4 µm) and in tail length and width, but this variation is partly observed within a collection. The apothecia of *O. comma* are usually light to bright rose-orange but sometimes also much paler. In several collections the pale cream-coloured apothecia grew in populations more or less separate from the bright orange ones, but no microscopical differences were noted. The pale form appears to occur in more shady situations, on bark lying on the ground but also when still-attached. The yellow-orange LBs in the paraphyses and marginal ectal excipulum are only occasionally so abundant that they yield a distinct pale blue-green colour in IKI. Apothecial size may strongly vary among collections. For instance, apothecia in Pl. 423: 7 measured 0.2–0.25 mm diam., in 10b 0.25–0.5 mm, in 10a 0.5–1 mm, and in 2a 0.5–1.5 mm. No differences could be observed in collections on hosts other than *Ulmus*.

Type studies. Several differences between Graddon's (1977) protologue and the data here evaluated from the holotype (Pl. 421: 5) are worth mentioning. The rehydrated apothecia attain a size of 1.1 mm although Graddon gave the size as 'ad 500 µm'. Graddon described and figured the spores as comma-shaped (geniculate), apparently neglecting their helicoid shape (see Fig. 160). His figure shows viable spores which can be concluded from the drawn spore bodies ('guttula unica impleta'); nevertheless, his spore measurements (5–7 × 1.5–1.75 µm) are slightly smaller than evaluated here in the dead state from the type, and the SBs are ellipsoid instead of subglobose and more distant from the spore apex than found in the present reexamination. Graddon described the paraphyses as 'sine epithecio', although they are covered by rather thick exudate (Pl. 421: 5b). The ascus base he described as 'non-furcati', and he figured all 8 spores with their tails pointing downwards, a never seen situation in any of the here studied collections of *O. comma*.

A specimen from Luxembourg (Manternach, on *Ulmus*, ex H.B. 6639b), from which an ascospore isolate (CBS 116275) and a sequence were gained, is designated here as **epitype** of *O. comma*. Only a drawing of the conidia in culture exist for it (Pl. 422: 2), but a photo from an unpreserved topotype shows asci and spores (IVV: 10.II.2007), and from another topotype (G.M. 2016-05-04.2) a further sequence was gained.

Misapplication. The material treated in Breitenbach & Kränzlin (1981) as *Habrostictis rubra* was found to be a mixture: the colour photo shows *O. comma*, whereas the microscopic drawing belongs to *O. carpoboloides* (an older name for *H. rubra*). The report of a distinct blue-green-olive IKI reaction in *O. comma* by Baral (1987b) concerns a misidentification and refers to *O. xanthoguttulata*. Persoon's concept of *Peziza aurea* included a mixture of *O. xanthostigma*, *O. comma*, and *Dacrymyces chrysocomus* (see under *O. xanthostigma*, p. 1405). The *O. xanthostigma* collection is designated here as lectotype of *P. aurea*, because Donk's (1964) designation of the *O. comma* collection is in conflict with the protologue.

Anamorph. The phragmosporous conidia of *O. comma* have repeatedly been observed on the natural substrate close to apothecia (Pl. 422: 4), partly in black fruitbodies of old perithecia or pycnidia of unidentified ascomycetes. In two ascospore isolates the same anamorph developed in pure culture (Pl. 422: 2, 5).

Phylogeny. Sequences were taken from one of our ascospore isolates of *O. comma* (H.B. 6639b, from Luxembourg, *Ulmus*, SSU V8–V9, ITS, LSU D1–D2) and from apothecia from the same site 16 years later (G.M. 2016-05-04.2, ITS, LSU D1–D8). They fully concur in the ITS region with a sequence from apothecia (H.B. 9993, from Germany, Wismar, *Ulmus*, ITS, described and illustrated in Montag & Richter 2017: 62). In all the intron is absent.

O. comma clustered highly supported in the core clade of section *Aurantiorubrae* when analysing (SSU+)ITS+LSU (Baral et al. 2017b, Phyl. 13). The distance in the ITS region is generally high, with 13–14% to *O. aurantiorubra*, 13.5% to *O. phragmotricha*, 14.5% to *O. mali*, 16% to *O. rubella*, and 16–17.5% to *O. jugulospora*. In the LSU region (D1–D2) the minimum distance was 3.7% to *O. phragmotricha* and 4% to *O. aurantiorubra* and *O. jugulospora*. In the SSU (V8–V9) *O. comma* concurs with *O. aurantiorubra* but differs from *O. phragmotricha* by 3 nt. Interestingly, the two strains of *O. comma* deviate at pos. 128 of 5.8S by C instead of T as in all other *Orbiliomycetes*, except for *O. guyanensis* (G), see Tab. 18).

A sequence of a specimen identified by B. Liu as *O. brasiliensis* or *O. decipiens* (B.L. 4099, HMAS 139701), for which no illustration was available, comprises ITS and LSU. It showed a high distance to *O. comma*, with which it formed a weakly supported clade when analysing LSU (Phyl. S16).

Ecology. *O. comma* appears to be rather common in suitable forests at planar to colline but also montane altitude in meso- to orotemperate and hemiboreal humid but also submediterranean semihumid, atlantic to continental Europe. The species was almost exclusively found on slightly or medium decayed bark of *Ulmus* (*Ulmaceae*), on xeric or sometimes recently fallen twigs, branches and trunks, mainly from trees that were killed by the elm disease. Especially those large pieces of bark that detach from the dead main trunk often bear thousands of apothecia of this *Orbilia*. In western and southern Europe a few samples indicate occurrence on *Moraceae* (*Broussonetia*, *Ficus*, *Morus*), Further exceptions concern two collections on *Faboideae*: on *Robinia* in southern France (according to wood anatomy) and on *Wisteria* in Denmark.

The vegetation includes thermophilous but also shady, e.g. riparian, rather undisturbed forests on more or less rich soils, such as *Pruno-Fraxinetum*, *Fraxino-Aceretum pseudoplatani*, and *Querco-Ulmetum*. The collections from southern France on *Ficus* were in small dense mixed angiosperm woodlands with *Fraxinus* etc. in the suprasub- to mesosubmediterranean lower Rhône valley, and that on *Robinia* in a suprasubmediterranean forest in the Massif Central (Cevennes). The sample on *Morus* in Ticino was on branches cut and deposited on a heap a few years ago (F. Delmenico pers. comm.), while that on *Wisteria* was on an attached branch (T. Læssøe pers. comm., see https://svampe.databasen.org/observations/9187203). In eastern Europe, *O. comma* was recorded on *Ulmus* in continental, cold-temperate to thermoboreal Russia (E. Popov pers. comm.) and suprasubmediterranean Ukraine (Yatsiuk 2018).

Previously, *O. comma* has been recorded merely from Great Britain. Clark (1980a, 1980b) discovered the fungus in Warwickshire, but reported also collections from Yorkshire and Scotland (Perth). The database of the British Mycological Society reports 39 records for Great Britain and northeastern Ireland, most of them on *Ulmus*, but also some questionable ones on other hosts (Kirk & Cooper, http://www.fieldmycology.net/Index.htm, accessed III.2015).

Specimens included. **GREAT BRITAIN**: **Yorkshire**, **South Yorkshire**, 18 km ESE of Sheffield, 2 km SE of South Anston, Anston Stones Wood, 80 m, branch of *U. glabra*, on bark, 16.V.2011, P. Thompson & B.M. Spooner (ø). – ibid., 1.3 km SE of South Anston, 90 m, branch of *U. glabra*, on bark, 16.V.2011, H.O. Baral, J.H. Petersen & T. Læssøe (H.B. 9510, J.H.P. 11.108, P.T., K(M) 170582, 1785472). – **East Midlands**, **Nottinghamshire**, 8.5 km SW of Gainsborough, 6 km ENE of Retford, Clarborough, 60 m, branch of ?*Ulmus*, on bark, 3.III.2014, H. Williams (H.W. Box A14, doc. vid.). – **West Midlands**, **Herefordshire**, 10.5 km SW of Ludlow, 8.5 km NNW of Leominster, N of Croft Castle, Fishpool Valley, 197 m, branch of *U. glabra*, on bark, 4.XII.2016, P. Thompson (P.T. 4/12/16-15, anam. substr., doc. vid.). – **Warwickshire**, 6 km WSW of Stratford-upon-Avon, S of Binton, Binton Hill, ~80 m, branch of *Ulmus*, on bark, I.1975, M.C. Clark (W.D. Graddon 2489, K(M) 36048, **holotype**, H.B. 5532 ø). – **East England**, **Suffolk**, 3.7 km ESE of Halesworth, NNW of Wenhaston, Bicker's Heath, 17 m, trunk of *U. minor*, on bark, 19.VII.2004, E. Batten (E.B. 4545, K(M) 158892, doc. vid.). – ibid., branch of *U. minor*, on bark, 22.VIII.2004 (E.B. 4553, K(M) 158893, doc. vid.). – ibid., 12.IX.2004 (E.B. 4560, K(M) 188009, doc. vid.). – ibid., 25.XII.2004 (E.B. 4575, K(M) 158910, doc. vid.). – ibid., 31.X.2004 (E.B. 4570, K(M) 199079, H.B. 7613a, anam. substr.). — **NORWAY**: **Aust-Agder**, 5 km ENE of Arendal, Tromøy, Kvernhuskjerr, 18 m, trunk of *U. glabra*, on bark, 12.IV.2008, T.H. Welwitsch (herb. Martius, BR, H.B. 8790 ø).

Orbilia neocomma Baral, S.F. Li, J.W. Guo, Z.F. Yu & G. Marson, **sp. nov.**, MB 825632 — Pls 424–425, Map 74

Etymology: named after the close resemblance to *O. comma*.

Typification: Australia, Queensland, Mingela, branch of indet. climber, 17.X.1998, G. Marson (ex H.B. 6280f, BRI AQ799182, holotype).

Latin diagnosis: *Similis* Orbiliae commae *sed ascosporae angustiores, cauda basali distincte curvata. Habitat ad corticem putridum ramulorum vel ramorum siccorum fruticum angiospermarum in zona tropica vel subtropica humida ad subhumida Americae septentrionalis et meridionalis, Asiae et Australiae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.25–)0.3–1(–1.5) mm diam., 0.13–0.2 mm high (receptacle 0.09–0.1 mm), pale to bright orange-rose, ± translucent, round to somewhat undulating, scattered to gregarious; disc slightly concave to slightly convex, margin distinct, 0–10(–30) µm protruding, smooth to very finely crenulate; sessile on a broad or narrow base, superficial, partly, immersed between fibres; dry light to deep orange(-rose). **Asci** *45–52 × 4.2–4.5(–5) {T}, †(25–)35–47(–53) × (3–)3.2–4(–5) µm {4}, 8-spored, spores *2–3-seriate (†1–2-seriate), intertwined, 4–5(–6) lower spores inverted {2} (often mixed); **apex** (†) strongly truncate (not or very slightly indented, laterally sometimes inflated); **base** with short to long, ± thin, flexuous stalk, T- to L-shaped. **Ascospores** *(5–)6–8(–9) × (1.3–)1.4–1.5(–1.6) µm {3} (~6–10 µm actual length), †(6–)6.5–7.5(–8.5) × 1.1–1.4 µm {3}, fusoid-clavate, apex obtuse to subacute, base strongly attenuated in a tail-like end or distinct tail *(1–)1.5–2(–2.5) × 0.3–0.6 µm, strongly helicoid (in profile view appearing 2–3× geniculate), tail straight or often slightly to strongly curved, entire spore strongly helicoid, performing ~1–1.5(–2) turns; **SBs** *0.9–1.5 × 0.7–0.9 µm {2}, (sub)globose to broadly tear-shaped, apically narrowed to a very short filum. **Paraphyses** slightly to medium (rarely strongly) clavate-capitate, terminal cells *14–22 × 3–4.2 µm {T}, †12.5–20.5 × 2.5–3.5 µm {1}, lower cells *9.5–14 × 1.5–2 µm {T}, †6–11 × 1.3–2 µm {1}; unbranched at upper septum. **Medullary excipulum** 50–90 µm thick, of dense textura intricata with many inflated cells, medium to sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, vertically oriented t. globulosa-prismatica from base to margin, 40–100 µm thick near base, cells *10–19(–26) × 9–16(–19) µm {3}; 30–40 µm thick at lower flanks, 15–20 µm near margin, of t. prismatica oriented at a 40–80° angle to the surface, marginal cortical cells */†6–10 × 2.5–4 µm {3}; **glassy processes** absent {4} or 1–3 × 3 µm {1}. **Anchoring hyphae** abundant, */†1.7–3 µm wide, walls 0.2–0.3(–0.5) µm thick {3}, forming a loose t. intricata or dense t. porrecta up to 50 µm thick, partly gelatinized. **SCBs** in paraphyses globose, 1.5–2.5 µm diam., in ectal excipulum ~2.5–3 µm {3}, small ring-shaped or rhomboid crystalloid SCBs sometimes seen {2}, **VBs** absent {2} or present {1}, slightly refractive. **Exudate** over paraphyses (0.3–)0.5–2(–3) µm thick, cloddy to often cap-like, hyaline to pale yellow, firmly attached, over margin and flanks 1–2 µm thick. — **ANAMORPH**: unknown (but see below).

Habitat: collected 0.2–3.5 m above the ground, corticated to partially decorticated, 5–13 mm thick twigs and branches of indet. climbers {3}, *Ficus* ?*benjamini* {1}, indet. angiosperm {1}, on strongly decayed bark {4} (periderm {T} and bast {4}), on textile {1}; partly in clefts, sometimes on old pyrenomycete, ± greyed, no algae. **Associated**: *Hyalorbilia* cf./aff. *orbiliicola* (parasitic on *O. neocomma*) {1/2}, *Hysteropatella* ?*prostii* {2}, *Orbilia brachychitonis* {1}, *O. floridensis*

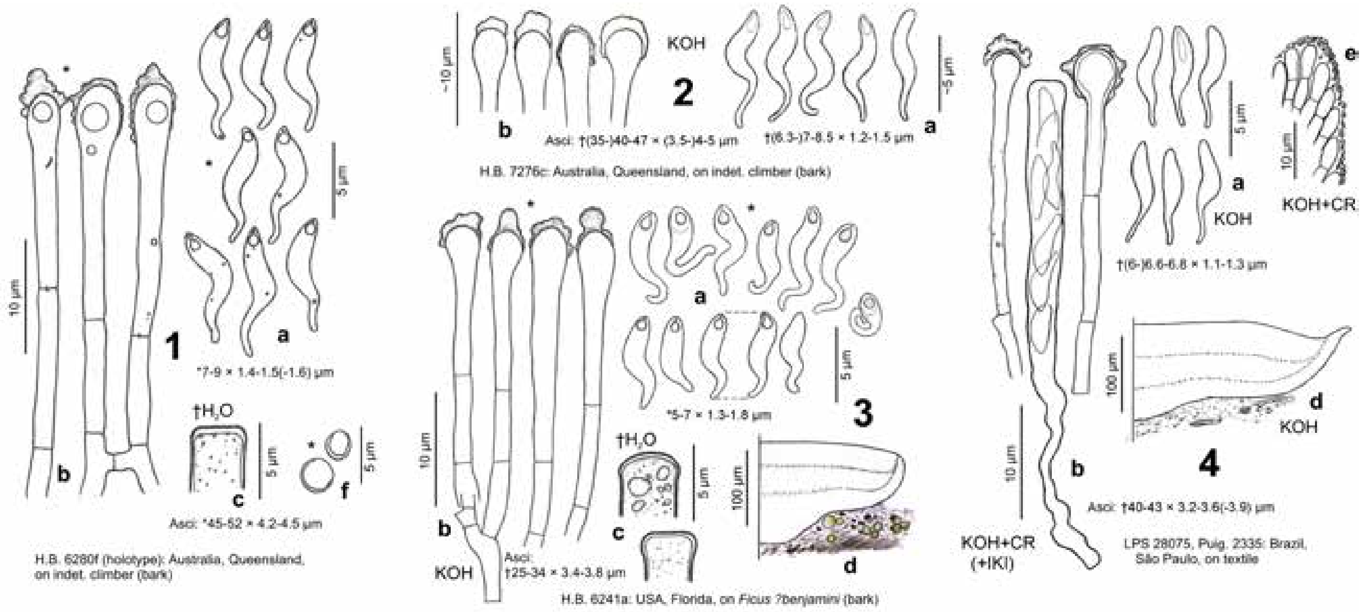

Plate 424. **1–4**: *Orbilia neocomma*. – **a**. ascospores (in 3a two ± in top view); **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., marginal ectal excipulum; **f**. SCBs in ectal excipulum.

{1}, *O. mammifera* {2}, *O. paracaudata* {1}, *O. scandens* {2}, *O. subfabacearum* {1}, *Rhytidhysteron ?rufulum* {1}. **Desiccation tolerance**: mature asci still viable after 2 months, some spores and many excipular cells still alive after 1 year. **Altitude**: 5–1850 m a.s.l. **Geology**: Devonian & Quaternary sedimentary rock; granite, metamorphic rock. **Phenology**: possibly throughout the year (rather long-lived).

Taxonomic remarks. *Orbilia neocomma* is very similar to European *O. comma*, from which it is separated by distinctly narrower ascospores with a tendency to perform 1.5(–2) turns, the curvature encompassing also the tail. Moreover, the exudate on the paraphysis apices of *O. neocomma* tends to form firmly attached caps. For the somewhat similar Australian *O. flexispora* (series *Orbilia*) see p. 1429.

Variation. Among the three Australian samples, two (Pl. 424: 1–2) have slightly longer spores than that from near Cairns (*/†6.5–7 × 1.2–1.3 µm) and a sample from Brazil (Pl. 424: 4). The shortest spores were found in the specimens from Florida (3) and China (Pl. 425: 3, *5–6 × 1.3–1.4 µm). In the Chinese one the paraphyses contained slightly refractive VBs, which were not seen in the three samples studied in the living state, instead, small crystalloid SCBs were seen in two of them (from Australia: Pl. 424: 1f; from Florida: IVV: H.B. 6241a). In the South American collection on textile (Pl. 424: 4) the margin distinctly protrudes, a feature not observed in the other specimens. Very short glassy processes were only seen in the sample from Cairns.

Map 74. Known distribution of *O. neocomma* in northeastern Australia.

Anamorph. In the holotype we found phragmoconidia (†47–63 × 3.3–4 µm, 9–11-septate, Pl. 425: 4) with curved ends which are similar in size and shape to the conidia of *O. comma*. However, in this collection several further *Orbilia* and one *Hyalorbilia* species were observed in the neighbourhood of *O. neocomma* to which the conidia might also belong.

Ecology. *O. neocomma* was found on rotten bark of xeric twigs and branches of angiosperms, mainly on twines of climbers, also on textile, in tropical to subtropical, humid to subhumid, winter-dry (monsoon-influenced) rainforests and savannahs in the Everglades of Florida (North America), South America, northeastern Australia (east of Great Dividing Range, here partly in eucalypt open woodlands), and southern China (montane evergreen broad-leaved forest).

Specimens included. **AUSTRALIA**: **Queensland**, Wet Tropics, 3 km NW of Cairns, 0.7 km E of Edge Hill, Cairns Botanical Garden, 5 m, branch of indet. climber, on bark, 26.VIII.2006, G. Marson (H.B. 8608a ø). – Einasleigh Uplands, 75 km SSW of Townsville, 2 km WSW of Mingela, 286 m, branches of indet. climber, on bark, 17.X.1998, G. Marson (ex H.B. 6280f, BRI AQ799182, **holotype**). – Brigalow Belt North, 49 km SE of Ayr, 4 km ESE of Gumlu, 12 m, twigs & branches of indet. climber, on bark, 19.X.1998, G. Marson (H.B. 7276c). — **USA**: **Florida**, 55 km SW of Miami, 12 km SW of Homestead, entrance to Everglades, branch of *Ficus ?benjamini*, on bark, ~12.IX.1998, L. Ferron (H.B. 6241a). — **BRAZIL**: **São Paulo**, 110 km NNE of Curitiba, Apiaí, ~900 m, on textile, X.1888, J. Puiggari (Puig. 2335, LPS 28075, separate convolute in holotype of *O. brasiliensis*, H.B. 6951b ø). — **CHINA**: **Yunnan**, **Yuxi**, Yimen, 54 km NW of Yuxi, NW of Fangtunxiang, Dalongkou, 1850 m, on branch of indet. angiosperm, V.2008, S.F. Li & J.W. Guo (J.W.G. ym2-16, YMFT, doc. vid.).

Orbilia disseminata (Henn.) Baral & E. Weber, **comb**. **nov**., MB 813747 — Pls 426–427

Basionym: *Helotium disseminatum* Henn., Hedwigia 41: 25 (1902)

Etymology: referring to the numerous, densely gregarious apothecia.

Typification: Brazil, Santa Catarina, Blumenau, leaves of *Arecales*, 1892, A. Möller (herb. Sydow, S-F9997, lectotype, designated here, MBT202635).

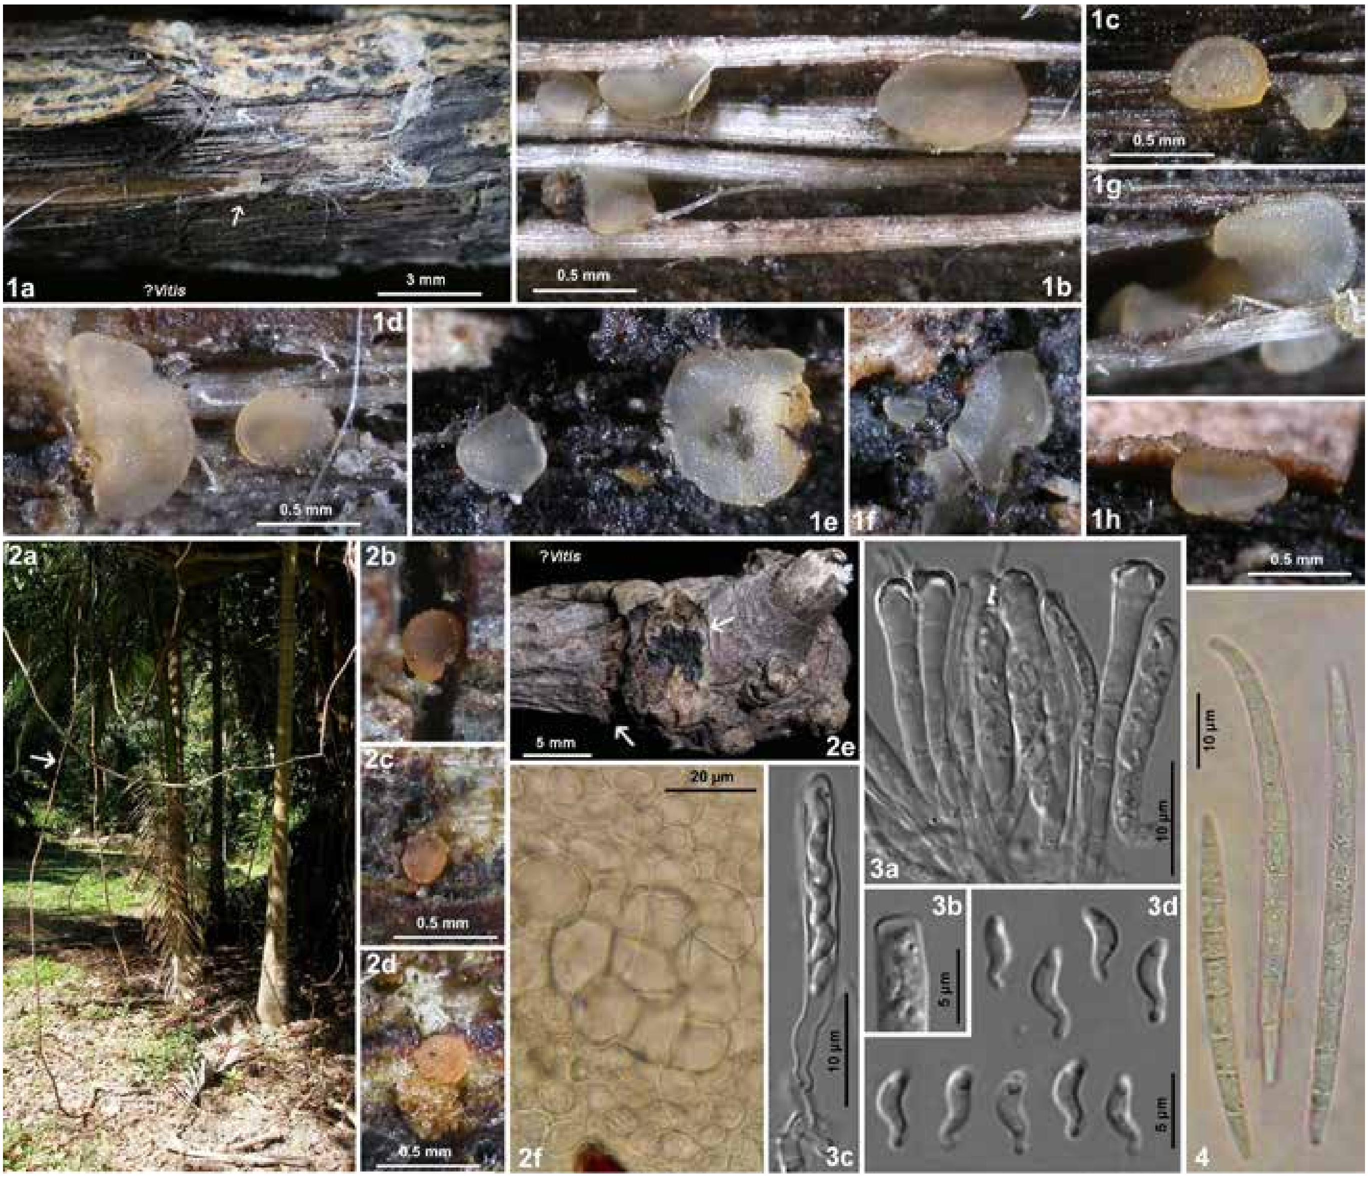

Plate 425. **1–4**: *Orbilia neocomma*. – **2a**. tropical rainforest with *?Cocos* and bamboo, hanging twines of indet. climber; **1a**. dead corticated twine; **1b–h**, **2b–d**. rehydrated apothecia; **2f**. basal excipular cells; **3a–c**. asci and paraphyses, ascus apex; **3d**. ascospores; **4**. conidia from substrate. – Living state, except for asci and conidia. – **3a–c**: phot. Z.F. Yu (DIC). — **1a–h**. H.B. 7276c: Australia, Queensland, Guthalungra, on indet. climber; **2a–f**. H.B. 8608a: ibid., Cairns, on indet. climber; **3a–d**. J.W.G. ym2-16: China, Yunnan, Yuxi, on indet. angiosperm; **4**. H.B. 6280f (holotype): Australia, Queensland, Mingela, on indet. climber.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1.2 mm diam., 0.26–0.3 mm high, light amber-ochraceous-brownish (Hennings: light yellow), slightly translucent, ± round, gregarious over large areas; disc flat, margin thin, not protruding, smooth or finely rough; broadly sessile or with an obconical broad base, superficial; dry bright reddish ochre-brown, without subiculum. **Asci** †35–42 × 3.6–4 µm, 8-spored, spores †2–3-seriate, 2 lower spores inverted; **apex** (†) strongly truncate (scarcely indented, laterally hardly inflated); **base** with short to medium long, ± thin, flexuous stalk, Y- or h-shaped. **Ascospores** †9–10 × 1.4–1.6 µm (~10–11 µm actual length), with narrowly fusoid upper part and sharply differentiated, very thin tail of †2.7–4 × (0.15–)0.25 µm, i. e., about half to nearly the length of the upper part, apex obtuse to subacute, medium to strongly helicoid; **SBs** visible as a very faint tear-shaped area. **Paraphyses** apically (medium to) strongly (to very strongly) capitate(-clavate), terminal cells †15–25 × 3–4.5 µm, lower cells †5–9.5 × 1.4–2.2 µm; unbranched at upper septum. **Medullary excipulum** 15–20 µm thick, of dense small-celled texture, sharply delimited. **Ectal excipulum** of thin-walled to slightly gelatinized, vertically oriented textura angularis-globulosa(-prismatica) from base to margin, 200–220 µm thick near base, cells †14–25 × 10–22 µm, common walls 0.2–1 µm thick; 20 µm thick near margin, oriented at a 70° angle to the surface, uppermost margin of t. prismatica oriented at ~45°, marginal cortical cells †11–19 × 5–10 µm, walls 0.3–1 µm thick; **glassy processes** absent. **Anchoring hyphae** restricted to the base, †2–4 µm wide, walls 0.2–0.4 µm thick, forming a dense, hyaline, 10 µm thick t. intricata-porrecta spreading over the substrate. **SCBs/VBs** no data available. **Exudate** over paraphyses (0.3–)1–2 µm thick, cloddy, hyaline, firmly or partly loosely attached, over margin and flanks 0.3–1 µm thick, sparse. **— ANAMORPH**: unknown.

Habitat: on medium rotten upperside of leaf sheaths of indet. *Arecales*, among the hairs and setae emerging from the host epidermis. **Associated**: none observed. **Desiccation tolerance**: unknown. **Altitude**: ~100 m a.s.l. **Phenology**: unknown.

Taxonomic remarks. *Orbilia disseminata* is easily recognized by its ascospores having abrupt, very thin tails. Herein the species differs from *O. comma* and *O. neocomma* which have spores of an otherwise similar shape and helicoid curvature. The spores of *O. disseminata* resemble in size and shape also those of *O. neglecta* (here assigned to series *Arthrobotrys*), but that species has falcate instead of helicoid spores, smaller and thinner apothecia with a distinct subiculum, almost no exudate at all, and partly H-shaped ascus bases.

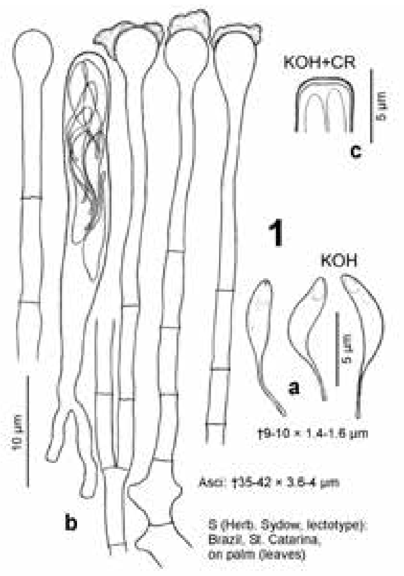

Plate 426. **1**: *Orbilia disseminata*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

Type studies. Hennings (1902a) described the spores as 'fusoid-acicular, strongly acute at both ends, 2-guttulate, 5–7 × 1–1.5 µm'. Dumont (1981: 334) stated the 'holotype' of *Helotium disseminatum* (in S) to be orbiliaceous, but he could not see any spores. In the present reexamination of this material, which is labelled 'isotype', only a few free spores could be found, and inside the asci they were only very difficult to see. Nevertheless, the apothecia in this rich material appear to be quite mature. The population looks homogeneous, for which reason a mixture would be highly improbable. Undoubtedly, Hennings overlooked the characteristic spore tails.

The convolute examined is obviously a syntype of *H. disseminata* and was sent by Hennings to Sydow, while Hennings' personal specimen in B was destroyed during the Second World War. The here redescribed duplicate in Sydow's herbarium is herewith designated as **lectotype** of *Helotium disseminatum* (Art. 9.11, Turland et al. 2018).

Ecology. *O. disseminata* was collected on dead, slightly rotten leaf sheaths of a palm in subtropical humid South America.

Specimens included. **BRAZIL**: **Santa Catarina**, 90 km NW of Florianopolis, Blumenau, ~100 m, leaf sheaths of *Arecales*, 1892, A. Möller (herb. Sydow, S-F9997, **lectotype**; H.B. 7690 [slide]).

Series *Rubellae*

Orbilia subgenus ***Habrostictis*** section ***Aurantiorubrae*** series ***Rubellae*** Baral & E. Weber, **ser. nov.**, MB 815009 –
Type species: *Orbilia rubella* (Pers.) P. Karst.

Etymology: named after the type species, *O. rubella*.

Latin diagnosis: *Apothecia rosea vel aurantia, margine albido-pilosa vel -dentata, pili marginales 1–10-septati, 3.5–6.5 µm lati, plus minusve crassitunicati, paraphyses apice spathulatae vel mammiformes.*

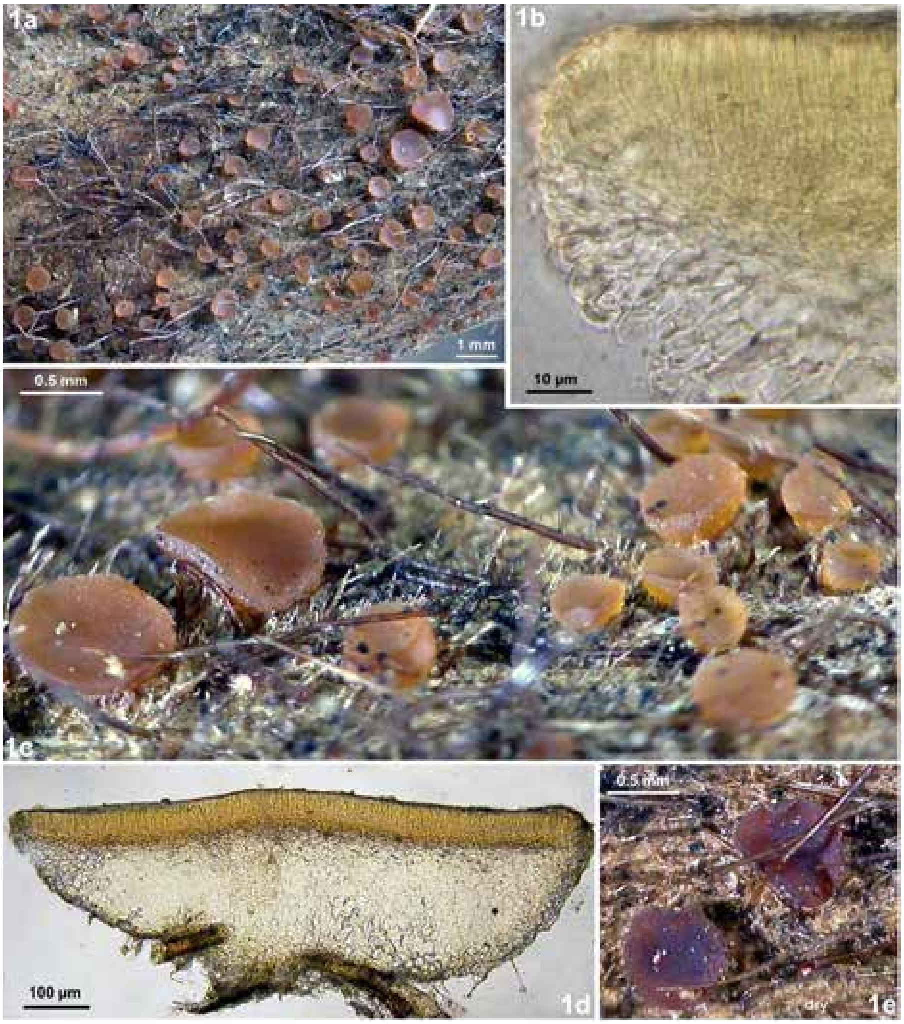

Plate 427. **1**: *Orbilia disseminata*. – **1a**, **c**. rehydrated apothecia; **1e**. dry apothecia; **1d**. apothecium in median section; **1b**. id., marginal ectal excipulum. – Dead state (in KOH). — **1a–e**. S (herb. Sydow, lectotype): Brazil, Santa Catarina, on indet. *Arecales*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.5–1.5(–3) mm diam., pale to bright rose-pink to orange-ochraceous, often somewhat urceolate, margin whitish pubescent-fimbriate or toothed, sessile or with a ± indistinct short stipe. **Asci** *35–60 × 3.3–5 µm, 8-spored, lower (2–)3–5(–7) spores inverted; **apex** (†) slightly to strongly truncate, not or slightly indented and laterally inflated; **base** T-, L- to Y-shaped. **Ascospores** *5.5–9.7 × 1–1.9 µm, subcylindric- to ellipsoid- or fusoid-clavate, apex obtuse to subacute, rarely rounded or acute, base often tail-like or with a distinct tail, straight or usually slightly to ± strongly curved or geniculate near base (often slightly helicoid), **SBs** 0.8–1.8 × 0.4–1 µm, globose to tear-shaped, apically narrowed to a small (sometimes wide) point, with a very short filum or attachment invisible. **Paraphyses** slightly to strongly spathulate to lageniform-mammiform at the apex, terminal cells (1.2–)1.5–3(–4)× longer than lower cells. **Ectal excipulum** cells near base *(7–)10–22(–34) × (5–)7–15(–18) µm, near margin forming thin- or often thick-walled cell rows; **hairs** free, 1–3- up to 3–10-septate, (10–)30–60(–93) × 3.5–6.5 µm, with †(0.3–)0.5–1.5(–2.7) µm thick lateral wall, **glassy processes** absent or present on tip of hairs, 10–60(–130) µm long. **SCBs** globose, often mixed with crystalloid ones; **VBs** consistently absent. **Exudate** 0.2–0.3 µm thick, continuous, indistinctly rough to granular, ± firmly attached over protruding part of paraphyses, rarely absent, over hairs sometimes up to 0.8 µm thick. — **ANAMORPH**: vermispora-like. **Conidiophores** not observed. **Conidia** phragmosporous, *28–78 × 3.5–6.7 µm (in situ), 3–15-septate, slightly to strongly curved (C- to ± canoe-shaped).

Key to the species of series *Rubellae*

1. Cellular part of hairs 30–60(–90) µm long, with 3–8(–10) septa, without or rarely with very short glassy caps of max. 1/10 of hair length 2

1. Cellular part of hairs 10–50 µm long, with (0–)1–3 septa, always tipped by glassy processes that are mostly longer than the cellular part 3

2. Spores *(5.5–)6–8.5(–9.8) × (1–)1.1–1.3(–1.5) µm, with a *0.3–0.6(–0.8) µm wide tail; bark of angiosperms (mainly *Salix*), thermoboreal to (oro)temperate and orosubmediterranean humid Europe, central Asia .... ***O. phragmotricha***, p. 826

2. Spores *(6.5–)7.5–9.3(–9.7) × (1.6–)1.7–1.8(–1.9) µm, base partly tail-like or with a *0.7–1 µm wide tail; inflorescence stems of *Yucca*, warm-temperate semiarid western North America .... ***O. paradoxoides***, p. 831

3. Spores †5.5–6.5 × 1.2–1.4 µm, sharply divided into an ellipsoid head and a filiform, †0.2–0.3 µm wide tail; glassy processes 10–22 µm long; bark of *Liquidambar*, warm-temperate humid eastern North America .... ***O. saccharifera***, p. 821

3. Spores *(7–)7.5–9.5 × 1.1–1.4 µm, with *0.4–0.8 µm wide tail or tail-like base; glassy processes 15–70(–130) µm long; bark of *Salix*, *Tilia* & *Ulmus* in cold-temperate humid central and northern Europe, bark of *Eucalyptus* & *Nerium* in inframediterranean semihumid southern Europe .... ***O. rubella***, p. 822

If cellular part of hairs with thin lateral walls, glassy processes 1–15 µm long, spores with acute apices: see *O. rehmii* (p. 904).

Habitat: on bark (exceptionally wood) of angiosperms, also inflorescence stems of large monocots, temperate to subtropical, humid to semiarid, always desiccation-tolerant.

Recognized species: 4.

Taxonomic remarks. Series *Rubellae* is erected here to include four species which are characterized by prominent, septate, mainly 4–6 µm broad, thick-walled hairs being partly tipped by glassy processes. Further characteristics include spathulate paraphyses and small, narrowly clavate ascospores with obtuse to subacute apices and slightly curved to geniculate tails or tail-like bases. The spore bodies are globose to broadly tear-shaped.

Series *Rubellae* appears to be morphologically close to series *Regales*, the latter differing mainly in the absence of septate marginal hairs and of crystalloid SCBs. Series *Commatoideae* and *Aurantiorubrae* differ from series *Rubellae* in the absence of septate hairs, predominant absence of glassy processes, in consistently capitate paraphyses, and the latter series also in narrowly tear-shaped to subulate SBs.

Species delimitation. The two European species *O. rubella* and *O. phragmotricha* have been confused in the past because of similar ascospores and hairs. However, the presence vs. absence of short to long glassy processes on the hair tips and differences in spore size unequivocally permit distinction between them.

Anamorph. Curved, vermispora-like phragmoconidia are known from pure culture in *O. phragmotricha* and from natural substrate in *O. rubella, O. saccharifera,* and *O. paradoxoides*. *O. phragmotricha* and *O. rubella* differ in longer conidia with more septa in comparison to *O. saccharifera,* and *O. paradoxoides*.

Phylogeny. DNA-data were available for two samples of *O. phragmotricha* (SSU+ITS+LSU) and two of *O. rubella* (ITS). When analysing (SSU+)ITS+LSU, series *Rubellae* clustered in the strongly or medium supported core clade of section *Aurantiorubrae* (Baral et al. 2017b, Phyl. 13) by forming a strongly or medium supported subclade with *O. aurantiorubra*/*O. jugulospora* and *O. comma*. Although *O. pisciformis* clustered highly supported as a sister taxon to series *Rubellae*, we preferred to keep it in series *Commatoideae* for morphological reasons.

Specific nucleotide positions. Molecular motifs to characterize series *Rubellae* have not been found, except for pos. 9 in the ITS2 region, which is ATTTCAAC**C** compared to **A** or **T** in other members of section *Aurantiorubrae* (*O. pisciformis* has ATTTCAAC**T**). Yet, species with **C** also occur in series *Abutilones*, *Albovinosae*, *Hyalinia*, and *Poitevinicae*, but only two share the motif ATTTCAAC**C** (*O. poitevinica*, *O. milinana* TFC Mic. 23222).

Ecology. All four included species are desiccation-tolerant and occur on woody angiosperms, mainly on bark, also on herbaceous stems. Different climatic regions are inhabited: *O. rubella* and *O. phragmotricha* were recorded from temperate to subalpine-boreal, humid to semihumid Europe and central Asia, whereas *O. saccharifera* is from subtropical humid eastern and *O. paradoxoides* from orotemperate semiarid western North America.

Orbilia saccharifera (Berk.) Baral, **comb. nov.**, MB 813748 — Pl. 428

Basionym: *Peziza saccharifera* Berk., Grevillea 3: 157 (1875)

≡ *Hymenoscyphus sacchariferus* (Berk.) Lindau, in Engler & Prantl, Nat. Pflanzenfam.1: 204 (1897)

≡ *Pseudohelotium sacchariferum* (Berk.) Sacc., Syll. Fung. 8: 298 (1889)

Etymology: referring to the marginal hairs of the apothecia resembling sugar-like granules.

Typification: USA, Alabama, unlocalized, branch of *Liquidambar*, undated, T.M. Peters (M.J. Berkeley 5208, K, holotype).

Misapplied name: Nannfeldt (1932: 252), as ?*Hyalinia rubella*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.7 mm diam., 0.12 mm high, light ochraceous throughout (Berkeley: 'pale orange'), round or often irregularly ellipsoid, margin ± undulating, gregarious; disc strongly concave, margin whitish-pubescent by short hairs projecting ~30 µm, exterior pubescent to furfuraceous; broadly sessile, superficial; dry deep ochre, margin ± incurved. **Asci** †(33–)35–47 × 3.2–3.6 µm, 8-spored, spores ± biseriate, ~4 lower spores inversely oriented; **apex** (†) slightly to medium truncate; **base** with long, thin, flexuous stalk, Y- to mostly L-shaped. **Ascospores** †5.5–6.5 × 1.2–1.4 µm, with ellipsoid-fusoid upper part and rather sharply differentiated narrow tail 2–2.8 × 0.2–0.3 µm, apex obtuse, tail often ± geniculate; **SBs** not seen. **Paraphyses** apically slightly clavate or often spathulate to obtusely lanceolate, terminal cells †(11.5–)15–22 × 2.4–3 µm, exceeding the asci by 3–6 µm, lower cells †6.5–9 × 1.3–2 µm, unbranched at upper septum. **Medullary excipulum** hyaline, 30–40 µm thick, of dense textura intricata, horizontally oriented, individual cells not clearly seen. **Ectal excipulum** hyaline, of thin-walled, indistinctly vertically oriented t. angularis from base to flanks, 20–25 µm thick near base, cells †7–12 × 5–9 µm, 15 µm thick at mid flanks, 10 µm at margin, here of t. prismatica oriented at a 30° angle; marginal cortical cells terminated in numerous hairs 30–50 × 4–6.5 µm, with a basal ~ 1–3-septate cellular part with †0.5–1 µm thick lateral walls, terminated by **glassy processes** 10–22 × 3–4.5(–5.5) µm, strongly stratified, medium refractive, curved ± outwards, hairs slightly agglutinated to form indistinct small teeth. **Anchoring hyphae** abundant, †2–3.4 µm wide, walls (0.2–)0.3–0.8 µm thick, forming a ± loose, gelatinized t. intricata 40–60 µm thick, covering lower flanks as a 5–20 µm thick gelatinized layer. **SCBs** no data available. **Exudate** over paraphyses very thin, smooth or finely rough, covering the protruding part, on hairs almost absent. **— ANAMORPH**: vermispora-like (presumed, from natural substrate {1}). **Conidiophores** not seen. **Conidia** unbranched, strongly curved (C-shaped), †28–30.5 × 4.5–4.8 µm, 3–5-septate.

Habitat: on thin, slightly decayed bark of corticated, ?thin branch of *Liquidambar* sp., in and along small cracks in periderm, slightly greyed, nearly no algae, closely associated with old black subperidermal ?pycnidia of unknown fungus. **Desiccation tolerance**: unknown, but certainly a desiccation-tolerant species, judging from orange-coloured, hairy apothecia and the greyed bark surface. **Altitude**: unknown (< 500 m a.s.l.). **Phenology**: unknown.

Taxonomic remarks. *Orbilia saccharifera* is characterized by short marginal hairs consisting of a solid glassy upper part and a basal thick-walled and septate lower part, and by small ascospores with a distinct tail. The species is similar to the European *O. rubella*, especially in hair characters. The spores more resemble those of the European *O. phragmotricha* but have a broader, more ellipsoid upper part and a thinner, more abruptly separated tail. The latter species also differs in the absence of glassy processes. The Australian *O. nanosperma* is comparable in having almost the same spore shape and size. However, this species is assigned to section *Hemiorbilia* here because the asci are provided with an apical dome.

Type studies. Although the protologue is devoid of microscopic features, it clearly concurs with the holotype which contains a single piece of bark with over a hundred apothecia. The sketch on the convolute shows apothecia, an ascus and a paraphysis probably drawn by Berkeley, with the remark 'spores not seen'. Free spores are indeed rare, but spores within asci were sometimes visible in CR mounts. A further remark 'cells on exterior darker brown and larger, forming granules on the surface' does not appear in the protologue. Such cells were not seen in the present reexamination, and probably refer to black yeasts on the apothecial exterior.

Nannfeldt (1932: 252) believed that *Peziza saccharifera*, *P. cruenta* Schwein. and some other taxa represented possible synonyms of *Hyalinia rubella* (s. Nannfeldt, = *Orbilia phragmotricha*), based on Massee's (1894b) redescription who examined the type material of *O. saccharifera* and considered it as a synonym of *P. cruenta*. Obviously, Massee overlooked the distinct spore tails when describing the spores as cylindric-oblong. Perhaps he saw spores only in the type of *P. cruenta* which could not be located in the present study (see p. 1668).

In the paper of Berkeley (1875), the type collection of *O. saccharifera* ('Berk. 5208') is, apparently in error, cited a second time under *Peziza rubella* a few lines before. As is seen on the label, this collection was first identified as *P. rubella* and later changed to *P. saccharifera*. It shares indeed many features with the European *O. rubella*.

Anamorph. The presumed anamorph of *O. saccharifera* with its strongly curved, canoe-shaped conidia is similar to that of *O. aurantiorubra* and many other species of this section (Pl. 428: 1g).

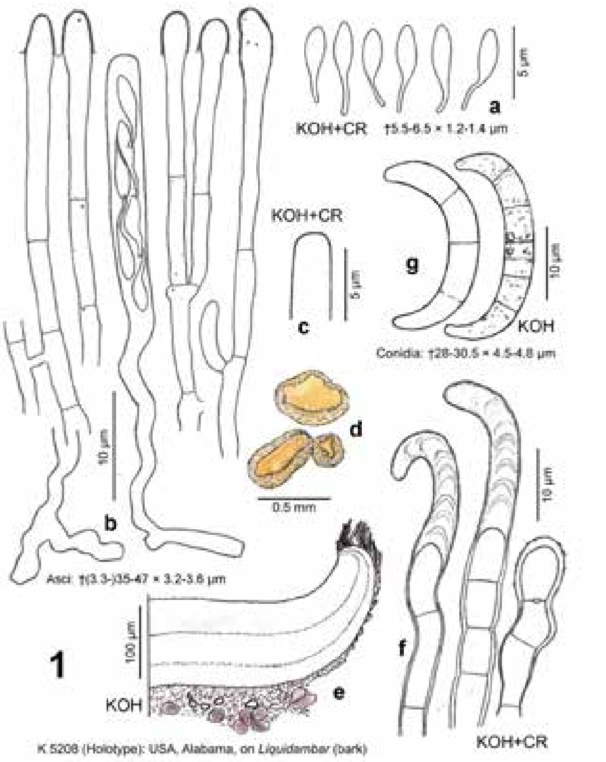

Plate 428. **1**: *Orbilia saccharifera*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. marginal hairs with glassy processes; **g**. conidia from substrate.

Ecology. *O. saccharifera* was collected on slightly decayed bark of a probably thin, obviously xeric branch of *Liquidambar* in warm-temperate humid eastern North America. The unknown type locality might have been in the centre of Alabama in the forests around the university, or in the hilly north where T.M. Peters also used to collect.

Specimens included. **USA**: **Alabama**, unlocalized, branch of *Liquidambar* [*styraciflua*], on bark, undated, T.M. Peters (herb. Berkeley 5208, K, **holotype**, H.B. 5345 ø, anam. substr.).

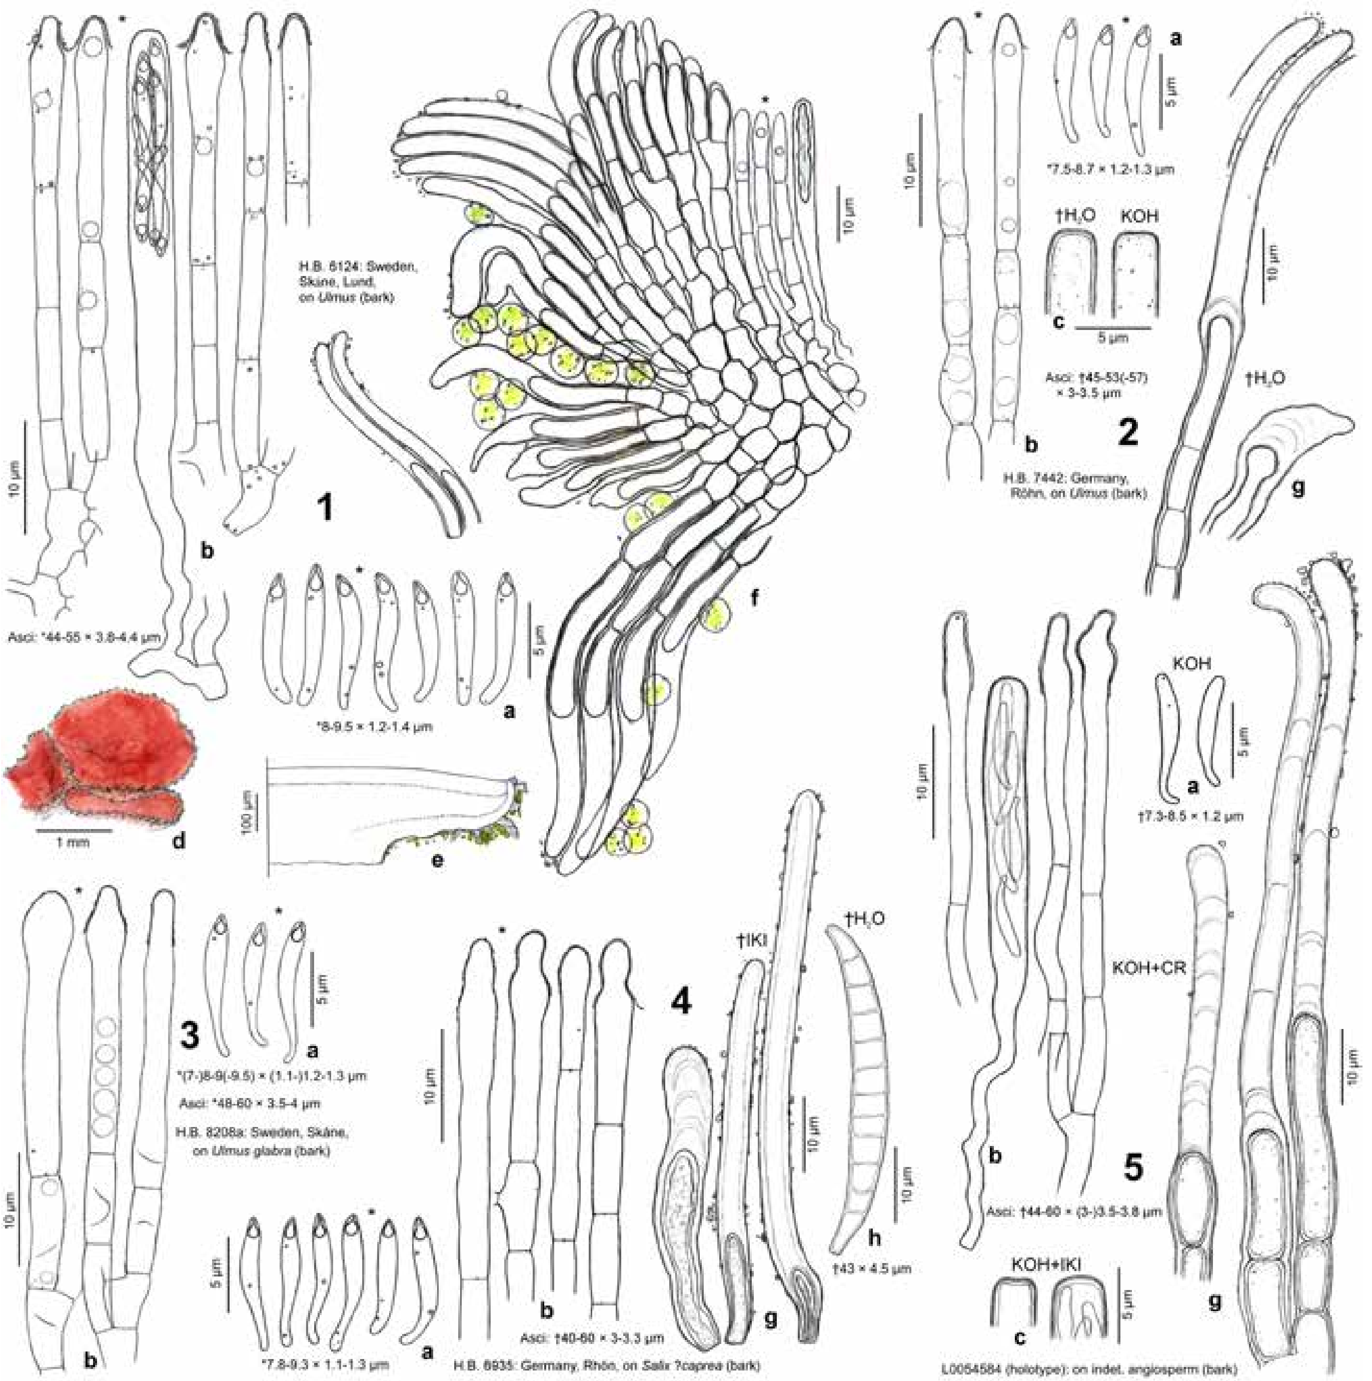

Plate 429. **1–5**: *Orbilia rubella*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia with dentate-hairy margin; **e**. apothecium in median section; **f**. id., ectal excipulum and hairs at margin and mid flanks; **g**. hairs tipped by long glassy processes; **h**. conidium from substrate.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.4–)0.6–2(–3) mm diam., 0.14–0.25 mm high (receptacle 0.1–0.18 mm), light to bright orange-rose to rose-pink, round to elliptical, somewhat compressed or undulating when fasciculate, scattered to loosely or densely gregarious in smaller or larger groups; disc young urceolate with incurved margins, soon ± flat, sometimes slightly convex, margin distinctly whitish(-yellowish) hairy or usually toothed, 10–90(–130) µm protruding (incl. hairs), teeth 50–160 × 50–100 µm; broadly sessile or with a broad, ± distinct stipe-like base 0.06–0.1 × 0.3–0.6 mm, superficial; dry light to bright cream- to orange-rose, margin somewhat inrolled. **Asci** *44–60 × (3.5–)3.7–4.5 µm {4}, †40–60 × 3–3.8 µm {4}, 8-spored, spores *4-seriate, (2–)3–5(–6) lower spores inverted {5} (sometimes mixed), pars sporifera *20–25 → 19 µm long; **apex** (†) medium to strongly truncate (not indented, laterally sometimes very slightly inflated); **base** with medium to very long, thin, flexuous stalk, T- to L-shaped. **Ascospores** *(7–)7.5–9.5 × 1.1–1.4 µm {6}, †7–8.5(–9.5) × 1–1.2 µm {2}, cylindric- to fusoid-clavate, partly subcylindrical, apex obtuse to subacute (to acute), base medium to strongly, rarely hardly attenuated, tail-like or with a distinct tail 1–3 × 0.4–0.8 µm, straight to somewhat curved, near base often slightly to medium geniculate (partly even helicoid); **SBs** *1.3–1.8 × 0.8–1 µm {5} tear-shaped, apically narrowed to a small point or very short filum. **Paraphyses** apically obtusely lanceolate to spathulate or lageniform, exceptionally ± cylindrical, terminal cells *(11–)14–25(–30) × 2.3–3.7(–4.2) µm {4}, †20–25.5 × 2.3–3 µm {1}, exceeding the living submature asci by 0–6 µm, lower cells *(5–)7–15 × 2–3.2(–4) µm {4}, †8–12 × 1.5–2(–2.7) µm {1}; unbranched at upper septum; hymenium pale rose. **Medullary excipulum** hyaline to pale rose, 40–120 µm thick, of medium dense textura intricata with many inflated cells, or of t. globulosa-angularis, indistinctly to sharply delimited from ectal excipulum from base to margin by a 10–40 µm thick layer of t. porrecta. **Ectal excipulum** subhyaline to light rose, of (†) thin-walled, vertically oriented t. globulosa-angularis-prismatica from base to mid flanks, 50–90 µm thick near base, cells *(8–)10–22(–30) × 7–17 µm {4}; 40–50 µm thick at lower flanks, 20–30 µm at mid flanks and margin, at submargin of t. prismatica(-angularis) oriented at a 45–80° angle to the surface, partly slightly gelatinized, at margin of t. prismatica oriented at 10–80°, marginal cortical cells */†(7–)9–18(–27) × 3–5(–6) µm {4}, agglutinated or somewhat free; **hairs** at margin and flanks 30–160 µm long, cellular basal part 10–50 × 3.5–6.5 µm, (0–)1–2(–3)-septate, lateral walls †(0.3–)0.5–1(–1.7) µm thick, terminated by **glassy processes** (3–)15–60(–100) {6} or (20–)100–130 {T} × (2.8–)3.5–5(–7.3) µm {7}, refractive, not or distinctly stratified, free or cohering to form teeth, usually more or less strongly outwards curved (but apices sometimes strongly inwards). **Anchoring hyphae** abundant, */†1.7–3 µm wide (near insertion 3.5–5 µm), walls 0.2 µm thick {3}, without or with up to 1 µm thick gelatinous sheath, forming a loose to medium dense hyaline t. intricata ~20–70 µm thick. **SCBs** usually present, globose, very low-refractive {4}, 1.5–2.5 µm diam., also thin plate-like or filiform, crystalloid SCBs in lower part of paraphyses and in excipular cells near base {3}. **Exudate** over paraphyses and glassy processes 0.1–0.3 µm thick, continuous to finely rough or granular, ± firmly attached. **— ANAMORPH**: vermispora-like (presumed, from natural substrate {4}). **Conidiophores**: not observed. **Conidia**: */†(28–)42–51 × 3.5–4.5 µm, (5–)8(–11)-septate {3}.

Habitat: (0–)1–2 m above the ground, on corticated, 6–60 mm thick (or more), still-attached, dead branches or standing trunks, also broken branches or detached bark lying on the ground (more or less exposed), of *Eucalyptus* sp. {1}, *Nerium oleander* {1}, *Salix caprea* {3/1}, *Tilia* sp. {1}, *Ulmus* sp. {2}, *U. glabra* {7}, on medium to very decayed bark {17} (bast, sometimes periderm), bark ± detaching, on outer but also inner surface, apothecia partly on periderm-free areas, sometimes entirely covered by loose periderm, often over or in holes of periderm, ungreyed, mostly without but sometimes covered by abundant green algae, closely associated with old perithecia of *Nitschkia* {1}, ?*Eutypella* {1}, indet. pyrenomycete {1}. **Associated**: ?*Eutypella* sp. {1}, *Graphis scripta* {1}, *Nitschkia* ?*collapsa* {1}, *Orbilia comma* {2}, *O. phragmotricha* {1}, *O. xanthoguttulata* {3}. **Desiccation tolerance**: a few asci survived for 2 weeks, ectal and medullary excipular cells and some paraphyses still viable after 3 months. **Altitude**: 5–135 m a.s.l. (Scandinavia), 590–800 m (central Europe), 110–530 m (southern Europe). **Geology**: humid Europe: Buntsandstein; granite, granitoid, gneiss, basalt; semihumid Europe: Carboniferous schist and greywacke, Lower Jurassic dolomite & marl. **Phenology**: I–VI, XI (rather long-lived).

Taxonomic remarks. *Orbilia rubella* is a rather constant, easily recognizable species, being characterized by prominent hairs consisting of a long, solid glassy upper part and a thick-walled, often septate, mostly shorter lower part. The closely related *O. phragmotricha* and *O. paradoxoides* differ in multiseptate hairs with or without very short glassy processes, the former also in smaller ascospores with a more distinct, thinner tail-like base and smaller SBs. Hairs similar as in *O. rubella* occur in the North American *O. saccharifera*, which deviates in much smaller spores with an abrupt tail. Species of series *Regales* (e. g., *O. aradi*, *O. euphorbiae*, *O. puyae*) have similar spores but are devoid of septate hairs, instead, their short glassy processes emerge directly from the marginal cells. *O. rehmii* (series *Abutilones*), on bark of *Malus*, resembles *O. rubella* but differs in much shorter glassy processes on thin-walled hairs, partly clavate paraphyses, and spores with acute apices.

Variation. Mainly the length of the glassy processes varies to some extent among the studied populations of *O. rubella*, being longest in the holotype. Yet, this character was generally found to vary considerably within *Orbilia* at the species level. Also the spores vary somewhat between cylindric- and fusoid-clavate, their bases being usually distinctly but sometimes only scarcely attenuated. One of the mediterranean samples from Portugal (on *Nerium*, IVV: H.B. 9980) did not deviate from those from cold-temperate Europe; its spore size of *7.5–9.5 × 1.2–1.4 µm fits perfectly, but the glassy processes were with 13–45 × 3–3.5 µm at the lower end of the range. The other (on *Eucalyptus*) was not studied by us, and only macrophotos of the apothecia and a microphoto of the hairs exist.

Nomenclature and type studies. The diagnoses of earlier authors are not adequate enough to recognize *O. rubella* as circumscribed in the present study. Except for a few of their voucher specimens which were reexamined and identified here as *O. phragmotricha*, *O. xanthoguttulata*, and *O. rehmii*, the identity of these reports remains unclear. This inadequacy was also emphasized by Rehm (1891: 459) who doubted whether the identity of Karsten's concept of *O. rubella* with that of Persoon will ever become clear. Phillips (1887: 334) described *C. rubella* with smooth apothecia and cylindrical spores of 6 × 2 µm, data excluding any of these species. Nannfeldt's (1932: 252) rather broad concept of *Hyalinia rubella* includes various orbiliaceous species (see under *O. phragmotricha*, p. 826, also under *O. cruenta*, p. 1668), whereas Saccardo's (1888: 778) interpretation refers to a basidiomycete (?*Sebacinales*).

Persoon (1801: 635), who collected *Peziza rubella* 'in spring on rotten bark', briefly described the apothecia as: 'fleshy-gelatinous, smooth, flesh-red (incarnato-rubra), subflexuous, margin finely subserrate' and '1.5 lin. (= ~3 mm) wide, at first subglobose'. In the Persoon Herbarium a single specimen under the name *P. rubella* (without collection data, L0054584 = L 910.261-535) can be found (Pl. 429: 5). About 10 apothecia were seen which measured 0.8–1.5 mm diam. when dry, growing on the outer surface of periderm and mainly bast of a min. ~3 cm thick branch of an unidentified, probably broad-leaved tree.

In the absence of any further voucher specimens studied by Persoon, this obviously authentic material is presumed here to be the **holotype** of *Orbilia rubella*, an opinion also shared by R. Arendholz (in sched.). The well-preserved specimen turned out to be conspecific with the below listed recent collections, but it is specifically distinct from those on which Karsten and Nannfeldt based their interpretation of *O. rubella*, and which are assigned to *O. phragmotricha* here. The Norwegian specimen from which a sequence was gained (ex H.B. 9046a, Pl. 430: 4, sq.: KT222354) is herewith designated as **epitype** of *O. rubella*.

Misapplication. A specimen identified by Fuckel (1871: 336, without description) as *Pezizella rubella* (on rotten wood and branches, autumn, near Oestrich, Fungi Rhenani 2382, M), was examined but no apothecia could be found. It was accepted by Rehm (1891: 459) as belonging to '*O. rubella*' (= *O. rehmii*). Fuckel's (1870: 299) brief description of this sample refers to a collection on wood of *Juglans regia*, with cylindrical, slightly curved spores of 6 × 2 µm; no information on the hairs is given, but Fuckel apparently saw no hairs since his generic diagnosis of *Pezizella* describes the apothecia as smooth, hence, the specimen can hardly have belonged in series *Rubellae*.

Beyer (1994: 207, 1998: 191) referred a collection on stems of *Rumex hydrolapathum* to *O. rubella* (in 1998 only tentatively). The purely microscopic description comprises slightly falcate spores *7–11 × 0.8–1 µm with a minute globose subapical

Plate 430. **1–5**: *Orbilia rubella*. – **1a**. moist *Fraxino-Aceretum pseudoplatani* with *Ulmus*; **1b–d**, **2a–c**, **3**, **4a**. fresh or rehydrated apothecia; **1f**, **4b**. marginal ectal excipulum in median section, with hairs tipped by glassy processes; **1g**, **5**. hairs in external view; **1e**. basal ectal excipulum in median section, with filiform SCBs; **4c**. id., with medullary excipulum and anchoring hyphae; **1h**. hymenium with protruding paraphyses; **4d**. mature ascus (SBs stained in CRB); **1i**, **4e**. ascospores. – Living state, except for **5** (KOH+CR), asci in **1h**, **4d**. – **2a–c**: phot. K. Homble. — **1a–i**. H.B. 8208a: Sweden, Skåne, on *Ulmus*; **2a–c**. 22.III.2009: Norway, Arendal, on *Ulmus*; **3**. H.B. 7442: Germany, Rhön, on *Ulmus*; **4a–e**. H.B. 9046a (epitype): Norway, Arendal, on *Salix*; **5**. L0054584 (holotype): unlocalized, on indet. angiosperm.

SB, rather unstalked asci with a partly H-shaped base, and 0–1-septate, flexuous, thin-walled (or solid?) hairs up to 50 × 5 µm. Considering the falcate spores with a gradually tapered base and globose SBs, this collection appears to be a member of section *Arthrobotrys* rather than *Aurantiorubrae*, perhaps related to *O. cardui*.

A few collections reported by R. Galán (in Pando & & Hernández 2001: 125) from southern and eastern Spain (on *Populus* wood and *Rubus* stems) under the name of *O. rubella* require reexamination.

Anamorph. We found four times near apothecia of *O. rubella* a few vermispora-like conidia which resemble those of *O. comma* but tend to be wider and to have more septa (Pl. 429: 4h). However, confusion between their anamorphs cannot be excluded, because *O. comma* was found two times in association with *O. rubella*.

Phylogeny. ITS sequences were taken from apothecia of two samples: on *Salix* from Norway and on *Nerium* from Portugal. They clustered with a 4.3 % distance in a medium supported clade. In both sequences the included short part of SSU shows that, in contrast to *O. phragmotricha*, the S1506 intron is absent. *O. rubella* clustered with a 5.3–5.5 % distance in a strongly supported clade with *O. phragmotricha* (Phyls 14, see also S15). Other members of section *Aurantiorubrae* show much higher distances, the closest being 11–11.5 % to *O. pisciformis* and 11–13 % to *O. jugulospora*. Further sequences are required to clarify whether mediterranean populations form a genetically distinct group.

Ecology. *O. rubella* was found on ± rotten bark of xeric branches, mainly of *Ulmus* and *Salix*, on ± acidic to basic, non-calcareous soil in supra- to orotemperate or hemiboreal (Norway) humid, subcontinental Europe. The scattered sites include the montane Rhön mountain range in central Europe and the lowlands of south Scandinavia. Krieglsteiner (2004: 657 fig. 50, as *Orbilia* spec. aff. *rubella*; pers. comm.) reported *O. rubella* from the Rhön area as not infrequent in ± montane, humid, cold and shady, medium base- and nutrient-rich ravine forests, preferably on *Ulmus glabra*. The vegetation there and in Scandinavia was a *Fraxino-Aceretum pseudoplatani*, in the Rhön sometimes also an *Epilobio-Salicetum capreae*, a transitional stage which develops in basalt quarries. Two samples were from inframediterranean semihumid Algarve of southern Portugal: on branch of *Nerium* in a scrubland (maquis) along a rivulet on calcareous soil, and on branch of *Eucalyptus* from a mixed eucalypt woodland on top of a mountain of acidic soil.

Specimens included. **NORWAY**: **Aust-Agder**, 5 km ENE of Arendal, Tromøy, Kvernhuskjerr, 18 m, branch of *Ulmus glabra*, on bark, 22.III.2009, T.H. Dahl (T.H.D. 73/09, doc. vid.). – ibid., trunk of *Salix caprea*, on bark, 15.IV.2009, T.H. Dahl (T.H.D. 116/09, H.B. 9046a, M-0291772, **epitype**; sq.: KT222354). – ibid., S of Alvekilen, 5 m, of *U. glabra*, on bark, 9.IV.2009, T.H. Dahl (T.H.D. 98B/09, non vid.). — **SWEDEN**: **Skåne**, 9 km ESE of Lund, NW of Dalby, Dalby Söderskog, branch of *Ulmus*, on bark, 3.V.1998, H.G. Unger, vid. T.R. Lohmeyer (T.R.L. 98/10, H.B. 6124, anam. substr.). – 6 km WNW of Röstånga, Söderåsen, Kvärkabäckens ravine, 135 m, branch of *U. glabra*, on bark, 3.VI.2006, T. Læssøe & H.O. Baral (H.B. 8208a, anam. substr.). — **GERMANY**: **Hessen**, Rhön, 18.3 km ESE of Fulda, 4.5 km N of Gersfeld, NE of Guckaisee, below Wasserkuppe, 800 m, branch of *Salix caprea*, on bark, 3.IV.2006, L.G. Krieglsteiner (L.K., non vid.). – 7 km NNE of Gersfeld, 2.5 km WNW of Wüstensachsen, Schafstein, 750 m, branch of ?*S. caprea*, on bark, 12.IV.2001, L.G. Krieglsteiner (H.B. 6935, anam. substr.). – ibid., 720 m, branch of *U. glabra*, on bark, 23.II.2007, L.G. Krieglsteiner (L.K., non vid.). – 6.3 km NE of Gersfeld, 2.2 km SSW of Ehrenberg-Wüstensachsen, Schwarzwald, 700 m, branches of *Ulmus*, on bark, 24.XI.2003, L.G. Krieglsteiner (L.K., H.B. 7442, anam. substr.). – **Bayern**, **Unterfranken**, Rhön, 27 km SE of Fulda, 3.5 km N of Bischofsheim, SSE of Holzberghof, Schwarzbach, Teufelsmühle, 700 m, branch of *U. glabra*, on bark, 3.IV.2006, L.G. Krieglsteiner (L.K., non vid.). – ibid., E of Holzberghof, 750 m, branch of *U. glabra*, on bark, 26.II.2007, L.G. Krieglsteiner (L.K., non vid.). – 5.3 km W of Sondheim, 3.5 km NW of Oberelsbach, Gangolfsberg, Elsbachschlucht, 605 m, branch of *Tilia*, on bark, 11.IV.2001, L.G. Krieglsteiner (L.K., non vid.). – 7.2 km NNW of Oberelsbach, 3 km W of Hausen, Eisgraben, 740 m, branch of *U. glabra*, on bark, 24.II.2007, L.G. Krieglsteiner (L.K., non vid.). – 4 km NNW of Oberelsbach, 3.2 km NW of Urspringen, Lichtenstein, 590 m, branch of *Salix caprea*, on bark, 25.IV.2001, L.G. Habitat: collected (0–)0.3–3 m above the ground, corticated, 8–80 mm thick branches, also 20 cm thick trunks, of *Acer platanoides* {1}, *A. pseudoplatanus* {1}, ?*Carpinus betulus* {1}, ?*Corylus avellana* {1}, *Fagus sylvatica* {1}, *Frangula alnus* {1}, *Fraxinus excelsior* {1}, ?*Populus sp.* {1}, *P. nigra* {2}, *P. tremula* {1/1}, *Salix* sp. {21}, *S. appendiculata* {1}, *S. aurita* × *caprea* {2}, *S. cantabrica* {2}, *S. caprea* {7/1}, *S. cinerea* {3/1}, *S. phylicifolia* {1}, *Sorbus aucuparia* {1}, *S. domestica* {1}, *Tilia* sp. {1}, *Ulmus* sp. {1}, *U. laevis* {1}, indet. angiosperm {2}, textile {1}, on (slightly to) medium, rarely strongly decayed, sometimes entirely detached bark {55} (periderm {10} and bast {25}), exceptionally on wood {4}, often on inner surface of detaching bark, also on edges along large cracks or on outer surface of bast below periderm that curls outwards, or in small holes or narrow crevices by pushing small lobes of periderm aside, ungreyed but sometimes blackened, algae sparse or absent, sometimes on or close to very old pyrenomycetes {5} (*Diatrype*, *Eutypella*, *Rosellinia*, ?*Teichospora*, *Valsa*). **Associated**: *Allophylaria macrospora* {1}, *Brachythecium rutabulum* {1}, *Cistella chlorosticta* {1}, *Crepidotus* sp. {1}, *Cryptocoryneum condensatum* {1}, *Cytidia salicina* {1}, *Diatrype bullata* {3}, *Durella atrocyanea* {1}, *Echinosphaeria strigosa* {1}, *Eutypella sorbi* {1}, *Exidia recisa* {1}, *Flammulina velutipes* {1}, *Frullania dilatata* {1}, *Helicogonium orbiliarum* (parasitic in *O. phragmotricha*) {1}, *Hysteropatella elliptica* {1}, *Lasiosphaeria* sp. {1}, *Merismodes* ?*anomala* {1}, *Metzgeria* sp. {2}, *Neonectria punicea* {1}, *Orbilia aurantiorubra* {4}, *O. auricolor* {1}, *O. carpoboloides* {1}, *O. eucalypti* {3}, *O. phanosoma* {1}, *O. poitevinica* {1}, *O. rubella* {1}, *O. subtrapeziformis* {1}, *O. xanthoguttulata* {5}, *Orthotrichum* sp. {1}, *Parmelia* sp. {1}, *Physcia* sp. {1}, *Propolis farinosa* {1}, *Radula complanata* {1}, *Rosellinia* sp. {1}, *Sclerococcum* sp. {1}, ?*Teichospora* sp. {1}, *Usnea* sp. {1}, *Valsa* sp. {1}. **Desiccation tolerance**: fully tolerant for max. 3.5 months but asci often already dead after 1 month, ascospores still viable after 4.5 months. **Altitude**: 18–470 m a.s.l. (Scandinavia), 260–1200 (central Europe), 900–1780 m (southern Europe), 1070–2400 m (central Asia). **Geology**: Buntsandstein, Muschelkalk, Lower to Middle Jurassic sand- & limestone, Cretaceous limestone, clay & sand, dolomite, Eocene calcareous marl- & sandstone, flysch, Tertiary molasse, Pleistocene moraine; granite, pegmatite, quartz, gabbro basalt, gneiss, schist, serpentinite. **Phenology**: throughout the year (long-lived).

Phenology of *O. phragmotricha*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
2	10	4	11	6	4	2	9	2	2	2	3

Taxonomic remarks. *Orbilia phragmotricha* is readily recognized by its very thick-walled, septate hairs without terminal glassy processes, and by small, narrowly fusoid to fusiform ascospores with a short, somewhat geniculate tail. *O. phragmotricha* is very close to the North American *O. paradoxoides*, especially in hair morphology, the latter differing in much wider spores. *O. rubella* deviates in larger spores and in short to long glassy processes on the hair tips. The glassy matrix of these processes appears to be of a nature different from the thick walls of the hairs of *O. phragmotricha*. The hair wall in *O. phragmotricha* seems to be composed of a dense gel matrix which corresponds to the less dense gel on the anchoring hyphae.

Variation. Considerable variation in hair size was noted: length varied from 20–30 µm up to 45–93 µm (mostly 30–50 µm), width from 2.8–4.5 µm up to 6–8.5 µm (mostly 4–6 µm), wall thickness between †0.5–1.3 and †1–2(–2.7) µm, and cell number from (2–)3–4 µm up to 5–7(–9) µm. In *O. paradoxoides* a similar variation was observed within the single known population, somewhat depending on the size of the apothecia (longer and wider hairs in larger apothecia). Although the spores of *O. phragmotricha* show only little variation, they slightly differ among the collections in length and/or width, and vary also in the apices between obtuse and acute. High variation was noted in apothecial colour which was mostly pale to light salmon-rose, but also deep orange.

Nomenclature and type studies. *O. phragmotricha* is proposed here as a nomen novum for *Orbiliaster paradoxus*. This taxon turned out to be conspecific with *Orbilia rubella* s. Karsten (p.p.maj.) and *Hyalinia rubella* s. Nannfeldt (p.p.). Karsten's (1870: 248, 1871: 102) concept of *O. rubella* was found to be quite consistent: six out of seven reviewed collections belonged to *O. phragmotricha*, but one (P. Karsten 4852) to *O. xanthoguttulata*. One (FFE 834) is a mixture of *O. phragmotricha* and *O. auricolor*. The rather long spores (8–12 × 0.5 µm) indicated by Karsten (l.c.) obviously include *O. xanthoguttulata*: his notes on the label of 4852 (apothecia golden yellow, spores 10–12 × 0.5 µm) refer to this species, whereas Karsten's (l.c.) macroscopic diagnosis of *O. rubella* refers to carneous-red apothecia with a lacerate margin, unlike *O. xanthoguttulata*. Later, Karsten (1885: 142) included a specimen of Rehm (Ascomyc. 461, = *O. rehmii* in the present study) in his concept of *O. rubella*.

Nannfeldt (1932: 252) had a rather broad concept of *Hyalinia rubella*. His description, which is restricted to excipular and hair characters, is solely based on FFE 834 (the population of *O. phragmotricha*). Nannfeldt described and illustrated the hairs as 30–40 × 3–5 µm, cylindrical, indistinctly or not at all septate, thin-walled, agglutinated as scale-like teeth. Reexamination of FFE 834 (H) in the present study showed, however, that the hairs are wider (30–55 × 5–7 µm), thick-walled, and up to 6-septate (Pl. 432: 5).

Nannfeldt's broad concept of *H. rubella* is documented by the fact that he accepted Karsten's inclusion of Rehm Ascomyc. 461 in this species. Nannfeldt further added with hesitation two specimens of Roumeguère, which were not revised in the present study. He also believed that the type of *O. coccinella* (herb. UPS) was possibly conspecific with *O. rubella*, and he even included the type of *Peziza rubinella* (= *O. vinosa*) in the scope of this species. Based on Massee's (1894a) redescription of *Peziza cruenta* and its asserted synonyms *P. rufula*, *P. fibriseda*, *P. saccharifera* and *P. regalis*, Nannfeldt referred all these five North American taxa, which are mainly accepted as different species in the present monograph, with some doubt to synonymy with *O. rubella*.

Based on a single recent Finnish collection, Huhtinen (1992) proposed ***Orbiliaster paradoxus*** as a new species. He placed it in the genus *Orbiliaster* because of the presence of long, septate hairs with a cyanophilous wall coating, and uninflated paraphyses, similar as in *Orbiliaster pilosus*. We have not examined the type specimen (TUR 99719) since Huhtinen's detailed description very well concurs with the present concept of *O. phragmotricha*. As the only difference to be mentioned, the paraphyses were described as cylindrical, 2 µm wide (in Huhtinen's drawing a width of 2–2.5 µm can be evaluated), whereas they were in our material */†2.5–4 µm wide and often distinctly lanceolate to spathulate. Because of the brief and

partly incorrect descriptions in Karsten (l.c.) and Nannfeldt (l.c.), Huhtinen overlooked the presence of *O. phragmotricha* in Karsten's herbarium.

The single specimen of ***O. texticola*** in M (Pl. 431: 3) contains a two-fold handwritten diagnosis. Since the collection was not distributed as exsiccata with copies of the diagnosis, *O. texticola* is to be considered to be an invalid herbarium name.

A specimen from Luxembourg (Dommeldange, on *Salix*, Pls 431: 7, 432: 9, IVV: H.B. 7535a), from which an ascospores isolate (CBS 117017) and a sequence were gained, is herewith designated as **epitype** of *O. phragmotricha*.

Not included collection. A Serbian sample on *Urtica dioica* (IVV: 2.IV.2018) resembles *O. phragmotricha* in the spores, spathulate paraphyses, and crystalloid SCBs, but has ± elongate orange apothecia which lack any hairs or glassy processes. It probably represents an undescribed species, which might belong in series *Rubellae*.

Anamorph. The phragmosporous conidia obtained in pure culture from a sample from Luxembourg (Pls 431: 7j; 432: 9) were only formed when the agar was flooded with water. Those found on the natural substrate in the Mongolian collection are much shorter and with fewer septa (Pl. 432: 7d).

Phylogeny. Sequences of *O. phragmotricha* were gained from cultures of two collections from Luxembourg (on *Salix* and *Fraxinus*) which comprise the S1506 intron, ITS, and LSU, the former also SSU. In the overlapping region they are identical except for 2 gaps in the ITS2. When analysing the ITS region, *O. phragmotricha* clustered strongly supported with a 5.3–5.5 % distance with *O. rubella* (Phyls 14, S15), the lowest distances being otherwise 9–9.3 % to *O. pisciformis*. In the LSU the distance to other members of section *Aurantiorubrae* lies at min. 3–5 %, and in the intron at min. 18–20 %.

Ecology. *O. phragmotricha* occurs on medium rotten, often detached bark (usually on the inner surface) of mainly xeric branches and trunks of different angiosperm trees, predominantly *Salicaceae*. In only two collections a few apothecia grew on decorticated wood: in one of them (H.B. 8238) the majority was on bast, whereas a sparse collection from Asturias (Spain) studied by E. Rubio was said to be exclusively on wood. The species seems to be not uncommon in colline to altimontane subcontinental, supra- to orotemperate central Europe, hemi- to thermoboreal Scandinavia, and oro- (rarely supra-)submediterranean humid southern Europe. Records are so far lacking from cold- to warm-temperate atlantic western and subatlantic or subcontinental northern regions of Europe. The vegetation includes various moist and more or less shady deciduous forests in ravines, near fens, or in floodplains. Two collections were made in continental central Asia on *Salix* in forests near rivulets in the orotemperate (sub)humid (winter-dry), montane to subalpine mountain taiga of the Altay region.

Orbilia paradoxoides Baral, **sp. nov.**, MB 813749 — Pls 433–434

Etymology: named after the resemblance to *O. phragmotricha* (≡ *Orbiliaster paradoxus*).

Typification: USA, Arizona, Clifton, inflorescence stem of *Yucca*, 1.VI.2003, G. Marson (ex H.B. 7880a, M-0276551, holotype).

Latin diagnosis: *Apothecia rehydratata 0.3–1.8 mm diam., roseo-aurantiaca, sessilia, margine albido-fimbriato. Ascosporae *6.5–9.7 × 1.6–1.9 µm, subcylindricae ad fusoideo-clavatae, apice obtusae, ad basim modice attenuatae et leniter vel distincte geniculatae, in statu vivo corpusculum refringens minutum lacrimiformem, ad apicem affixum continentes. Paraphyses ad apicem valde inflatae, spathulatae vel lageniformes. Habitat ad caules siccos putridos inflorescentiae* Yuccae *in zonameso temperata semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–1.3(–1.8) mm diam., 0.14–0.24(–0.3) mm high (receptacle 0.07–0.13 mm), light to bright rose or orange-rose, not or somewhat translucent, round to elliptical, scattered to (sub)gregarious; disc first slightly to strongly concave, finally flat, margin 0–30 µm protruding (15–60 µm incl. hairs), fimbriate by prominent whitish hairs, partly forming irregular teeth; broadly sessile, slightly to strongly erumpent between fibres, rarely superficial; dry bright orange(-rose), nearly closed. **Asci** *49–54 × 4.5–5 µm, †39–56 × 3.5–4 µm, 8-spored, spores (†) biseriate, ~3–5 lower spores inverted (often mixed), pars sporifera *19–25 µm long; **apex** (†) strongly truncate (slightly indented, laterally sometimes distinctly inflated); **base** with short to medium long, thin, flexuous stalk, T-, L- or Y-shaped. **Ascospores** *(6.5–)7.5–9.3(–9.7) × (1.6–)1.7–1.8(–1.9) µm, †6.4–9.2 × 1.5–1.7 µm, subcylindrical to fusoid-clavate, apex obtuse (to subacute), base medium attenuated in a tail-like end, rarely a distinct tail of 1.5–2.5 × 0.7–1 µm, here mostly slightly to medium geniculate; **SBs** *0.9–1.3 × 0.5–0.7 µm, tear-shaped, apically narrowed to a small to wide point. **Paraphyses** apically medium to strongly spathulate to lageniform or mammiform, terminal cells *13–24 × 3–4(–4.8) µm, †2.5–4(–4.8) µm wide, exceeding the dead asci by 4–7 µm, lower cells *(5–)7.5–16 × 2–2.6 µm, †1.7–2 µm wide; very rarely branched at upper septum, hymenium pale rose. **Medullary excipulum** hyaline, 30–70 µm thick, of dense textura intricata, finally very loose in centre, partly with many inflated cells, medium sharply delimited from ectal excipulum only towards margin. **Ectal excipulum** hyaline, of thin-walled († slightly gelatinized), irregularly to strictly vertically oriented t. globulosa-angularis-prismatica from base to mid flanks or margin, 60–100(–200) µm thick near base, cells *10–24(–34) × 6–14(–18) µm; 20 µm thick near margin (25–35 µm at uppermost margin), of light orange t. (angularis-)prismatica(-porrecta) oriented at a 10–30° angle to the surface, marginal cortical cells *5–13 × 3–4.5 µm, without yellow LBs; **hairs** †30–90 × (3.5–)4–6(–6.5) µm, 3–10-septate, wall †0.5–1.5(–2) µm thick, externally partly tuberculate by granular exudate, ± coherent to form indistinct teeth, **glassy processes** absent. **Anchoring hyphae** abundant, †(2.5–)3–4 µm wide, walls 0.3–0.7 µm

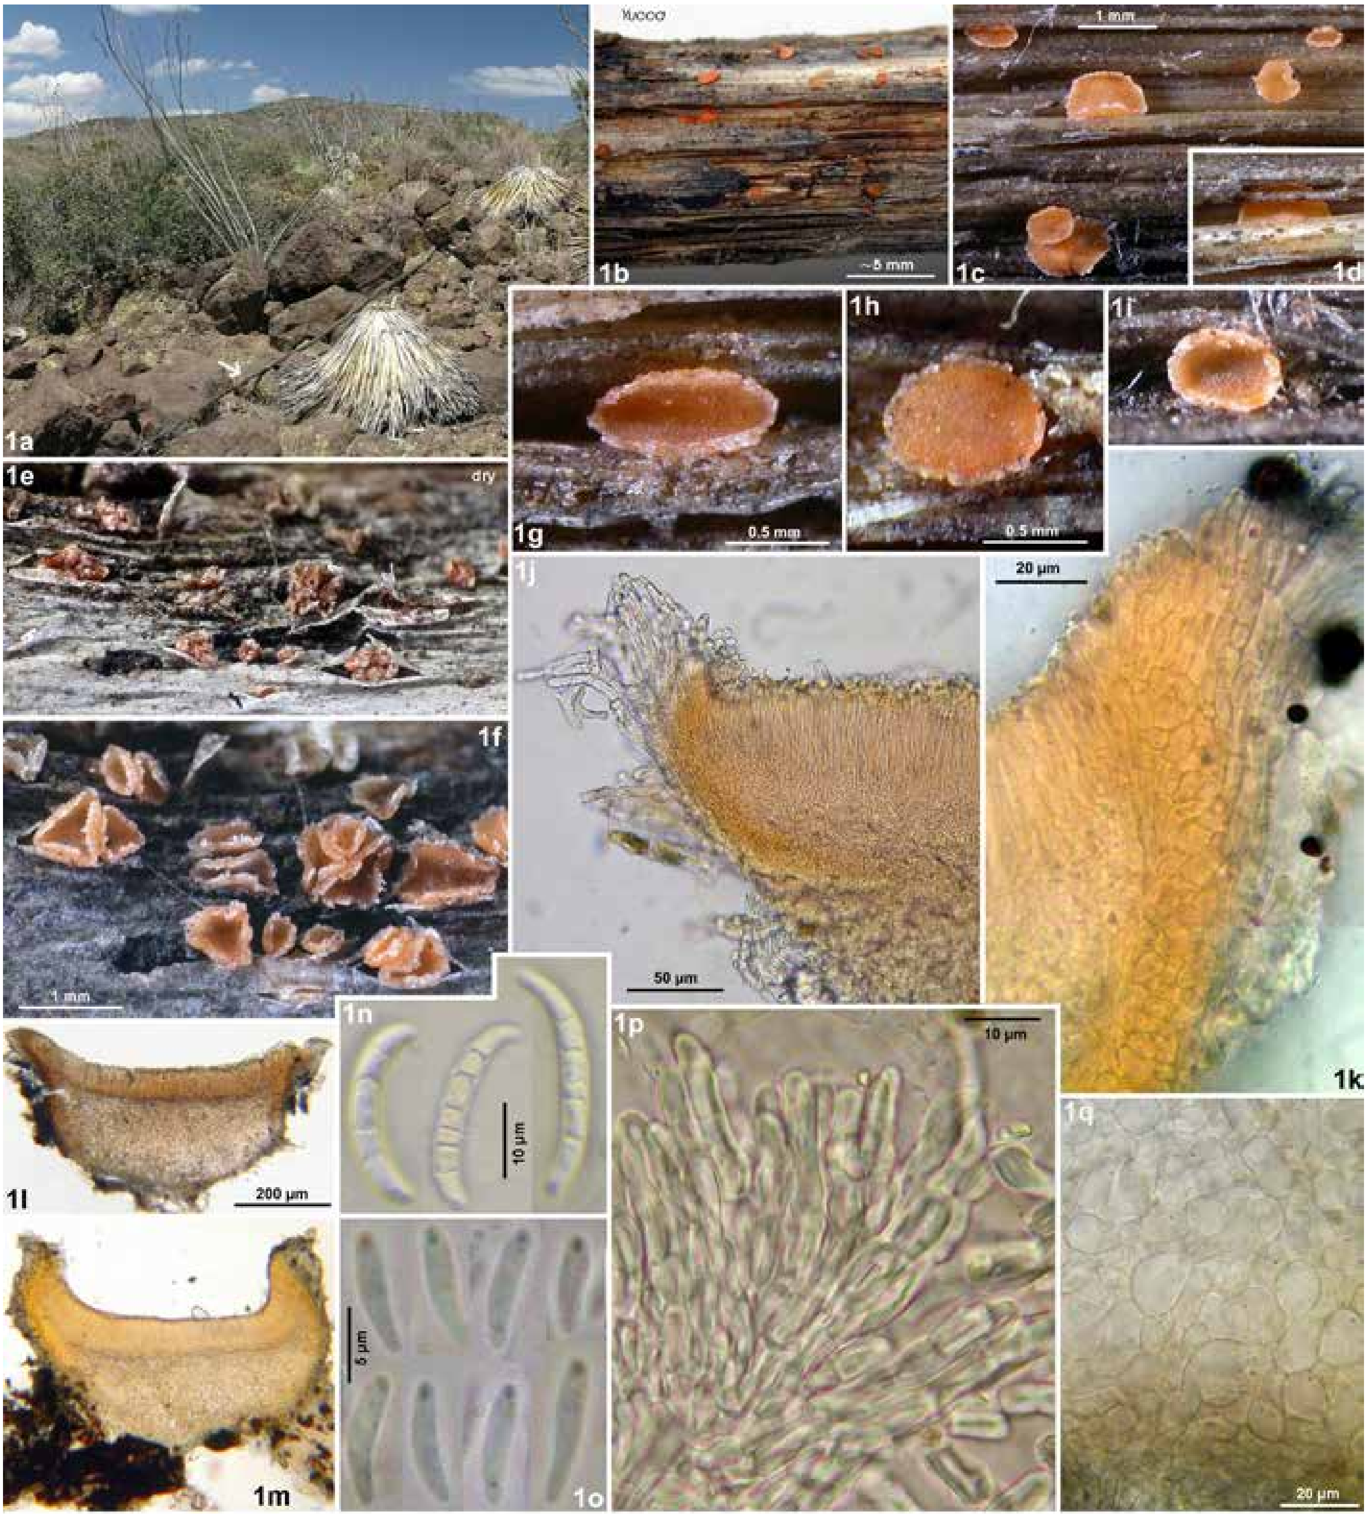

Plate 434. **1**: *Orbilia paradoxoides*. – **1a**. mountainous desert vegetation with *Yucca elata* and *Fouquieria splendens*; **1b**. dead xeric stem of *Yucca*; **1c–d**, **f–i**. rehydrated apothecia; **1e**. dry apothecia; **1l–m**. apothecia in median section; **1j–k**. id., marginal region; **1p**. hairs; **1q**. id., basal excipular cells; **1o**. ascospores; **1n**. conidia from substrate. – Living state, except for **1j**, **n**, **p** (in H_2O). — **1a–p**. H.B. 7880a (holotype): USA, Arizona, on *Yucca*.

thick, forming a thick loose t. intricata. **SCBs** in paraphyses globose, indistinct; in ectal excipulum (near margin) not observed. **Exudate** over paraphyses 0.2–0.3 µm thick, indistinctly rough, firmly attached; over hairs ~0.3–0.8 µm thick, rough-tuberculate. **— ANAMORPH**: vermispora-like (presumed, from natural substrate). **Conidiophores** not seen. **Conidia** unbranched, medium curved (slightly C-shaped), †24–31 × 3.5–4.5 µm, 4–6-septate.

Habitat: collected 0.2–0.6 m above the ground, 10–30 mm thick inflorescence stems of *Yucca* sp., strongly decayed and greyed, on epidermis-free areas or in cracks of epidermis, sometimes on epidermis, green algae very sparse. **Associated**: *Dothideales*, *Orbilia bicknellensis*, *O. denticulata*, *O. lentiformis*, *O. pleiolentiformis*, *Pragmopora* sp. **Desiccation tolerance**: most excipular and medullary cells, in some apothecia also many paraphyses and some mature asci still viable after 28 months. **Altitude**: 1510 m a.s.l. **Geology**: Oligocene to Miocene volcanic rock (basalt, andesite, rhyolite). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia paradoxoides* is very closely related to Eurasian *O. phragmotricha*, from which it differs in the larger, especially wider ascospores with a less distinct, much thicker tail-like base, apically more strongly inflated paraphyses with a more abrupt beak, and in the absence of crystalloid SCBs in the living paraphyses and excipular cells. In hair morphology the two species closely concur.

Anamorph. The medium curved phragmoconidia found on the substrate near apothecia are similar to those of the other species of series *Rubellae* (Pl. 434: 1n).

Ecology. The single very abundant collection was made on strongly decayed xeric inflorescence stems of *Yucca* in a warm-temperate semiarid mixed grass-scrubland adjacent to creosotebush-tarbush desert scrub in a mountainous volcanic area in the Chihuahuan desert of the southwest of Northern America.

Specimens included. **USA**: **Arizona**, Mogollon Rim, 31 km ENE of Safford, 20 km SSE of Clifton, 1510 m, inflorescence stem of *Yucca elata*, 1.VI.2003, G. Marson (M-0276551, **holotype**; **isotype** in H.B. 7880a, anam. substr.).

Series *Aurantiorubrae*

Orbilia subgenus ***Habrostictis*** section ***Aurantiorubrae*** series ***Aurantiorubrae*** – Type species: *Orbilia aurantiorubra* Boud.

Etymology: named after the type species, *Orbilia aurantiorubra*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–1(–1.7) mm diam., pale to bright (yellow-)orange, also cream to rose, margin smooth to finely rough or crenulate, sessile or with a short and broad stipe **Asci** *(35–)40–70(–82) × (3.7–)4–5.2(–5.5) µm, 8-spored, lower (or upper) 3–5 spores inverted; **apex** (†) strongly truncate, partly distinctly indented, not or distinctly laterally widened; **base** L-, Y- or h-shaped. **Ascospores** *(9–)10–14 (–17.2) × 1–1.6 µm, narrowly fusiform, apex acute to acuminate, base slightly to strongly narrowed, tail-like or with a distinct tail, medium to very strongly curved near base (± helicoid, upper part falcate), **SBs** *(2–)2.5–5(–5.5) × (0.3–)0.5–1.1 µm, straight, narrowly tear-shaped to subulate, apically narrowed to a small point or sometimes a distinct filum. **Paraphyses** slightly to medium capitate-clavate, terminal cells 1–2.5(–3.5)× longer than lower cells. **Ectal excipulum** cells near base *7–23(–27) × 6–15(–24) µm; **glassy processes** absent or 1–9 µm up to 10–23 µm long. **SCBs** globose mixed with crystalloid ones; **VBs** absent; **LBs** hyaline, sometimes yellow-orange (carotenoids). **Exudate** (0.3–)1–3(–4) µm thick, continuous or cloddy-granular, loosely to firmly attached, hyaline to pale yellowish. — **ANAMORPH**: vermispora-like. **Conidiophores** short (2–10 µm). **Conidiogenous cells** monoblastic or sympodial. **Conidia** phragmosporous, *13–37 × 2.4–5.7 µm (in situ), 3–6(–9)-septate, slightly to strongly curved.

Habitat: bark or rarely wood of angiosperms, humid to semihumid, temperate to submediterranean or subtropical, always desiccation-tolerant.

Recognized species: 3.

Taxonomic remarks. Beside the type species *O. aurantiorubra*, the very closely related *O. jugulospora* is regarded as the only taxon that belongs with certainty to series *Aurantiorubrae*. A third species, *O. binchuanensis*, is tentatively included because of its similar ascospores, although spore orientation within the asci is opposite to the other two species and the vital characters are unknown.

Series *Aurantiorubrae* is characterized by long and narrow ascospores that are gradually attenuated above into an acute to acuminate end which contains a narrowly tear-shaped to subulate spore body, and below into a thin or thick, rounded, distinctly geniculate or hooked end. In fact, the spores exhibit a distinct helicoid curvature mainly towards the base, whilst the upper part is more or less falcate. Although the helicoid curvature is quite obvious, its sense of rotation could not clearly be seen. Similar spores occur in series *Xanthoguttulatae* and *Abutilones*, but their high molecular distance forced us to recognize different series for them. For the morphological differences to series *Abutilones*, *Xanthoguttulatae*, and *Hyalinia* see under these series.

A remarkable feature of series *Aurantiorubrae*, which is also often seen in series *Commatoideae* and *Rubellae*, is the presence of crystalloid SCBs in paraphyses and excipular cells, comprising filiform, rod- to S- or ring-shaped but also rhomboid structures. These three series show a comparatively low molecular distance among each other, except for the only species with available DNA data which lacks crystalloid SCBs (*O. caulicola*), which clustered separate from those with crystalloid SCBs. A possibility would be to include series *Rubellae* and *Commatoideae* in series *Aurantiorubrae*, based on the sequences of *O. rubella*, *O. phragmotricha*, *O. pisciformis*, and *O. comma*, but more molecular data is required to find a good solution.

Species delimitation. *O. aurantiorubra* is possibly a collective species of two very closely related taxa occurring on different hosts, based on slight differences in spore length and molecular data. *O. jugulospora* is genetically sharply separated, nevertheless, it is not easy to recognize this species morphologically, except that its conidia are distinctly narrower than in *O. aurantiorubra*.

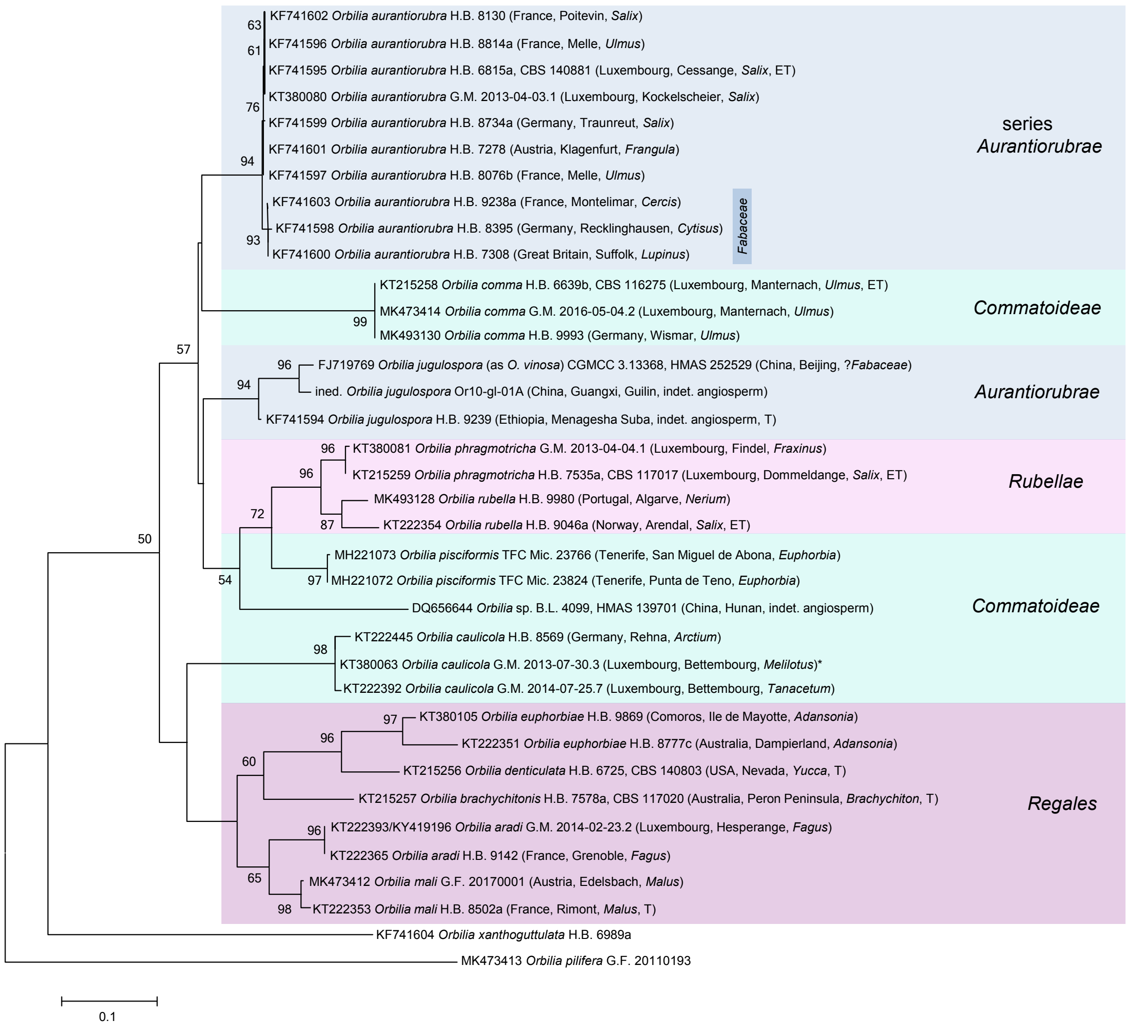
Anamorph. Very similar C-shaped conidia were obtained in pure culture of *O. aurantiorubra* and *O. jugulospora*, which are distinctly shorter and with a tendency to fewer septa compared to the otherwise similar conidia of *O. comma* and *O. phragmotricha*.

Phylogeny. DNA-data were available for *O. aurantiorubra* and *O. jugulospora*, which formed a strongly supported subclade in the analysis of the ITS region by Quijada et al. (2014b), or a medium supported clade in the analyses of ITS+LSU or ITS (Phyls 13, S15), or did not form a clade in Phyls 14 or S16. *O. aurantiorubra* clustered in Baral et al. (2017b, SSU+ITS+LSU) in a strongly supported clade with *O. comma* (series *Commatoideae*) and series *Rubellae*.

O. aurantiorubra was previously considered by us to be closely related to *O. xanthoguttulata* because of rather strong morphological similarities in the teleomorph, although the two species differ in their anamorphs: vermispora-like in the former and dicranidion-like in the latter species. The two species are disposed in different series because they clustered in our molecular analyses always in very different clades. This high molecular distance is also seen in the analysis of Quijada et al. (2014b), who investigated the phylogenetic relationship between members of series *Aurantiorubrae* and *Xanthoguttulatae* based on ITS sequences of 17 strains of series X*anthoguttulatae*, nine of *O. aurantiorubra*, and one of *O. jugulospora*.

Specific nucleotide positions. No molecular motif that unequivocally characterizes series *Aurantiorubrae* has been found. In the LSU D1–D2, pos. 516 is GGA**T**AAA in *O. aurantiorubra* and *O. jugulospora*, which is rather extraordinary within section *Aurantiorubrae* where it is GGA**C**AAA as in most other *Orbilia* spp., but it is GGA**T**AAA also in *O.* (aff.) *farnesianae*, *O. paracaudata*, and *O. amarilla* of series *Piliferae*, a majority of section *Helicoon*, and some species of series *Arthrobotrys*.

Ecology. At least two of the three included species are desiccation-tolerant. All grew on bark of angiosperms, rarely



Phylogenetic analysis 14. Phylogram of series *Aurantiorubrae* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (36 sequences, 648 positions, aligned with MUSCLE) using the T3+G model in MEGA6 (500 replicates). The tree is rooted with *O. pilifera* and *O. xanthoguttulata*. Asci 8-spored in all taxa; T = type, ET = epitype, * = without partial 5.8S and ITS2.

Key to species of series *Aurantiorubrae*

1. Upper spores consistently inverted within asci (acute SB-containing end pointing downwards)........2
1. Lower spores predominantly inverted within asci........3

2. Spores entirely strongly curved (helicoid)........ ***O. pseudobrevistipitata***, p. 863 & ***O. bomiensis***, p. 865 (series *Xanthoguttulatae*)
2. Spores slightly curved (falcate) except for the strongly bent basal end, *9.5–13.5 × 1–1.3 µm; angiosperm bark, subtropical humid eastern Asia........***O. binchuanensis***, p. 844

3. SBs 2–3(–3.3) µm long; paraphysis apices ± ellipsoid; apothecia yellow(-orange), rarely whitish........see ***O. xanthoguttulata*** (series *Xanthoguttulatae*), p. 848
3. SBs (2.7–)3–5 µm long; paraphysis apices clavate-capitate; apothecia (yellowish-)orange(-rose)........4

4. Spores strongly helicoid (basally hooked), *(9.5–)10.5–12(–13) × 1–1.4 µm; SBs mainly 0.4–0.6 µm wide; conidia *2.5–3.5 µm wide, 3(–4)-septate; angiosperm bark, cold-temperate to subtropical humid eastern Asia, northeastern Africa........***O. jugulospora***, p. 843
4. Spores medium helicoid, *9–12.5 up to 12–15(–17) × 1.1–1.6 µm wide; SBs mainly 0.7–1 µm wide; conidia mainly *4–5 µm wide, 4–6-septate; bark (rarely wood) of mainly *Salix*, *Ulmus* and *Fabaceae*, hemiboreal to (oro)temperate humid and mesomediterranean semihumid Europe, Macaronesia, western Asia, eastern North America........***O. aurantiorubra***, p. 834

on wood. *O. aurantiorubra* is known from hemiboreal to mesomediterranean, humid to semihumid Europe and appears to occur also in North America. *O. jugulospora* and *O. binchuanensis* were found in temperate to subtropical humid areas of Asia and Africa.

Orbilia aurantiorubra Boud., Hist. Class. Discom. Eur.: 103 (1907) — Pls 435–438, Map 77

Etymology: named according to the orange-red apothecial colour.

Typification: France, Haute-Marne, Vitry le François, branch of *Salix*, II.1877, D. Richon (herb. Boudier, PC, holotype); Luxembourg, Cessange, Bois de Cessange, branch of *Salix caprea*, 5.XI.2000, G. Marson (ex H.B. 6815a, M-0291763, epitype, designated here, MBT385120, ex-epitype culture: CBS 140881; sq.: KF741595).

Misapplied names: Schweinitz (1832: 177, p.p.), as *Peziza vinosa*; Schröter (1893: 120), as *O. rubella*; Baral (in Baral & Krieglsteiner 1985: 28), as *O. vinosa.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.4–1.2(–1.7) mm diam., 0.14–0.25(–0.35) mm high (receptacle 0.14–0.18 mm), pale or usually light to bright orange-apricot (to brick-red), more rarely yellow-orange, yellowish-cream or salmon-rose(-orange), hardly to medium translucent, round, strongly undulating when large, scattered to often ± densely gregarious in smaller or larger groups; disc slightly concave, soon flat, margin distinct, 0–5 µm protruding, smooth to finely rough; broadly sessile or with a narrow stipe-like base 0.03–0.13 × 0.18–0.2 mm, superficial; dry bright to deep ochraceous-orange or mostly orange-rose-apricot to brick- or blood-red, with thick protruding margin. **Asci** *(45–)52–70(–82) × (4.2–)4.5–5.2(–5.5) µm {15}, †(39–)45–65(–75) × (3.5–)4–4.5(–5.2) µm {12}, 8-spored, spores *4-seriate, 3–5 lower spores inverted {14} (rarely or often mixed: sometimes 1–3 apical spores inverted, sometimes also lower spores not inverted), pars sporifera *22–38 → 18 µm long; **apex** (†) strongly truncate (rarely slightly indented and laterally inflated); **base** with short to often very long, thin, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *9–12.5 {21} or 11–13.5 {19} or (12–)13–15(–17.2) {25} × (1.1–)1.2–1.5(–1.6) µm {60} (in situ, actual length ~11.5–14 µm up to ~14–18 µm), †(9–)9.5–13 {8} or (10.5–)12–14.5(–15) {11} × (1.1–)1.2–1.4(–1.5) µm {19}, narrowly fusiform with (sub)cylincrical middle part, with gradually tapering, acute to acuminate apex, base slightly to medium attenuated (tail-like) or with a tail of 1.5–3 × 0.6–1 µm, often very slightly inflated at the end, distinctly helicoid (looking falcate in profile view), near base medium to mostly strongly geniculate; **SBs** *(2.7–)3–5(–5.5)((–6)) × (0.6–)0.7–1 µm {22} → 2.3–3.7 × 1–1.3 µm, narrowly tear-shaped to subulate, also abruptly narrowed to a filum of ± equal length. **Paraphyses** apically uninflated to slightly or medium (rarely strongly) capitate-clavate, exceptionally spathulate or ± moniliform, (0–)3–6 µm protruding beyond dead asci, terminal cells *(10–)14–30(–35) × (2.2–)2.5–4(–5.3) µm {8}, †1.8–4(–4.7) µm wide {2}, lower cells *(8–)11–18(–22.5) × 1.3–2.7 µm {7}, near base *3–10 × 2–3.5 µm; rarely branched at upper septum, hymenium subhyaline to light orange. **Medullary excipulum** in total 50–170 µm thick, upper part 0–50 µm thick, hyaline to pale rose, of dense textura intricata with globose to angular inflated cells, lower part 50–120 µm thick, of dense to medium loose, large-celled t. globulosa-angularis (cells *7–20 × 6–12.5 µm), irregular to upwards oriented, near margin often forming a distinct, subhyaline to light yellow-orange-rose, horizontal t. porrecta 8–20 µm thick, partly only here sharply delimited. **Ectal excipulum** very pale to light rose or orange, of thin-walled († slightly gelatinized), vertically oriented t. angularis(-globulosa) from base to lower flanks, 25–80(–200) µm thick near base, cells *7–23(–27) × 6–15(–24) µm {6}; 15–20 µm thick at mid flanks and margin, at mid flanks of t. prismatica-angularis oriented at an 80–90° angle to the surface, at margin of t. prismatica-porrecta at 45–90°, marginal cortical cells */†6–15 × (3–)3.5–5(–6) µm {4}, **glassy processes** absent, exceptionally present, 1.5–6 × 3.5–4 µm {1}. **Anchoring hyphae** ± abundant, *2–3.2 µm wide, walls 0.2(–0.3) µm thick {3}, forming a loose or dense hyaline t. intricata-porrecta up to 50 µm thick. **SCBs** in paraphyses globose {11}, 1.2–2(–3) µm diam.; also filiform to S-shaped {12}; excipular cells on lower and mid flanks with inconspicuous to strongly refractive, thin (rarely thick), horseshoe- or often ring- to S-shaped, also rhomboid, hyaline to rarely pale yellow-orange SCBs {18}, marginal cortical cells also with globose SCBs 0.8–3 µm diam; **LBs** in ectal excipulum and paraphyses minute, sparse, hyaline, rarely yellowish. **Exudate** over paraphyses (0.3–)1–2(–4) µm thick, cloddy to granular, also cap-like, hyaline to pale yellowish, firmly attached (large clods also detaching); over margin and flanks rough-cloddy, subhyaline to pale yellow-chlorinaceous, (0.5–)1–5(–7) µm thick. — **ANAMORPH**: vermispora-like (from ascospore isolate {3} and natural substrate {10}). **Conidiophores** reduced, *2–5(–8) × (1–)1.5–2.5 µm {2}, conidia formed terminally or sympodially. **Conidia** phragmosporous, cylindrical with ± tapered ends, slightly to strongly curved (C-shaped), with straight to curved middle part, *(15.5–)19–24(–32.5) {4} or (25–)27–32(–37) {4} × (3.7–)4–5(–5.7) µm {8} (in situ), †(15–)19–29.5 × (2.4–)3–3.7(–4) {4}, ((3–))(4–)5(–6)((–9))-septate {10}, containing a number of minute LBs and a large globose, non-refractive central vacuole, rarely also some large LBs.

Habitat: collected (0.2–)0.5–3(–12) m above the ground, also sometimes on the moist ground, on corticated, (4–)10–50(–100) mm thick branches, more rarely twigs or trunks, of *Acer pseudoplatanus* {1}, ?*Ailanthus altissima* {1}, *Cercis siliquastrum* {2}, *Chamaecytisus proliferus* {1}, *Cytisus scoparius* {14}, *Elaeagnus pungens* {1}, *Euphorbia characias* {1}, *Frangula alnus* {3}, *Fraxinus excelsior* {1}, *Genista florida* {1/1}, *Lupinus arboreus* {2}, *Prunus padus* {1}, ?*Quercus* sp. {1}, *Salix* sp. {33}, *S. alba* {2/1}, *S. aurita* {1}, *S. aurita* × *caprea* {2}, *S. caprea* {20/1}, *S. cinerea* {7/2}, *S. rosmarinifolia* {1}, *Spartium junceum* {1}, *Ulex europaeus* {3}, *Ulmus* sp. {17/3}, *U. laevis* {5}, *U. minor* {4/1}, indet. angiosperm {2}; on slightly to strongly decayed bark {120} (periderm {14} and bast {40}), rarely wood {11}, on exterior of bark but often in small holes or clefts of periderm or on periderm-free areas, also frequently on inner surface of detached hanging bark; rarely on textile {1}; often on or near intact or usually very old pyrenomycetes and coelomycetes (*Chaetosphaeria*, *Cryptodiaporthe*, *Cucurbitaria*, *Diaporthe*, *Diatrype*, ?*Diplodia*, *Eutypella*, *Hypoxylon*, *Karstenula*, *Nectria* etc.), slightly to strongly covered by green algae, rarely in or close to beetle galleries, or in small holes made by ?birds. **Associated**: *Allophylaria macrospora* {1}, *Arthonia cinnabarina* {1}, *Arthrobotrys* sp. {1}, ?*Bacidia* sp. {1}, *Bionectria ralfsii* {2}, *Brachythecium rutabulum* {1}, *Calycina claroflava* {1}, *Calycina* sp. Plate 435. **1–7**: *Orbilia aurantiorubra* (on *Salix* and *Ulmus*). – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia (fresh); **e**. apothecia in median section; **f**. id., margin; **g**. basal cells of ectal excipulum with SCBs; **h**. conidiophores; **i**. conidia (**4** from substrate; **2**, **5** from culture).

Taxonomic remarks. *Orbilia aurantiorubra* is well characterized by its rather distinctly though not strongly helicoid ascospores with geniculate, rather thick bases and acute subulate apices that contain long, narrowly tear-shaped to subulate SBs. The species resembles *O. xanthoguttulata* and *O. succulenticola* in having almost the same spore shape and size, except that the attenuated part of the spore apices tends to be longer and the included SBs are distinctly longer by hardly overlapping in their length (3–5 µm vs. 2–3 µm). *O. aurantiorubra* further differs in (rose-)orange apothecia that consistently lack a distinct stipe, clavate-capitate paraphysis apices, the presence of crystalloid SCBs and almost consistent absence of both yellow LBs and glassy processes, and an anamorph with unbranched (phragmosporous) conidia. For two very similar subtropical species, the Afro-Asian *O. jugulospora* (p. 843) and the Chinese *O. binchuanensis* (p. 844), see there.

Variation. Rather high variation in length of the ascospores and spore bodies is observed within the present concept of *O. aurantiorubra*. In a majority of the collections (including the type) the spores measured 11–14 µm in length (in situ), especially on the favourite substrates *Salix* and *Ulmus* (Pl. 435: 1, 4, 6–7, Pl. 437: 3f). Yet, a number of specimens showed spores of only 9–12(–13) µm, especially when growing on *Fabaceae* (Pls 436, 438) or rarely extraordinarily long spores of (12–)14–16(–17) µm (on *Salix* and *Ulmus*, see Pls 435: 3; 437: 2d, 6). Also a collection on *Elaeagnus* from England showed spores 14–15 µm long (J.P. Priou pers. comm.). The SBs vary in length from 2.7–3.5 µm up to 4.7–5.5 µm by showing a rather

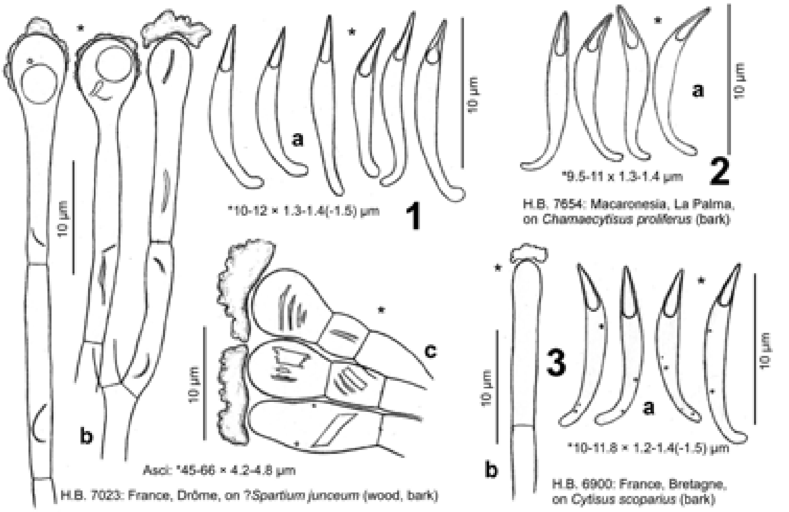

Plate 436. **1–3**: *Orbilia aurantiorubra* (on *Fabaceae*). – **a**. ascospores; **b**. paraphyses; **c**. marginal ectal excipulum in median section.

strict correlation with spore length. Whether different taxa are involved in this variation is not clear.

Typically, the crystalloid SCBs are thin and look as if filiform though they are in fact like a membrane, but in two collections, on *Cytisus* (Pl. 438: 2c–e) and *Ulmus* (Pl. 437: 7b–c), they were partly thicker and semicircular to keyhole-shaped. The latter collection showed short glassy processes at the margin (Pl. 437: 7a) and also some minute yellowish LBs in the excipular cells, according to photographs by I. Wagner, features which were not seen in any of the here studied specimens.

Apothecial colour varied rather considerably between orange-red, yellow-orange and pinkish, but this variation is sometimes observed within a collection (Pl. 437: 3a–e).

Taxa concept. When sorting all records according to spore length, fabaceous substrates remarkably accumulate at the shorter-spored end of the list. In addition to this, short-spored collections on *Fabaceae* predominantly derive from warmer and milder, atlantic to mediterranean climatic regions where the recorded host genera preferably occur (see Map 77). However, several exceptions break this rule. For instance, two records on *Ulmus* from Austria (G.F. 20090147) showed spores of only *9.5–12 µm (G. Friebes pers. comm.), and in four specimens on *Fabaceae* (*Cercis*, *Cytisus*, *Genista*, *Lupinus*) the spores measured *10–13 or 11–13 µm. A collection on *Salix* from a subcontinental montane region (Pl. 437: 3f) showed spores of mainly *10.5–12.5 µm length, while one on *Lupinus* from an atlantic lowland region (H.B. 7298a) had slightly longer spores (*11–13 µm). Rather long spores (up to 15–17 µm) were not only seen in records from subatlantic to continental regions but also from submediterranean areas in western France and northern Spain where *Ulmus* and *Salix* occur. Sharp limits in spore length could not be drawn, because specimens on *Salix* and *Ulmus* not infrequently showed a spore length of *(10–)11–13 µm.

A remarkable situation in northwestern France (Bretagne) confirms a correlation between spore size and substrate. J.P. Priou (pers. comm.) collected here frequently on *Fabaceae* (*Cytisus* and *Ulex*) but also sometimes on *Euphorbia*, *Frangula*, *Salix*, and *Ulmus* (Map 77): all specimens on *Fabaceae*, *Euphorbia* and *Frangula* had short spores (*9–11, 10–12, rarely 11–13 µm), whereas those on *Ulmus* and *Salix* but also *Elaeagnus* had longer spores of *11.5–14 or 13–14 µm. On the other hand, the three available samples on *Frangula* differed in spore length between *9–11 µm (France), *11 µm (Belgium), and *12–13.2 µm (Austria).

A few literature reports also appear to confirm a certain correlation between spore size and substrate (Boudier 1904–10: on *Salix* from Champagne, drawn with a length of (11.5–)13–16.5 µm; Spooner 2001: on *Ulmus* from Surrey and *Acer pseudoplatanus* from Devon, *11–14 × 1–1.5 µm; Priou 2005: on *Cytisus scoparius* in Bretagne and Portugal, *9–13 × 1.2–1.6 µm).

The single studied specimen from North America (atlantic lowland, on ?*Quercus*, IVV: H.B. 7726) showed a spore length at the lower range (†9–11 × 1.2–1.5 µm). In spore shape it is similar to *O. xanthoguttulata*, with subacute apices and the widest part often closer to the apex, but the shape of the paraphyses seems to exclude that species.

Type studies. To the group of long-spored specimens belongs also the holotype of *O. aurantiorubra* (on *Salix*), for which Boudier (1907: 103, 1904–10: 268) gave a spore size of 15–18 × 2 µm. Yet, his values are undoubtedly too large, a frequent phenomenon in his work. From the magnification of his drawing (Boudier 1908 [1904–10]: pl. 464, see Fig. 150: 1) a spore size of (11.5–)13–16.5 × 1.2–1.4 µm can be evaluated, which much better corresponds to the present study of the holotype (Pl. 435: 6). Boudier described the spores as elongate-cylindrical, vermiform, but largely overlooked that one end is acute. Obviously, he depicted dead spores since his illustration is devoid of spore bodies and the upper spore end rarely recognizable.

Boudier (l.c.) measured the asci as 60–80 × 5–6 µm. From his plate a size of 60–78 × 4.2–5.5 µm can be evaluated (the figured asci appear to be dead). This is slightly above measurements found here in the holotype. The width of the paraphysis apices he gave as 5–7 µm (?living state). We have evaluated 4.5–6.5 µm from the plate but only †2–4.7 µm in the type material. Boudier described and depicted 'one or several oil drops' in the paraphysis apices, which do not seem to have been yellow, since they are colourless on his drawing and the paraphyses were described as 'white'. This allows to exclude identity with *O. xanthoguttulata*, in addition to the orange apothecial colour and the clavate paraphysis apices, which did not contain LBs in the holotype (see Pl. 435: 6b). Very probably, these hyaline drops were globose SCBs which disappear when mounting in KOH. According to its wood anatomy, the substrate of the holotype is *Salix*, not *Ulmus* as stated in the protologue. That this material represents the holotype is obvious from the fact that the studied branch fragment with the associated *Xanthoria* (IVV: H.B. 6894) is exactly the fragment that Boudier depicted (Fig. 150: 1).

A specimen from Luxembourg (Cessange, on *Salix*, Pl. 435: 5, IVV: H.B. 6815a) from which an ascospore isolate (CBS 140881) and a sequence were gained is designated here as **epitype** of *O. aurantiorubra*.

Misapplication. Undated and unlocalized specimens in the Schweinitz Herbarium (925-182, PH, BPI) under the name *Peziza vinosa* might correspond to Schweinitz's (1832: 177) report of *Peziza vinosa* from North America. They contained *O. tenuispora* with straight spores (section *Helicoon*, on wood, Pl. 562: 3), and the two in PH also abundantly *O. aurantiorubra* with helicoid spores (on bark, IVV: H.B. 7726b). Schröter's

(1893: 120) report as *O. rubella* (on bark of *Salix*, *Populus*, *Ulmus*) from Silesia (Goszczowice, Lubiąż, Wrocław, Zielona Góra in Poland; Niesky in Germany) undoubtedly refers to *O. aurantiorubra*, according to the description and substrate. At the time when Baral (in Baral & Krieglsteiner 1985: 28) applied the name *O. vinosa* to two samples of *O. aurantiorubra* from Stuttgart (Maierwald, on *Ulmus*), *O. vinosa* in the present sense was still unknown to the author.

Anamorph. The conidia of *O. aurantiorubra* resemble those described for *Chionomyces ponapensis* Matsush. (on bark from tropical Micronesia), a species mentioned under *Vermispora* (see p. 247). In most cases, including our pure cultures, conidia were observed in collections on *Salix*, but a few were also seen on *Ulmus*, *Cytisus*, and *Cercis*.

Conidial size varied between the populations especially in length, also in the number of septa. Short conidia (~19–24 µm) were seen, e.g., in pure culture (Pl. 435: 2, with 3 septa) but also on natural substrate (Pl. 437: 8, with 5 septa, both examples on *Salix*). Conidia of the longer type (~22–33 µm) were mostly 5-septate, while conidia of *34–37 µm with 9 septa were occasionally seen in pure culture (Pl. 437: 10b right, on *Salix*) and on natural substrate (J.P.P. 29004, on *Cytisus*).

Phylogeny. Sequences of a total of nine specimens were gained during Quijada et al.'s (2014b) study, and a tenth later (G.M. 2013-04-03.1). Three of them were on *Fabaceae*, one on *Frangula*, two on *Ulmus*, and four on *Salix* (Tab. 69). All sequences comprise the ITS region, but three also LSU (H.B. 6815a and G.M. 2013-04-03.1 on *Salix*, H.B. 9238a on *Cercis*) and two also SSU (H.B. 6815a, 9238a). Most of them were taken from apothecia, mainly by L. Quijada, but two originate from pure culture (H.B. 6815a, G.M. 2013-04-03.1). In all 10 sequences the absence of the S1506 intron could be verified.

Based on these data, *O. aurantiorubra* shows a rather high distance to the morphologically similar *O. jugulospora* (ITS 9–11.5%, LSU D1–D2 2.9–3.2%, SSU V8–V9 2.4%). Both species differ from *O. xanthoguttulata*/*O. succulenticola* by ~25–26% in the ITS and 6–8% in the LSU.

Variance in the entire ITS region among samples on non-fabaceous hosts was 0–2 nucleotides (0–0.4%) and no gaps. Both the high molecular similarity and the lack of correlation between nucleotides and substrate or geographical origin support the present species concept of a single species. For instance, the specimen on *Frangula* from eastern Austria shows full identity with one of the *Ulmus* samples from western France, whereas three samples on *Salix* are identical with the other on *Ulmus*. The two on *Ulmus* are from the same collection area in western France, but deviate by 1 nt at pos. 98 in ITS1. At this position three samples have C, three T, and one is ambiguous (Tab. 69). The deviation at pos. 405 is unequivocal according to the chromatogram.

Also among the three fabaceous hosts ITS variance was only 0–0.4% without gaps. Thereby, the specimen on *Cytisus* from Germany unequivocally deviates by 2 nt from those on *Cercis* from southern France and *Lupinus* from England, which are identical (Tab. 69). The distance between fabaceous and non-fabaceous hosts ranges at 0.4–0.9%, thereby 2 nucleotides consistently deviate between the two groups (pos. 35 & 92, T vs. C), and 3 consistent gaps occur in the non-fabaceous group (pos. 61–62 & 369, Tab. 69).

Although the three strains on *Fabaceae* formed a strongly supported subclade within the clade of *O. aurantiorubra* (Phyl. 14), the observed ITS distance lies within the currently accepted range of variation of a single species. Among the three available LSU sequences, the two on *Salix* are identical (D1–D2, 554 nt) whereas that on *Cercis* differs by 0.3%. The two available SSU sequences (V8–V9, 363 nt) concur between *Salix* and *Cercis*.

Ecology. *O. aurantiorubra* was found on varyingly decayed bark (rarely wood) of xeric twigs, branches, and trunks of angiosperm trees and shrubs, predominantly *Salix* {70}, less often *Ulmus* {27} and *Fabaceae* {25}, rarely other plant families, exceptionally ± woody herbaceous stems (*Euphorbia*). The collections are mainly from planar to montane altitude and include cold- to warm-temperate, atlantic to continental, but also orotemperate, hemi- to thermoboreal, orosub- to mesosubmediterranean, and supra- to mesomediterranean, humid to semihumid regions. A single record from warm-continental humid North America (Pennsylvania) suggests a circumpolar distribution in the northern hemisphere. The vegetation includes thermophilous and shady forests (e.g., *Salicetum cinereae*, *Alno-Ulmion*, *Fraxino-Aceretum pseudoplatani*). The single Macaronesian collection was in a thermomediterranean semihumid *Chamaecytisus* (tagasaste) plantation at the foot of the laurel and pine forest.

Specimens included. **GREAT BRITAIN**: **West Midlands**, **West Midlands**, 14 km NNW of Birmingham, 1 km N of Walsall, Mill Lane, 128 m, 10.X.2015, P. Thompson (P.T. 10/10/2015-9, doc. vid.). – **East England**, **Suffolk**, 4 km ESE of Halesworth, NNW of Wenhaston, Bicker's Heath, 15 m, branch of *Cytisus scoparius*, on bark, 22.II.2006, S.M. Francis (E.B. 4667, K(M) 227420, doc. vid.). – ibid., branch of *C. scoparius*, on bark, 30.XI.2006, S.M. Francis (H.B. 8379a). – 4.5 km NE of Leiston, Minsmere Haven, S of Sluice, 1 m, twig of *Lupinus arboreus*, on wood, 15.II.2003, E. Batten (E.B. 4391-2 ø, H.B. 7298a). – 5 km SW of Southwold, 1.8 km NNW of Dunwich, Dunwich Forest, 15 m, stems of *L. arboreus*, 7.III.2003, E. Batten & S.M. Map 77. Known distribution of *O. aurantiorubra* in Europe and Macaronesia (right: closeup of western France); magenta = *Ulmus*, cyan = *Salix*, orange = *Fabaceae*, white = other hosts, indet. angiosperms, textile.

Etang près La Croix, 47 m, branch of *C. scoparius*, 25.XII.2003, J.P. Priou (J.P.P. 23146, doc. vid.). – **Pays-de-la-Loire**, **Loire-Atlantique**, 2 km NE of Kercabellec, 4.2 km WSW of Assérac, S of Mesquéry, Pen-Bé, 5 m, branch of *C. scoparius*, 10.XI.2006, J.P. Priou (J.P.P. 26174, non vid.). – **Maine-et-Loire**, 8 km NNW of Angers, 1 km NW of Cantenay-Épinard, Parc de la Roche, 25 m, branch of indet. angiosperm, on bark, 9.II.1985, M. Galand (J.M. 8502A). – 16 km WNW of Angers, W of St.-Clément-de-la-Place, Château des Brosses, branch of ?*Ulmus* ('*Laurus*'), on bark, 17.II.1985, M. Galand (J.M. 8504A). – **Poitou-Charentes**, **Deux-Sèvres**, 13 km ESE of Melle, Coudré, centre ville, 158 m, trunk of *Ulmus* (?)*minor*, on bark, 4.III.2006, M. Hairaud & B. Coué (ex H.B. 8076b; sq.: KF741597). – 13.5 km N of Melle, 2 km SW of La Mothe-St.-Héray, La Dame de Chambrille, 103 m, branch of *Ulmus*, on bark, 17.IV.2008, H.O. Baral (ex H.B. 8814a; sq.: KF741596). – 14 km WSW of Niort, 1.2 km NNE of Amuré, Marais Poitevin, Port Goron, 5 m, branch of *Ulmus*, on bark, 15.IV.2008, J.P. Priou (ø). – 1 km ENE of Le Vanneau-Irleau, Marais Poitevin, 3 m, branches of *Salix*, on bark, 15.IV.2008, H.O. Baral & J.A. Camy (H.B. 8805a ø). – 4 km NW of St.-Hilaire-La-Palud, Marais Poitevin, 4 m, branches of *S. aurita*, on bark, 25.IV.2006, H.O. Baral (H.B. 8130; sq.: KF741602). – **Vienne**, 6.5 km NW of Adriers, 1 km S of Nérignac, E of Les Aimardières (farm), 160 m, trunk of *Ulmus*, on bark, 19.III.2006, B. Coué (ø, non vid.). – **Centre**, **Loiret**, 10 km N of Montargis, 4 km NNE of Cepoy, E of les Ricordelles, Loing river, 75 m, twig and branch of *Ulmus*, on bark & old pyrenomycete, 28.II.1998, A. Reynaud (H.B. 6062). – **Champagne-Ardenne**, **Marne**, 16.5 km NE of Reims, N of Isles-sur-Suippe, 80 m, branch of *Salix caprea*, on bark, 2.II.1998, M. Langlois (H.B. 6040). – **Haute-Marne**, Champagne, ~9 km N of Vitry le François, St.-Amand-sur-Fion, branch of *Salix*, on bark and *Diatrype bullata*, 110 m, II.1877, D. Richon (herb. Boudier, PC, **holotype**, H.B. 6894 ø). – **Franche-Comté**, **Doubs**, 5 km SE of Besançon, E of La Vèze, marais de Saône, ruisseau des Moulins, 385 m, branch of *Salix*, on bark, 11.IV.2013, G. Moyne (ø). – **Bourgogne**, **Côte-d'Or**, 32.5 km NNE of Dijon, 2.3 km NW of Selongey, SE of Foncegrive, Ruisseau de la Venelle, 310 m, branch of *Salix*, on bark and *D. bullata*, 30.X.2009, J.P. Priou (J.P.P. 29210, doc. vid.). – 33 km NE of Dijon, NW of Fontaine-Française, Étang Pagosse, 230 m, branch of *Ulmus*, on bark, 26.X.2009, J.P. Priou (J.P.P. 29203, non vid.). – **Rhône-Alpes**, **Loire**, 19 km WSW of Roanne, 4 km WSW of Arcon, Forêt de l'Assise, le Gué de la Chaux, 1060 m, branch of *Salix*, on bark, 7.V.2010, J.P. Priou (H.B. 9301 ø). – 26 km NNW of St.-Étienne, Montrond-les-Bains, at river Loire, 340 m, *Ulmus*, on bark, 3.I.1994, A. Ayel (doc. vid.). – ~2 km ENE of Montrond-les-Bains, St.-André-le-Puy, 360 m, branch of *Salix*, on bark, 30.V.1994, A. Ayel (ø). – **Drôme**, 13 km SE of Montélimar, SW of Abbaye d'Aiguebelle, 215 m, branch of *Cercis siliquastrum*, on bark, 22.IX.2009, G. Marson (H.B. 9238a; sq.: KF741603). – 1 km NNW of Nyons, W of Col du Pontias, 400 m, branch of *C. siliquastrum*, on bark, 13. VIII.2009, G. Marson (only conidia, anam. substr.). – **Provence-Alpes-Côte d'Azur**, **Bouches-du-Rhône**, 3 km SW of Aix-en-Provence, La Baume, Chemin de la Blaque, branch of *Ulmus minor*, on bark, 145 m, 1.XI.2006, H. Aeberhard (H.B. 9087a ø, anam. substr.). – **Alpes-de-Haute-Provence**, 10 km ESE of Sederon, W of Curel, 765 m, branch of *Spartium junceum*, on bark & wood, 17.VIII.2001, G. Marson (H.B. 7023). – **Languedoc-Roussillon**, **Hérault**, ~13 km SE of Bédarieux, ?2.5 km NW of Neffiès, ?SSE of Vailhan, Le chateau d'eau, ~150 m, branch of *Cytisus scoparius*, on bark, 6.V.2005, G. Garcia (G.G. 05050604, doc. vid.). — **SPAIN**: **Asturias**, 10 km WSW of Gijón, 1 km ESE of Serín, San Andrés lake, 31 m, branches of *Salix*, on wood, 9.IX.2008, E. Rubio (E.R.D. 4578, doc. vid.). – 3.7 km NE of Pola de Somiedo, SW of La Falguera, 1170 m, branch of *Ulmus minor*, on bark, 20.IV.2013, E. Rubio (E.R.D. 5826, doc. vid.). – 11 km SE of Pola de Somiedo, 6 km SE of Valle de Lago, 1560 m, on twig of ?*Genista florida*, on bark and stromata of *Geejayessia*, 4.VI.2013, J.P. Priou (J.P.P. 13124, doc. vid.). – 55 km WSW of Avilés, NE of Orrea, 500 m, branch of *Ulex europaeus*, on wood, 29.II.2008, E. Rubio (E.R.D. 4387, doc. vid.). – 30 km SE of Oviedo, 3 km SSW of Cabañaquinta, Mirador de Cotobello, 1175 m, branch of *Genista florida*, on bark, 26.VI.2019, J. Díaz (ø, doc. vid.). – **Cataluña**, **Barcelona** 25 km NNW of Barcelona, 4.8 km NE of Terrassa, 322 m, branch of *Ulmus*, on bark, 1.II.2014, J. Bometón (J.B. 0448/14). — **PORTUGAL**: **Guarda**, Beira Interior Norte, 26 km SE of Guarda, 3.5 km NE of Sabugal, SW of Rendo, 820 m, branch of *Cytisus scoparius*, on bark, 1.I.2005, J.P. Priou (J.P.P. 25007, non vid.). – ibid., 2.3 km S of Rendo, Quinta dos Prados, 843 m, branch of *Salix*, on bark, 23.XI.2019, M.A. Ribes (doc. vid.). — **SERBIA**: **Vojvodina**, 3 km NW of Novi Sad, 75 m, branch of *Salix alba*, on bark, 21.III.2015, D. Savić (FG-372, doc. vid.). – Fruška Gora, 12 km SW of Novi Sad, 1 km SSW of Beočin, Erdelj, 235 m, branch of indet. angiosperm, on bark, 2.III.2015, D. Savić (FG-371, doc. vid.). — **MONTENEGRO**: 17 km SSW of Podgorica, 1 km W of Bistrice, 8 m, branch of *Salix*, on bark, 20.II.2016, B. Perić (B.P. Dgf/C7D-20-02-16, doc. vid.). — **UKRAINE**: **Lugansk**, 11 km NNW of Slavyanoserbsk, 4.5 km NW of Trehizbenka, 55 m, branch of *Salix rosmarinifolia*, on bark, 8.V.2011, A.Y. Akulov, vid. S. Helleman (CWU Myc AS4407, S.H. 740, anam. substr., doc. vid.). — **RUSSIA (West)**: **Pskov**, **Loknya**, 42.5 km NNW of Velikiye Luki, 9 km N of Nasva, N of Bashovo, 126 m, branch of *Ulmus laevis*, on bark, 17. VIII.2011, E.S. Popov (E.S.P. 11-0043, doc. vid.). – **Bryansk**, **Suzemka**, Bryanskiy Les, 95 km SSW of Bryansk, 14 km SSE of Trubchevsk, NW of Chukhrai, Nerussa river, 138 m, twig of *U. laevis*, on bark, 23.X.2012, E.S. Popov (LE 248007, non vid.). – **Oryol**, **Znamenskoye**, Orlovskoye Polesiye, 75 km ENE of Bryansk, 63 km NW of Oryol, 2.3 km NE of Elenka, Vytebet river, 174 m, twig of *U. laevis*, on bark, 19.X.2012, E.S. Popov (LE 248003, 248004, non vid.). – **Rostov**, **Krasny Sulin**, 90 km NNE of Rostov-on-Don, 15 km NE of Krasny Sulin, Osinovka river, 185 m, on bark of *Salix*, 17.VI.2001, Y.A. Rebriev (LE, non vid.). – **Sholokhovsky**, 230 km WNW of Volgograd, 1 km SW of Veshenskaya, 57 m, bark of *Salix*, 7.X.2006, E.S. Popov (LE 247258, doc. vid.). – **Volgograd**, **Svetly Yar**, Volga-Akhtuba, 33 km SE of Volgograd, 9 km NE of Svetly Yar, E of Sotovo lake, -7 m, twig of *Ulmus minor*, on bark, 21.IX.2012, E.S. Popov (LE 248300, non vid.). — **MACARONESIA**: **Canary Islands**, **La Palma**, Cumbre Nueva, 3.5 km SSW of San Pedro, W of Las Ledas, 700 m, branch of *Chamaecytisus proliferus*, on bark, 5.I.2005, P. Karasch (P.K. LP 012005-17, H.B. 7654a). — **USA**: **Pennsylvania**, Bethlehem, Salem, ?100 m, branch of ?*Quercus*, on bark, undated, collector unknown (herb. Schweinitz 925-182, PH 01029282, 01029283, H.B. 7726 ø).

Orbilia jugulospora Baral, in Quijada et al., Phytotaxa 175: 10 (2014) — Pls 439–440

Etymology: named after the very acute, spiky spore apex.

Typification: Ethiopia, Addis Ababa, Menagesha Suba, branch of indet. angiosperm, 22.XII.2009, U. Lindemann (ex H.B. 9239, M-0257566, holotype; sq.: KF741594)

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.7(–0.9) mm diam., 0.12–0.2 mm high (receptacle 0.07–0.11 mm), bright orange(-ochraceous) [T] or rose(–pink) {1}, (semi)translucent, round, scattered to gregarious; disc flat, margin distinct, not protruding, smooth; sessile or with a broad stipe 0.02–0.05 × 0.28 mm, superficial; dry bright orange-rose. **Asci** *46–50 × 4–4.2 {T} or 5.5 µm {1}, †42–67 × 3.8–4.2 µm {1}, 8-spored, spores *4-seriate in two bundles, 3–5 lower spores inverted {3} (often strongly mixed, sometimes some upper spores inverted), pars sporifera *25 µm long; **apex** (†) strongly truncate (never distinctly indented, laterally not or distinctly inflated), hemispherical in side view, thin-walled; **base** with short to very long, thick or thin, flexuous stalk, L-shaped. **Ascospores** *(9.5–)10.5–12(–13) × 1–1.4 µm {4} (~12–16 µm actual length), †10–12 × 0.9–1.1 µm {T}, narrowly fusiform, apex acute to acuminate, base gradually narrowed in a tail-like end or in a tail of 2–3.5 × 0.4–0.7 µm with rounded, partly very slightly inflated end, strongly curved (helicoid), near base hook-like; **SBs** *3–4.5 × (0.3–)0.4–0.6(–0.8) {4}, subulate, straight. **Paraphyses** apically slightly to medium clavate-capitate, terminal cells *26–27 × 3–4 µm {T}, †17.5–20 × 3–4 µm {1}, lower cells *5.5–13 × 1.5–2 µm {2}; unbranched at upper septum, hymenium pale orange. **Medullary excipulum** hyaline to pale orange, 30–50 µm thick, of loose to dense textura intricata with inflated cells, sharply delimited from ectal excipulum (at mid flanks by a t. porrecta). **Ectal excipulum** pale orange, of (*) thin-walled, vertically oriented textura globulosa-angularis(-prismatica) from base to margin, 70–110 µm thick near base, cells *9–14 × 6–10 µm {T}; 20 µm thick at flanks, 15–20 µm at margin, oriented at a 50–80° angle to the surface, marginal cortical cells *7.5–10 × 3.5–5 µm {T}; **glassy processes** absent. **Anchoring hyphae** medium abundant, *1.8–2.5 µm wide, walls 0.2 µm thick {T}. **SCBs** globose, in paraphyses 1.5–2.4 µm diam., in basal and marginal ectal excipulum 2.5–3 µm diam., here also rod- to sickle- (half-moon) or ring-shaped {T}, medium to strongly refractive, subhyaline; **LBs** in ectal excipular cells at lower flanks 0.2–0.4 µm diam., in groups, bright yellow-orange (carotenoids). **Exudate** over paraphyses 0.2–2 µm thick, cloddy-continuous to granular, very pale yellowish, firmly attached, over margin and flanks 1–2.5 µm thick, cloddy. **— ANAMORPH**: vermispora-like (from ascospore isolate {2}. **Conidiophores** reduced, *2.5–10 × 1.5–3.5 µm, at first cylindrical, later moniliform (bulbous) by proliferation. **Conidia** *((10.3–))(13–)16–28(–31) × ((2.2–))(2.4–)2.6–3.4 µm, ((1–))3(–4)-septate {2}, slightly to strongly curved, either entirely or more towards the ends, containing a number of minute or up to ~0.5–1 µm large droplets (probably LBs) near the walls of each cell.

Habitat: standing, or lying on dry ground, corticated, 9–?30 mm thick branches of ?*Fabaceae* sp. {1}, indet. angiosperms {3}, on slightly to medium decayed bark {4} (periderm {4} or inner surface of bark {1}), ± close to old pyrenomycete {T}, partly darkened, without algae. **Associated**: foliose liverwort, *Stilbella* sp. {1}. **Desiccation tolerance**: ± fully viable for 3 weeks. **Altitude**: 2520 m a.s.l. (northeastern Africa), 1250 m (northeastern China), 20–?500 m (southern China). **Geology**: Proterozoic metamorphic rock. **Phenology**: V, IX, XII (probably throughout the year).

Taxonomic remarks. *Orbilia jugulospora* is very similar to the more temperate, mainly European *O. aurantiorubra*. It differs only gradually in somewhat narrower, partly apically more acuminate and basally more hook-like ascospores, and in a tendency to narrower SBs. In the holotype the presence of yellow-orange LBs and hyaline half-moon-shaped (crystalloid) as well as globose SCBs in the ectal excipulum is remarkable. Stronger differences are seen in the anamorph and molecular data.

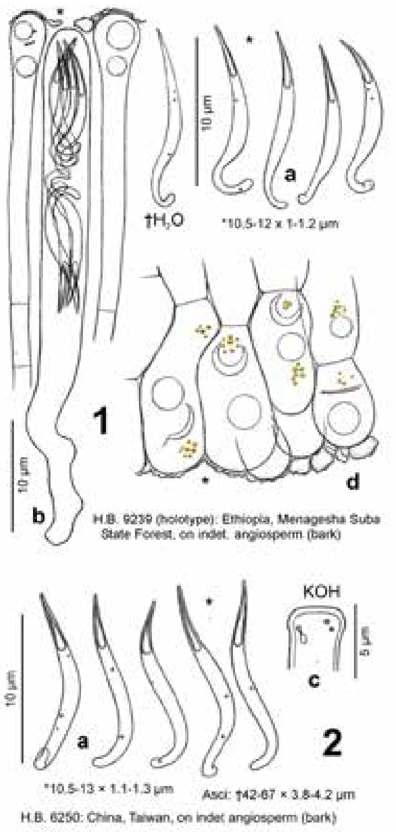

Plate 439. **1–2**: *Orbilia jugulospora*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. median section of ectal excipulum at lower flanks (cells containing SCBs and yellow-orange LBs).

Variation. The abundant paratype collection from Taiwan differs from the holotype in slightly wider asci and spores, distinctly wider SBs, and gregarious apothecia with a rose-pinkish colour. Only the spores were alive when this specimen was studied. Also in the specimen fom Beijing the ascospores are slightly wider (*10.5–12.5 × 1.2–1.4 µm, Pl. 440: 3a), while in that from Guangxi spore size (*~11–12.5 × 1–1.1 µm) concurs with the holotype. In both the colour of the fresh apothecia was orange(-red). Only the spores and the elements of the culture are alive on the photos of these two records, therefore, the presence of SCBs or LBs is unknown in all of the Asian samples.

Type studies. In the protologue, the holotype in M was erroneously given by the first author as isotype and 'herb. Baral' as holotype, also the H.B. number 9239 was wrongly ascribed to U. Lindemann. In fact, a duplicate of the holotype does not exist, nor does a duplicate of the paratype exist in the herbarium of R. Kirschner. The sparse holotype consisted of only seven apothecia, all of which were used up during microscopic and molecular study.

Anamorph. In pure culture of the samples from Beijing and Guangxi, conidia very similar to *O. aurantiorubra* developed, though distinctly narrower and with mainly 3 instead of 5 septa (X.Z. Jiang pers. comm., Pl. 440: 3b–d, 4b). No conidia could be found near apothecia of the holotype.

Phylogeny. A sequence taken from apothecia of the holotype from Ethiopia comprises SSU (without S1506 intron), ITS and LSU, and sequences from two Chinese cultures include ITS and LSU (also here the intron is clearly absent in one of them). The two Chinese cultures differ from the holotype by 5 % in the ITS, and between each other by 2.5 % (all deviating 13 nt are in the ITS1), which seems to indicate that the present concept of *O. jugulospora* is too wide. In the LSU D1–D2 the distance within *O. jugulospora* is 1.2 % between the Chinese strains and the holotype and 0.4 % within China.

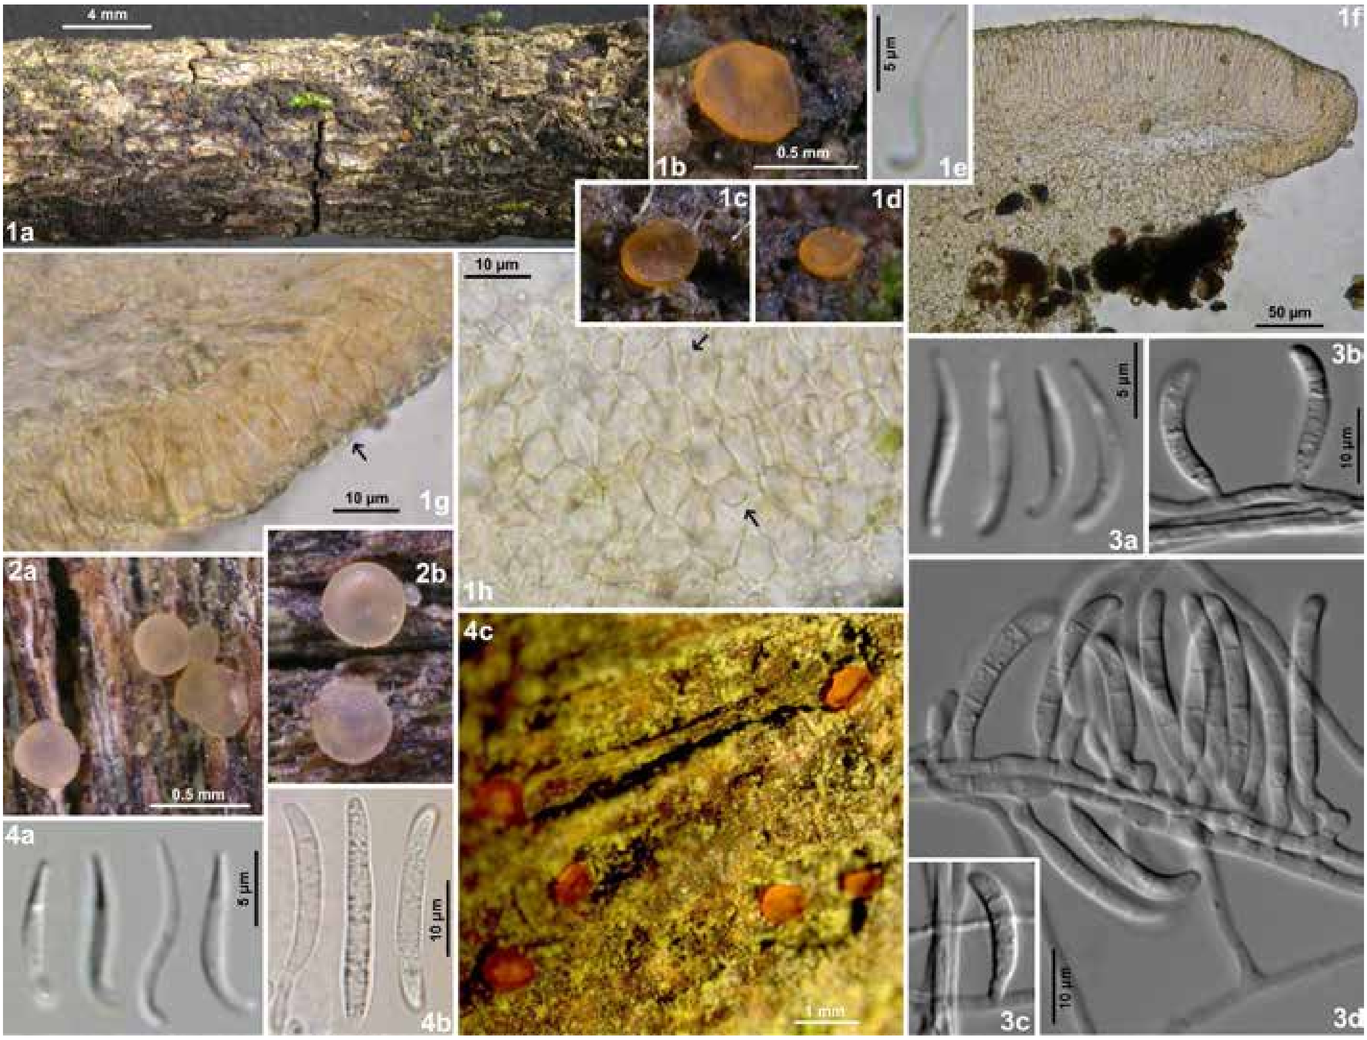

Plate 440. **1–3**: *Orbilia jugulospora*. – **1a**. corticated mesic branch; **1b–d**, **2a–b**, **4c**. rehydrated apothecia (**2**: after 12 years); **1f**. apothecium in median section; **1g–h**. id., ectal excipulum (base and lower flanks), some cells with crystalloid SCBs (arrows); **1e**, **3a**, **4a**. ascospores; **3b–d**, **4b**. conidiophores and conidia, from pure culture. – Living state, except for **1e**, **2c** (in H_2O). – **3a–d**, **4a–c**: phot. X.Z. Jiang (**3a–d**, **4a**: DIC). — **1a–h**. H.B. 9239 (holotype): Ethiopia, Menagesha Suba, on indet. angiosperm; **2a–c**. H.B. 6250: Taiwan, Taipei, on indet. angiosperm; **3a–d**. HMAS 252529: China, Beijing, on ?*Fabales*; **4a–c**. Or10-gl-01A: China, Guangxi, on indet. angiosperm.

The three samples of *O. jugulospora* form in our analyses of ITS+LSU, ITS, or LSU a strongly (Phyls 13–14, S15) or medium (Phyl. S16) supported clade which clustered in the LSU and combined tree sister to *O. aurantiorubra*. For the distances to *O. aurantiorubra* see under that species (p. 839).

Ecology. *O. jugulospora* was found on medium decayed bark of ± xeric, corticated branches of unidentified angiosperms. The holotype was from a warm-temperate humid though somewhat winter-dry, evergreen, afromontane, predominantly broad-leaved forest at the western slope of an old volcano in the central plateau of the Ethiopian highlands, and the paratypes from orotemperate eastern and subtropical humid (monsoon-influenced) southeastern humid Asia.

Specimens included. **ETHIOPIA**: **Oromia**, 22 km WSW of Addis Ababa, 10 km NW of Sebeta, southern part of Menagesha Suba State Forest, 2520 m, branch of indet. angiosperm, on bark, 22.XII.2009, U. Lindemann (ex H.B. 9239, M-0257566, **holotype**; sq.: KF741594). — **CHINA**: **Beijing**, **Mentougou**, 98 km W of Beijing, NE of Sujiancun, Lingshan Scenic Area, ~1250 m, branches of ?*Fabales*, on bark, 18.V.2008, X.Z. Jiang (jx-2000a, HMAS 252529, CGMCC 3.13368, anam. cult., doc. vid.; sq.: FJ719769 as *Orbilia* sp., HQ110696 as *O. vinosa*). – **Guangxi**, **Guilin**, Longsheng, forest along G321 state road (unlocalized), 200–800 m, branch of indet. angiosperm, on bark, IX.2010, X.Z. Jiang (Or10-gl-01A, anam. cult., doc. vid., sq.: ined.). – **Taiwan**, **Taipei**, 5 km SE of Taipei, 2 km NW of Wen Shan, Xianyan rd., near Ping An church, 20 m, branch of indet. angiosperm, on bark, 27.IX.1998, R. Kirschner (R.K. 405 ø, H. B. 6250).

Orbilia binchuanensis Baral & Hong Y. Su, sp. nov., MB 813761 — Pls 441–442

Etymology: named after the county Binchuan in the province of Yunnan.

Typification: China, Yunnan, Binchuan, branch of indet. angiosperm, 20.X.2008, X.M. Gao, H.Y. Su & X.J. Su (ex H.B. 8979c, M-0276443, holotype).

Latin diagnosis: *Differt ab* Orbilia aurantiorubra *ascosporis superioribus inverse orientatis, cellulis marginalibus excipuli processis vitreis praeditis, apotheciis minoribus. Habitat ad corticem putridum rami uvidi arboris angiospermae in zona subtropica humida Asiae meridio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–0.5 mm diam., 0.1 mm high (receptacle 0.08 → 0.06 mm), light cream(-orange), translucent, round, scattered; disc flat, margin not protruding, finely crenulate, with teeth of 15 × 30 µm; sessile on a narrowed base, superficial; dry brownish. **Asci** †(28–)31–36 × 3.3–4.2 µm, 8-spored, spores †~4(–8)-seriate, ± 4 upper spores inverted (not mixed), pars sporifera †20–26 µm long; **apex** (†) strongly truncate (sometimes very slightly indented, laterally not inflated), hemispherical in side view, thin-walled; **base** with very short to medium long, ± thick, flexuous stalk, L- or Y-shaped. **Ascospores** *(9.5–)11–12.7 × 1–1.3 µm, †10–11.5(–13.5) × (0.8–)0.9–1.1(–1.3) µm (~11–15 µm actual length), narrowly (cylindric-)fusoid, apex subacute to acute, base medium attenuated, with rounded end, main part (very) slightly (to medium) curved, tail-like base or tail of 1.5–2 × 0.7–0.8 µm, (very) strongly bent, falcate or very slightly helicoid; **SBs** *2–3.5 × 0.7–1 µm, subulate, straight. **Paraphyses** apically slightly clavate, terminal cells †13–18 × 1.7–2.5 µm,

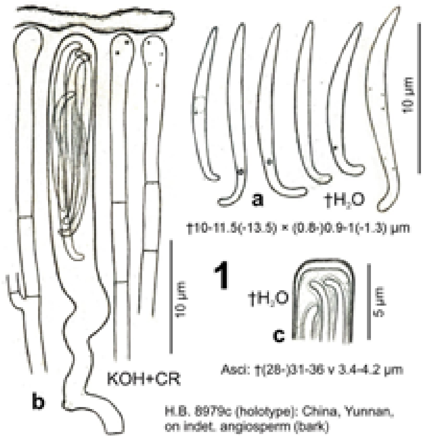

Plate 441. **1**: *Orbilia binchuanensis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

lower cells *5.5–9 × 1.5–2 µm, †6–7 × 1.2–1.5 µm; unbranched at upper septum. **Medullary excipulum** 25 µm thick, of medium dense textura intricata-angularis, indistinctly delimited from ectal excipulum. **Ectal excipulum** of (†) thin-walled, irregularly oriented t. angularis-globulosa at base and flanks, 50 µm thick near base, cells †8–12 × 7–9.5 µm; 25 µm thick at flanks, 12 µm at margin, mid flanks abruptly of t. prismatica oriented at a 10–20° angle to the surface, marginal cortical cells †7–10 × 2.5–3 µm; **glassy processes** 10–23 × 2.5–3.3 µm, medium refractive, distinctly stratified, pale yellow-ochre, distinctly outwards curved, coherent to form small teeth. **Anchoring hyphae** sparse, †2–3 µm wide, walls 0.2 µm thick. **SCBs** and **VBs** unknown. **Exudate** over paraphyses 1.5–3 µm thick, continuous, pale yellowish, loosely attached, over glassy processes 0.2–0.5 µm thick, rough. **— ANAMORPH**: unknown.

Habitat: on corticated, ~25–30 mm thick branch of unidentified angiosperm lying on moist ground, on very decayed bark (bast), strongly darkened, without algae. **Associated**: *Hyalorbilia japonica*, *H. multiguttulata.* **Desiccation tolerance**: dead in all parts when examined after 3 months. Altitude: 2700 m a.s.l. **Geology**: mafic volcanic rock. **Phenology**: X.

Taxonomic remarks. *Orbilia binchuanensis* differs from *O. aurantiorubra* and *O. jugulospora* in the upper spores being consistently inversely oriented, in much shorter asci, and in the presence of glassy processes which provoke a crenulate margin. The apothecia are thinner and less pigmented.

Ecology. The very sparse collection was on the outside of rotten bark of a hygric branch of an unidentified angiosperm in an evergreen broad-leaved forest with *Castanopsis*, *Cinnamomum*, *Lithocarpus*, *Quercus*, *Rhododendron* etc. in the subtropical humid (winter-dry) highlands of southeastern Asia. The apothecia grew in close neighbourhood of two *Hyalorbilia* species.

Specimens included. **CHINA**: **Yunnan**, **Dali**, Binchuan, 42 km NNE of Dali, Jizushan, ~2700 m, branch of indet. angiosperm, on bark, 20.X.2008, X.M. Gao, H.Y. Su & X.J. Su (ex H.Y.S. jz-3/H.B. 8979c, M-0276443, **holotype**).

Series *Xanthoguttulatae*

Orbilia subgenus ***Habrostictis*** section ***Aurantiorubrae*** series ***Xanthoguttulatae*** Baral, Quijada & E. Weber, **ser. nov.**, MB 815011 **–** Type species: *Orbilia xanthoguttulata* Baral

Etymology: named after the type species, *O. xanthoguttulata*.

Latin diagnosis: *Series* Xanthoguttulatae *sensu stricto seriei* Aurantiorubrae *similis sed conidia staurospora (typo* Dicranidion*), paraphyses apice ellipsoideae ad spathulatae, corpuscula crystalloidea carentia, guttulae luteae minutae plerumque copiose praesentes differt.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.3–1(–2) mm diam., whitish or pale to bright pinkish, yellow, ochraceous-orange or red-brown, margin smooth to distinctly crenulate, sessile or with ± distinct short stipe. **Asci** *(26–)30–74(–82) × 3.3–5.4 µm, 8-spored, lower or upper (2–)3–5(–6) spores inverted; **apex** (†) slightly to strongly truncate, sometimes slightly to distinctly indented, laterally rarely slightly inflated; **base** T-, L-, Y- or h-, never H-shaped. **Ascospores** *8–16 × 0.7–1.8 µm, (very) narrowly fusoid to fusiform(-clavate), apex subacute to acuminate, rarely obtuse, base slightly to strongly narrowed to an often ± distinct tail, medium to strongly curved towards base or entirely (falcate or mostly helicoid, right- or left-handed), **SBs** *1–6 × 0.4–1.2 µm, straight, tear-shaped to subulate, rarely ellipsoid to globose, apically narrowed to a point or ± short filum. **Paraphyses** not or slightly to strongly inflated at the apex, capitate-clavate or ellipsoid-spathulate to lageniform, terminal cells 0.8–7× longer than lower cells. **Ectal excipulum** cells near base *(8–)10–25(–28) × (6–)8–15(–20) µm (on ± xeric substrate) or */†(15–)20–50(–70) × (10–)15–40(–60) µm (on hygric substrate), near margin of t. angularis to t. prismatica-porrecta; **glassy processes** absent or 1–10 µm up to 40–70 µm long. **SCBs**

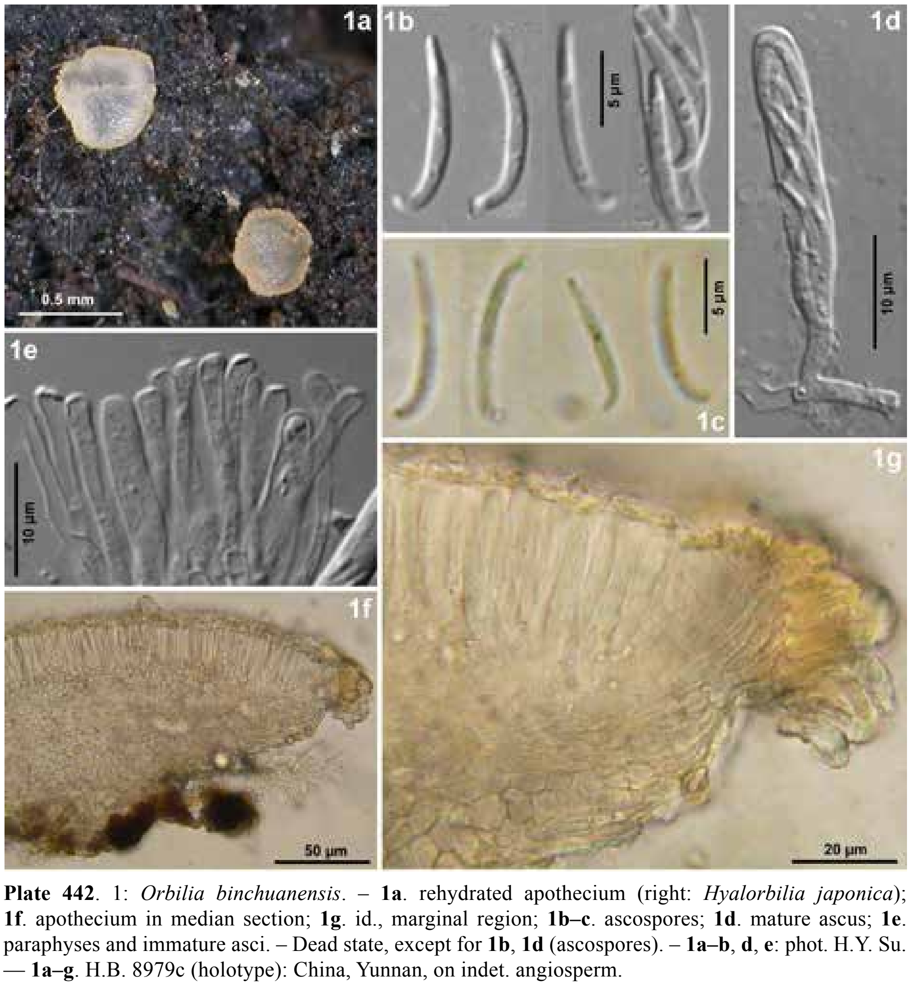

Plate 442. 1: *Orbilia binchuanensis*. – **1a**. rehydrated apothecium (right: *Hyalorbilia japonica*); **1f**. apothecium in median section; **1g**. id., marginal region; **1b–c**. ascospores; **1d**. mature ascus; **1e**. paraphyses and immature asci. – Dead state, except for **1b**, **1d** (ascospores). – **1a–b**, **d**, **e**: phot. H.Y. Su. — **1a–g**. H.B. 8979c (holotype): China, Yunnan, on indet. angiosperm.

absent or globose to elongate, sometimes crystalloid; **VBs** absent or present; yellow **LBs** (carotenoids) absent or present. **Exudate** 0.1–2.5 µm thick, cloddy-granular to cap-like, loosely or firmly attached, hyaline or pale yellowish. **— ANAMORPH**: dactylella- or dicranidion-like. **Conidiophores** mostly unbranched, 2–200 µm long, 2–4 µm wide at the base, 1.8–2.4 µm at the tip. **Conidiogenous cells** monoblastic or sympodial. **Conidia** either phragmosporous, cylindric(-clavate), *15–42 × (3.8–)5–7(–8) µm, straight, (0–)1–3(–5) septate, or staurosporous, 2-armed, without stipe (U-shaped), *18–37 × 9–11 µm.

Habitat: bark and wood, temperate to mediterranean or tropical, humid to semiarid, desiccation-tolerant or -sensitive.

Recognized species: 8, plus 1 unnamed species ('affinis').

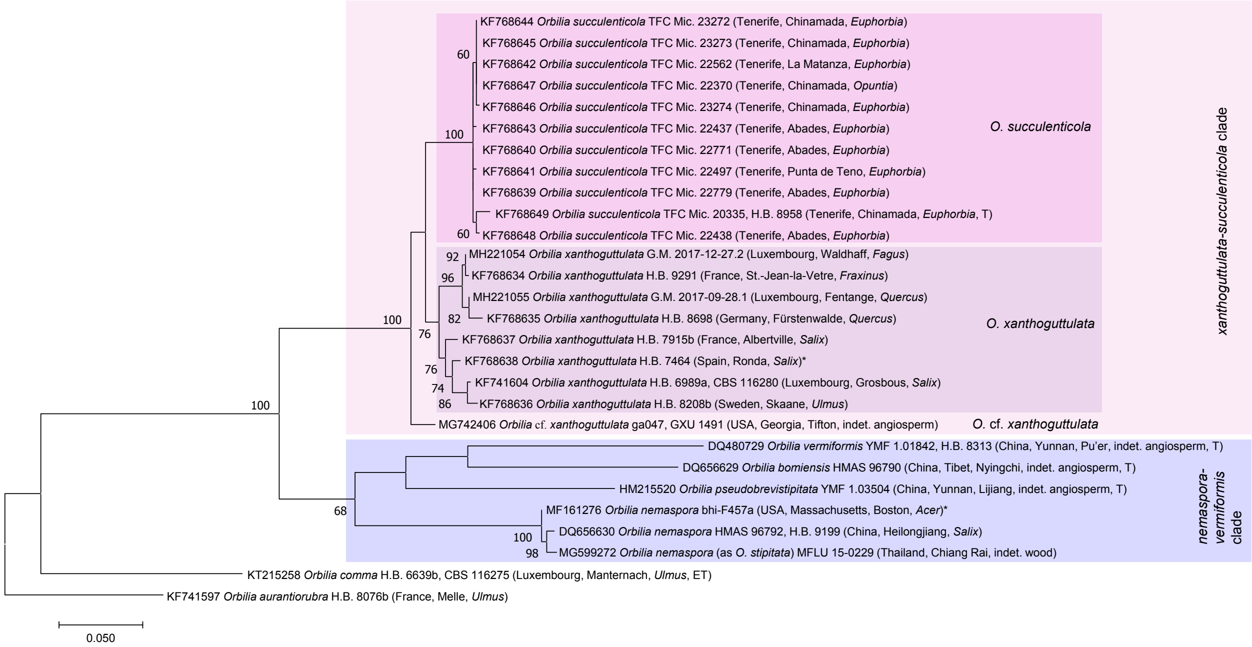
Taxonomic remarks. Series *Xanthoguttulatae* is segregated from series *Aurantiorubrae* and *Hyalinia* mainly because of its molecular data, which group *O. xanthoguttulata* and the very similar *O. succulenticola* (*xanthoguttulata-succulenticola* clade) close to taxa around *O. nemaspora* (*nemaspora-vermiformis* clade). Despite this strong phylogenetic result, members of the *nemaspora-vermiformis* clade closely resembles series *Hyalinia* morphologically as well as in their predominantly desiccation-sensitive apothecia. On the other hand, *O. xanthoguttulata* and *O. succulenticola* resemble species of series *Aurantiorubrae* morphologically as well as in their high desiccation tolerance. Also a certain correlation between different conidial types and desiccation tolerance is observed: more or less desiccation-intolerant species of series *Hyalinia* and series *Xanthoguttulatae* (*nemaspora-vermiformis* clade) have straight phragmoconidia, desiccation-tolerant species have C-shaped (series *Aurantiorubrae*) or staurosporous conidia (*O. xanthoguttulata*). Based on this character correlation, we originally distinguished only two series, *Aurantiorubrae* and *Hyalinia*.

Further differences between these groups were found in the type of SCBs, the presence of yellow LBs (carotenoid), and in the shape of paraphysis apices. A combination of globose and crystalloid SCBs is typical of series *Aurantiorubrae* and *Hyalinia*, whereas in the *xanthoguttulata-succulenticola* clade crystalloid SCBs are consistently absent and globose SCBs rare. In the *nemaspora-vermiformis* clade crystalloid SCBs were only occasionally seen and globose SCBs sometimes (however, several species were mainly studied in the dead state). The paraphyses and marginal excipular cells of *O. xanthoguttulata* and *O. succulenticola* contain varying amounts of yellow LBs. *O. bomiensis* resembles species of the *xanthoguttulata-succulenticola* clade in its yellow apothecia, but the location of the pigment is unclear because living cells were not studied. In the *xanthoguttulata-succulenticola* clade the paraphysis apices are ellipsoid-spathulate, whereas series *Aurantiorubrae* and *Hyalinia*, and also the *nemaspora-vermiformis* clade feature capitate-clavate (or uninflated), the latter also lageniform apices (*O. pseudobrevistipitata*).

In ascospore and SB morphology the four groups are rather similar in their helicoid spores with a strongly tapered base and a usually acute apex that contains an elongate tear-shaped spore body. Slight differences are noted in spore curvature: members of series *Hyalinia* and the *nemaspora-vermiformis* clade have usually strongly helicoid spores, whilst those of series *Aurantiorubrae* and the *xanthoguttulata-succulenticola* clade tend to have only slightly helicoid spores. In *O. bomiensis* the distinctly wider spores are twisted left-handed and have only slightly tapered bases, and the SBs are globose, whereas in other members of the *nemaspora-vermiformis* clade and in series *Hyalinia* the spores are twisted right-handed. In *O. crenatofalcata* and one collection of *O. crenatonemaspora* (series *Hyalinia*), however, the spores are falcate or only very slightly helicoid.

O. binchuanensis, *O. bomiensis*, *O. pseudobrevistipitata* and *O. spirillospora* deviate from the remaining species of series *Xanthoguttulatae* and *Hyalinia* in the upper spores being inverted within the asci, also in growing on more xeric substrate. *O. spirillospora*, *O. crenatonemaspora*, and also *O. nemaspora* p.p. are outstanding in their rather long SBs.

Species delimitation. *O. xanthoguttulata* and *O. succulenticola* are morphologically very similar but genetically and geographically distinct. Likewise, *O. vermiformis* and *O. nemaspora* are easily confused, differing mainly in spore width. *O. crenatonemaspora*



Phylogenetic analysis 15. Phylogram of series *Xanthoguttulatae* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (28 sequences, 646 positions, aligned with MUSCLE) using the T3+I model in MEGA7 (500 replicates). The tree is rooted with *O. aurantiorubra* and *O. comma*. Asci 8-spored in all taxa; T = type, ET = epitype, * = without partial ITS2.

Key to species of series *Xanthoguttulatae*

1. Lower spores inverted within asci (SBs pointing towards base); SBs tear-shaped to subulate 2
1. Upper spores inverted within asci (SBs pointing towards base); SBs globose to subulate 8

2. Paraphyses with ellipsoid to spathulate(-mammiform) apex, usually containing yellow LBs; substrate xeric 3
2. Paraphyses with capitate (± globose) apex or uninflated, without yellow LBs; substrate hygric 4

3. Spores *(10–)11–14.5(–16) × (1.2–)1.3–1.6(–1.8) µm; SBs 1.8–3.3 µm long; marginal cortical cells *(4–)7–11(–14) × (3–)4–7(–9) µm, oriented at a 70–90° angle, terminated by 0–9 µm long glassy processes; bark (rarely wood) of various angio-, rarely gymnosperms, boreal humid to thermomediterranean semihumid Europe .... ***O. xanthoguttulata***, p. 848
A collection from subtropical North America is morphologically identical but its DNA data place it between this and *O. succulenticola* (p. 851).
3. Spores *(9–)9.5–11(–12) × (1–)1.2–1.5(–1.6) µm; SBs 1.7–2.6 µm long; marginal cortical cells *8–13 × (3–)4–5(–6) µm, oriented at a 30–80° angle, terminated by 8–18 µm long glassy processes; wood of *Euphorbia*, *Opuntia*, inframediterranean semihumid to arid Macaronesia .... ***O. succulenticola***, p. 853
A collection on *Chamaecytisus* from the upper mesomediterranean semihumid caldera de Teide (> 2000 m) is without a sequence but morphologically identical.

4. Spores falcate or only very slightly helicoid 5
4. Spores consistently medium to strongly helicoid; wood & bark of angiosperms, also bamboo 6

5. Spores *8–9.5(–9.8) × 0.8–0.9(–1) µm, asci †25–30 × 2.8–3.2 µm; wood of *Populus*, supra(sub)mediterranean (semi)humid southern Europe .... ***O. crenatofalcata*** (series *Hyalinia*), p. 883
5. Spores *9.5–13.7 × 1–1.2 µm, asci †25–45 × 3–4.5 µm .... see under 6 (*O. crenatonemaspora*)

6. Marginal cortical cells †2.7–5 µm wide, tipped by 7–35 µm long glassy processes; apothecial margin distinctly denticulate; spores *(9.5–)10–12(–13.7) × 1–1.1(–1.2) µm; SBs 2.5–5.5 µm long; subtropical humid southern China .... ***O. crenatonemaspora***, p. 862
6. Marginal cortical cells †(3–)5–10(–13) µm wide, without glassy processes; apothecial margin smooth or denticulate; spores *8–11.3 µm long; SBs 1.5–3.7 µm long 7

7. Spores *(8.8–)9.5–11.3 × 1–1.1(–1.3) µm, fusoid, with distinct thin tail; SBs 1.5–1.8 µm long; (sub)tropical humid eastern Asia, Carribean region, Madagascar .... ***O. vermiformis***, p. 856
7. Spores *(8–)8.5–10(–11) × 0.7–0.8 µm, narrowly fusoid, tail often indistinct; SBs 1.6–2(–3.7) µm long; cold-temperate to tropical humid America, Europe, Comoros, eastern Asia .... ***O. nemaspora***, p. 858

8. Spores *10–13.5 × 1.5–1.7 µm, twisted like a left-hand thread, base only slightly tapered to a rounded end; SBs ± globose; apothecia bright yellow-orange, margin crenulate by long glassy processes; hygric wood of indet. angiosperm, orotemperate, cold-continental humid central Asia .... ***O. bomiensis***, p. 865
8. Spores max. *1.1 µm wide, twisted like a right-hand thread, base strongly tapered; SBs elongate tear-shaped to subulate; apothecia pale cream to light orange-ochre 9

9. Spores *13–14 × 1–1.1 µm, twisted by 1.5 turns; margin smooth, without glassy processes; xeric bark of *Hibiscus*, tropical humid northeastern Australia .... ***O. spirillospora***, p. 866
9. Spores *8–11 × 0.7–0.9 µm, twisted by only 1 turn; margin smooth to distinctly crenulate or dentate; xeric or hygric wood & bark of indet. angiosperms, (sub)tropical humid eastern Asia 10

10. Apices of paraphyses slightly capitate, covered by thick exudate; apothecial margin with 5–10 µm long cortical cells tipped by (8–)20–40(–50) µm long glassy processes; spores †9–11 × 0.7–0.8 µm .... ***O.* aff. *pseudobrevistipitata***, p. 864
10. Apices of paraphyses spathulate to lageniform, covered by thin exudate; apothecial margin with (10–)13–20 µm long hair-like cortical cells tipped by 0–5(–13) µm long glassy processes; spores *8–10.3 × 0.8–0.9 µm .... ***O. pseudobrevistipitata***, p. 863

is not easily delimited from *O. scolecospora* of series *Hyalinia*. The remaining species of series *Xanthoguttulatae* were too rarely collected in order to know their variability.

Anamorph. The two recognized clades differ in the anamorph: dicranidion-like in the *xanthoguttulata-succulenticola* clade, dactylella-like in the *nemaspora-vermiformis* clade (but anamorphs are unknown in some taxa).

The dicranidion-like conidia of *O. xanthoguttulata* are characterized by the lack of a stipe. They are quite extraordinary within section *Aurantiorubrae*, but resemble those of series *Orbilia*. Despite this similarity, a phylogenetic relationship was not supported. Similar conidia but with a distinct short stipe occur in *O. siculispora* (series *Abutilones*, with often more than two arms), and in the rather unrelated *O. ovalis* (section *Lentiformes*). We have observed this anamorph only in *O. xanthoguttulata*, while that of *O. succulenticola* still needs to be detected.

Within the *nemaspora-vermiformis* clade, ascospore isolates have been gained from *O. vermiformis* (Yu et al. 2007a), *O. nemaspora* (Liu 2006), and *O. pseudobrevistipitata* (Qin et al. 2011). Their dactylella-like, 1–5-septate, cylindric-clavate conidia are formed on short to very long conidiophores. Trapping organs were not observed when nematodes were added.

Phylogeny. DNA-data were available for two species of the *xanthoguttulata-succulenticola* clade (*O. xanthoguttulata*, *O. succulenticola*) and four of the *nemaspora-vermiformis* clade (*O. bomiensis*, *O. pseudobrevistipitata*, *O. nemaspora*, *O. vermiformis*). They comprise mainly the ITS region, in two species of each clade also LSU and in *O. xanthoguttulata* SSU. The S1506 intron occurred in one species of the former clade and three of the latter.

In different phylogenetic analyses (Quijada et al. 2014b, Baral et al. 2017b, Phyls 7, 13, S15), the two clades clustered together with high support but also high distance. The strongly supported *xanthoguttulata-succulenticola* clade includes two very closely related species, whereas the four species of the *nemaspora-vermiformis* clade formed a medium, weakly, or strongly supported sister group with a high distance among the species (Phyls 13, 15, S15). Because of their obvious molecular similarity and the low support of the *nemaspora-vermiformis* clade we here include both clades in a single series, although their different anamorphs would support recognition of more than one series. The above-mentioned morphological similarities between the *xanthoguttulata-succulenticola* clade and series *Aurantiorubrae* on the one hand, and between the *nemaspora-vermiformis* clade and series *Hyalinia* on the other hand are problematic regarding unsequenced taxa which are difficult to place in the proper group. The phylogenetic position of series *Xanthoguttulatae* is rather isolated and unresolved, showing a high molecular distance to other groups. For further discussion see under series *Hyalinia* (p. 868).

In a most parsimonious analysis of the ITS region by Yu et al. (2007a), *O. vermiformis* clustered with 93 % bootstrap support with taxa belonging to series *Drechslerella* of section *Arthrobotrys*. Therefore, the authors wondered why *O. vermiformis* did not produce any nematode-trapping organs. However, the tree does not show the distances between the sequences, also it contains mainly members of section *Arthrobotrys* but not any of subgenus *Habrostictis* other than *O. vermiformis*.

Specific nucleotide positions. One position in the LSU D1 is highly characteristic of series *Xanthoguttulatae* in comparison to other members of section *Aurantiorubrae*: pos. 159 is AGAGG**T** vs. AGAGG**A** in most other *Orbiliomycetes* (never **T**). Two further positions are characteristic only when excluding *O. nemaspora*: pos. 127 CTGGA**T** vs. CTGRR**G** (rarely CTGGT**G** or CTGGG**A**), pos. 135 GG**A**TT vs. **C** (rarely **T**); except for a few exceptions, also these 2 nucleotides are unique within the genus *Orbilia*.

The *xanthoguttulata-succulenticola* clade has a unique motif at pos. 160–180 of LSU D1 (**G**GCTTCGGTTGT**A**GC**T**CCGG**T**) in which it deviates from the majority of related groups at the positions in bold, pos. 160 being even unique within *Orbilia*. Pos. 180 is also T in the *O. nemaspora* clade, series *Hyalinia*, and section *Ovoideae*, but C in any other *Orbilia* spp. (with rare exceptions having T). The *xanthoguttulata-succulenticola* clade is further characterized at pos. 292 (CTC**T**AA) in contrast to all other *Orbilia* spp. which have CTC**A**AA, except for section *Lentiformes* and *Gamsylella arcuata* (and most basal orbiliaceous genera) which also have CTC**T**AA.

Ecology. *O. xanthoguttulata* and *O. succulenticola* are desiccation-tolerant species. The former occurs in temperate to subalpine humid and mediterranean semihumid Europe mainly on bark of various angiosperms, whereas the latter is only known from inframediterranean semiarid Macaronesia on wood of succulents. Members of the *O. nemaspora* clade are desiccation-sensitive or slightly -tolerant and were recorded in (sub)tropical humid to semihumid Asia, Australia, Africa, and South America, and in warm- to cold-temperate humid North America, Europe, and Asia, also in cold-continental altimontane central Asia (*O. bomiensis*).

1. Xanthoguttulata-succulenticola clade

Orbilia xanthoguttulata Baral, in Quijada et al., Phytotaxa 175: 12 (2014) — Pls 443–444, Map 78

Etymology: named according to the yellow lipid bodies in both paraphyses and marginal excipular cells.

Typification: Spain, Guadalajara, Cantalojas, branch of *Genista* (?)*florida*, 30.X.1991, A. Raitviir & R. Galán (AH 6796, holotype).

Misapplied names: Baral (1987: 428), as *O. comma*; Karsten (1870: 248, 1871: 102, p.p. [P. Karsten 4852]), as *O. rubella*; Rehm (1891: 447, fig. 9–10; 458), as *O. curvatispora*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–1(–1.5) mm diam., 0.19–0.31 mm high (receptacle 0.11–0.15(–0.22) mm), pale to light yellowish-cream or mostly golden yellow, also ochraceous-orange, sometimes turning deep orange to blood-red with age, rarely whitish; somewhat translucent, round, lobate when large, scattered to gregarious; disc slightly concave to flat, margin ± thick, 0–15 µm protruding, smooth; often with a distinct, cylindrical to obconical stipe 0.05–0.2(–0.3) × 0.2–0.4(–0.8) mm, superficial or slightly erumpent from bast; dry light to deep honey-yellow-ochre to yellow-orange, orange-apricot-red, or vermilion-red. **Asci** *(47–)53–74(–82) × (4–)4.2–5(–5.3) µm {10} → 5.7–5.8 µm wide, †(40–)44–67(–79) × (3.5–)3.8–4.6(–5) µm {7}, 8-spored, spores *4-seriate, ± helicoidally twisted, (2–)3–5(–6) lower spores inverted {14} (not or rarely mixed), pars sporifera *23–30(–35) {8} long (†20–30 µm), rarely *30–36(–39) µm {1} (†30–40 µm); **apex** (†) strongly truncate (sometimes distinctly indented, laterally not widened); **base** with short to very long, thin, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(10–)11–15(–16) ((–18)) × (1.2–)1.3–1.6(–1.8) µm {24} (~12–17 µm actual length), †(9.2–)10.5–14(–14.7) × (1–)1.1–1.3(–1.5) µm {10}, narrowly fusiform with (sub)cylindrical middle part, apex acute (to acuminate), base slightly to strongly attenuated, falcate to mostly distinctly helicoid, medium to strongly curved especially near base; **SBs** *(1.5–)2–3(–3.3) × 0.7–1.1 µm {18}, tear-shaped to subulate, apically narrowed to a point, rarely to a short filum. **Paraphyses** apically (slightly to) medium or strongly inflated, spathulate (to submammiform), terminal cells *11–31 × (2.5–)3–4.5(–5.7) µm {9}, †2.5–4.2 µm wide {2}, exceeding the living or dead asci by 2–8 µm, lower cells *9–15 × 1.3–2.1 µm {4}, †1–1.7 µm wide {3}; never branched at upper septum; hymenium (pale to) light to bright yellow. **Medullary excipulum** hyaline, 20–70 µm thick, sometimes up to 150 µm in centre, of medium loose to dense textura intricata with many inflated cells, very sharply delimited from ectal excipulum by a parallel 10–20(–30) µm thick layer of dense or loose t. porrecta. **Ectal excipulum** hyaline, towards margin usually light to bright yellow-orange, of thin-walled, vertically oriented t. globulosa-angularis-prismatica, 50–100(–180) µm thick at base, 30–100 µm at lower flanks, cells *10–25(–28) × 6–17(–20) µm {7}; 15–30 µm thick at mid flanks and margin, at margin of t. angularis-globulosa oriented at a 70–90° angle {8}, marginal cortical cells clavate to subglobose, *(4–)7–11(–14) × (3–)4–7(–9) µm {5}; **glassy processes** present, (0–)1–5(–9) × 3–5(–7) µm {~15}, conical, low to high refractive, sometimes stratified, hyaline to pale yellowish, ± curved outwards if not very short, also ± absent {5}, often difficult to distinguish from exudate. **Anchoring hyphae** sparse or abundant, *(1.5–)2–3(–4) µm wide, walls 0.2–0.3(–0.4) µm thick {4}, with or without scattered yellowish LBs 0.3–1.5 µm diam., sometimes forming a dense t. intricata up to 40–50 µm thick, partly gradually intergrading with excipular cells. **SCBs** in paraphyses, margin and flanks usually absent, rarely globose, very low-refractive; **LBs** bright to deep golden yellow(-orange) (carotenoids), near apex and in lower half of paraphyses 0.2–1(–2) µm diam., scattered or mostly rather abundant {~57}, rarely absent {2}; in medullary excipulum 1–2.5 µm diam., sparse; in ectal excipulum near margin scattered or abundant, small to large; deep blue-green-olive when applying IKI to water mount. **Exudate** over paraphyses forming individual, conical to convex or truncate glassy caps on nearly all apices, (0.3–)0.5–2 µm thick {~22}, smooth to warted, firmly attached, hyaline, rarely absent, over margin and flanks 0.2–0.5 µm thick. — **ANAMORPH**: dicranidion-like (from ascospore isolate {1} and natural substrate {1}). **Conidiophores** not seen. **Conidia** U-shaped, 2-armed, *18–37 × 9.2–11 µm {2}, arms *4.2–5 µm wide, 2–5-septate, base truncate or conical, stipe absent or nearly so.

Habitat: collected 0–5 m above the ground, on 9–80 mm thick, ± corticated branches (also thick trunks) of *Abies alba* {1}, ?*Betula* sp. {1}, *Carpinus betulus* {1}, *Castanea sativa* {1}, *Cercis siliquastrum* {2}, *Cornus sanguinea* {1}, *Crataegus* sp. {1}, *Eucalyptus*

Phenology of *O. xanthoguttulata*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
4	6	10	10	9	6	2	5	5	5	5	4

Taxonomic remarks. *Orbilia xanthoguttulata* is readily recognized by its spathulate paraphysis apices which mostly contain many small to large yellow LBs, which also occur in the lower half of paraphyses and in the ectal excipulum at mid flanks and margin, and give the distinct yellow colour to the apothecia. With its helicoid spores with tear-shaped SBs in the acute apices, *O. xanthoguttulata* closely resembles *O. aurantiorubra* (series *Aurantiorubrae*) but also *O. vermiformis* (*nemaspora-vermiformis* clade), which both differ not only in colour but also in having uninflated to capitate-clavate paraphysis apices without abundant LBs, and the margin consistently without glassy processes. *O. xanthoguttulata* further differs from these two species in its dicranidion-like anamorph, and from *O. aurantiorubra* in lacking crystalloid SCBs.

Variation. The length of ascospores and especially of SBs varies to a considerable extent. Depending on the population, spore length ranges from *10–12 µm up to *13.5–16 µm (mainly 11–14 µm), and SB length from 1.8–2.4 µm up to 2.8–3.3 µm. Spore width is usually *1.3–1.5 µm, rarely 1.2–1.3 µm (Pl. 443: 1) or 1.6–1.8 µm (Pls 443: 5; 444: 10). Spores of 10–13 µm were observed at mediterranean sites (e. g., Pls 443: 2; 444: 10) as well as in northern France and Scandinavia, and spores of the longer range occurred likewise across Europe.

Two collections on *Picea* bark from Glarus and Oberallgäu (Pls 443: 3–4; 444: 11) showed almost unpigmented apothecia besides light yellow ones. In one of them (443: 3) the ascospores were a bit more spirally twisted, with more attenuated basal ends and longer SBs, also glassy processes were not seen at the margin. However, glassy processes were in specimens on angiosperm hosts also often very short (around 1–3 µm), and sometimes predominantly absent, also difficult to distinguish from exudate. Three further samples on conifers (on wood, boring dust and bark of *Abies* and *Picea*) had bright yellow-orange apothecia, and also here one on *Picea* showed more strongly helicoid spores and that on *Abies* (IVV: 21.IV.2018) extraordinarily long spores of *(14–)16–17(–18) × 1.4–1.6 µm. Apothecial pigmentation was found to depend on the intensity of illumination: apothecia growing exposed possessed abundant yellow LBs whereas those below the bark were quite unpigmented. No molecular data were available for samples on conifers.

Misapplication. During revision of *O. rubella* in P. Karsten's herbarium, one of the specimens turned out to belong to *O. xanthoguttulata*. Also Rehm's (1891) description of *O. curvatispora* (spores worm-shaped, helicoid, apices of paraphyses egg-shaped inflated, with a yellowish oil drop; Germany, Bayern, Sugenheim, on dry-rotten hanging twigs of *Quercus*) very probably refers to a specimen of *O. xanthoguttulata*. Baral (1987b) misapplied the name *O. comma* to the pesent species when reporting yellow LBs with a blue-green IKI reaction.

Not included collection. Although the only known North American collection, described in Shao et al. (2018), fits very well European *O. xanthoguttulata* in morphology of both teleomorph and anamorph it was not included in the present description because of deviating molecular data (see below).

Anamorph. Despite morphological similarities between *O. xanthoguttulata* and *O. aurantiorubra*, the two species strongly differ in their anamorphs. The conidia of *O. xanthoguttulata* (Pls 443: 6; 444: 14) resemble *Dicranidion amazonense* (on palm leaves from Peru) in size and absence of a stipe. However, a broadly truncate base which we have seen in many conidia of *O. xanthoguttulata* is not reported for *D. amazonense*. Conidia of *O. eucalypti* and *O. tremulae* have also a very similar shape but are distinctly smaller.

Phylogeny. Sequences of eight European samples of *O. xanthoguttulata* were available, all comprising the S1506 intron and the ITS region, five also LSU and four SSU. One of them was gained from pure culture (H.B. 6989a) by G. Hagedorn and seven from apothecia by L. Quijada, M. Weiß, and G. Marson. From pure culture of the sample from Georgia (North America), ITS (intron region not covered) and LSU were obtained (Shao et al. 2018).

Within the European strains, variation of 0.6–3.5 % was observed in the entire ITS region, but no correlation between these distances and the geographical origin within Europe or the spore size if available could be noted. However, a correlation with the host is seen when retrieving a phylogeny from the ITS region (Phyl. 15, see also Quijada et al. 2014b): samples on *Quercus*, *Fagus*, and *Fraxinus* formed a strongly supported clade, while those on *Salix* and *Ulmus* clustered in a medium supported sister clade.

In the LSU D1–D2 domain the European sequences differ only at pos. 539 (C in H.B. 7915b and 7464, both on *Salix*; T in H.B. 6989a on *Salix*, G.M. 2017-12-27.2 on *Fagus*, and 2017-09-28.1 on *Quercus*). The American ga047 and Macaronesian *O. succulenticola* also have T. In the four available SSU sequences *O.*

H.B. 8170a: France, Melle, on *Ulmus*; **7**. P.P. 20070426-5: Poland, unlocalized, on *Salix*; **8a–b**. H.B. 9182b: France, Nyons, on *Quercus*; **9**. H.B. 7464: Spain, Málaga, on *Salix*; **10**. 17.III.2011: Spain, Alicante, on *Ulmus*; **11**. H.B. 5330: Switzerland, Glarus, on *Picea*; **12**. P.P. 20070825: Poland, Śrem, on *Crataegus*; **13a–b**. H.B. 9291: France, Loire, on *Fraxinus*; **14**. H.B. 7884b: Luxembourg, Junglinster, on *Fagus*.

xanthoguttulata showed no variation in the (V7–)V8–V9 region. In the intron it varies by 1–4 %, and also here the strains on *Salix* and *Ulmus* clustered in an unsupported separate clade (Phyl. S14). For the differences to *O. succulenticola* see below.

The sample from Georgia clustered distantly from *O. xanthoguttulata* and *O. succulenticola* when analysing the ITS and/or LSU region (Phyls 13, 15, S15, S16, Shao et al. 2018), though in the combined analyses in a medium supported clade with *O. succulenticola*. Here an ITS distance of 3.3–5.5 % is observed to *O. xanthoguttulata* and 5–5.5 % to *O. succulenticola*, the 3.3 % distance being to the Spanish strain from Málaga. The Georgia sample also differs in having an insert of 11 nt in the ITS2. The S1506 intron appears to be absent, considering the used ITS5 primer and a high signal at the 3'-end of SSU. In the LSU this sample deviates from *O. xanthoguttulata* and *O. succulenticola* by 2 nt in the D1 and 2 nt in the D2 domain (pos. 132, 160, 456, 471), but due to 1–2 variable nt in European *O. xanthoguttulata* and 1 in *O. succulenticola* the distance ranges at 0.6–1.5 %. The D3 domain was not available in *O. succulenticola*; also here 1 nt (pos. 936, GT**C**C) deviates from *O. xanthoguttulata* (G.M. 2017-09-28.1, GT**T**C). All these deviations are unequivocal in the available chromatograms, and they suggest that the sample from Georgia belongs to a different, cryptic taxon.

Ecology. *O. xanthoguttulata* shows a remarkably diverse ecology. The species was collected on undecayed to decayed bark (rarely wood) of xeric branches or sometimes trunks of angiosperm trees and shrubs, predominantly *Salicaceae* {26}, *Ulmus* {7}, and *Quercus* {9}, rarely gymnosperms. The collections are from humid to semihumid, atlantic to subcontinental sites in thermo- to hemiboreal northern Europe, meso- to orotemperate western and central Europe, and orosub- to thermomediterranean southern Europe. In mediterranean samples a much higher desiccation tolerance than in central European samples was observed. The vegetation includes *Querco-Fagetum*, *Fraxino-Aceretum pseudoplatani*, *Abieto-Fagetum*, *Picea-Vaccinietum*, *Salix-Betula-Populus*-pioneer vegetation in quarries, floodplain forests, thermophilous shrubs, and mediterranean maquis. The not included sample from eastern North America was in a subtropical humid angiosperm forest.

Map 78. Known distribution of *O. xanthoguttulata* in Europe.

Specimens included. **NORWAY**: **Aust-Agder**, 5 km ENE of Arendal, Tromøy, Kvernhuskjerr, 18 m, trunk of *Salix caprea*, on bark, 15.IV.2009, T.H. Dahl (T.H.D. 116/09, H.B. 9046b ø, doc. vid.). – ibid., S of Alvekilen, 5 m, on bark of *Ulmus glabra*, 9.IV.2009, T.H. Orbilia succulenticola Quijada, Baral & Beltrán-Tej., in Quijada et al., Phytotaxa 175: 13 (2014) — Pls 445–446, Map 79

Etymology: named after the inhabited branches of succulent plants.

Typification: Macaronesia, Tenerife, Punta Hidalgo, branch of *Euphorbia canariensis*, 20.X.2008, L. Quijada & E.V. Rodríguez (TFC Mic. 20335, holotype; sq.: KF768649).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.6–1(–1.2) mm diam., (0.18–)0.23–0.3(–0.37) mm high (receptacle 0.14–0.15 → 0.1–0.12 mm), light yellowish-ochraceous, slightly translucent, ± round, scattered to gregarious in small groups; disc flat to slightly convex, margin thin, not protruding, very finely crenulate; sessile on an obconical stipe up to 0.07 × 0.35 mm, superficial; dry slightly concave, deep ochraceous-brownish(-orange). **Asci** *(51–)55–63(–67) × (4–)4.2–4.8(–5.4) µm {7}, †42–57 × 3.4–4 µm {10}, 8-spored, spores *2–4-seriate, (2–)3–4(–5) lower spores inverted {6} (sometimes slightly mixed), pars sporifera *20–23 µm long; **apex** (†) strongly truncate (not or very slightly indented, laterally never inflated); **base** with medium to long, thin, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(9–)9.5–11(–12) × (1–)1.2–1.5(–1.6) µm {8} (~10–13 µm actual length), †(8.3–)9–10(–10.4) × (0.9–)1–1.3 µm {10}, fusiform-clavate, apex acute, base medium to strongly attenuated in a ± distinct, sometimes swollen tail of 1.7–3.5(–5) × 0.5–0.7(–1) µm (ca. 1/4–1/3 of spore length), inequilateral to slightly curved in upper part, medium (to strongly) so in region of tail, slightly helicoid; **SBs** *(1.7–)2–2.4(–2.6) × (0.6–)0.8–1(–1.2) µm {8}, tear-shaped, apically narrowed to a short, hardly visible filum. **Paraphyses** apically slightly to medium (rarely strongly) clavate-spathulate(-ellipsoid), terminal cells *(16.5–)22–28(–34) × (2.5–)3–4(–5) µm {7}, (†) 1–8 µm longer than dead asci, lower cells *(5–)7–11(–14) × 1.5–2 µm {6}; rarely branched at upper septum, hymenium pale yellowish-ochraceous. **Medullary excipulum** hyaline, 70–125 µm thick, of medium loose to dense textura intricata with many inflated cells, sharply delimited by a t. porrecta mainly at flanks. **Ectal excipulum** hyaline, of (†) thin-walled, vertically oriented t. prismatica-angularis at base and flanks, 50–75 µm thick near base, cells *(8.5–)10–23(–28) × (6.5–)9–13(–18.5) µm {6}; 20 → 10 µm thick near margin, of light yellowish-ochraceous t. prismatica oriented at a 30–80° angle to the surface, marginal cortical cells *8–13 × (3–)4–5(–6) µm {7}; **glassy processes** 8–18 × 3–5 µm {6}, at flanks 2–10 × 4–6 µm, medium refractive, indistinctly

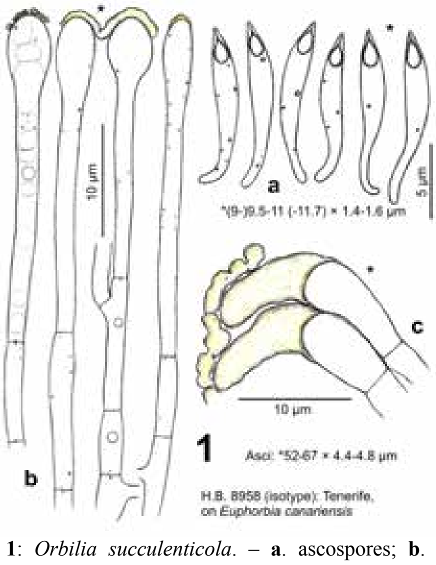

Plate 445. **1**: *Orbilia succulenticola*. – **a**. ascospores; **b**. paraphyses; **c**. marginal cortical cells with glassy processes in median section.

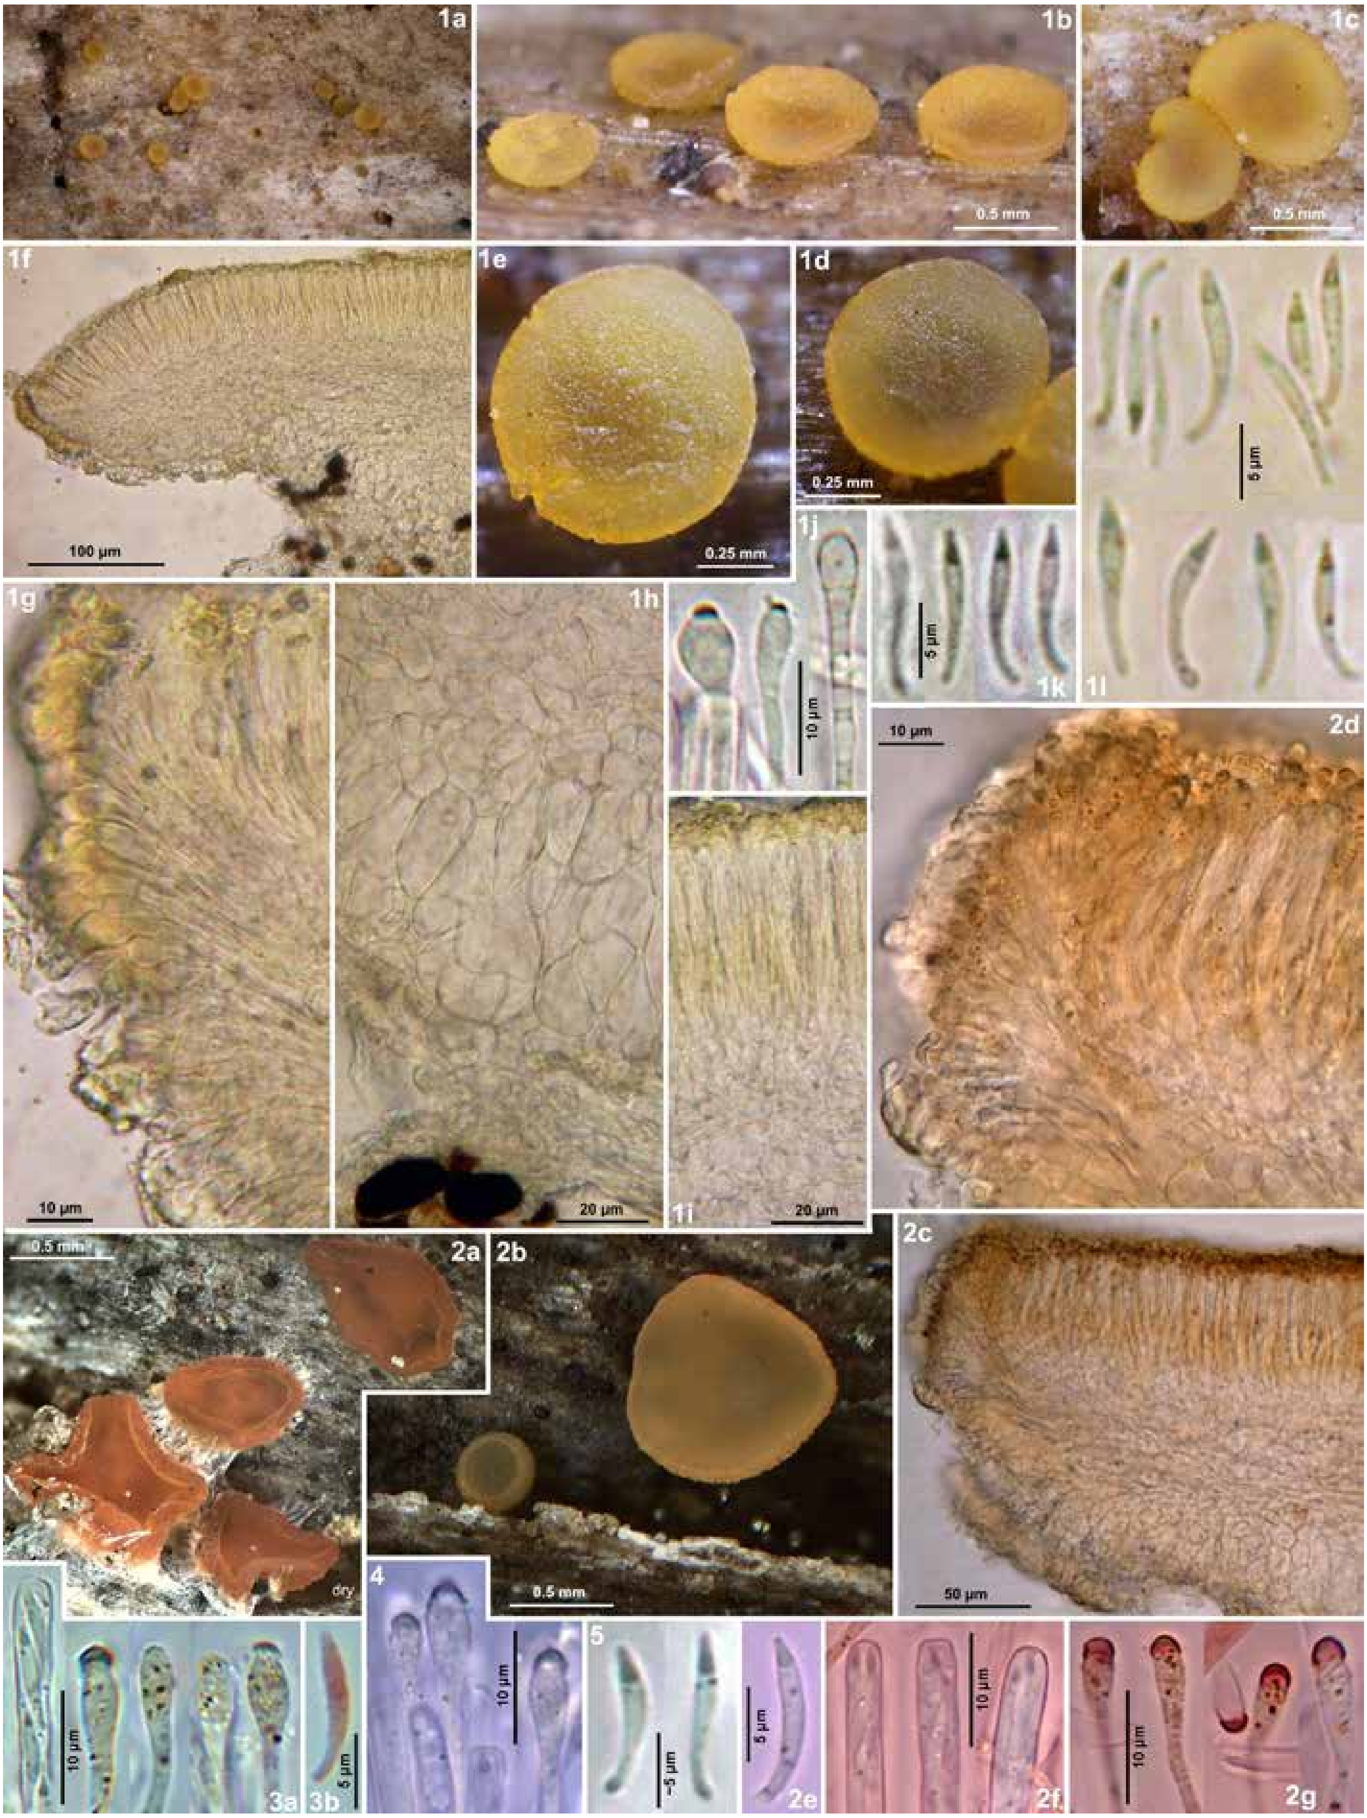

Plate 446. **1**, **3–5**: *Orbilia succulenticola*; **2**: *O.* cf. *succulenticola*. – **1a–d**, **2b**. rehydrated apothecia; **2a**. dry apothecia; **1f**, **2c**. apothecia in median section; **1g**, **2d**. id., ectal excipulum at margin; **1h**. id., near base; **1j**, **2f–g**, **3a**, **4**. asci and paraphyses; **1k–l**, **2e**, **3b**, **5**. ascospores. — Living state, except for **2g** (in CR), **3b** (in CR), ascus in **3a**. – **1j–k**, **2–5**: phot. L. Quijada (**1b**, **1l**: from Quijada et al. 2014b). — **1a–l**. H.B. 8958 (TFC Mic. 20335, **1a–i**, l: isotype, **1j–k**: holotype): Tenerife, Anaga, Punta Hidalgo, on *Euphorbia canariensis*; **2a–g**. TFC Mic. 23292: Vilaflor, on *Chamaecytisus*; **3a–b**. TFC Mic. 23229: La Matanza, on *E. canariensis*; **4**. TFC Mic. 22119: Punta de Teno, on *E. balsamifera*; **5**. TFC Mic. 22822: Güímar, on *E. atropurpurea*.

stratified, consistently outwards curved, covered by yellowish exudate. **Anchoring hyphae** very abundant, *2.2–2.8(–3.5) µm wide, walls 0.2(–0.3) µm thick {1}, forming a medium dense, hyaline, not or medium gelatinized t. intricata ~10–20(–60) µm thick. **SCBs** in paraphyses and ectal excipulum absent but sometimes indistinct small globose SCBs seen in paraphyses. Bright to deep golden yellow(-orange) **LBs** (carotenoids) absent {T} or scattered to abundant near apex and in lower half of paraphyses and in marginal ectal excipulum {9}, 0.4–0.7 µm diam. **Exudate** over paraphyses (0.3–)1–1.5(–2) µm thick, granular-cloddy, sometimes cap-like, pale yellowish-ochraceous, firmly attached, over margin and flanks 1.5–3.5 µm thick, cloddy. — **ANAMORPH**: unknown.

Habitat: collected on the ground (but not in close soil contact), 2–7 cm thick decorticated xeric branches of *Euphorbia atropurpurea* {1}, *E. balsamifera* {2}, *E. canariensis* {5}, *E. lamarckii* {2}, *Opuntia maxima* {1}, on strongly decayed wood (inner and outer surface) {10}, slightly greyed, no algae. **Associated**: none observed. **Desiccation tolerance**: ectal and medullary excipulum, also some paraphyses and mature asci viable after 1 month. **Altitude**: 45–402 m a.s.l. **Geology**: basaltic flows and pyroclasts, ignimbrite. **Phenology**: I–II, VII–VIII, X–XI (throughout the year, long-lived).

Taxonomic remarks. *Orbilia succulenticola* closely resembles *O. aurantiorubra* (series *Aurantiorubrae*) in ascospore features, especially samples on *Fabaceae* (Pl. 436) which show about the same spore size. It differs in distinctly shorter SBs, more ellipsoid (spathulate) apices of paraphyses, the absence of S-shaped SCBs, the presence of short glassy processes, and in apothecial colour.

Based on its yellow apothecial pigment located in small LBs, ellipsoid paraphysis apices, and glassy processes, *O. succulenticola* is obviously much more closely related to *O. xanthoguttulata*, which mainly differs in longer spores and slightly longer SBs, also in slightly shorter and wider marginal cortical cells oriented at a higher angle, and in shorter glassy processes. However, most of these features overlap to some extent, for instance, only those spore length values given in brackets overlap while the predominant ones lie in the range of */†9–11 and */†11–14.5 µm, respectively.

O. succulenticola may be confused with *O. euphorbiae* (series *Regales*) and *O. pseudeuphorbiae* (series *Neodactylella*), though mainly because of the same substrate. The two species differ in shorter spores with rounded to obtuse apices and less tail-like bases, in much smaller SBs (0.8–1.8 × 0.3–1 µm), and in the paraphyses with usually more distinctly spathulate to lageniform apices, some of which containing yellow LBs in the lower but never in the apical part.

Variation. *O. succulenticola* shows only little variation in the length of spores and SBs, thus rather sharply permits separation from the similar *O. xanthoguttulata* based especially on spore length. The type collection of *O. succulenticola* further differs in virtually lacking yellow LBs in paraphyses and excipular cells (Pls 445: 1; 446: 1f-j), and in more ellipsoid than spathulate paraphysis apices without prominent exudate caps. However, the nine paratype collections of *O. succulenticola* show sparse to rather abundant bright yellow LBs in the lower and upper part of paraphyses, and the inflated apices are often more elongate and sometimes spathulate and often covered by thick caps of exudate (Pl. 446: 2g, 3–4).

Not included collection. A more recent sample not mentioned in Quijada et al. (2014b) grew at high altitude (2083 m) on a different host (*Chamaecytisus*, IVV: TFC Mic. 23292). Nevertheless, it matches *O. succulenticola* quite well in the length and shape of spores (*10.5–11.3 × 1.2–1.5 µm) and SBs (2–2.5 µm) and in the yellow-orange LBs occurring in abundance especially in the paraphyses.

Map 79. Known distribution of *O. succulenticola* in Tenerife (Macaronesia, yellow = not included collection).

Phylogeny. From apothecia of *O. succulenticola*, B. Liu obtained ITS and LSU D1–D2 from the isotype (H.B. 8958), and L. Quijada ITS sequences of ten samples from eight collection sites other than the type locality. The observed variation in the ITS region within these sequences lies in the range of 0–1 %. This relatively low variation could be explained by the fact that *O. succulenticola* is so far only known from lowland regions of Tenerife. Regrettably, no DNA was taken from the rather lately collected sample on *Chamaecytisus* from the Canary pine woodland.

The distance to *O. xanthoguttulata* lies in the range of 4–6 % in the entire ITS region, whereas in the LSU only 1 nt differs from the majority of *O. xanthoguttulata* sequences (pos. 611: TG**T**TG vs. TG**C**TG), but further 1–2 nt (pos. 539, 553) deviate depending on the strain and completeness of the sequences. In all 11 sequences of *O. succulenticola* the S1506 intron is absent, in contrast to all six sequences of European *O. xanthoguttulata* in which the intron is present. All this confirms that the two morphologically similar species are sharply separated, reflecting their different geographical distribution and host spectrum.

Ecology. *O. succulenticola* appears to be restricted to the inframediterranean, semihumid to arid xerophytic scrubland of Macaronesia, where it was mainly collected in the cardonal (*Periploco laevigatae-Euphorbietum canariensis*), but also in the tabaibal dulce (*Ceropegio fuscae-Euphorbietum balsamiferae*), *Launaeo arborescentis-Schizogynetum sericeae*, and *Ceropegio dichotomae-Euphorbietum aphyllae* (L. Quijada & E. Beltrán-Tejera pers. comm.). It occurs on dead, xeric, decorticated branches of different succulent *Euphorbia* species, particularly *E. canariensis*, also *Opuntia*, always close to the ground. The not included record on a xeric branch of *Chamaecytisus* was from an upper mesomediterranean semihumid summit broom-scrub in the Canary pine woodland (*Sideritido solutae-Pinetum canariensis*) on phonolite of Vilaflor at the south-exposed slope of the southern rim around the caldera of the volcano Teide.

Specimens included (always on decorticated branches). **MACARONESIA**: **Canary Islands**, **Tenerife**, Buenavista del Norte, 4.8 km WSW of Buenavista del Norte, Punta de Teno, El Tosconito, 216 m, *Euphorbia lamarckii*, 8.XI.2009, leg. Not included. **MACARONESIA**: **Canary Islands**, **Tenerife**, Adeje, 5 km NW of Vilaflor, 9.5 km SSW of Teide, Lomo el Dornajito, 2083 m, branch of *Chamaecytisus proliferus*, on wood, 12.XII.2012, L. Quijada (TFC Mic. 23292, doc. vid.).

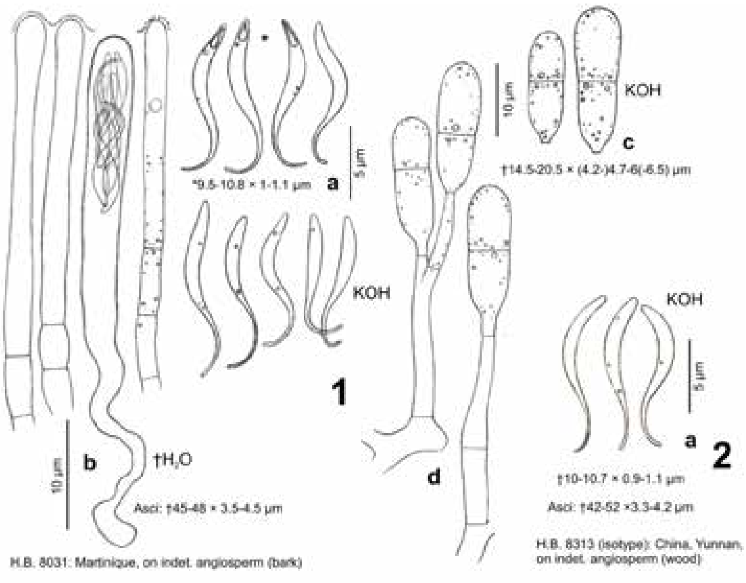

Plate 447. **1–2**: *Orbilia vermiformis*. – **a**. ascospores; **b**. ascus and paraphyses; **c–d**. conidia and conidiophores from substrate (on older apothecia).

2. *Nemaspora-vermiformis* clade

Orbilia vermiformis Baral, Z.F. Yu & K.Q. Zhang, in Yu et al., Mycotaxon 99: 272 (2007) — Pls 447–448

= *Dactylella vermiformis* Z.F. Yu, Ying Zhang & K.Q. Zhang, in Yu et al., Mycotaxon 99: 275 (2007).

Etymology: named according to the worm-shaped ascospores.

Typification: China, Yunnan, Xiaoheijiang, root of indet. angiosperm, 3.IX.2005, M. Qiao (YMFT 1.01842, holotype of teleomorph; YMF 1.01842, holotype of anamorph; sq.: DQ480729).

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated 0.4–2 mm diam., 0.18–0.4.5 mm high (receptacle 0.13–0.26 → 0.09–0.1 mm), whitish to pale yellowish-cream, turning light carneous with age, slightly to medium translucent, round, (densely) gregarious in medium to large groups; disc slightly concave to slightly convex, margin distinct, 5–10(–30) µm protruding, (very) finely crenulate; sessile on a broad base or with a hidden stipe 0.08–0.1 × 0.3–0.35 mm, superficial. **Asci** */†39.5–62 × 3.3–5 µm {T}, †40–53 × 3.3–4.2(–4.5) µm {3}, 8-spored, spores *4-seriate, (2–)4 lower spores inverted {2} (rarely mixed); **apex** (†) medium to strongly truncate (not or slightly to strongly indented, laterally not inflated); **base** with short to long, medium thin, flexuous stalk, L- to Y-shaped. **Ascospores** *(8.8–)9.5–11.3 × 1–1.1(–1.3) µm {2} (~10–13 µm actual length), †(8–)9–11(–12) × 0.9–1.1(–1.2) µm {3}, narrowly fusoid to fusiform, apex obtuse to subacute or acute, base strongly attenuated in a ± indistinctly differentiated narrow tail of 2.5–5 × 0.15–0.4 µm, strongly helicoid (always twisted like a right-hand thread {2}); **SBs** (1.3–)1.5–1.8 × 0.4–0.8(–1) µm {1}, tear-shaped, apically narrowed to a very short filum. **Paraphyses** apically uninflated or only very slightly clavate, terminal cell †21–32 {1} × 2–3 µm {2}, lower cells †4–6 × 1.8–2.8 µm {1}; unbranched at upper septum. **Medullary excipulum** 20–30 µm thick, of dense textura intricata-angularis-porrecta, medium to very sharply delimited from ectal excipulum. **Ectal excipulum** of (†) thin-walled, indistinctly oriented t. angularis(-prismatica) from base to margin, 100–300 µm thick near base, cells †20–45 × (10–)15–35 µm {2}; 100 → 40 µm thick at flanks, 20–40 µm thick at margin, oriented at a 70–80° angle to the surface, marginal cortical cells †(6–)9–14(–17) {3} × (4.5–)5–7 {1} or (6–)8–12(–13) {2} µm; **glassy processes** absent {3}. **Anchoring hyphae** abundant, †2–4(–5) µm wide, walls 0.2(–0.3) µm thick {2}, forming a dense hyaline, not or slightly gelatinized t. intricata-angularis 40–150 µm thick {2}. **SCBs** in paraphyses globose to elongate, crystalloid SCBs absent; **VBs** ?absent. **Exudate** over paraphyses 0.1–0.2 µm up to 0.3–1 µm thick, granular-cloddy or ± continuous, not loosely attached; over margin and flanks absent. — **ANAMORPH**: dactylella-like (from ascospore isolate {1, Yu et al. 2007a} and natural substrate {1}). **Conidiophores** septate, erect, simple, sometimes branched, 70–150 µm long, 3 µm wide at base and 1.8–2 µm wide at tip {Yunnan}, †22–30 µm long, 2.7–3.6 µm wide at base, 1.2–1.8 µm at tip {Martinique}, conidia formed terminally, singly or often on sparsely sympodially proliferating branches. **Conidia** cylindrical to cylindric-clavate, rounded at the distal end, narrowed and truncate at the proximal end, here often with a distinct basal protrusion, straight, sometimes slightly curved, (0–)1-septate, *20–30(–37) × 5.8–8 µm {Yunnan}, †14.5–20.5 × 4.2–6.5 µm {Martinique}.

Habitat: lying on moist ground, corticated or decorticated, ~6–15 cm thick branches and roots of indet. angiosperm {2}, ?*Mangifera indica* {1}, on ± deeply slightly to strongly decayed wood {2} and bark {1} (periderm), somewhat blackened, without algae. **Associated**: none observed. **Desiccation tolerance**: only a few spores still viable after 1 month. **Altitude**: 90–1100 m a.s.l. **Geology**: China: Jurassic-Cretaceous sedimentary rock; Comoros: volcanic igneous rock. **Phenology**: V, IX, XII (in tropical belt possibly throughout the year).

Taxonomic remarks. *Orbilia vermiformis* is very similar to *O. nemaspora*, from which it mainly differs in the ascospores being wider in their upper part in contrast to the thin tail-like lower part, perhaps also in less inflated paraphyses and in the anamorph (see below). Whether differences in the presence of VBs exist remains unclear due to lack of studies on living specimens.

Variation. The collection from Martinique differs from specimens from southern China and the Comoros in distinctly narrower marginal cortical cells.

Anamorph. The conidia in the type culture of *O. vermiformis* as reported by Yu et al. (l.c.) are somewhat larger and more clavate than those observed on the natural substrate in the collection from Middle America, in which also the conidiophores were shorter. Nevertheless, we think that the American specimen belongs to *O. vermiformis*. *O. nemaspora* has a very similar anamorph: the conidia of *O. vermiformis* are slightly shorter and (0–)1-septate, whereas those of *O. nemaspora* were sometimes 2–3(–4)-septate when formed in pure culture.

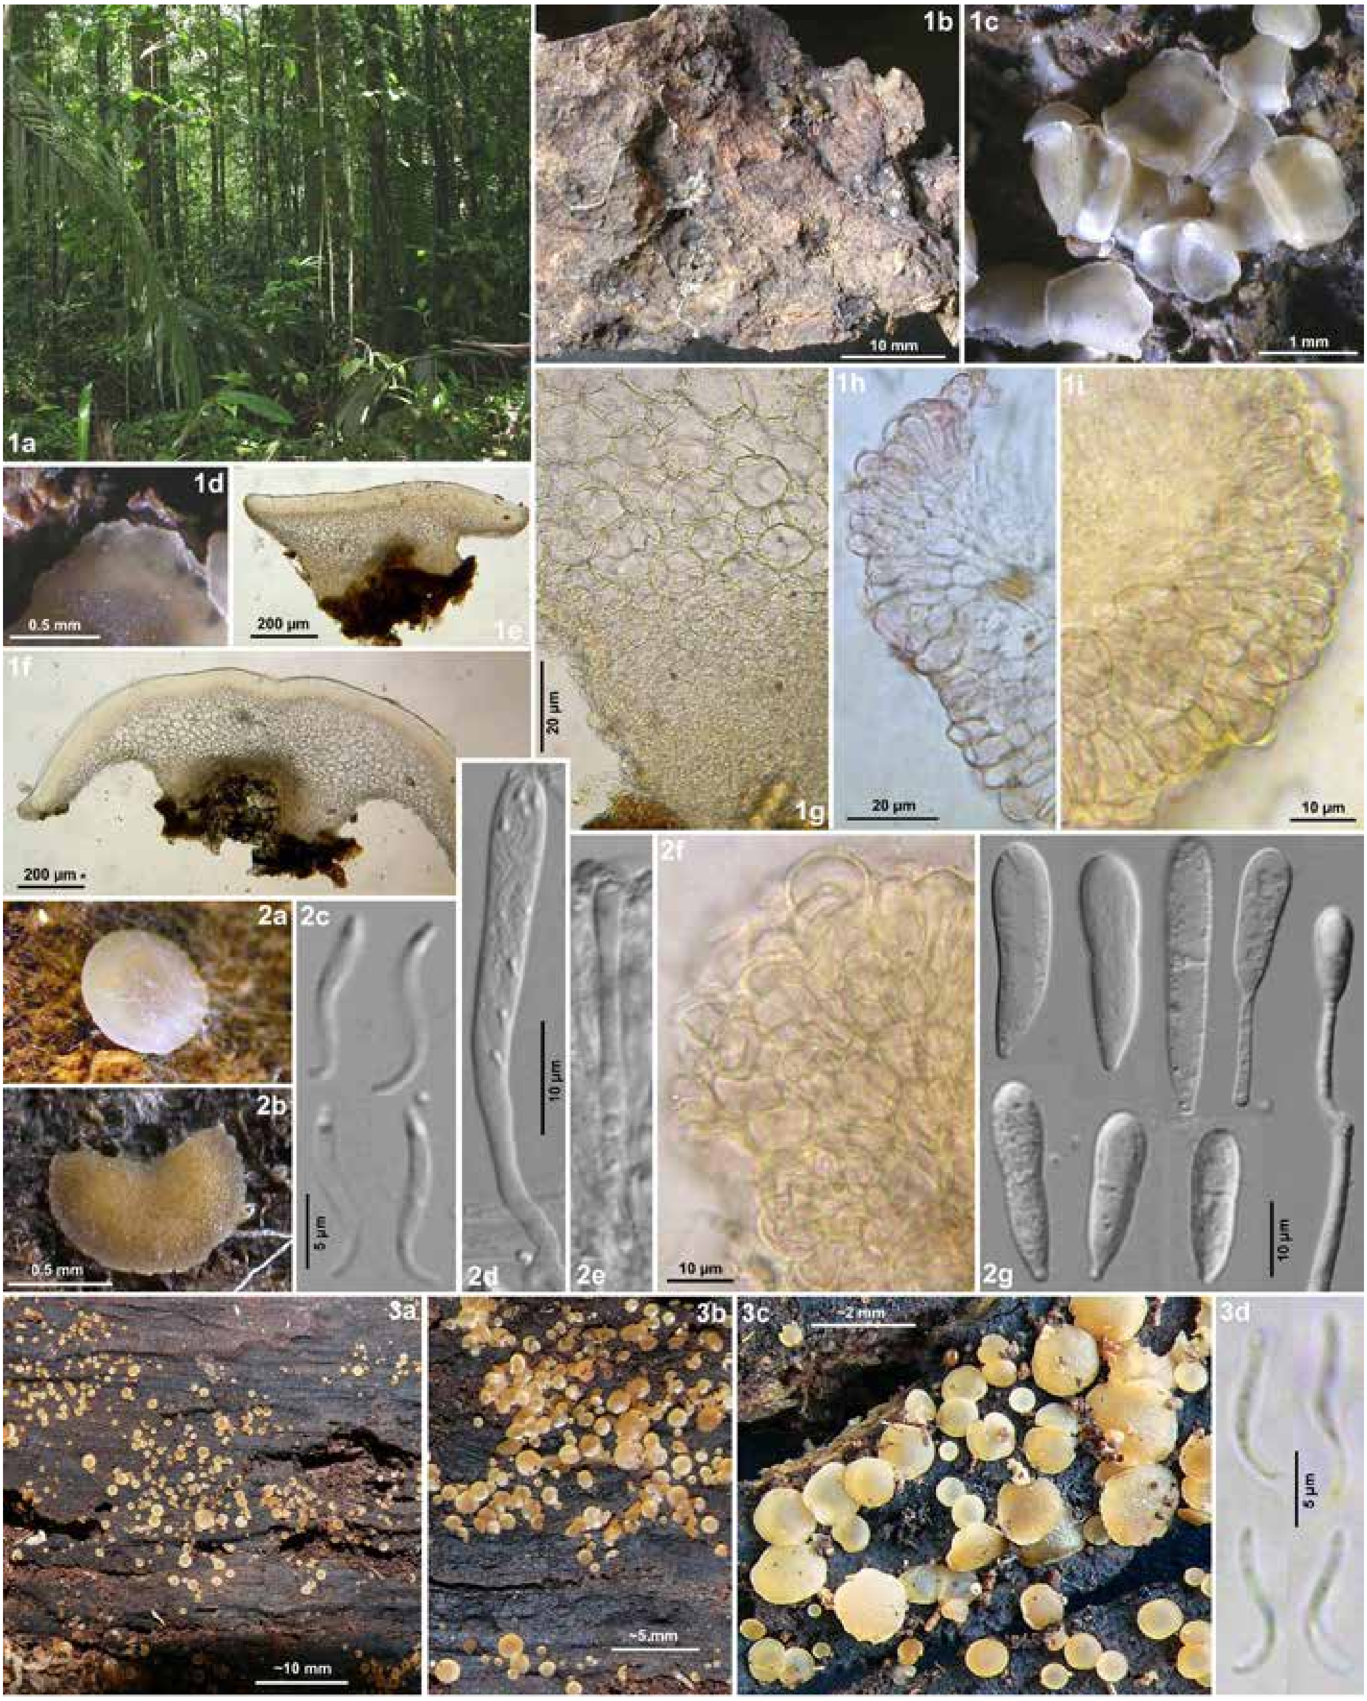

Plate 448. **1–3**: *Orbilia vermiformis*. – **1a**. tropical rainforest; **2a**, **3a–c**. fresh apothecia; **1c–d**, **2b**. rehydrated apothecia; **1e–f**. apothecia in median section; **1g**. id., basal ectal excipulum with dense layer of anchoring hyphae; **1h–i**, **2f**. id., marginal ectal excipulum; **2d**. mature ascus, **2e**. paraphysis; **2c**, **3d**. ascospores; **2g**. conidia and conidiophores from culture. – Living state, except for **1e–i** & **2f** (in KOH), **3d** & ascus in **2d** (in H_2O). – **1a**: phot. C. Lechat; **2a**, **c–e**, **g**: from Yu et al. (2007a, DIC); **3a–c**: phot. M. Pélissier. — **1a–i**. H.B. 8031: Martinique, on indet. angiosperm; **2a–g**. YMF 1.01842 (holotype): China, Yunnan, on indet. angiosperm; **3a–d**. H.B. 9747: Comoros, on ?*Mangifera*.

Yu et al. (2007a) compared *Dactylella vermiformis* with other species of *Dactylella* with 1-septate conidia. Accordingly, *Arthrobotrys* (‘*Dactylella*’) *pseudoclavata* has larger conidia and forms 3-dimensional networks, *D. arrhenopa* and *D. polyctona* have smaller conidia. *Dactylellina entomopaga*, a springtail capturing species, has similar 1-septate, 15–28 × 4.5–5.5 µm large conidia, which are, however, formed on denticles in a loose capitate arrangement (Drechsler 1944b).

Phylogeny. The ITS sequence gained from the type culture by Yu et al. (2007a) clustered in our analysis in the weakly (ML) or strongly (NJ) supported *nemaspora-vermiformis* clade of series *Xanthoguttulatae* (Phyls 15, S15) but with a high distance to other species, the closest percentage being to *O. nemaspora* (12.5 %). The S1506 intron is present and likewise shows a high distance to other species, the lowest percentage being to *O. nemaspora* (12 %), with which it formed only here a strongly supported clade (Phyl. S14).

Ecology. The type of *O. vermiformis* grew on rather undecayed wood of an angiosperm root in a subtropical humid (winter-dry) evergreen broad-leaved mountain forest at the southern end of Hengduan Shan, the southeastern extension of Himalaya. The collections from Martinique (Caribbean region) and Mayotte (Comoros, northwest of Madagascar) were on rotten angiosperm bark or wood in tropical humid and wet and dry rainforests at low altitude.

Specimens included. **CHINA**: **Yunnan**, **Pu'er**, Ning'er, 64 km N of Pu'er, Xiaoheijiang, ~1100 m (2100 m in protologue is erroneous), root of indet. angiosperm, on wood, 3.IX.2005, M. Qiao (YMFT 1.01842, **holotype** of *O. vermiformis*; H.B. 8313, **isotype**; YMF 1.01842, **holotype** of *D. vermiformis*, anam. cult.; sq.: DQ480729). — **LESSER ANTILLES**: **Martinique**, 5 km SE of La Sérénité, 3 km ENE of Petit Bourg, Le St.-Esprit, Le Bois La Charles, ~100 m, branch of indet. angiosperm, on bark, 8.XII.2005, C. Lechat (H.B. 8031, C.L.L. 5610, anam. substr.). — **COMOROS**: **Mayotte**, 14.5 km WSW of Mamoudzou, 1 km W of Chiconi, N of Baie de Chiconi, 90 m, branch of ?*Mangifera indica*, on wood, 23.VI.2012, M. Pélissier (J.P.P. 12186, H.B. 9747).

Orbilia nemaspora Baral, Bin Liu, A.I. Romero, Healy & Pfister, **sp. nov.**, MB 813762 — Pls 449–450, Map 80

Etymology: referring to the ascospores resembling nematodes.

Typification: USA, Massachusetts, Concord, log of *Acer*, 26.VII.1995, D.H. Pfister (ex D.H.P. 135 & ex H.B. 5308, M-0276538, holotype).

Misapplication: Ekanayaka et al. (2018), as *Orbilia stipitata* (p.p.).

Latin diagnosis: *Similis* Orbiliae vermiformi *sed ascosporae angustiores, paraphyses ad apicem saepe leniter ad valde capitatae, status anamorphicus conidiis 1–3-septatis. Habitat ad lignum putridum, raro corticem ramorum vel truncorum uvidorum arborum angiospermarum in zona tropica ad supratemperata humida Americae, Africae et Asiae.*

Description: — **TELEOMORPH**: **Apothecia** moist/rehydrated 0.3–0.8 or often 0.5–1.8(–3) mm diam., 0.18–0.38 mm high (receptacle 0.13–0.17 → 0.09–0.12 mm), fresh white or pale carneous to light yellow-ochre, rehydrated (dead) light yellowish-ochraceous to rose-orange or brick-red or reddish-brown with distinct dark translucent centre, round, slightly undulating when large, gregarious; disc flat, eventually medium convex, margin distinct, 0–5 µm protruding, smooth {1} or (very) finely to distinctly crenulate or denticulate {9}; sessile on a broad base or often stipitate, stipe sometimes hidden, obconical to cylindrical, 0.1–0.35 × 0.3–0.6 mm, superficial; dry bright (dirty) yellow-ochre-orange. **Asci** *36–45 × 3.3–3.8(–4) {2}, †(29–)31–45(–54) × 2.8–3.4 µm {11}, 8-spored, spores ± 4-seriate, 4(–5) lower spores inverted (sometimes mixed) {3}, pars sporifera *14–22 → 9–10 µm long; **apex** (†) strongly truncate (not or slightly indented, laterally not widened); **base** with medium to very long, thin, flexuous stalk, T- to L-, Y- or h-shaped. **Ascospores** *(8–)8.5–10(–11) × 0.7–0.8 µm {7} (~11–13 µm actual length), †(7.5–)8.5–9.5(–10)((–12)) × (0.5–)0.6–0.7(–0.8)((–0.9)) µm {12}, very narrowly fusoid to fusiform, apex (*) subacute to acuminate, (†) more obtuse, base ± strongly attenuated in an indistinctly differentiated narrow tail of 2–3.5 × 0.2–0.3 µm, strongly helicoid (always twisted like a right-hand thread), strongly curved especially near base; **SBs** *1.6–2 {4} or 3–3.7 {1} × 0.4–0.5(–0.7) µm {5}, narrowly tear-shaped to subulate, apically narrowed to a (very) short filum. **Paraphyses** apically uninflated or often slightly to medium, sometimes strongly (clavate-) capitate, terminal cell *21–28 × 2–3.3 µm {2}, †24–30 × (1.5–)2–3.3(–4) µm {5}, lower cells *4–7 × 2.2–3.7 µm {1}, †4.5–7 × 1.4–2.2 µm {1}; partially branched at upper septum. **Medullary excipulum** hyaline to pale cream, 15–40 µm thick, of irregularly horizontal textura intricata-porrecta, not or slightly to medium gelatinous, without or with many inflated cells, (very) sharply delimited from ectal excipulum. **Ectal excipulum** hyaline, of (†) thin-walled t. globulosa-angularis from base to margin (orientation indifferent or vertical), 120–300 µm thick at base, cells */†(15–)20–50(–70) × (10–)15–45(–60) µm {8}; 30–100 µm thick at lower flanks, cells at mid flanks *15–23 × 9–17 µm, 15–45 µm near margin, oriented at 45–90°, marginal cortical cells *(8–)10–17 × (5–)7–10(–14) µm {2}, †8–15 × (3–)5–8.5(–10) µm {4}, globose to broadly clavate, thin-walled, mostly forming 10–30 × 10–40 µm large teeth-like protrusions, **glassy processes** absent {11}. **Anchoring hyphae** sparse to often abundant, */†1.5–3(–4.5) µm wide, walls 0.2–0.3 µm thick {5}, usually forming a dense, 20–50 µm thick t. intricata(-angularis) at base and on stipe surface, not or sometimes strongly gelatinous. **SCBs** at flanks and margin (also in the inflated cells of medullary excipulum) brick-shaped {2}, ± low-refractive, 2–4 × 0.7–1.4 µm, or absent {2}; **VBs** in paraphyses medium refractive, globose to elongate {2}. **Exudate** abundant or sparse to almost absent, over paraphyses 0.2–1.5(–2.5) µm thick, rough-continuous or granular to cloddy, loosely attached or forming firmly attached caps, hyaline; over margin and flanks (0.2–)0.5–2 µm thick, granular to rough-cloddy, hyaline (to yellow-brown). — **ANAMORPH**: dactylella-like (from ascospore isolate {1, Liu 2006} and natural substrate {2}). **Conidiophores** (mainly after Liu 2006) ?unbranched, 20–206 µm long, 3–4 µm wide at the base, 1.8–2.4 µm at the tip. **Conidiogenous cells** monoblastic or sympodial. **Conidia** cylindric-clavate, *22.5–42 × 5–8 µm {China}, †17.5–23.5 × 5.3–6.3 µm {Puerto Rico} or †18–19 × 4 µm {Comoros}, rounded above, attenuated and truncate below, 1-septate {2} or (0–)1–3(–4)-septate {China}.

Habitat: lying on moist ground, sometimes in mud in the flooding zone of rivulets, corticated or decorticated, 5–30 cm thick branches or thick logs and cut stumps of *Acer* sp. {3}, *Alnus glutinosa* {1}, *Betula pendula* {1}, *Eucalyptus viminalis* {1}, *Salix* sp. {1}, *Ulmus* sp. {1}, indet. angiosperm trees {8}, stem of bamboo (*Dendrocalamus giganteus*) {1}, on deeply (slightly to) medium or strongly decayed wood {15} or bark {2}, on upper or lateral side, sometimes with many green algae and brown hyphae, partly in or near old beetle galleries (also on boring dust) {4}. **Associated**: *Brachysporium nigrum* {1}, ?*Cacumisporium capitulatum* {1}, *Hyalorbilia fagi* {1}, *H. puertoricensis* {1}, *Hypoxylon* sp. {1}, *Orbilia* ?*brochopaga* {1}, *O.* ?*clavispora* {1}, *O. latispora* {1}, *O. sarraziniana* {1}, *O. sinensis* {1}, *Sclerococcum* sp. {1}, indet. pyrenomycete {2}, acro- and pleurocarpous mosses {1}. **Desiccation tolerance**: obviously desiccation-sensitive, a few spores still viable after 22 months. **Altitude**: 5–430 m a.s.l. **Geology**: Cretaceous flysch, Miocene sand- & limestone, Quaternary sediments; granite, felsic plutonic rock. **Phenology**: VI–XI (temperate northern hemisphere), I–III (southern hemisphere), in tropical belt perhaps throughout the year.

Taxonomic remarks. *Orbilia nemaspora* is characterized by narrowly fusiform (worm-like), strongly helicoid ascospores and desiccation-sensitive, rather large apothecia with a very finely crenulate margin but without glassy processes. For the very similar *O. vermiformis* see p. 856. Morphologically very similar are *O. crenatomarginata* and *O. scolecospora* (series *Hyalinia*), which differ in narrower marginal cortical cells tipped by glassy processes and in ring-shaped crystalloid SCBs, the former also in shorter asci and spores. *O. nemaspora* further resembles *O. aurantiorubra*, from which it differs in less pigmented, desiccation-sensitive apothecia and a large celled, very thick basal ectal excipulum which sometimes contains brick-shaped SCBs, also in smaller spores. The slightly desiccation-tolerant *O. pseudobrevistipitata* differs mainly in lageniform paraphyses and the upper spores being inversely oriented in the asci. The

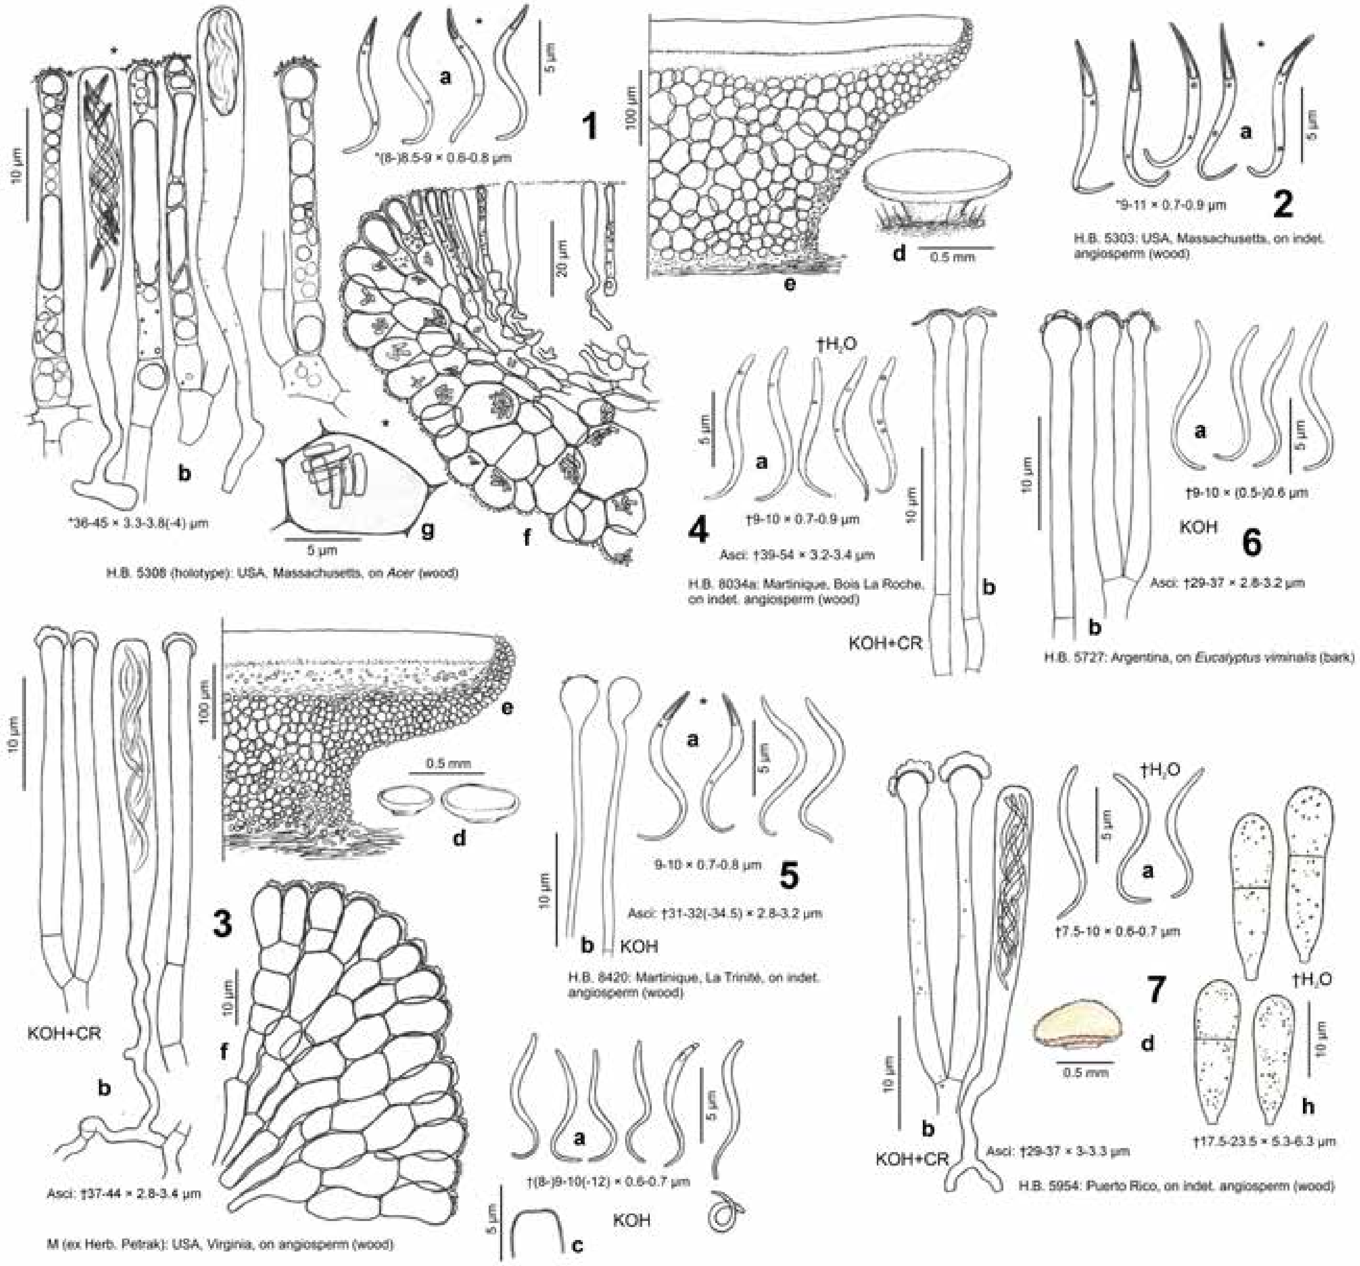

Plate 449. **1–7**: *Orbilia nemaspora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. fresh or rehydrated apothecia; **e**. apothecia in median section; **f**. id., ectal excipulum at margin and mid flanks; **f–g**. living excipular cells with brick-shaped crystalloid SCBs; **h**. conidia from substrate (formed on apothecium).

latter peculiarity is also one of the distinguishing features against *O. bomiensis* and *O. spirillospora*.

The Chinese *O. crenatonemaspora* deviates in marginal teeth made up of narrower, elongate cortical cells tipped by 7–35 µm long glassy processes, and in larger, especially wider spores containing larger SBs (2.5–5.5 × 0.6–0.9 µm).

Variation. Significant variation within *O. nemaspora* was observed in the apical inflation of the paraphyses ranging from uninflated to strongly capitate. Three specimens with not or only slightly inflated paraphyses showed a tendency to longer asci (Pl. 449: 1, 3–4, also in H.B. 5314). SBs are generally rather short but in one collection they were distinctly longer (Pl. 449: 2). The margin is almost always ± crenulate by forming small teeth, but in a collection from Virginia it is smooth (3). Also the thickness of the exudate over the paraphyses is very different among the collections, forming firmly attached caps on 3 and 7 and in H.B. 5314, but a mostly thinner granular layer in the other collections. In a sample from Martinique (Pl. 449: 4) the anchoring hyphae were strongly gelatinized (Pl. 450: 1f), and the marginal cortical cells showed a tendency to be rather narrow, characters not seen in the other specimens. The presence of brick-shaped SCBs in the ectal excipulum was observed in two samples on *Acer* from Massachusetts (holotype and the unillustrated D.H.P. 172), and their absence in the two samples on *Alnus* and *Betula* from Serbia; all other samples lack data on SCBs as their excipula were studied in the dead state. The apothecia much vary in size: in one collection some attained 2–2.8 mm (Pl. 450: 1c), but in another they measured only 0.3–0.5 mm (Pl. 449: 3d).

Literature reports. Romero (1994: 114) described *O. nemaspora* (as *Orbilia* sp.) with sessile apothecia with a bright orange colour and a smooth and slightly undulating margin. The asci are given much wider (35–40 × 5–7 µm), perhaps by artificial flattening, also the paraphysis apices abruptly thickened to 4–5 µm. However, one of her specimens was examined (Pl. 449: 6) and found to have narrow asci and paraphyses, and apothecia with distinct though hidden stipes.

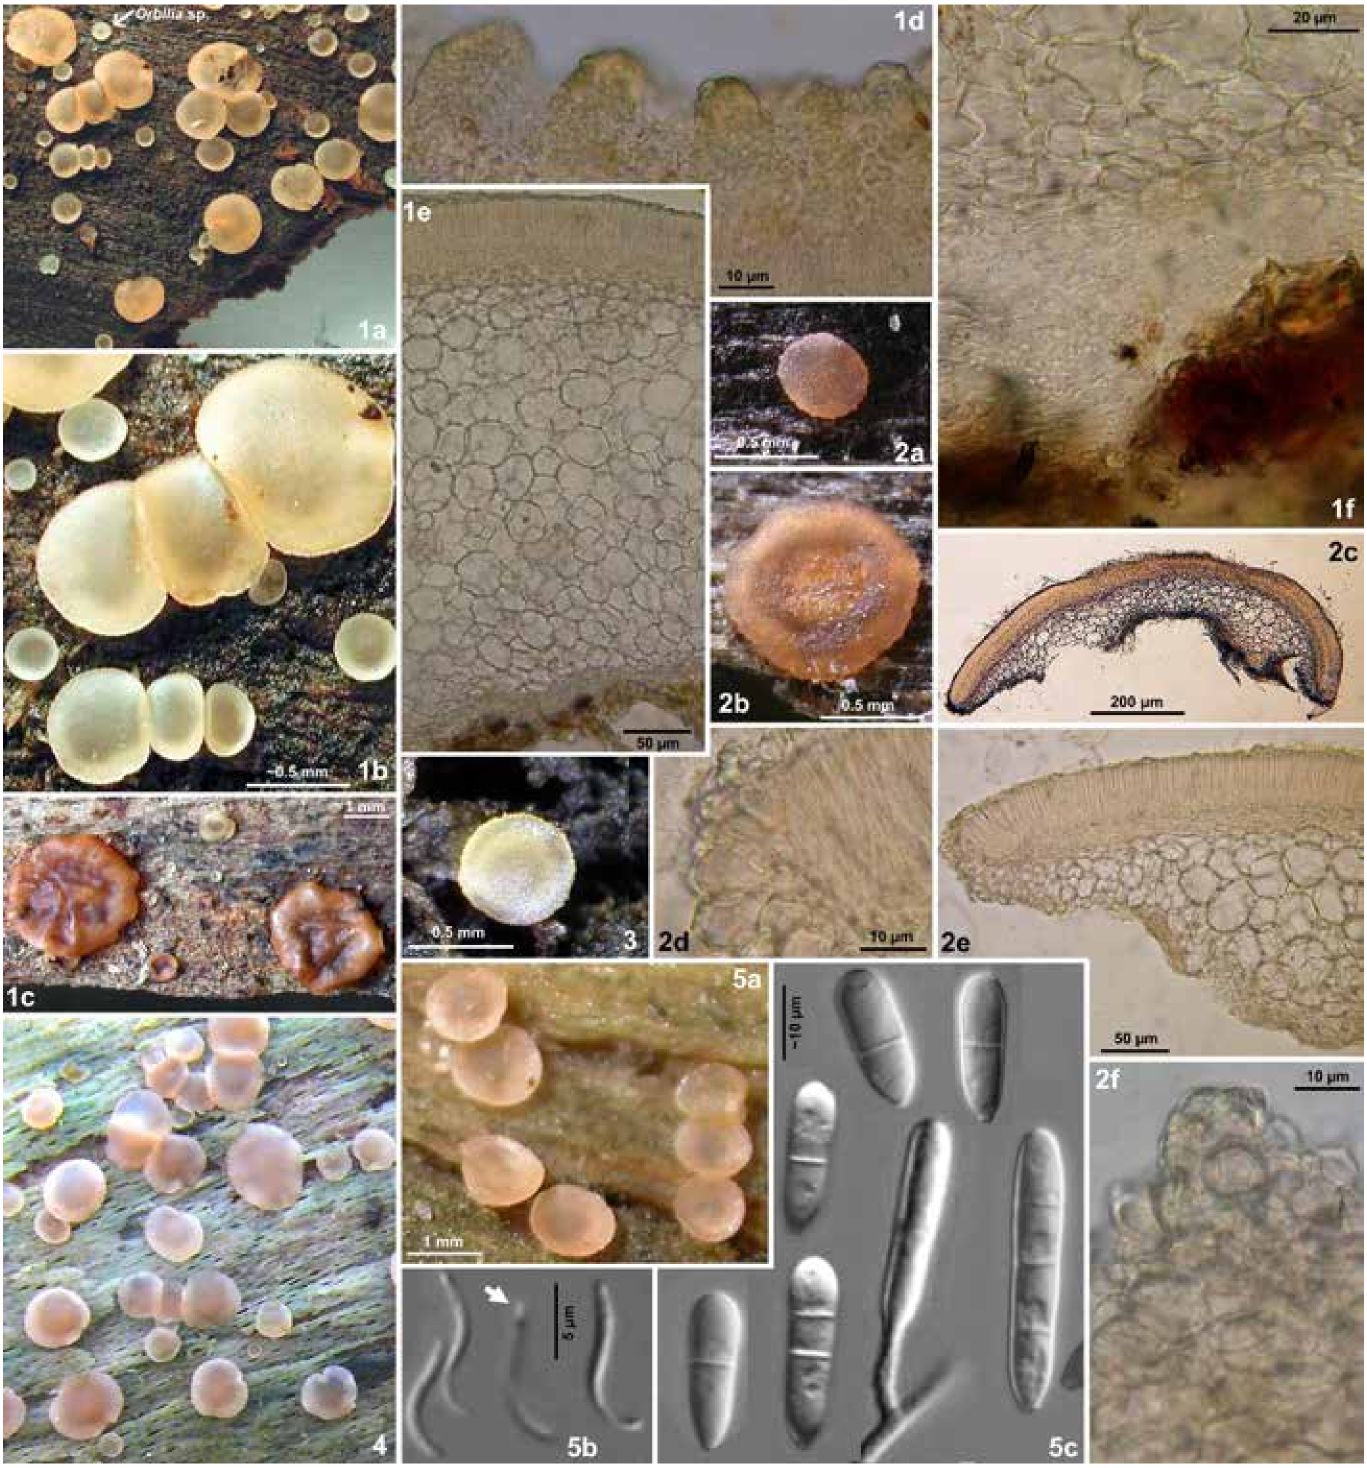

Plate 450. **1–5**: *Orbilia nemaspora*. – **1a–b**, **4**, **5a**. fresh apothecia (**1a–b** mixed with *Orbilia* sp. ?*brochopaga* H.B. 8034b); **1c**, **2a–b**, **3**. rehydrated apothecia; **2c**, **e**. apothecia in median section; **1e**, **2d**. id., ectal excipulum at flanks and margin; **1d**, **2f**. marginal teeth; **5b**. ascospores; **5c**. conidia and conidiophore from culture. – **1a–b**: phot. C. Lechat; **4**: phot. M. Pélissier; **5**: from Liu (2006, fig. 46, DIC). — **1a–e**. H.B. 8034a: Martinique, Bois La Roche, on indet. angiosperm; **2a–f**. H.B. 8420: ibid., La Trinité, on indet. angiosperm; **3**. H.B. 5727: Argentina, Buenos Aires, on *Eucalyptus*; **4**. J.P.P. 13073: Comoros, Mayotte, on indet. angiosperm; **5a–c**. HMAS 96792 (H.B. 9199): China, Heilongjiang, on *Salix*.

A collection from northern China under the name *Orbilia* sp. (Liu 2006: 114, figs 46–47; Pl. 450: 5) fits well *O. nemaspora*, according to the present reexamination. The evaluated spore size (†8–9.5 × 0.6–0.8 µm) concurs with Liu's measurement whereas the scale on his microphoto yields too high values. Bayliss Elliott (1916: 417) reported under the name *O. curvatispora* a collection on branches of *Quercus* from Warwickshire, Great Britain, with 'spirally curved' (helicoid) spores 10–15 × 1 µm, which excludes a species of series *Arthrobotrys*. The spores are reminiscent of *O. nemaspora*, a species so far only known from extra-European regions.

Anamorph. The anamorph of *O. nemaspora* is very similar to that of *O. vermiformis*. In the Chinese ascospore isolate reported by Liu (2006) the conidia tend to be distinctly longer than on the natural substrate in the collections from Puerto Rico and the Comoros, possessing often 2–3(–4) septa, a feature not observed so far in *O. vermiformis*.

Phylogeny. From pure culture of the Chinese sample, Liu et al. (2006a) gained a sequence (ITS+LSU D1–D2), which clustered in their analyses in a clade with *O. bomiensis*, though with high distance and low (ITS) or medium support (LSU). An ITS sequence from apothecia of a North American collection (Boston, bhi-F457a) is incomplete in the ITS2 but, unlike the Chinese one, covers also the 3'-end of SSU where it includes the S1506 intron. For this strain also SSU (V3–V5) and LSU (D2–D3) were available. In the ITS region it differs from the Chinese strain merely by 1 nt in ITS1, and also in the LSU 1 nt differs in D2. When reexamined, this sample contained only *Hyalorbilia fagi* (H.B. 10000), therefore, the sequence is assumed here to originate from a mixed population.

Another strain from Boston (bhi-F166 = H.B. 9994) was sequenced by R.A. Healy (D. Haelewaters pers. comm.), but its sequence was not available. Sequences of four samples from Florida under the name *Orbilia* sp. gained by R.A. Healy et al. also belong to *O. nemaspora* from their rDNA. All four sequences comprise almost the entire intron and ITS1, one also ITS2. In the ITS1 two of them fully concur with bhi-F457a, while the other two deviate from them by 1–2 nt. Also in the intron the North American strains differ by only 0–1 %.

Orbilia stipitata as described by Ekanayaka et al. (2018) from Northern Thailand on unidentified wood appears to be a mixture of 2–3 species. The authors compared their sequence with *O. nemaspora* (strain B.L. 4201) as closest match, though differing in '15 base pairs in ITS and LSU'. However, we see only 7 nt difference between them, 3 in ITS and 4 in LSU, therefore, it seems that this sequence belongs to *O. nemaspora*. However, the illustrated asci and spores appear to belong to two other species (see p. 1685). Surprisingly, the sequence deviates from *O. nemaspora* in the S1506 intron by ~ 10–12 % (and from *O. vermiformis* by 8 %), suggesting a chimere, but BLAST search for the intron alone yields also *O. nemaspora* and *O. vermiformis* as best hits.

The lowest distance of *O. nemaspora* is found to *O. vermiformis*, ranging at 12.5 % in the ITS and at 12 % in the S1506 intron. In the LSU (D1–D2) the lowest distance was to *O. xanthoguttulata* and *O. succulenticola* (6 %). In comparison, the distance to *O. bomiensis* is 14.5 % (ITS) and 7.3 % (LSU). *O. nemaspora* and *O. vermiformis* form a strongly supported clade only in the analysis of the intron (Phyl. S14).

Ecology. *O. nemaspora* is known from rotten, hygric wood, exceptionally bark, of angiosperm trees (mainly unidentified). The examined collections either derive from tropical humid (± wet and dry) Middle America and southeastern Africa (Comoros), subtropical humid (winter-dry) South America, cold-temperate humid (winter-dry) northeastern China, tropical humid (winter-dry) northern Thailand, and continental cold-temperate to subtropical humid eastern North America. Remarkable is the absence of *O. nemaspora* in Europe, except for two very recent records in the humid Fruška Gora in northern Serbia, one at low altitude (subprasubmediterranean) at a rivulet (with *O. sarraziniana*), the other on top of the mountain (cold-temperate) away from water and on the upper, exposed side of the branch.

According to D. Pfister (1995 in litt.), the species is 'one of the most common Orbilias at my study site this July and August'. During her study of micromycetes on logs of *Eucalyptus viminalis*, Romero (1994) likewise found the species very frequently and during most of the year (II, V, VIII, XI). All the here included collections were on wood, only that from South America on *Eucalyptus* was on bark, and one from the Comoros on bamboo. Yet, Romero reported her collections to grow always on bark, on both the outer and inner surface.

Map 80. Known distribution of *O. nemaspora* in Northern and Middle America.

Specimens included. **USA**: **Massachusetts**, Middlesex, 27 km NW of Boston, 2.8 km NNE of Concord, Punkatasset Hill, Hutchins Pond, 45 m, log of *Acer*, on wood, 26.VII.1995, D.H. Pfister (D.H.P. 170 [O.135], FH, **isotype**; ex H.B. 5308, M-0276538, **holotype**); – ibid., log of *Ulmus*, on wood, 12.VII.1995, D.H. Pfister & S.H. Goldbarg (D.H.P. Orbilia crenatonemaspora Baral & Hong Y. Su, **sp. nov.**, MB 813763 — Pls 451–452

Etymology: named after the denticulate (crenate) apothecial margin and the similarity to *Orbilia nemaspora*.

Typification: China, Yunnan, Jinguangsi, ?log of indet. angiosperm, 25.X.2008, H.Y. Su, X.M. Gao & Y.G. Yan (ex H.B. 8926, M-0276462, holotype).

Latin diagnosis: *Similis* Orbiliae nemasporae *sed apothecia margine crenata, ascosporae longiores, corpuscula refringentia longiora, excipulum cellulis marginalibus processis vitreis praeditis. Habitat ad lignum vel corticem putridum uvidum in zona subtropica humida Asiae meridio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–1.4 mm diam., 0.1–0.18 mm high (receptacle 0.1 → 0.07 mm), greyish-white to pinkish-isabelline or carneous-brownish, translucent, round, ± gregarious; disc flat to medium convex, margin 0–10 µm protruding, dentate, with distinct hyaline teeth 25–60 × 30–50 µm; broadly sessile or with a distinct stipe 0.05–0.1 × ?0.2 mm, superficial, dry cream to yellowish. **Asci** †(25–)30–40(–45) × (3–)3.2–4(–4.5) µm {5}, 8-spored, spores *4-seriate, ~4 lower spores inverted {4}, pars sporifera †16–25 µm long; **apex** (†) strongly truncate (not indented, laterally uninflated); **base** with short to long, ± thin, flexuous stalk, T-, L-, Y- to h-shaped. **Ascospores** *(9.5–)10–12(–13.7) × 1–1.1(–1.2) µm {2} (~12–18 µm actual length), †(9.5–)10.5–12.5(–13.5) × (0.7–)0.8–1(–1.1) µm {5}, narrowly fusoid-clavate, apex subacute to acute, base gradually attenuated, medium to strongly curved (helicoid, twisted like a right-hand thread), rarely falcate; **SBs** *~2.5–3.7 × 0.6 {2} or 3.5–5.5 × 0.6–0.9 µm {T}, subulate, apically narrowed to a small point, straight. **Paraphyses** apically slightly to medium (clavate-)capitate, terminal cell †13–16 {1} or 18–24 {T} × (2–)2.5–3.5(–4) µm {2}, lower cells †3–5 × 1.5–1.8(–2) µm wide {1}; unbranched. **Medullary excipulum** 70 µm thick, of ± dense, small-celled textura globulosa-angularis, sharply delimited from ectal excipulum only at flanks (here of t. intricata with inflated cells). **Ectal excipulum** of (†) thin-walled to slightly gelatinized, irregularly oriented t. globulosa-angularis(-prismatica) from base to mid flanks or margin, 70 µm thick near base, cells *12–25(–29) × 9–19 µm {2}; 20–40 µm thick at flanks, 15–30 µm at margin, of. t. globulosa, or of t. prismatica oriented at a 45° angle to the surface, marginal cortical cells */†7–14(–20) × (2.7–)3.3–4(–5) {3}; **glassy processes** 7–17 {1} or 20–35 {T} × 3–4 µm {2}, low to medium refractive, not stratified, coherent to form distinct teeth. **Anchoring hyphae** sparse at base, †1.8–2.7 µm wide, walls 0.2 µm thick {1}. **SCBs** in apices of paraphyses short-cylindrical, refractive, in ectal excipulum at flanks and margin globose, ~3–4 µm diam., here also crystalloid, filiform SCBs {1}; **VBs** not observed. **Exudate** over paraphyses 1–2 µm thick, cloddy, loosely attached, over margin 0.1–0.2 µm thick loose granules. — **ANAMORPH**: unknown.

Habitat: on the moist ground, decorticated or corticated, 15 mm thick branches, also ?logs of indet. angiosperm trees {3}, on medium to strongly decayed wood {2} and bark {1}, sometimes blackened, no algae. **Associated**: *Orbilia scolecospora* {1}, small mosses. **Desiccation tolerance**: after 3 weeks only some ascospores viable. **Altitude**: 1750–2730 m a.s.l. **Geology**: Jurassic & Paleogene sedimentary rock, metamorphic rock. **Phenology**: VII–VIII, X.

Taxonomic remarks. *Orbilia crenatonemaspora* differs from *O. vermiformis* and *O. nemaspora* in the presence of glassy processes which emerge from narrower marginal cortical cells, furthermore in a tendency to longer ascospores and SBs. From *O. nemaspora* it differs also in distinctly wider spores, and from *O. vermiformis* in a less distinct spore tail.

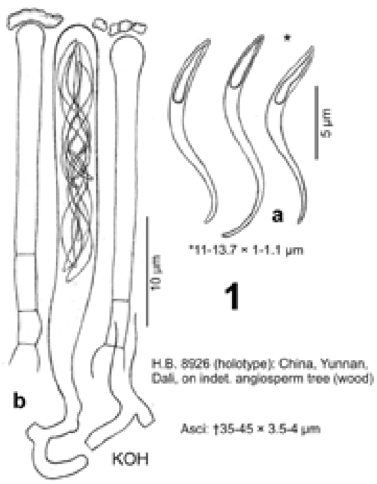

Plate 451. **1**: *Orbilia crenatonemaspora*. – **a**. ascospores; **b**. ascus and paraphyses.

Although they look like VBs, the elongate bodies in the apices of living paraphyses closely concur with those of *O. crenatomarginata* (series *Hyalinia*) and are, therefore, quite probably SCBs. The combination of globose/elongate and crystalloid SCBs is so far unknown within series *Xanthoguttulatae*, therefore, it might well be that molecular data would place *O. crenatonemaspora* in series *Hyalinia*. This view is supported by a strong similarity in the spores to *O. laevimarginata*, especially Pl. 462: 2b, though being much smaller there. Two collections are mentioned under *O. scolecospora* (series *Hyalinia*: Caucasus, Pl. 463: 2; Argentina, see Fig. 164) because their spore length better fits that species, but they are only known in the dead state.

Variation. The five included collections are only tentatively placed together. In the holotype and the topotype (H.B. 8931) the asci, spores and SBs are slightly longer than in the other samples. In the samples from Dali the spores are only slightly helicoid (ljs-2) and or even falcate (ljs-3, Pl. 452: 4b, 5b), resembling those of *O. crenatofalcata* though being distinctly longer. The presence of glassy processes was not tested in these two samples, but the distinct marginal teeth are probably composed of them. In H.B. 8694a the glassy processes are shorter than in the holotype, but the cortical cells are longer, hence the marginal teeth have a similar size. Differences were also noted in the size of the terminal cells of paraphyses (longer and narrower in the type compared to H.B. 8694a). The delimitation from *O. nemaspora* is not very sharp, because also here distinct small teeth generally occur, though glassy processes could never be confirmed (see Pl. 450: 1d).

Ecology. *O. crenatonemaspora* inhabits rotten, hygric wood and bark of unidentified angiosperm trees. Collections are from subtropical humid (winter-dry) evergreen mountain forests at the eastern extension of Himalaya in southern China.

Specimens included. **CHINA**: **Yunnan**, **Dali**, Yongping, 35 km ENE of Baoshan, virgin forest around Golden Light temple (Jinguangsi), 2730 m, ?log of indet. angiosperm, on wood, 25.X.2008, H.Y. Su, X.M. Gao & Y.G. Yan (H.Y.S. jgs-28, ex H.B. 8926, M-0276462, **holotype**); – ibid., branch of indet. angiosperm, on bark, 25.X.2008, H.Y. Su et al. (H.Y.S. jgs-27, CBCD, H.B. 8931). – **Dali**, Dali, 59 km WSW of Lijiang, NW of Jinmugu, Laojunshan, 2700 m, branch indet. ?angiosperm, on bark, 15.VIII.2008, H.Y. Su, X.J. Su & X.N. Orbilia pseudobrevistipitata (L. Qin, M. Qiao & Z.F. Yu) Baral & E. Weber, in Zhang et al., Phytotaxa 203: 251 (2015) — Pls 453–454

≡ *Dactylella pseudobrevistipitata* L. Qin, M. Qiao & Z.F. Yu, in Qin et al., Ann. Microbiol. 63: 594, fig. 2 (2011)

Etymology: named after the very short conidiophores similar as in the unrelated *Hyalorbilia brevistipitata*.

Typification: China, Yunnan, Lijiang, indet. angiosperm bark, 18.IX.2009, L. Qin (YMF 1.03504, holotype; sq.: HM215520).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.5(–0.9) mm diam., 0.17 mm high (receptacle 0.1 mm), pale to light cream- or orange-ochre, round, slightly undulating when large, singly or in pairs; disc slightly concave to flat, margin distinct, slightly protruding, finely powdered; with an indistinct hidden stipe 0.08 × 0.06 mm slightly immersed in detritus; dry light cream-orange. **Asci** *(26–)30–36 × (3.2–)3.6–4 µm {1}, †30–35(–40) {1} or 38–44 {T} × 3–3.4 µm {2}, 8-spored, spores 4-seriate, 4 upper (very rarely lower) spores inverted (not mixed) {2}, pars sporifera †16–25 µm; **apex** (†)

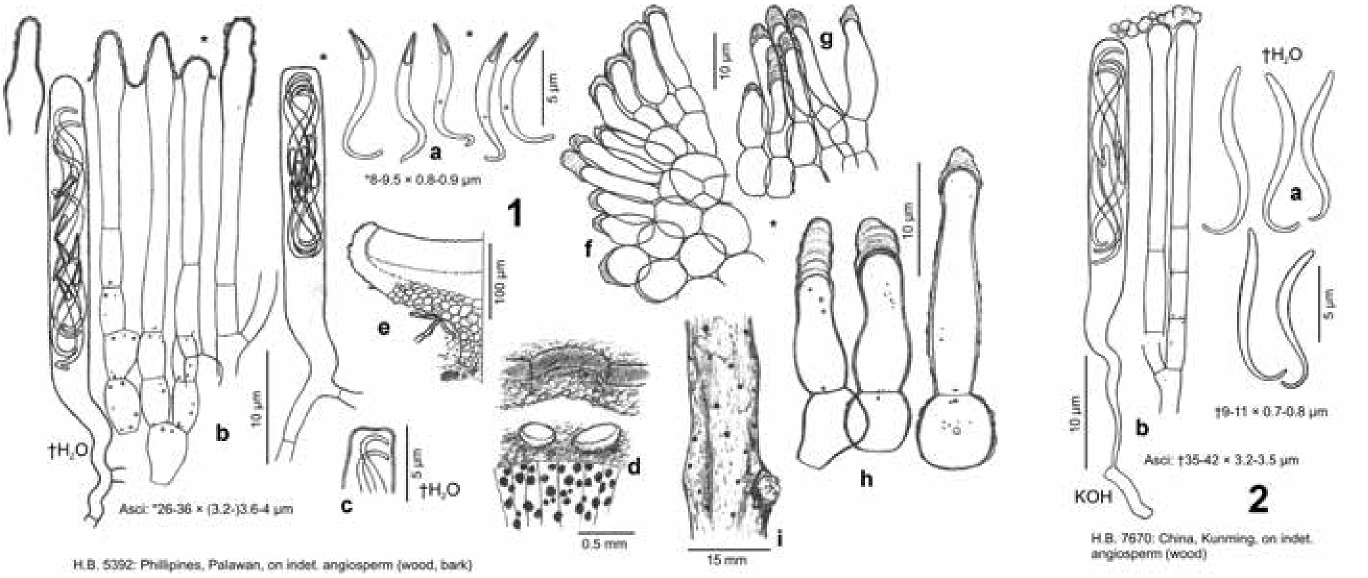

Plate 453. **1**: *Orbilia pseudobrevistipitata*; **2**: *O.* aff. *pseudobrevistipitata*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. rehydrated apothecia on boring dust over wood surface, positioned below emergence hole in detached bark; **e**. apothecia in median section; **f**. id., ectal excipulum and hair-like cortical cells with short glassy processes at margin; **g–h**. id., external view; **i**. corticated branch perforated by emergence holes.

strongly truncate (not indented, laterally not or slightly inflated); **base** with short to long, ± thin, flexuous stalk, L- to Y-shaped. **Ascospores** *8–9.5 {1} or 9–10.3 {T} × 0.8–0.9 µm {2} (~10–13 µm actual length), †(0.7–)0.8 µm wide {1}, narrowly fusiform, apex acute to acuminate, base strongly attenuated in a thin, indistinctly differentiated tail of 1.7–3.5 × 0.3–0.5 µm, strongly helicoidally twisted especially near base (like a right-hand thread, exceptionally falcate); **SBs** 2.2–3 × 0.5–0.6 µm {1}, ~3.5–3.8 × 0.7 µm {T}, narrowly tear-shaped to subulate. **Paraphyses** apically obtusely lanceolate to (sub)lageniform, exceptionally slightly clavate, terminal cell †17–28 {2} × 2–2.3 {T} or 2.4–3(–3.5) {1} µm, exceeding the dead asci by 3–7 µm, lower cells *4–6 × 2.5–3 µm {1}; unbranched at upper septum. **Medullary excipulum** light orange, 30 µm thick in centre, of small-celled indistinct texture, sharply delimited from ectal excipulum. **Ectal excipulum** ± hyaline, of thin-walled textura globulosa-angularis from base to margin, indistinctly oriented at a 45° angle, 40 µm thick near base of receptacle, cells *14–20 × 11–15 µm; 30 µm thick at lower flanks, 20 µm at mid flanks and margin, marginal cortical cells *(10–)13–20 × 3.5–5.3 µm, somewhat free (hair-like) or ± agglutinated to form small teeth, tipped by highly-refractive, pale yellow-orange, distinctly stratified **glassy processes** 0–5(–13) × 3–3.7 µm. **Anchoring hyphae** very sparse, 2–3 µm wide, walls 0.2–0.3 µm thick. **SCBs** and **VBs** apparently absent. **Exudate** over paraphyses 0.2–0.4 µm thick, continuous, slightly rough, firmly attached, covering the inflated protruding part; over margin and flanks absent. **— ANAMORPH**: dactylella/vermispora-like (from ascospore isolate {1, Qin et al. 2011}). **Conidiophores** formed as short lateral outgrowths, *(2–)4–7(–11) × 2–3 µm, aseptate. **Conidiogenous cells** monoblastic {T}. **Conidia** *(18–)22–36(–39) × (3.8–)5–6(–6.7) µm, (1–)2–**3**–4(–5)-septate, cylindrical with rounded ends, straight or sometimes slightly curved, sometimes constricted at septa, containing quite a few distinct LBs at septa and lateral wall {T}. **Chlamydospores** and **trapping organs** not observed in pure culture (with nematode *Panagrellus redivivus*).

Habitat: hanging (?1.5 m above the ground, 13–15 mm thick) or on the moist ground, branches of indet. angiosperm trees {2}, on red-brown boring dust between slightly decayed bark and wood {1} or on bark {2}, on blackened patches, no algae. **Associated**: ?*Opegrapha* and other crustose lichens (on periderm) {1}. **Desiccation tolerance**: asci still viable after a few weeks, ectal excipulum, basal cells of paraphyses, and ascospores viable after ~2 months {1}. **Altitude**: 2–450 m a.s.l. **Phenology**: IX, XI.

Taxonomic remarks. *Orbilia pseudobrevistipitata* resembles, e.g., *O. crenatomarginata* or *O. laevimarginata* (series *Hyalinia*) in its helicoid ascospores. Further characteristic features of this species are ± lageniform paraphyses reminiscent of series *Abutilones*, and an inverse orientation of the upper spores like in some other species of the *nemaspora-vermiformis* clade (*O. bomiensis*, *O. spirillospora*) and of series *Abutilones* (e.g., *O. milinana*).

Variation. Based on unpublished data of the teleomorph of the collection from Yuxi (Pl. 454: 2), from which the holotype was obtained in culture, *O. pseudobrevistipitata* is considered here to be conspecific with the unsequenced specimen from Philippines (Pls 453: 1; 454: 1). The specimen from Yuxi deviates in slightly longer spores that contain larger SBs, also in longer asci and narrower paraphyses, while the excipular characters were not studied by Qin et al. (2011). Only two apothecia were present on the natural substrate, which were used up when obtaining the pure culture, therefore, the authors did not describe the teleomorph in their paper (Z.F. Yu pers. comm.). However, besides the anamorph (Pl. 454: 2e), also apothecia developed in culture which show a smooth margin (2a).

Not included collection. A more montane specimen from southern China (Kunming, Pls 453: 2; 454: 3) seems to represent a species of its own: it differs in the tips of paraphyses being slightly capitate instead of lageniform, covered by a thicker exudate, also in much shorter marginal cortical cells (†5–10 × 3–4.7 µm) tipped by much longer and narrower glassy processes of (8–)20–40(–50) × 2(–2.5) µm forming distinct teeth. In the length of the SBs this resembles the specimen from Yuxi, but the spores are slightly longer.

Anamorph. *Dactylella pseudobrevistipitata* was described by Qin et al. (2011) based on the ascospore isolate of the Yuxi sample. It is characterized by cylindrical, not or slightly curved phragmoconidia with rounded ends formed on very short conidiophores. These strongly reduced conidiophores and the somewhat vermispora-like conidia are quite untypical for a dactylella-like anamorph but reminiscent of series *Aurantiorubrae*.

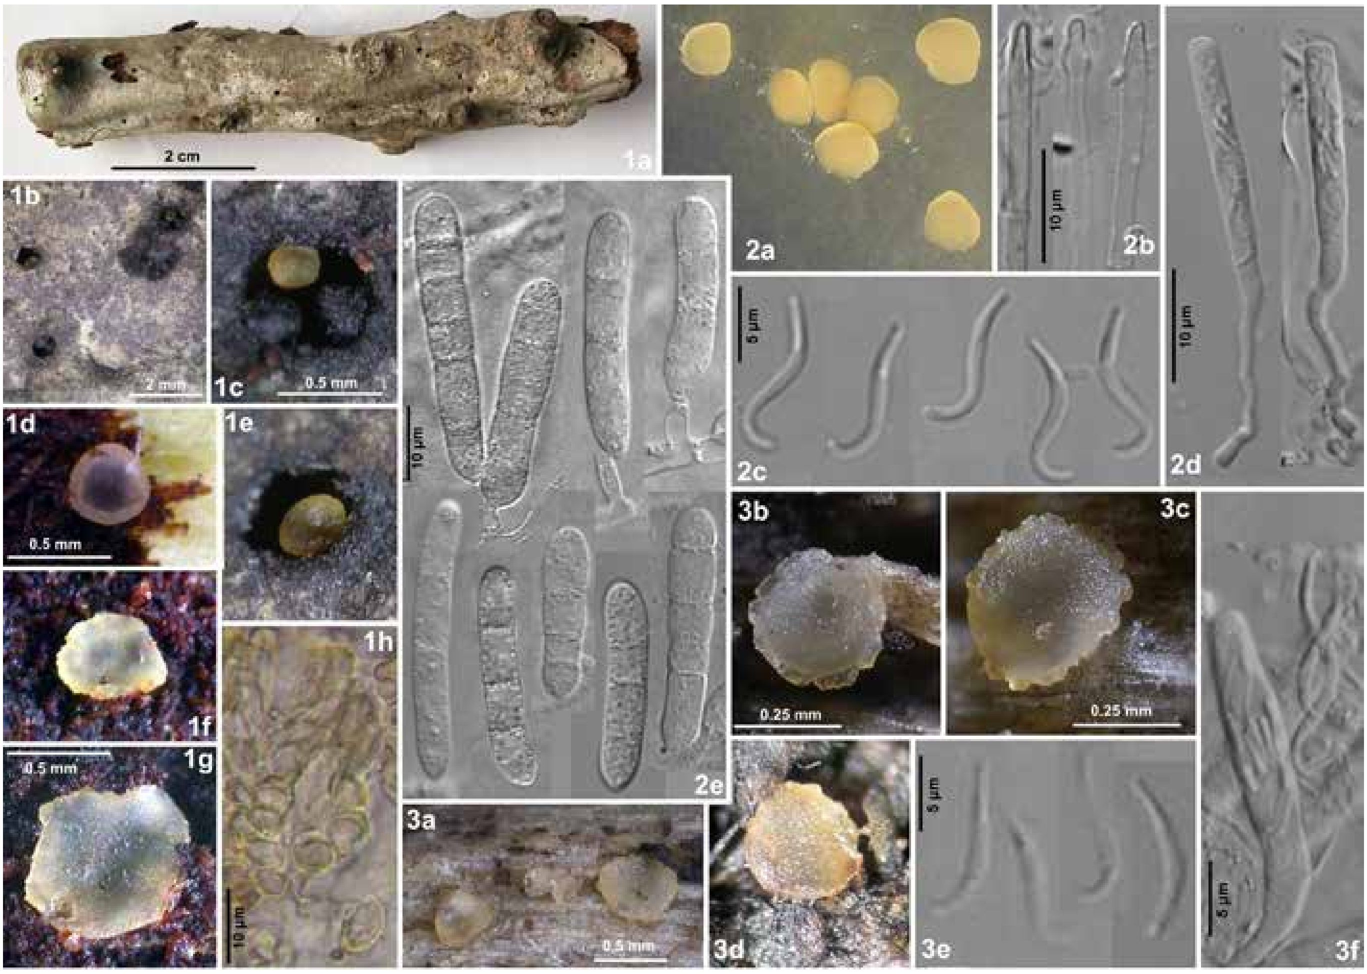

Plate 454. **1–2**: *Orbilia pseudobrevistipitata*; **3**: *O.* aff. *pseudobrevistipitata*. – **1a**. corticated branch perforated by small emergence holes; **1b–g**, **3a–d**. rehydrated apothecia (**1b–c**, **e** in emergence holes); **2a**. fresh apothecia grown on agar; **1h**. marginal ectal excipulum (external view); **2b**. paraphyses; **2d**, **3f**. asci; **2c**, **3e–f**. ascospores; **2e**. conidia and conidiophores from culture. – Living state, except for **1h**, **2b**, asci in **2d**, **3f** (in H_2O). – **2e**: from Qin et al. (2011), **2a–d**, **3d–f**: phot. Z.F. Yu (DIC). — **1**. H.B. 5392: Philippines, Palawan; **2**. YMF 1.03504 (holotype): China, Yunnan, Yuxi; **3**. H.B. 7670: ibid., Kunming (all from indet. angiosperms).

Phylogeny. An ITS sequence obtained by Qin et al. (2011) from the ex-type strain comprises S1506 intron and ITS. It shows a high distance in the ITS region to other species, e.g. 12 % to *O. nemaspora*, 14.5 % to *O. vermiformis* and *O. bomiensis*. The intron shows a high distance to members of series *Hyalinia* (~20 %) but also to *O. vermiformis* and *O. nemaspora* (18–19 %) and *O. xanthoguttulata* (17 %).

Ecology. The holotype of *O. pseudobrevistipitata* was collected on hygric bark of an angiosperm branch in a valley near a brook (Y. Zhang pers. comm.) in a subtropical humid (winter-dry) evergreen forest in southern China. The not included sample from Kunming was on decorticated wood in a similar forest (with *Quercus*). The specimen from Philippines grew on rotten boring dust and bark of a corticated xeric branch of an angiosperm tree at a sandy river bank of the sea shore at the tropical humid (winter-dry) west coast of Palawan island (Philippines, southeastern Asia). The apothecia occurred mostly in small groups on a thin layer of red-brown boring dust between bark and wood in the abundant galleries of a bark beetle, hidden below the loosely attached bark, always below the scattered, round, 0.6–0.75 mm large emergence holes, ca. 1 mm beneath their upper rim, rarely on bark at the edge of the emergence hole. Therefore, the branch seemed to be devoid of apothecia at first glance.

Specimens included. **CHINA**: **Yunnan**, **Yuxi**, Yuanjiang, 100 km SW of Yuxi, 3 km NNW of Lijiang, near Thermal Spring (Reshuitang), ~450 m (‘500 m’), indet. angiosperm bark, 18.IX.2009, L. Qin (YMF 1.03504, **holotype**, permanent slide, anam. cult., doc. vid.; sq.: HM215520, as *Brachyphoris brevistipitata*). — **PHILIPPINES**: **Palawan**, 55 km NNE of Puerto Princesa, 3.5 km E of Sabang, St. Paul Subterranean National Park, Underground River, 2 m, branch of indet. angiosperm tree, on wood, bark and boring dust, 20.XI.1995, P. Wagner (H.B. 5392).

Not included. **CHINA**: **Yunnan**, **Kunming**, ~12 km NE of Kunming, Songhuaba, ~2000 m, branch of indet. angiosperm, on wood, 18.X.2004, Z.F. Yu (Z.F.Y. shb-1, YMFT, H.B. 7670).

Orbilia bomiensis Bin Liu, Xing Z. Liu, W.Y. Zhuang in Liu et al., Fungal Diversity 22: 109 (2006) — Pl. 455

Etymology: named after the collection site (Bomi, Tibet).

Typification: China, Tibet, Bomê, wood of indet. angiosperm, 16.VII.2004, B. Liu & X.Z. Liu (HMAS 96790, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–2 mm diam., up to 0.26 mm high (receptacle 0.13 → 0.07 mm), bright yellow-orange, semitranslucent, round, scattered; disc slightly concave to flat, margin 20 µm protruding, distinctly crenulate with hyaline ± conglutinate hairs; broadly sessile or with a stipe 0.15 × 0.15–0.17 mm, superficial; dry deep reddish-orange. **Asci** †38–45(–63) × (3.1–)3.5–4.7 µm, 8-spored, spores ± 4-seriate (spirally twisted), 4 upper spores inverted (not mixed); **apex** (†) slightly truncate; **base** with short, medium thick, flexuous stalk, T- to L-shaped. **Ascospores** *10–13.5 × 1.5–1.7 µm (actual length ~15–17 µm), narrowly fusoid, apex strongly attenuated, subacute, base moderately narrowed, rounded; very strongly curved (helicoid, twisted like a left-hand thread), less so near apex; **SBs** 0.7–1 µm diam., ± globose, very close to apex. **Paraphyses** apically uninflated to only slightly clavate, terminal cell

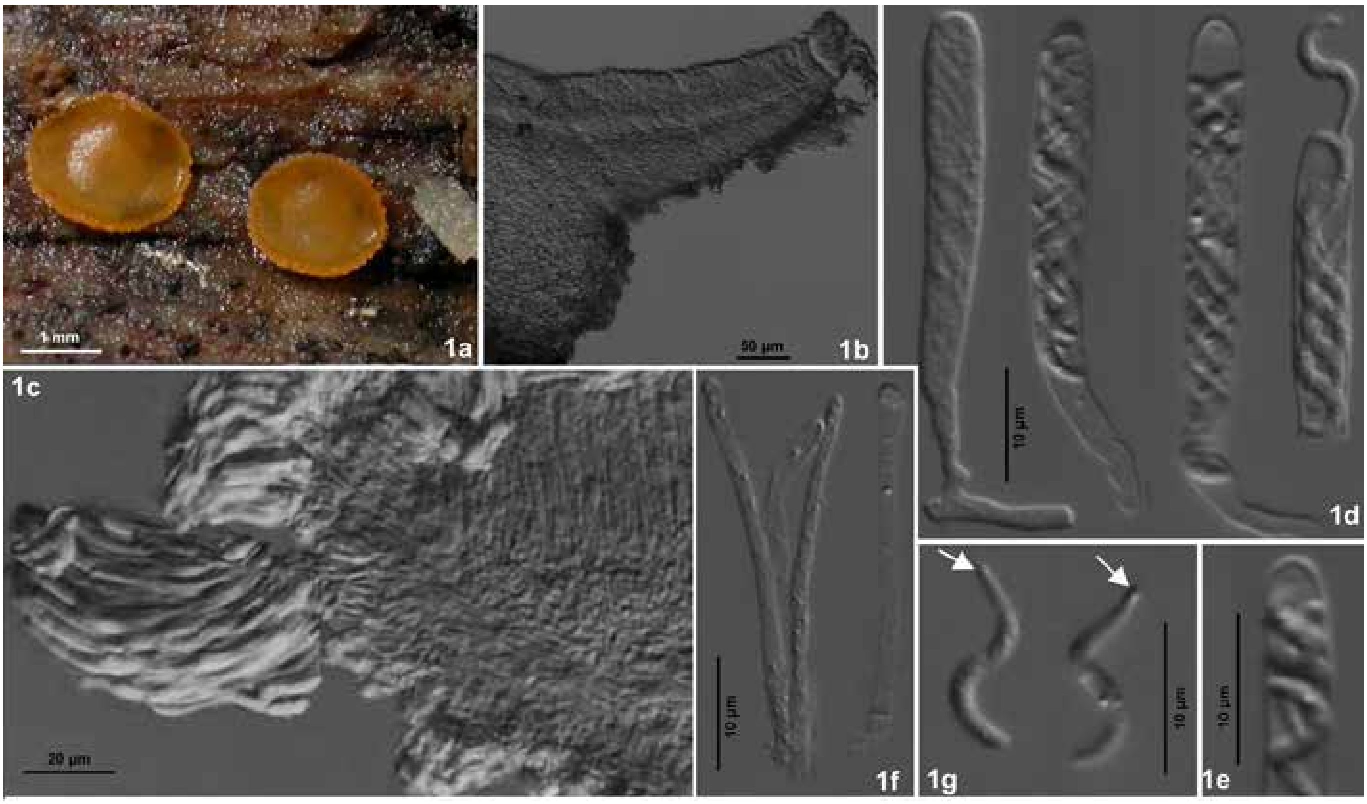

Plate 455. **1**: *Orbilia bomiensis* (holotype). – **1a**. fresh apothecia; **1b**. apothecium in median section; **1c**. id., ectal excipulum near margin, with long glassy processes; **1d**. asci and liberated ascospore; **1e**. ascus apex; **1f**. paraphyses; **1g**. ascospores. – Dead state (in H_2O), except for spores (?). — **1a–g**. from Liu et al. (2006b, DIC), HMAS 96790: China, Tibet, on indet. angiosperm.

†~29–33 × (1.5–)1.8–2.5 µm, lower cells †?7 × 1.5–2 µm; unbranched at upper septum. **Medullary excipulum** 15–25 µm thick, of textura intricata-angularis. **Ectal excipulum** of thin-walled slightly gelatinized, t. globulosa-angularis(-prismatica) from base to mid flanks, ± vertically oriented, 20–150 µm thick near base, cells †13–25 × 7–10 µm; 20 µm thick near margin, of t. porrecta oriented at a 50° angle to the surface, marginal cortical cells †~10–15 × 3.5 µm; **glassy processes** (15–)40–70 × 3–5 µm, highly-refractive, slightly stratified, coherent to form irregular teeth. **Anchoring hyphae** not examined. **SCBs** and **VBs**: no data available. **Exudate** over paraphyses very thin, firmly attached, over margin and flanks not seen. **— ANAMORPH**: unknown.

Habitat: on rotten wood of indet. angiosperm tree lying on moist ground. **Associated**: none mentioned. **Desiccation tolerance**: unknown. **Altitude**: 3100 m a.s.l. **Phenology**: VII.

Taxonomic remarks. *Orbilia bomiensis* was not examined in the present study, and the here presented description is based on the protologue. The species is characterized by very strongly helicoid ascospores, which are obviously twisted like a left-hand thread, judging from the available photographs, given that the photo is not mirror-inverted (Pl. 455: 1d, right ascus). They are only moderately tapered towards base, and contain a short, ± globose SB in the strongly attenuated, ± acute apex. An uncertainty about the SBs as described in the protologue remains, however, because the spores are possibly not alive on the photos, although they were said to have been studied in the living state. A striking feature is also the bright yellow-orange colour of the rather large apothecia. As in *O. pseudobrevistipitata* and *O. spirillospora*, the upper spores are inversely oriented within the asci.

The species appears to be related to *O. spirillospora*, *O. crenatomarginata*, and *O. scolecospora*. However, these and all the other species of series *Xanthoguttulatae* and *Hyalinia* differ in the spores being twisted like a right-hand thread. The three mentioned species deviate in narrowly tear-shaped to subulate SBs, the latter two in the lower spores being inversely oriented within the asci, and *O. scolecospora* in smaller asci and spores.

Phylogeny. From apothecia of the holotype Liu et al. (2006a) gained a sequence (ITS+LSU, S1506 intron absent) which clustered in their analyses in a clade with *O. nemaspora* (see above). *O. bomiensis* shows a high distance to other species of series *Xanthoguttulatae*, the lowest percentage being 14.5% in the ITS to *O. pseudobrevistipitata* and 3.3–4% in the LSU D1–D2 to the *xanthoguttulata-succulenticola* clade (but 6.5% to *O. nemaspora*). In our analyses it clustered in the ITS+LSU tree (Phyl. 13) in the medium supported *nemaspora-vermiformis* clade, but in the LSU tree (Phyl. S16) strongly supported with the *xanthoguttulata-succulenticola* clade.

Ecology. *O. bomiensis* was collected on rotten hygric wood of an unidentified angiosperm tree in an orotemperate (altimontane) humid (winter-dry), continental floodplain forest in the eastern part of Himalaya.

Specimens included. **CHINA**: **Tibet**, **Nyingchi** (Linzhi), 36 km ESE of Bomê (Bomi), 1.3 km ENE of Songzong, 3100 m, wood of indet. angiosperm, 16.VII.2004, B. Liu & X.Z. Liu (B.L. X033, HMAS 96790, **holotype**, doc. vid.).

Orbilia spirillospora Baral & G. Marson, **sp**. **nov**., MB 813764 — Pls 456–457

Etymology: named after the strongly helicoid ascospores resembling members of *Spirillaceae* (*Proteobacteria*).

Typification: Australia, Queensland, Cape Tribulation, branch of *Hibiscus tiliaceus*, 30.VIII.2006, G. Marson (ex H.B. 8487a, BRI AQ799192, holotype).

Latin diagnosis: *Apothecia rehydratata 0.25–0.6 mm diam., pallide luteolo-cremea, sessilia, margine laevi. Ascosporae *13–14 × 1–1.1 µm, anguste fusiformes, apice acuminatae, basi valde attenuatae, conspicue helicoideae, dextrorsum convolutae sesqui-anfractae, corpusculum refringens anguste lacrimiformem ad subulatum, ad apicem filo longo affixum continentes,*

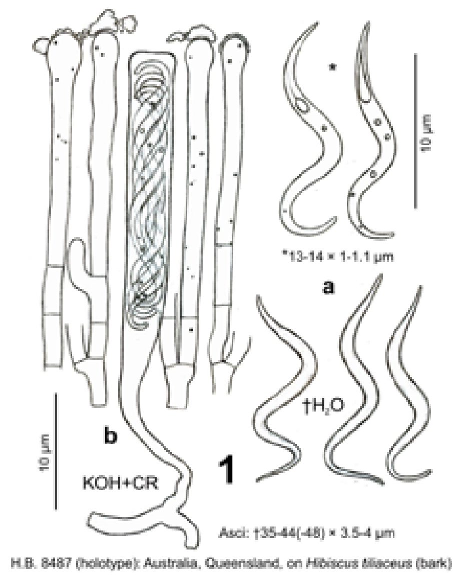

Plate 456. **1**: *Orbilia spirillospora*. – **a**. ascospores; **b**. ascus and paraphyses.

superiores inverse orientates. Paraphyses ad apicem leniter clavato-capitatae, exsudato valido tectae. Excipulum marginale absque processis vitreis. Habitat ad corticem putridum rami sicci Hibisci tiliacei *in zona tropica humida Australiae septentrio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.25–0.5(–0.6) mm diam., 0.09–0.1 mm high (receptacle 0.07–0.08 mm), pale to light (yellowish-)cream, ± translucent, round to slightly undulating, very scattered; disc (slightly concave to) flat, margin distinct, not protruding, smooth; sessile, superficial; dry light cream to rosaceous. **Asci** †35–44(–48) × 3.5–4 µm, 8-spored, spores 4-seriate (spirally twisted), 4 upper spores inverted (not mixed), pars sporifera †23–25 µm long; **apex** (†) medium to strongly truncate (not indented, laterally rarely slightly inflated); **base** with short and thick to mostly long and thin, flexuous stalk, Y-shaped. **Ascospores** *13–14 × 1–1.1 µm, †11.5–14 × 0.9–1 µm (~16–20 µm actual length), very narrowly fusiform (acicular), apex acuminate, base attenuated in a narrow tail-like base or tail of 2.5–3 × 0.2–0.3 µm, strongly helicoid (twisted by ~1.5 turns, always like a right-hand thread); **SBs** 5–6 × 0.7 µm in situ (~5.5–7 µm actual length), narrowly tear-shaped or subulate, rarely ellipsoid, apically narrowed to a short, rarely long filum. **Paraphyses** apically slightly (to medium) clavate-capitate, terminal cell †18–24 × 2–3 µm, lower cells †(3–)4–5(–9) × 1.2–1.6 µm; rarely branched at upper septum. **Medullary excipulum** 10–15 µm thick, of dense textura intricata, sharply delimited from ectal excipulum. **Ectal excipulum** of thin-walled, indistinctly vertically oriented t. angularis from base to margin, 35–45 µm thick near base, cells */†6–19 × 5–13 µm; 10–15 µm thick near margin, oriented at a 40–80° angle to the surface, marginal cortical cells †6–8 × (3–)4–6 µm; **glassy processes** absent. **Anchoring hyphae** abundant, †1.5–2.5 µm wide, walls 0.2 µm thick. **SCBs** and **VBs** unclear. **Exudate** over paraphyses 0.3–2 µm thick, granular-cloddy, hyaline, loosely or often firmly attached; over margin and flanks 0.5–1 µm thick, cloddy to continuous. **— ANAMORPH**: unknown.

Habitat: collected 2–3.5 m above the ground, corticated, 13–20 mm thick, hanging branches of *Hibiscus tiliaceus*, on strongly decayed bark (on periderm and especially in small holes on bast), greyed, no algae. **Associated**: *Orbilia* ?*subfabacearum*. **Desiccation tolerance**: some basal excipular cells and some spores still viable after 8.5 months. **Altitude**: 15 m a.s.l. **Geology**: Devonian sedimentary rock. **Phenology**: probably rather long-lived.

Taxonomic remarks. *Orbilia spirillospora* is readily recognized by its comparatively long, narrowly fusiform, strongly helicoid ascospores with consistently 1.5 turns or slightly more, the upper 4 spores being inversely oriented, and by lacking glassy processes at the margin. Species with similar spores and spore orientation (*O. bomiensis*, *O. pseudobrevistipitata*, *O. scolecospora*) clearly differ in spore size and in showing hardly more than 1 turn, also in the presence of glassy processes. *O.*

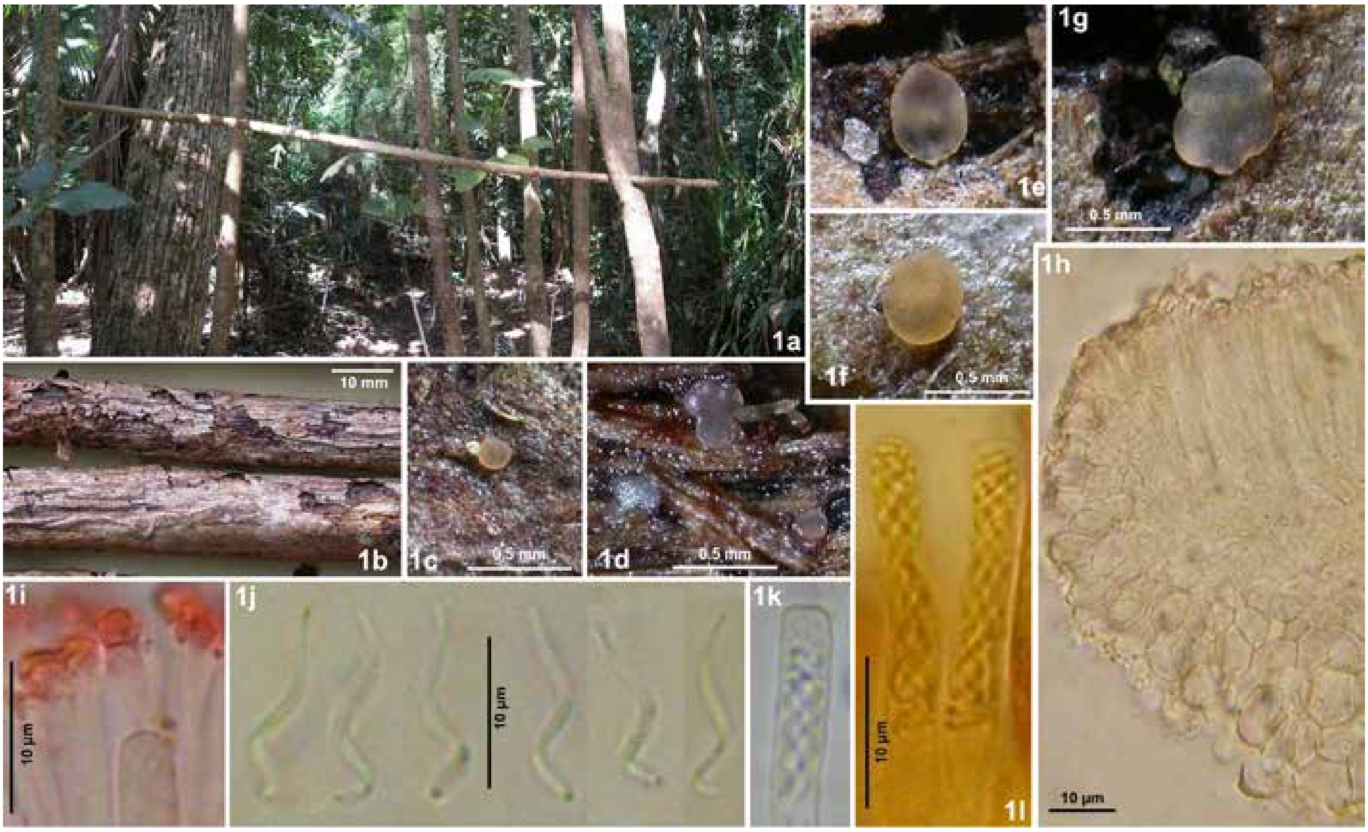

Plate 457. **1**: *Orbilia spirillospora* (holotype). – **1a**. tropical rainforest, the inhabited branch was vertical before it was drawn in this position; **1b**. dead branches of *Hibiscus tiliaceus*; **1c–g**. rehydrated apothecia; **1j**. ascospores; **1k–l**. asci; **1k**. ascus apex; **1i**. paraphyses; **1h**. ectal excipulum in median section (flanks and margin). – Dead state (**1k** in H_2O, **1h**, **j** in KOH, **1i** in KOH+CR, **1l** in KOH+IKI). — **1a–l**. H.B. 8487a: Australia, Queensland, on *Hibiscus*.

pseudobrevistipitata also differs in paraphysis shape, and *O. bomiensis* in the spores being only slightly narrowed at base and in being twisted like a left-hand thread, in much shorter, ± globose SBs, and in larger, bright orange-yellow apothecia.

Ecology. *O. spirillospora* was collected on rotten xeric bark of a climber (*Hibiscus tiliaceus*, Cottonwood) in a tropical, humid, monsoon-influenced (winterdry) evergreen forest with a very high precipitation during summer, at the coastline of northeastern Australia.

Specimens included. **AUSTRALIA**: **Queensland**, Wet Tropics, border of Daintree forest, 47 km N of Port Douglas, 5 km N of Cape Tribulation, 15 m, branch of *Hibiscus tiliaceus*, on bark, 30.VIII.2006, G. Marson (ex H.B. 8487a, BRI AQ799192, **holotype**).

Series *Hyalinia*

Orbilia subgenus ***Habrostictis*** section ***Aurantiorubrae*** series ***Hyalinia*** Baral & E. Weber, **ser. nov.**, MB 815012 –
Type species: *Hyalinia crystallina* (Quél.) Boud.
[= *Orbilia crenatomarginata* (Höhn.) Sacc. & Trotter]

= *Hyalinia* Boud., Bull. Soc. Mycol. Fr. 1: 114 (1885), nom. illegit. (ICN Art. 53.2), non *Hyalina* Stackh. 1809 (*Phaeophyceae*)
≡ *Orbilia* subgroup III *Hyalinia* (Boud.) Velen. Mon. Discomyc. Bohem. p. 102 (1934, unranked).

Etymology: referring to the translucency of the non-pigmented apothecia in the type species.

Latin diagnosis: *Apothecia haud tolerantia ad siccitatem, hyalina ad pallide rosacea vel ochracea, ad marginem partim dentata, dentes e processis vitreis compositi, cellulae excipuli corpusculis crystalloideis hyalinis continentes, ascosporae angustae, falcatae vel helicoideae, in statu vivo corpusculum refringens lacrimiformem vel subuliformem continentes.*

Description: — **TELEOMORPH**: **Apothecia** hydrated 0.15–1.5 mm diam., whitish or pale rosaceous or yellowish-ochraceous, margin smooth or usually finely to distinctly crenulate or dentate, sessile or with an indistinct stipe. **Asci** *23–37 × 3–4 µm, 8-spored, lower ~4 spores inverted; **apex** (†) slightly to strongly truncate in front view, never indented or laterally inflated, thin-walled; **base** never H-shaped. **Ascospores** *6–10.5 × 0.6–1.3 µm, (very) narrowly fusoid to fusiform, apex rounded to acute, base gradually tapered, often tail-like or with a distinct tail, strongly curved (often strongest near base), helicoid (right-handed), also falcate; **SBs** 1.7–3.5 × 0.2–0.5(–0.7) µm, tear-shaped to subulate, with or without a short filum. **Paraphyses** not or only slightly to medium inflated at the apex, clavate-capitate, terminal cells 2–5 × longer than lower cells. **Ectal excipulum** cells near base *9–20(–28) × 7–16(–20) µm, near margin of t. angularis to t. porrecta; **glassy processes** 0–3 µm long or often 4–10 µm up to 60, rarely 100–200 µm long. **SCBs** globose to elongate, always associated with crystalloid ones; **VBs** absent. **Exudate** (0.2–)0.5–2(–3) µm thick, continuous to cloddy-granular, loosely or firmly attached, hyaline to pale yellowish. **— ANAMORPH**: dactylella-like. **Conidiophores** unbranched 40–110 µm long, 3–4.3 µm wide at the base, 1.3–2 µm at the tip. **Conidiogenous cells** monoblastic or sympodial (geniculate or candelabrelloid). **Conidia** phragmosporous, *7.5–50 × 2.8–12 µm, ellipsoid- to cylindric-clavate or cylindrical, straight, (0–)1–6(–7)-septate. **Chlamydospores** and **trapping organs** unknown.

Habitat: Hygric or rarely mesic wood and bark of angiosperms, rarely gymnosperms, temperate to montane or subtropical to tropical, semiarid to humid, desiccation-sensitive.

Recognized species: 4.

Taxonomic remarks. Members of series *Hyalinia* are characterized by very narrowly fusoid, curved ascospores with mostly subacute to acuminate apices containing subulate SBs, and with attenuated or often tail-like, very narrow bases. The spores are typically strongly helicoid and intertwined within the asci, but may also be falcate with an only very slight helicoid twist (*O. crenatofalcata*). Glassy processes which form marginal teeth are typical of this series, though being very short or completely absent in *O. laevimarginata*. Their presence has been considered as a key character of this group by both Höhnel (1907a) and Spooner (1987: 159, 188) who recognized *Hyalinia* at the generic level. Further characteristics are the very long terminal cells of paraphyses in relation to the lower cells, and a dactylella-like anamorph. Hyaline, globose and crystalloid SCBs occur in association in all four included species.

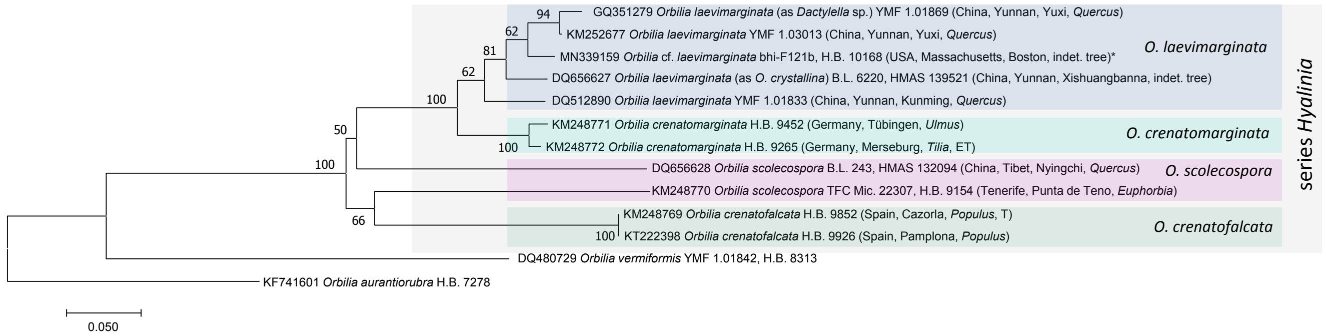
Series *Hyalinia* shows very strong morphological similarities to the *nemaspora-vermiformis* clade of series *Xanthoguttulatae*, from which it can hardly be separated without molecular data. From series *Xanthoguttulatae* s.str. and series *Aurantiorubrae* members of series *Hyalinia* differ in whitish, drought-intolerant apothecia. In the frequent presence of prominent marginal teeth it differs from all of them.

Species delimitation. Among the four included species, merely *O. crenatofalcata* appears to be easily recognizable by its falcate spores. A more or less smooth apothecial margin characterizes the genetically diverse Chinese *O. laevimarginata* which, however, appears to occur also in a form with distinct marginal teeth, while the frequently collected, mainly European *O. crenatomarginata* may rarely have a smooth margin. That species is sharply separated from the similar extra-European *O. scolecospora* by spore and SB size. However, the latter was too rarely collected and sequenced in order to know much about its variability, while molecular data suggests that different taxa are involved (see Phyl. 16).

Anamorph. Ascospore isolates were only gained from *O. laevimarginata* (Y. Zhang et al. 2015). The obtained dactylella-like, 1(–3)-septate, cylindric-ellipsoid conidia were formed on rather short conidiophores, and trapping organs were not observed when nematodes were added. The presumed anamorph of *O. crenatomarginata*, which was rarely observed on the natural substrate, differs hereof in rather long conidiophore and much larger, clavate, multiseptate conidia.

Phylogeny. The phylogenetic position of series *Hyalinia* based on rDNA sequences of *O. crenatomarginata*, *O. laevimarginata*, *O. crenatofalcata*, and *O. scolecospora* remained somewhat unclear. In the combined analysis of section *Aurantiorubrae* it clustered with low support with series *Xanthoguttulatae* (Phyl. 13), whereas in that of the genus *Orbilia* (Phyl. 7) it clustered medium supported sister to the *xanthostigma-tremulae* clade of section *Orbilia*. In the combined analysis in Baral et al. (2017b), series *Hyalinia* clustered unresolved with other members of subgenus *Habrostictis*. The dactylella-like anamorph with its often sometimes conidiophores would suggest a relationship to series *Neodactylella* of section *Arthrobotrys*. However, no such relationship could be deduced from our phylogenetic analyses, and also three morphological features argue against this: distinctly helicoid ascospores and crystalloid SCBs are so far completely absent in section *Arthrobotrys*, and H-shaped ascus bases have never been observed in series *Hyalinia* but frequently so in section *Arthrobotrys.*

The here practised placement of series *Hyalinia* in section *Aurantiorubrae* is supported by strong morphological affinities to the *nemaspora-vermiformis* clade, which includes *O. vermiformis*, *O. nemaspora*, *O. pseudobrevistipitata*, and *O. bomiensis*. This clade did not cluster with series *Hyalinia*, but



Phylogenetic analysis 16. Phylogram of series *Hyalinia* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (13 sequences, 605 positions, aligned with MUSCLE) using the K2+I model in MEGA7 (500 replicates). The tree is rooted with *O. aurantiorubra* and *O. vermiformis*. Asci 8-spored in all taxa; T = type, ET = epitype, * = without partial ITS2.

formed a sister clade of the *xanthoguttulata-succulenticola* clade. Series *Hyalinia* and series *Xanthoguttulatae* form two strongly supported but rather distant clades, particularly when analysing ITS+LSU or ITS (Phyls 13, S15). The molecular distance between the two series is also obvious when analysing the S1506 intron (Phyl. S14).

Also in the phylogenetic analysis of the ITS region by Liu et al. (2006a), series *Hyalinia* [with *O. crenatomarginata* (as *O. crystallina*) and *O. scolecospora*] clustered distant from series *Xanthoguttulatae* [with *O. bomiensis* and *O. nemaspora* (as *Orbilia* sp.)], but as in our analyses the phylogeny of these two clades remained unresolved. The same result was obtained by Zhang et al. (2015), who named both clades '*Hyalinia*'. In Liu et al.'s (2006a) LSU analysis, series *Xanthoguttulatae* clustered with medium support as a sister group to sections *Aurantiorubrae*, *Helicoon*, and *Arthrobotrys*, while series *Hyalinia* clustered as a sister group to all of them.

Specific nucleotide positions. Several nucleotides being characteristic of series *Hyalinia* in comparison to other series of subgenus *Habrostictis* have been found. In the 5.8S region series *Hyalinia* has at pos. 133 TCCG**G**A vs. TCCG**A**A or TCCG**T**A in other groups (Tab. 68). In the LSU D1 domain it has at pos. 206 TCG**C**GGA (or TCG**A**GGA) vs. TCG**T**AGA in other taxa, though rarely TCG**C**AGA (*O. ebuli*) or TCA**T**AGA (*O. gemma*) (not shown), and at pos. 241 CT**G**C (or TT**G**C) vs. TT**A**C, CT**A**C, TT**T**C, TT**T**T, or TC**T**A in other groups, though rarely TT**G**C (*O. milinana*, *O.* aff. *farnesianae*, *O. tianmushanensis*) (Tab. 68). Also the combination of pos. 171 & 174 is characteristic (G**C**GG**T**C), occurring otherwise only in *O. milinana* (G**C**GA**T**C). A gap at pos. 555 in the D2 domain is very diagnostic: TTA–AG vs. TTA**T**AG or sometimes TTA**C**AG in other *Orbiliomycetes*.

Ecology. All four included species are desiccation-sensitive, except for a slight tolerance in *O. scolecospora*. They occur on wood and bark, mainly of angiosperms. The geographical and climatic distribution includes temperate humid Europe, Asia, and North America (*O. crenatomarginata*), supra(sub) mediterranean semihumid southern Europe, subtropical subhumid eastern Asia (*O. laevimarginata*), and tropical humid Middle America (*O.* cf. *crenatomarginata*).

Key to species of series *Hyalinia*

1. Upper spores inverted within asci; spore apex acute to acuminate .... see **series *Xanthoguttulatae***, p. 845
1. Lower spores inverted within asci (SB-containing end pointing towards ascus base); spore apex rounded to acute 2

2. Spores falcate or only very slightly helicoid 3
2. Spores consistently medium to strongly helicoid 4

3. Spores *8–9.5(–9.8) × 0.8–0.9(–1) µm, asci †25–30 × 2.8–3.2 µm; wood of *Populus*, supra(sub)mediterranean (semi)humid southern Europe .... ***O*. *crenatofalcata***, p. 883
3. Spores *(9.5–)10–12(–13.7) × 1–1.1(–1.2) µm, asci †25–45 × 3–4.5 µm; wood & bark of angiosperms, subtropical humid southern China .... ***O*. *crenatonemaspora*** (series *Xanthoguttulatae*), p. 862

4. Spores predominantly > 9 µm long; SCBs in paraphyses globose to elongate, in excipular cells partly brick- to rod-shaped.. .... see ***O*. *nemaspora***, p. 858 & ***O*. *vermiformis***, p. 856 (series *Xanthoguttulatae*)
4. Spores predominantly < 9 µm long; SCBs in paraphyses and excipular cells globose to elongate, and ring- to keyhole-shaped or rhomboid 5

5. Marginal cortical cells *(2–)4–6 µm wide, sometimes with very short glassy processes (< 3 µm), rarely forming distinct teeth; spores *(6–)7–8(–8.5) × 0.75–0.9(–1) µm, apex subacute to acute; conidia (0–)1(–3)-septate, *7.5–13 × 2.8–3.8 µm, formed in clusters on distinct denticles; wood & bark of *Quercus* etc., subtropical humid China .... ***O*. *laevimarginata***, p. 877
5. Marginal cortical cells *2.2–4 µm wide, generally tipped by 4–10 up to 100–200 µm long glassy processes forming marginal teeth (rarely without teeth); spore apex rounded to subacute; conidia (3–)5–6(–7)-septate, *31–50 × 6.8–12 µm, formed singly at the conidiophore tip (presumed anamorph of *O. crenatomarginata*) 6

6. Spores *7–8.5(–9) × (0.6–)0.7–0.8(–0.9) µm; SBs 1.7–2.2(–2.7) µm long; wood & bark of various angiosperms (often *Tilia*), rarely gymnosperms, hemiboreal to mesosubmediterranean (semi)humid Europe & North America .... ***O*. *crenatomarginata***, p. 870
6. Spores *(7–)8–9(–10.5) × 0.9–1.2(–1.3) µm; SBs 2.2–3.5 µm long; wood and bark of *Eucalyptus*, *Euphorbia*, *Quercus*, cold-continental to subtropical, humid to arid Asia, Australia, Macaronesia, South America .... ***O*. *scolecospora***, p. 879

Wakefield (K(M) 36047, holotype of ***O. curvatispora* var. *minor***).

Misapplied name: Boudier (1904–10: 269, pl. 465), as *Hyalinia rosella* (misspelling for *roseola*, see p. 1683).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–1(–1.2) mm diam., in total 0.1–0.2(–0.25) mm high (receptacle 0.05–0.1 mm), watery greyish-white, sometimes with a very faint, rarely distinct rosaceous(-violaceous) or cream-carneous tint, strongly translucent (glassy), round, gregarious; disc flat or slightly convex, margin denticulate to dentate, with ~10–30 small to usually rather large and distinct triangular teeth of 30–100 × 60–120 µm {9}, 0–15 µm protruding beyond disc, rarely smooth in some {1} or all {4} apothecia, always smooth at flanks; broadly sessile or with a broad, obconical, ill-defined stipe 0.05–0.1 × 0.17–0.3 mm, superficial; dry pale to light yellowish-ochraceous-chlorinaceous to rosaceous-orange-brownish. **Asci** *24–34(–37) × (2.9–)3.2–3.8 µm {8}, †20–34 × 2.4–3.3 µm {16}, 8-spored, spores 4–8-seriate, strongly spirally twisted within both the living and dead asci, pars sporifera *9.5–13(–15) µm, †10–19 µm, ~4 lower spores inversely oriented {7} (never mixed); **apex** (†) slightly to strongly truncate (never indented or laterally inflated); **base** with very short to medium long, thick or thin, flexuous stalk, L- or h-shaped. **Ascospores** *7–8.5(–9) × (0.6–)0.7–0.8(–0.9) µm {12} (~9–12 µm actual length), †(6.5–)7–8(–9) × 0.6–0.8(–0.9) µm {18}, very narrowly fusoid(-clavate), upper part almost cylindrical but slightly narrowed towards rounded to subacute apex, base (medium to) strongly attenuated, tail-like or with a distinct tail ~2–3 × 0.2–0.3(–0.4) µm; (*/†) strongly curved especially near base (helicoid, always twisted like a right-hand thread); **SBs** 1.7–2.2(–2.7) × (0.2–)0.3–0.4(–0.5) µm {6}, narrowly tear-shaped (to ellipsoid), apically narrowed to a short filum (but filum sometimes invisible). **Paraphyses** apically cylindrical or very slightly (rarely medium) capitate, terminal cell *11–20 × (1.7–)1.9–2.8(–4) µm {6}, †1.5–2.5 µm wide {2}, lower cells *2.7–5.5 × 1.9–3.3(–4) µm {4}, †2.5–4.5 × 1.3–2.5 µm {2}, rarely branched at upper septum; hymenium hyaline to pale rose. **Medullary excipulum** hyaline, 10–30 µm thick, of dense textura globulosa-angularis(-intricata), not sharply delimited from ectal excipulum. **Ectal excipulum** of thin-walled t. globulosa-angularis from base to margin, (30–)80–110(–150) µm thick near base, cells *10–28 × 8–20 µm {7}, 15–30 µm thick at lower flanks, cells *7–20 × 5–16 µm {2}, 10–15 µm thick at mid flanks and margin, oriented at 30–45°, marginal cortical cells forming a t. porrecta oriented at 0–20°, sometimes running out in free hairs, cells *7–22 × 2.2–4 µm {8}; **glassy processes** 4–10 {3} or (6–)10–50(–62) {16} × (2–)2.5–3.5(–4) {18} µm, low- to high- refractive, sometimes stratified, curved upwards {7}, tightly conglutinate. **Anchoring hyphae** sparse to abundant, */†1.5–3 µm wide (near insertion –4.5 µm), walls 0.2(–0.3) µm thick {5}, without gel or sometimes forming an up to 30 µm thick, glassy-gelatinized t. intricata. **SCBs** in terminal cells of paraphyses and marginal cortical cells globose or elongate-cylindric, (1.2–)1.7–2.3(–3) µm diam., low- to high-refractive, mostly 1 per cell, in lower part of ectal excipulum 1 or more per cell; crystalloid SCBs in terminal and lower cells of paraphyses and in ectal excipulum from base to margin {21}, medium to high-refractive, in paraphyses filiform to S-shaped or rhomboid, in excipulum ring- to keyhole- or horseshoe-shaped, (2–)3–7(–8) × (2–)3–5(–7.5) µm {6}, also plate-like or filiform; **VBs** absent. **Exudate** over paraphyses continuous to cloddy, externally rough to granular, hyaline or pale yellowish, (0.3–)1–2(–3) µm thick, loosely attached; over margin and flanks finely granular or cloddy, 0.3–1 µm thick. — **ANAMORPH**: dactylella-like (presumed, from natural substrate {3}). **Conidiophores** unbranched, septate, erect, up to *~100–110 µm long {1}, 3.5–4 µm wide at the base, 2 µm at the tip, forming a single terminal conidium. **Conidia** *31–50 × (6.8–)8–10.5(–12) µm, ellipsoid-clavate, (3–)5–6(–7)-septate {2}, containing quite a few minute LBs.

Habitat: on underside of decorticated or corticated, 1–10 cm thick branches and much thicker stumps and logs lying on (very) moist but also rather dry ground (never exposed to dry air), of ?*Acer* sp. {1}, *A. pseudoplatanus* {1}, *A. rubrum* {1}, *Betula* sp. {2}, *Carpinus betulus* {8}, *Corylus avellana* {2}, *Eucalyptus globulus* {1}, *Fagus sylvatica* {4}, *Fraxinus excelsior* {1}, *Larix* sp. {1}, *Populus* sp. {2/1}, ?*P. alba* {1}, *P. nigra* {1}, *P. tremula* {1}, *P. tremuloides* {1}, *Prunus avium* {1}, *P. cerasus* {1}, *Quercus* sp. {1/1}, *Q. robur* {1}, *Q. petraea* {1}, *Salix* sp. {6/2}, *S. caprea* {1}, *Tilia* sp. {18/3}, *T. cordata* {2}, *T. platyphyllos* {2}, *T. tomentosa* {1}, *Ulmus* sp. {2}, indet. angiosperms {6}, on 0.5–2 mm or often over 10 mm deep medium to mostly strongly decayed wood {55}, sometimes brown-rotten, also often on bark {27} (periderm {3} or bast {11}), on periderm-free bast or on inner surface of detaching or detached bark, sometimes deep inside large, hollow stumps, green algae absent or sparse, sometimes on black hyphomycetes or subiculum of e.g., *Lasiosphaeria*, or close to old rhizoids of *Armillariella* {1}. **Associated**: *Capronia* sp. {1}, *Collybia cookei* {1}, *Diaporthales* {1}, *Holwaya mucida* {1}, *Hyalorbilia inflatula* {1}, *Lachnum* aff. *virgineum* {1}, *Lasiosphaeria hirsuta* {3}, *Olla transiens* {1}, *Orbilia dryadum* {1}, *O. epipora* {1}, *O. eucalypti* {1}, *O. naumburgensis* {1}, *O. orientalis* {1}, *O.* ?*sarraziniana* {1}, *Pachyella violaceonigra* {1}, *Pleurothecium* sp. {1}, *P. recurvatum* {1}, *Scutellinia* sp. {1}, *Sporidesmium phaeosporum* {1}, *Subulicystidium longisporum* {1}, *Trichia* sp. {1}, *Tulasnella cystidiophora* {1}. **Desiccation tolerance**: after 1 week some excipular cells still viable, but all other elements dead; asci usually dead after half a day, some ascospores rarely viable after 27 months (H.B. 5163); conidia still viable after 2.5 months. **Altitude**: 5–865 m a.s.l. (temperate atlantic to subcontinental Europe), 5–1180 m (± mediterranean Europe), 100–1020 m (continental Europe & Asia). **Geology**: Ordovician silt- & sandstone, Silurian shale, Permian (Rotliegend), Buntsandstein, Muschelkalk, Keuper, Jurassic & Cretaceous sand-, mud-, silt-, marl- & limestone, dolomite, flysch, Tertiary clay, marl & molasse, Pleistocene loess, marl, peat; mica schist, gneiss, serpentinite, ophiolite, basalt. **Phenology**: throughout the year (especially in spring and summer).

Phenology of *O. crenatomarginata*

Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
2	6	11	16	10	9	9	8	3	5	3	0

Taxonomic remarks. *Orbilia crenatomarginata* is characterized by small, strongly helicoid, narrowly fusoid, worm-shaped ascospores with ± obtuse apices and gradually tapered, tail-like bases, also by ± long glassy processes being agglutinated to form usually very distinct triangular teeth at the apothecial margin, and by the presence of ring- to horseshoe-shaped crystalloid SCBs, especially in the ectal excipulum (see Pls 458: 1f, 2i; 460: 1). For the morphologically very similar *O. laevimarginata* see p. 877.

The similar, mainly subtropical *O. scolecospora* differs merely in larger, especially wider spores and longer SBs, while the temperate to tropical, extra-European *O. vermiformis* and *O. nemaspora* of series *Xanthoguttulatae* differ, besides slightly larger spores, in the absence of glassy processes and in wider marginal cortical cells, finally in 1–3-septate conidia. The eastern Asian *O. pseudobrevistipitata* (series *Xanthoguttulatae*) differs, e. g., in lageniform paraphyses and in the upper spores inversely oriented, also in very short glassy processes. Ring-shaped crystalloid SCBs also occur in *O. scolecospora* and *O. laevimarginata*, while in *O. nemaspora* brick-shaped SCBs were observed.

Variation. *O. crenatomarginata* was found to show a comparatively low degree of variation. Mainly the length of the glassy processes and consequently that of the marginal teeth varied, resulting in either distinctly denticulate or sometimes almost even margins. Very short to almost absent teeth were only seen in a few collections, e. g., in one from Wienerwald, in which the ca. 10 µm long glassy processes formed an indistinctly crenulate margin (IVV: H.B. 5254). Sometimes, toothed and ± smooth apothecia grew intermingled, e. g., in Pl. 458: 6 and Pl. 459: 9, 11. In any case, the glassy processes were never entirely absent on the marginal cells.

In extra-European collections, distinctly denticulate margins were reported by Spooner (1987: 188, USA) and Raitviir (1991: 362, Russian Far East), and were also observed in the here reported specimens from Middle and Northern America, and central and eastern Russia. Though not explicitly mentioned, marginal teeth were probably also present in a report from Michigan (USA) by Kanouse (1936: 99). The so far single record on coniferous wood (*Larix*, Yakutsk, northeastern Russia, Pl. 459: 9, IVV: H.B. 8705) did not differ in any respect from those on angiosperm substrate.

Slight variation was noted in spore width, ranging from †0.5–0.6 µm (type of *O. crenatomarginata*) up to †0.7–0.8 µm (type of *O. crystallina*). Spore curvature and also shape slightly varies among the here illustrated collections. This variation is particularly obvious when comparing spores in the dead state; it might originate from influences during dying, such as collapsing, or to some degree from inexact observation. A spore size of *8.5–10.5 × 0.8–0.9 µm was observed in a very recent sample from England (N. Aplin pers. comm.), the seemingly first record for the British islands, its length distinctly exceeding the typical values.

Literature reports. The differences which Boudier (1904–10) saw between *H. crystallina* (on *Salix*) and *H. roseola* (on *Tilia*) rely exclusively on macroscopy. He described the apothecia of his *H. roseola* (l.c., p. 269, pl. 465, as *H. rosella*) as pale rose, with obtuse marginal teeth and a very short and broad stipe; those of his *H. crystallina* (l.c., p. 269, pl. 466) were entirely white, with more prominent acute marginal teeth and without a stipe. In the present study no correlation between these features and the inhabited hosts could be observed. The microscopic features always concurred quite well among the specimens from different hosts. As in the type of *H. crystallina* on (?)*Quercus* (Pl. 458: 7) no apothecial stipe could be observed in our study of the *H. roseola* collection, and the marginal teeth were very similar though sometimes absent (Pl. 458: 6).

The dimensions of dead asci and spores in the lectotype of *H. crystallina* as evaluated by Spooner (1987, Pl. 458: 8) and in the present study closely concur with those of the other here studied collections on various substrates, except for a few details: contrary to Spooner's analysis, the paraphyses are branched and densely septate in their lower part. Spooner described the spores as 'laterally flattened', which appears to correspond to a strong constriction a little below the centre in some of the spores drawn by him. This peculiarity was not seen by us in any of the studied specimens, irrespective of whether the spores were alive or dead. Living discharged spores are actually circular in cross section. Since dead spores often become more or less laterally flattened by collapsing during shrinkage, the reported constriction is undoubtedly present only in dead spores.

Inaccurate reports of cylindrical spores without distinctly tapered ends are found in Quélet (1878), Boudier (1904–10: pl. 466), Breitenbach & Kränzlin (1981), and Raitviir (1991: 362). Boudier's description gives a spore size of 10–12 × 2 µm for *H. roseola* and 8–11 × 2 µm for *H. crystallina*. From his plates, however, a size of 8.5–10.5 × 1–1.3 and 8.5–10.2 × 0.9–1.1 µm can be evaluated, respectively (direct distance from end to end). Also Quélet (1878) gave a spore size of '0.012 mm'. Possibly these high values refer to the actual length of the helicoid spores rather than to the length in situ. Under the name *O. crenatomarginata* Velenovský (1934: 102) reported some Bohemian collections with a denticulate margin (on *Alnus*, *Carpinus* and *Quercus*), which appear to fit our present concept, although he figured strongly helicoid spores with often 1.5–2 turns (Fig. 154: 3). Priou & Poncelet (2006) provided a detailed account under the name *O. crystallina*, based on two fresh specimens from Bretagne and Rhône-Alpes. Their illustration includes spore bodies and horseshoe-like crystalloid SCBs in the excipular cells.

Nomenclature and type studies. When transferring *Helotium crystallinum* to *Orbilia*, Baral (1994) overlooked the homonym *Orbilia crystallina* Rodway. Followingly, the combination *Orbilia crystallina* (Quél.) Baral is a nomen illegitimum (ICN 53.1) and the next oldest epithet *crenatomarginata* has to be chosen as basionym of the present species.

Quélet (1878) described ***Helotium crystallinum*** based on two collections, one with white apothecia from bark of *Salix* near Paris (leg. É. Boudier) and 1 with finally rosaceous apothecia from bark of *Quercus*, probably from French Jura (?leg. L. Quélet). A third collection (from bark of *Tilia*, Doubs), had pale rose apothecia and was collected by Quélet shortly after he published *Helotium crystallinum*. Although Quélet (1878) did not mention the difference in colour between the two first samples, he (in sched.) attributed the *Tilia* collection the rank of a variety (as '*Cistella cristallina* Q. v. *roseata*') when transferring *H. crystallinum* to *Cistella*, apparently mainly because of its rose colour. Boudier (1885) described his new genus *Hyalinia* on the basis of the *Salix* collection, but he had also examined Quélet's *Tilia* collection (see Boudier 1904–10: 269, pl. 465). Contrary to Quélet, Boudier distinguished the two collections at the species level by naming the *Salix* specimen *Hyalinia crystallina* and the *Tilia* specimen *H. rosella* (Fr.) Boud. (a misspelling for *roseola*). Boudier's separation into two species was accepted during a reexamination by Nannfeldt (1932: 266), but also by Grelet (1948b: 105) and Moser (1963) who merely copied Boudier's opinion and data.

The 'very abundant' *Salix* collection from Paris was not examined in the present study. It was depicted by Boudier in the fresh state (Boudier 1904–10: pl. 466), and his plate does not leave any doubt about its identity with *O. crenatomarginata*. Boudier stated that both *H. crystallina* and *H. roseola* are rather rare species, and we feel that he saw at that time only these two collections.

According to Nannfeldt (1932: 266), two specimens under the name *Cistella crystallina* are found in UPS, both obviously from Quélet's herbarium. One of them is the *Tilia* collection depicted by Boudier under the name *H. rosella*. This specimen ('Champ. Vallon, on [bark of] *Tilia*, 31.III.1879, L. O.'; the initials refer to Lucien Quélet) is redescribed here (Pl. 458: 6) and confirmed to be *O. crenatomarginata*. The data indicated by Boudier ('Dr Quélet qui l'avait trouvée en mars, dans le Doubs, sur des écorces de Tilleul pourries') undoubtedly refers to the collection from 'Champ. Vallon', according to a handwritten note by Quélet on p. 403 in his personal copy of Quélet (1873) (J.P. Priou pers. comm.).

The other specimen in UPS is undated and unlocalized, and it is the one that was redescribed by Nannfeldt (1932: 252), Spooner (1987: 187), and in the present study (see Pl. 458: 7–8). Though devoid of collection data, Nannfeldt (1932: 252) seems right when stating that L. Quélet is the finder of this specimen, because the included handwritten diagnosis says that the hymenium was 'finally rose', which excludes Boudier's collection. Apart from the rose colour, the diagnosis in this specimen corresponds quite well to the protologue of *Helotium crystallinum*. We conclude that this is the specimen on bark of *Quercus* from Jura. Since the protologue of *Helotium crystallinum* comprises two collections, a lectotype has to be chosen. Spooner (1987: 188) named the *Quercus* collection 'lectotype' in the collection data, which we consider as a valid lectotypification of this species. There is only bark present in the lectotype, and the host genus could not clearly be verified from the bark anatomy.

Obviously, the two illustrations by Boudier (l.c., pls 465–466) are based on authentic material of *Helotium crystallinum*. The *Salix* collection (pl. 466) was mentioned by Quélet in the protologue, thus should be considered as paratype of *H. crystallinum*. The *Tilia* collection (pl. 465) was made by Quélet after he published the taxon, hence it is only authentic material. *Hyalinia roseola* in Fries's sense is a doubtful taxon (see p. 1683).

Four authentic specimens of ***Hyalinia crenatomarginata*** from FH were examined, and the identity with *H. crystallina* is confirmed here, which was also asserted by Svrček (1954: 20) without type study and without any comment. Two of the specimens were mentioned by Höhnel in the protologue and bear handwritten data of his diagnosis. In one (from Haltertal) no apothecia could be found, whereas the other (from Judenau) is very rich and is illustrated here (Pl. 458: 5). Höhnel's notes on the label of the latter specimen have clearly contributed to the data in the protologue. The specimen from Judenau (V.1906, FH) is designated here as **lectotype** of *O. crenatomarginata*, and a specimen from Germany (Merseburg, on *Tilia*, IVV: H.B. 9265), from which a sequence was gained, is designated here as **epitype**.

In the holotype of ***O. tiliacea***, Svrček (1954) found only a single minute apothecium (0.05 mm diam.) with immature asci 24–27 × 2–2.5 µm. Reexamination showed, however, that 12 small apothecia (rehydrated 0.05–0.17 mm) occur along the border of a beetle gallery. These have minute marginal teeth consisting of 15–30 × 2.5–3 µm large glassy processes. No asci were found in the two largest of them. Neither Velenovský nor Svrček saw marginal teeth, although there is no doubt that they were dealing with the same apothecia. Svrček considered *O. tiliacea* as a nomen dubium, but it is tentatively here placed in synonymy with *O. crenatomarginata* due to the teeth and the substrate. The ascospores reported by Velenovský (1–2 µm, ellipsoid, biguttulate) are probably stray spores.

Svrček (1954: 20) revised material of ***O. roseohyalina*** (Karlštejn, X.1926, PRM 151742) and designated it as lectotype, although this collection is not mentioned in Velenovský's protologue. However, it is mentioned on Velenovský's unpublished manuscript plate of that taxon, which contains three collections: two from Karlštejn (on wood of *Cornus*, 14.IV.1923; on wood of indet. angiosperm, X.1926) and one from Mnichovice (on *Robinia*, VII.1926). We assume that it was a lapsus when Velenovský omitted the collection of X.1926 in the protologue of *O. roseohyalina* which now represents the only preserved specimen.

The present study of this lectotype (Pl. 458: 3) on wood of ?*Salix*, according to the wood anatomy) confirms Svrček's result as being conspecific with *Hyalinia crystallina.* However, the material is a mixture: the fragments of a decorticated branch contain seven apothecia with denticulate margins, but also two of *Orbilia* (?)*sarraziniana*. Furthermore, a fragment of a detached bark bears immature *Orbilia ?aurantiorubra*. Velenovský's drawing shows denticulate apothecia and thick exudate which fit well *O. crenatomarginata*, whereas his depicted oblong-ellipsoid spores do not belong to the described *Orbilia*.

The holotype of ***O. curvatispora* var. *minor*** has asci and pars sporifera at the lower end of the length range of *O. crenatomarginata*, and comparatively small apothecia (0.15–0.35 mm) and marginal teeth (10–20 × 25–35 µm, glassy processes 8–20 × 2.8–3.5 µm), but the other characters of this Caribbean collection would fit well (Pl. 458: 4). Dennis' (1954) measurement gives longer and narrower spores than here found (8–10 × 0.3 µm) but his figure of mainly S-shaped spores (see Fig. 159: B) undoubtedly refers to a helicoid curvature, unlike *O. curvatispora* (= *O. auricolor*). Also the paraphyses are figured strongly capitate by Dennis, but they were not enlarged or only slightly to medium so in the present reexamination. Dennis overlooked the small marginal teeth, therefore, he did not compare this taxon with *O. crenatomarginata*. Because of the occurrence in the tropics and the rather small asci, the species should be compared with the subtropical Chinese *O. laevimarginata* or the genetically aberrant collection on *Quercus* bark from cold-temperate Northern America.

Anamorph. The presumed anamorph of *O. crenatomarginata* was two times observed in close association with the apothecia (Pl. 460: 2–3). The conidia differ from those of *O. vermiformis* and *O. nemaspora* (series *Xanthoguttulatae*) in being longer and with many more septa, while they resemble those reported for *O. cardui*, *O. clavispora*, *O. cotoneastri*, and *O. rhopalota* (series *Neodactylella* of section *Arthrobotrys*). They tend to be larger and more distinctly clavate instead of cylindrical as in some of those mentioned species. The conidia of *O. rectispora* (series *Neodactylella*) differ in being longer and narrower and more fusoid. A rather close match is observed to the type of *Dactylella rhopalota* as described by Drechsler (1943b), which differs in sometimes proliferating (geniculate) conidiophore tips and in being isolated from leaf mould. Its conidia fit quite well, especially H.B. 6635, though they tend to be longer in the

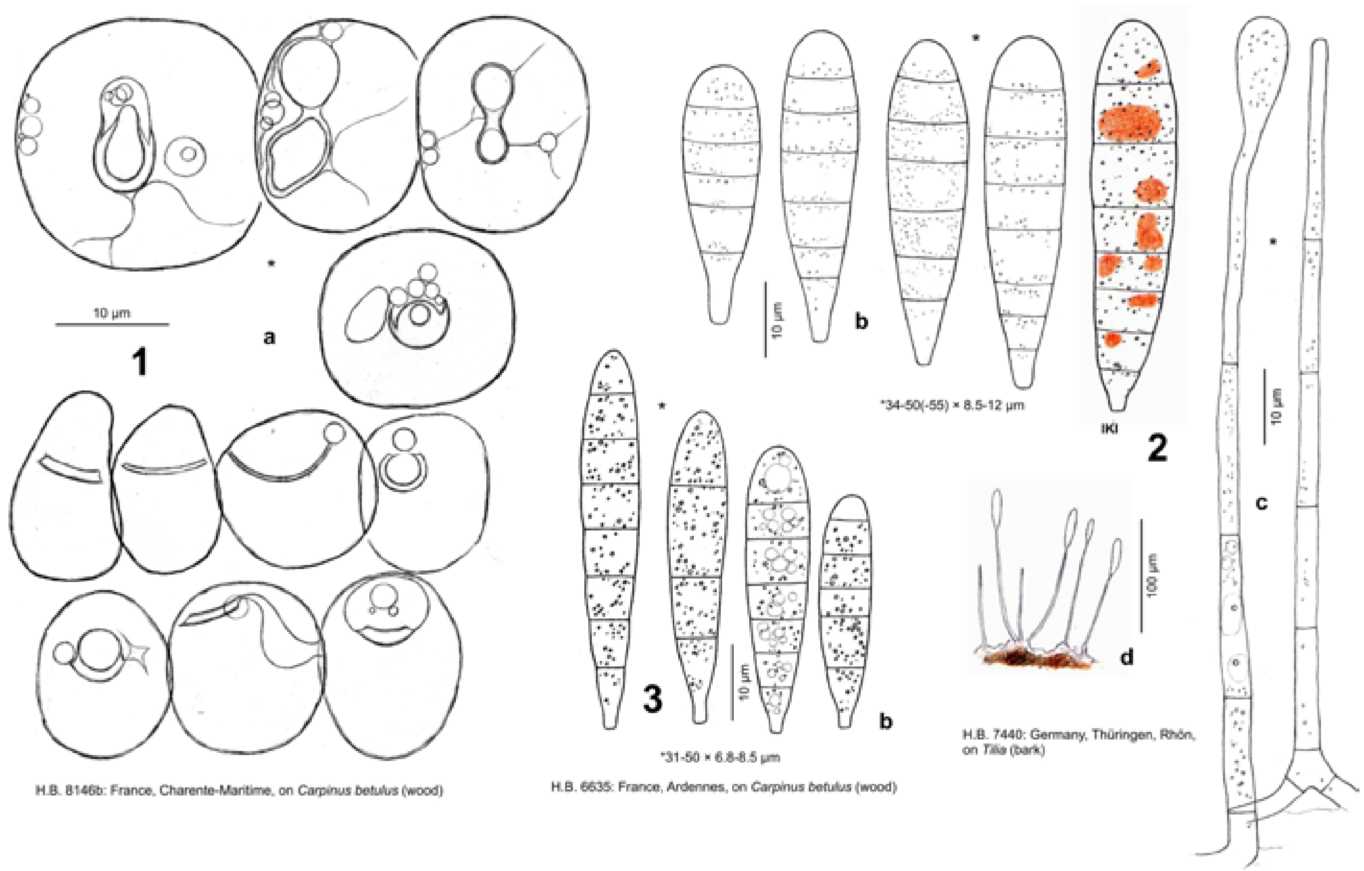

Plate 460. **1–3**: *Orbilia crenatomarginata*. – **a**. ectal excipular cells containing globose and crystalloid SCBs; **b**. conidia from substrate (right conidium in IKI staining glycogen); **c–d**. conidiophores with conidia, from substrate.

protologue (*36–60 × 6.7–9.6 µm) and with up to 10 septa. In H.B. 7440 numerous projecting conidiophores occur over the uneven inner surface of bark (Pl. 459: 2), and the conidia at their tips are distinctly wider than in H.B. 6635 and also wider than in the type of *D. rhopalota* (see Pl. 460).

D. minuta closely resembles the present anamorph in conidial shape, but differs in distinctly larger conidia. Also *O. xinjiangensis* (series *Neodactylella*) has smaller conidia than given for *D. minuta*. Grove (1884) gave the conidiophores of *D. minuta* as 120–150 µm long and the conidia as 60–70 × 14–15 µm. From the magnification of the two figured conidia a size of 60–68 × 13–14 µm can be evaluated, while the sketch under smaller scale shows conidiophores of c. 110–185 µm length and conidia of roughly 60–75 × 16–19 µm. Given that these data are correct, *D. minuta* seems to represent a species different from *O. crenatomarginata*. The type material of *D. minuta* exists in K (Rubner 1996) and consists of a piece of dead wood though without any trace of the fungus. A culture was probably not made by Grove, and further records are unknown.

Phylogeny. The two sequences gained from apothecia of European specimens (H.B. 9265, Merseburg, on *Tilia*; H.B. 9452, Tübingen, on *Ulmus*) comprise SSU, ITS, and LSU. In H.B. 9452 the S1506 intron is present whereas in H.B. 9265 it is absent. The two strains show a distance of 1.6% in the ITS region and 0.5% in the LSU (D1–D2). From Chinese *O. laevimarginata* they deviate by 8.5–12% in the ITS, and by 17.5–18.5% in the intron. *O. scolecospora* differs from *O. crenatomarginata* by 17–18% in the ITS, and *O. crenatofalcata* by 18%.

O. crenatomarginata and *O. laevimarginata* clustered in a strongly supported clade in our analyses of ITS (Phyls 16, S15) or in a weakly supported clade when analysing the intron (S14). *Dactylella rhopalota* as represented in GenBank (strains from Netherlands identified by Rubner 1996) falls in series *Neodactylella* of section *Arthrobotrys*, therefore, *D. rhopalota* is not the anamorph of *O. crenatomarginata*, at least in the sense of Rubner.

Ecology. *O. crenatomarginata* grows on ± strongly rotten wood and bark of hygric branches and logs or stumps of angiosperm trees (mainly *Tilia* {23} and *Salicaceae* {13}), exceptionally gymnosperms (*Larix*). *Tilia* seems to be a favourite substrate, which was also suspected by Engel (1994) who found the species 'very frequently' on that host, mostly on bast, in the northern Frankenalb near Bayreuth (Bayern). Already Svrček (1978) mentioned for Czechia a frequent occurrence on bast of *Tilia*. As more rare substrates he mentioned *Carpinus*, *Sorbus aucuparia*, and *Salix*, and Kotlaba (1981, from Karlštejn) *Betula pendula*. *Quercus* as substrate was indicated by Quélet (1878), Velenovský (1934: 102), and Spooner (l.c.).

O. crenatomarginata was recorded in atlantic to continental, humid to sometimes semihumid, supra- to orotemperate central and eastern, but also in mesotemperate western and suprasub- to mesosubmediterranean southern Europe, very continental oroboreal subhumid (winter-dry) northeastern Asia (Yakutsk), and cold-temperate to hemiboreal humid North America. Also Kanouse (1936: 99, Michigan) and Spooner (1987: 188, Ithaca)

4a–e. H.B. 7683: France, Ille-et-Vilaine, on *Tilia*; **5**. H.B. 9304: France, Essonne, on *Tilia*; **6**. H.B. 9005: Canada, Québec, on *Populus*; **7**. P.P. 20070827: Poland, Kłodzko, on *Tilia*; **8**. 17.III.2007: Luxembourg, on indet. angiosperm; **9a–b**. H.B. 8705: Yakutia, on *Larix*; **10a–b**. E.R.D. 4724: Spain, Asturias, on *Eucalyptus*; **11a–c**. H.B.: 9452: Germany, Tübingen, on *Ulmus*; **12**. H.B. 8704: Yakutia, on (?)*Salix*; **13**. 15.IV.2011: Germany, Grimma, on *Betula*; **14**. 16.V.2015: France, Rochefort, on indet. angiosperm.

reported specimens from the northeast of USA (but see under *O. laevimarginata*, p. 879), and Raitviir (1991: 362) from the far east of Russia (Primorje). It is remarkable that only a single very recent record from Great Britain and Denmark and none from Scandinavia came to our notice. The type of *O. curvatispora* var. *minor* from the Caribbean region represents the only sample from the humid tropics, in case it does not belong to *O. laevimarginata* or a different species.

Map 81. Known distribution of *O. crenatomarginata* in Europe.

The vegetation in central Europe includes various acidic to calcareous deciduous forests in shady valleys and creeks as well as thermophilous slopes. *O. crenatomarginata* is a desiccation-sensitive species that grows on the underside of fallen branches and logs. Although a single collection was made on a dry hanging, 2 cm thick branch in 17 m above the ground, the apothecia were only obtained in a moist chamber several weeks after collection (M. Unterseher pers. comm.), therefore, it is assumed that they grew under constant moisture conditions and were not present when the branch was collected. This deviated from typical specimens merely in very indistinct marginal teeth of very short glassy processes.

Specimens included. **GREAT BRITAIN**: **South East England**, **West Sussex**, 5.5 km E of Haywards Heath, 9 km WNW of Uckfield, Sheffield Park, 51 m, branch of *Carpinus betulus*, on wood, 4.IX.2019, N. Aplin (N.A. 4919, anam. substr., doc. vid.). — **DENMARK**: **Sjælland**, 3 km S of Tibirke, 1.3 km NW of Ramløse, S of Ellemose, 5 m, log of *Salix*, on bark, 2.VIII.2015, T. Læssøe (C [tl-2015-710846], doc. vid.). – 1.8 km ESE of Lillerød, Allerød Sø, 47 m, log of *Salix*, on wood, 2.VIII.2015, R. Riis-Hansen & T. Rønhave Larsen, vid. T. Læssøe (doc. vid.). — **GERMANY**: **Brandenburg**, Märkisch-Oderland, 14 km ESE of Eberswalde, 3.5 km NW of Bad Freienwalde, Räuberlinde, 3 m, branch of *Tilia*, on bark, 15.VIII.1973, D. Benkert (BHU, as *O. curvatispora*). – **Sachsen**, 6 km NNE of Chemnitz, 1 km E of Glösa, Indianerteich, 330 m, log of *Populus*, on wood, 22.VIII.1998, M. Eckel (H.B. 6212b). – 7.5 km SE of Chemnitz, E of Einsiedel, Einsiedler Wald, 390 m, branch of *Tilia*, on wood, 25.IV.2011, B. Mühler (ø, doc. vid.). – 6 km NW of Leipzig, 1 km SW of Wahren, Burgaue, 100 m, branch of *T. cordata*, on wood, 13.VI.2003, M. Unterseher (LZ, H.B. 7431). – 14 km SW of Grimma, 3 km W of Bad Lausick, Schildholz, 155 m, log of *Betula*, on wood, 15.IV.2011, N. Hiller, vid. I. Wagner (ø, doc. vid.). – **Sachsen-Anhalt**, 29.5 km NNW of Magdeburg, 7.3 km NNW of Colbitz, Colbitzer Heide, 86 m, log of *Tilia*, on wood, 1.XI.2018, T. Richter. – 17 km WSW of Merseburg, 2.5 km WSW of St. Micheln, Müchelholz, 190 m, branch of *Tilia*, on bark, 5.IV.2010, S. & P. Rönsch (ex H.B. 9265, M-0291776, epitype; sq.: KM248772). – 5.3 km WSW of Freyburg, ESE of Hirschroda, Balgstädter Lehden, 160 m, branch of *Tilia*, on wood, 13.IX. & 11.X.2008, W., E. & A. Huth (ø, doc. vid.). – 2.7 km WSW of Naumburg, S of Almrich, Sperlingsholz, 195 m, branch of *Fagus sylvatica*, on wood, 24.VIII.2006, W. Huth (ø, non vid.). – 4 km N of Naumburg, 1.5 km E of Großjena, Gerodig, 170 m, branch of *Prunus cerasus*, on wood, 20.V.2007, W. Huth (ø, non vid.). – ibid., log of *Populus tremula*, on wood, 13.IX.2008, W. Huth (ø, non vid.). – 5 km NW of Naumburg, 1.2 km NW of Kleinjena, Poppera-Holz, 200 m, branch of *Fraxinus excelsior*, on wood, 20.IV.1987, W. Huth (JE, non vid.). – ibid., IV.1988, W. Huth (W.H., non vid.). – **Thüringen**, Wartburgkreis (Rhön), 10 km WNW of Meiningen, 1.5 km NNW of Kaltennordheim, Karlsberg, 450 m, branch of *Tilia*, on bark, 24. XI.2003, L.G. Krieglsteiner (L.K., H.B. 7440, anam. substr.). – **Bayern**, **Oberbayern**, 20 km NE of München, 10 km WSW of Erding, Eichenrieder Moos, 470 m, log of *Salix*, on wood & bark, 16.V.1975, A. Einhelliger 128/5 (as *H. crystallina*, M). – **Oberfranken**, 21 km W of Bayreuth, 2.8 km NW of Hollfeld, ESE of Freienfels, Lindenallee, 430 m, branch of *Tilia*, on bark, 24.II.1990, H. Engel (H.E. 12671, H.B. 4014). – ibid., branch of *Tilia*, on bark, 1.V.1990, H. Engel (H.E. 12913, H.B. 4068). – 14 km S of Coburg, 2 km N of Unnersdorf, Heidleite, 330 m, on bark of *Tilia*, 2.IV.1993, H. Engel (H.E. 93/02–13, H.B. 4955). – **Baden-Württemberg**, 3.5 km N of Stuttgart-Vaihingen, 1.8 km NE of Büsnau, N of Pfaffensee, 430 m, log of *Carpinus betulus*, on wood, 30.IV.1995, A. Gminder (H.B. 5276). – 6 km NE of Tübingen, ENE of Pfrondorf, Tiefenbach, N of Einsiedlersteg, 410 m, log of *Tilia cordata*, on wood, 4. VIII.1992, H.O. Baral & K. Siepe (H.B. 4727). – ibid., E of Einsiedlersteg, 420 m, stump of *Tilia*, on wood, 13.X.1996, H.O. Baral (H.B. 5631a). – E of Pfrondorf, Tiefenbach, 385 m, branch of *Fagus sylvatica*, on wood, 24.IX.2018, H.O. Baral (ø). – 1 km SE of Pfrondorf, S of Rauhalde, 345 m, log of *Ulmus*, on bark, 3.II.2002, H.O. Baral (H.B. 7097). – ibid., 14.XI.2010, H.O. Baral (H.B. 9452 ø; sq.: KM248771). — **LUXEMBOURG**: **Gutland**, **Luxembourg**, 1 km NE of Luxembourg, Fort Thüngen, 310 m, on bark of ~*Tilia*, 26.VII.1901, V. Noppeney (LUX 42496, Feltgen as *O. leucostigma*, on *Pinus*). – 7.5 km SE of Luxembourg, 0.8 km NW of Hassel, Louknoeppel, 327 m, on indet. angiosperm, 17.III.2007, B. Schultheis, vid. G. Marson (ø). — **FRANCE**: **Bretagne**, **Ille-et-Vilaine**, 3 km NNE of Guichen, 1 km SW of Le Pont-Réan, La Massaye 62 m, bark of *Tilia*, 15.II.2005, J.P. Priou & A. Poncelet (J.P.P. 25031, H.B. 7683). – **Pays de la Loire**, **Maine-et-Loire**, 3 km NE of La Pommeraye, 0.5 km NW of Chateaupanne, *Salix*, 22.V.1997, J. Mornand (non vid.). – **Poitou-Charentes**, **Charente-Maritime**, 6 km NW of Rochefort sur mer, near St.-Laurent de la Prée, Bois Madame, 5 m, branch of ?*Quercus*, on bark, 18.III.2007, J. Robert (doc. vid.). – 19 km S of Rochefort, 3 km WSW of St.-Gemme, La Grande Vergne, 26 m, branch of indet. angiosperm, on wood, 16.V.2015, P. Tanchaud (ø, doc. vid.). – 25 km SSE of Niort, 2.5 km ESE of la Villedieu, Forêt d'Aulnay, La Borne St.-Léger, 115 m, branch of *Carpinus betulus*, on wood, 28.IV.2006, P. Cimon (doc. vid.). – **Prince Edward Island**, 16.5 km WSW of Charlottetown, 1.5 km ENE of Bonshaw, log of *Populus*, on bark, 29.V.2019, A. Carter (doc. vid.).

Not included. **Trinidad**, 3 km NNW of Diego Martin, River Estate 45 m, log of indet. angiosperm, on wood, 13.I.1921, E.M. Wakefield (K(M) 36047, holotype of *O. curvatispora* var. *minor*, H.B. 5446 ø).

Orbilia laevimarginata Baral, Y. Zhang & Z.F. Yu, in Zhang et al., Phytotaxa 203: 247 (2015) — Pls 461–462, Map 82

Etymology: named after the typically smooth apothecial margin.
Typification: China, Yunnan, Qinglongzhen, branch of *Quercus*, 3.XI.2004, Z.F. Yu (ex H.B. 7667, M-0276498, holotype).

Description: — **TELEOMORPH**: **Apothecia** fresh (0.14–)0.2–0.5(–1.2) mm diam., 0.08–0.14 mm high (receptacle 0.05–0.06 mm), greyish-white to pale pink, translucent, round, gregarious; disc flat, eventually slightly to medium convex, margin thin, not protruding, smooth {3}, also with prominent broad teeth 25–30 × 60–80 µm, 12–14 per apothecium {1}; sessile on an obconical base, superficial. **Asci** *23–28(–32) × 3.4–3.6 µm {1}, †20–27 × (2.5–)2.9–3.2 µm {2}, 8-spored, spores *~4-seriate, ~4 lower spores inverted {1}, pars sporifera *9–15 µm long; **apex** (†) slightly to medium truncate (not indented, laterally not inflated); **base** with short to long, ± thick, flexuous stalk, L-, h- to Y-shaped. **Ascospores** *(6–)7–8(–8.5) × 0.75–0.9(–1) µm {4} (~9–10 µm actual length), †7.5–9 × 0.7–0.8 µm {3}, narrowly fusiform, apex ± acute, base gradually attenuated, with a thin tail of 1.7–3 × 0.15–0.4 µm, strongly curved (helicoid, twisted like a right-hand thread); **SBs** *1.8–2(–2.2) × 0.3–0.4(–0.5) µm {1}, subulate, apically narrowed to a small point, straight. **Paraphyses** apically uninflated to mostly slightly clavate-capitate, terminal cell *(8–)12–19 × 2–3.2 µm {1}, lower cells *2.5–5 × 1.7–3 µm {1}; branched only in lower part. **Medullary excipulum** hyaline, 10–15 µm thick, of dense textura intricata-angularis, indistinctly delimited from ectal excipulum. **Ectal excipulum** hyaline, of (†) thin-walled textura globulosa-angularis from base to mid flanks, 30–?80 µm thick near base, cells *13–22 × 11–17 µm {1}; 10–13 µm thick near margin, of t. angularis, marginal cortical cells *4.5–8 × 4–6 µm {1}, at uppermost margin of narrow cortical cells *5–8 × 2–3 µm oriented at a 10–20° angle to the surface; **glassy processes** absent or sometimes present, 1.5–2.5 × 2.8–3 µm {1}, high-refractive, somewhat stratified. **Anchoring hyphae** sparse, †2–2.7 µm wide, walls 0.2 µm thick {1}. **SCBs** in paraphyses globose, 1.7–2.6 µm diam., medium refractive, together with filiform to rhomboid or ring-shaped, hyaline crystalloid SCBs {1}; **VBs** absent. **Exudate** over paraphyses 0.2–0.5 µm thick, continuous, with scattered granules, loosely attached, over margin and flanks 0.3–1(–1.5) µm thick, ± cloddy. — **ANAMORPH**: dactylella-like (from ascospore isolate {3}). **Conidiophores** ± unbranched, septate, erect, *41–50 µm long, 3–4.3 µm wide at the

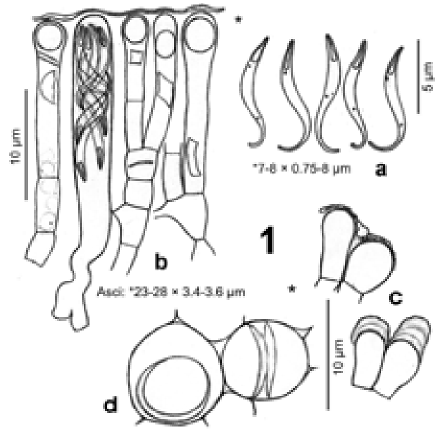

Plate 461. **1**: *Orbilia laevimarginata*. – **a**. ascospores; **b**. ascus and paraphyses (containing globose and crystalloid SCBs); **c**. marginal cortical cells partly tipped by glassy process; **d**. ectal excipular cells containing crystalloid SCBs.

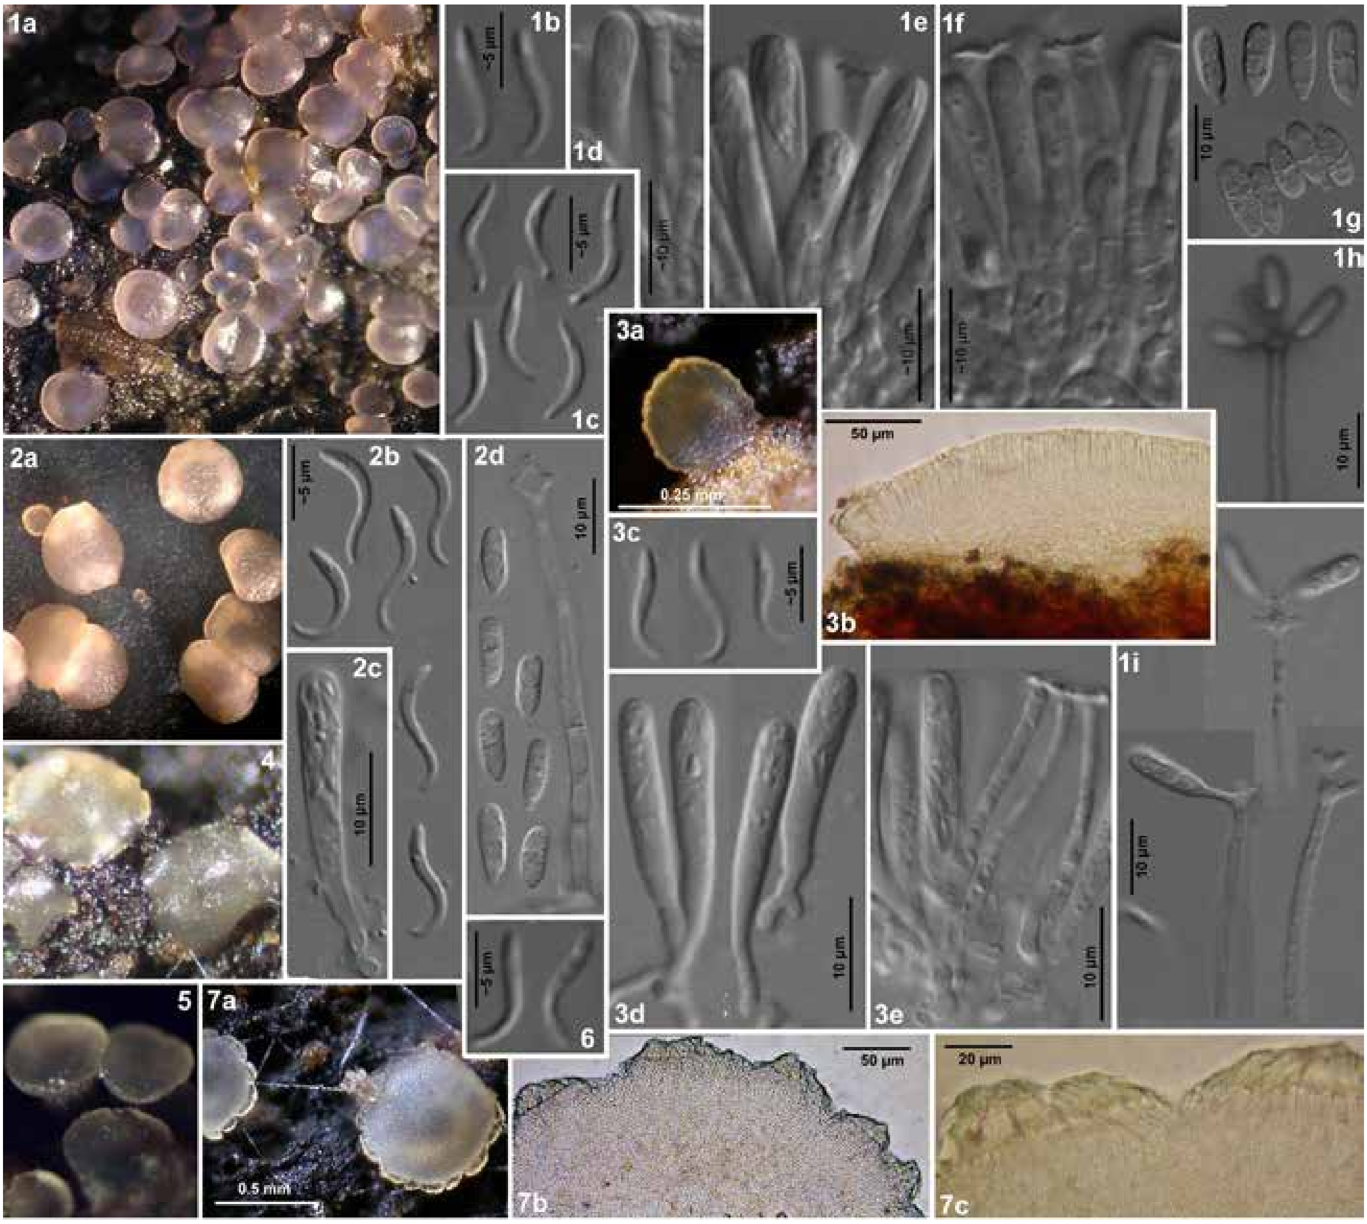

Plate 462. **1–6**: *Orbilia laevimarginata*; **7**: *O.* cf. *laevimarginata*. – **1a**, **2a**, **4**, **5**. fresh apothecia (**2a** on agar); **3a**, **7a**. rehydrated apothecia; **3b**. apothecium in median section; **7b–c**. dentate margin in top view; **1d–f**, **2c**, **3d–e**. asci and paraphyses; **1b–c**, **2b**, **3c**, **6**. ascospores (**1b** & **3c** from substrate, **1c** & **2b–c** from culture); **1g**, **2d**. conidia from culture; **1h–i**, **2d**. conidiophores from culture. – All ascospores and conidia and 2 asci (**1e**, **2c**) in living state. – **1**, **2**, **3c–e**: phot. Y. Zhang (DIC, p.p. from Zhang et al. 2015), **4**, **5**: phot. Z.F. Yu, **6**: from Liu et al. (2007a, DIC). — **1a–i**. YMFT 1.01833: China, Yunnan, Kunming, on *Quercus*; **2a–d**. YMFT 1.03013: ibid., Yuxi, on *Quercus*; **3a–e**. H.B. 7667 (holotype): ibid., Kunming, on *Quercus*; **4**. ?Z.F.Y. xz-1: ibid., Chuxiong, on indet. woody substrate; **5**. H.B. 8978b: China, Yunnan, Dali, on ?*Fagus*; **6**. HMAS 139521: China, Xishuangbanna, on indet. wood; **7a–c**. H.B. 8693: J.W.G. lq2–68: China, Yunnan, Yuxi, on indet. angiosperm.

base, tapering gradually to *1.3–1.6 µm at the tip, here expanded and bearing 1–10 denticles of 2–5 × 1.3–1.6 µm, conidia in capitate clusters (candelabrelloid), occasionally proliferating to form additional clusters. **Conidia** *(7.5–)8.5–12(–13) × 2.8–3.8 µm {3}, (0–)1(–3)-septate, cylindric-ellipsoid with conical to apiculate base, containing several small LBs. **Chlamydospores** absent. **Trapping organs** not observed when nematodes were added.

Habitat: on moist ground, corticated to decorticated, 4–5 cm thick branches of *Quercus* sp. {4}, ?*Fagus* sp. {1}, indet. woody substrate {2}, on entirely strongly decayed wood {4} and bark {2} (periderm and bast), without algae. **Associated**: *Helicogonium hyphodisci* (parasitic in *O. laevimarginata*) {1}. **Desiccation tolerance**: not tested (probably intolerant). **Altitude**: 1000–2700 m a.s.l. **Geology**: Proterozoic, Paleozoic & Jurassic to Cretaceous sedimentary rock; mafic volcanic & metamorphic rock. **Phenology**: VII–XI.

Taxonomic remarks. This taxon is only known from a few records from broad-leaved evergreen forests in Yunnan, southern China. It deviates from *O. crenatomarginata* in a typically ± smooth apothecial margin and a deviating anamorph. Glassy processes were either absent or very short and only occasionally seen. The marginal cortical cells are shorter and wider, also the ascospores tend to be more fusiform by having ± acute apices in comparison to *O. crenatomarginata*. *O. vermiformis* (series *Xanthoguttulatae*) differs in larger spores and conidia, and apparently also in the absence of crystalloid SCBs.

In the collection from Xishuangbanna (HMAS 139521) reported by Liu (2006: 67) and Liu et al. (2007a), the spore apices are less acute, and the marginal cortical cells more elongate (~ 11 × 4–5 µm) by forming a distinct textura porrecta. This texture is reminiscent of *O. crenatomarginata*, though it seemed to lack distinct glassy processes, judging from the photo. However, Liu (l.c.) mentioned glassy processes of 9.5–16 × 2.5–3 µm in his description, and a microphoto that was not included in his thesis shows prominent broad teeth 25–30 × 60–80 µm, 12–14 per apothecium (B. Liu pers. comm.).

Not included collections. Spores and marginal cortical cells similar to the latter specimen were noted in two Chinese records examined by us (H.B. 8693, Pl. 462: 7; H.B. 8744), which possess glassy processes of ~10–20 µm length forming distinct marginal teeth. An anamorph was not observed in these samples with glassy processes and DNA data were not gained, therefore, they are not included in the above description.

A collection on inner surface of *Quercus* bark from Boston, Massachusetts (IVV: bhi-F121b) was only studied in the dead state. It has apothecia with very distinct marginal teeth of 15–30 × 20–80 µm and spores that fit well *O. laevimarginata* or *O. crenatomarginata*. However, its DNA data suggest a species intermediate between both (see below). A not examined, unillustrated collection on *Quercus* bark from Ithaca, New York, identified as *Orbilia crystallina* by Spooner (1987: 188), might belong here. Also the two Canadian collections on *Acer* and *Populus* here included in *O. crenatomarginata* would require molecular investigation.

Anamorph. An anamorph was obtained in pure culture of three samples (no culture was obtained in qlx-1, and B. Liu's culture did not sporulate). In sharp contrast to the presumed anamorph of *O. crenatomarginata*, the conidia are much smaller and possess only 0–3 septa, emerging from 1–10 prominent denticles clustered at the tip of conidiophores (Pl. 462: 1g–i, 2d, Zhang et al. 2015), somewhat similar as in drechslerella-like anamorphs. However, no trapping devices were formed in contact to nematodes.

Phylogeny. Sequences were available for four Chinese samples and one from North America, comprising ITS, four also the S1506 intron (the one from Xishuangbanna did not cover the intron region). In our phylogenetic analyses of the ITS region, *O. laevimarginata* clustered in a weakly supported clade sister to the European *O. crenatomarginata* (Phyls 16, S15, see also Zhang et al. 2015). Rather high distances occur among the four Chinese sequences: the two samples from Dalongkou (ym-87 and ym3-52) differ by a 1.5 % ITS distance from each other (2 % in the intron), the sample from Xishuangbanna (HMAS 139521) deviates from those by 5–6 % in the ITS, and that from Kunming (ya-17) by 7–8 % (3.5–4 % in the intron). The latter two differ from each other by 6.5 % in the ITS. The distance of European samples of *O. crenatomarginata* to all these Chinese strains ranges at 8.5–12 % in the ITS (18–19 % in the intron).

The sample from Massachusetts (bhi-F121b) comprises SSU V2–V5, S1506 intron, and ITS (ITS2 incomplete). It clustered in the ITS region among the variable sequences of *O. laevimarginata* with a 4–6.5 % distance (8.5 % to *O. crenatomarginata*), whereas the S1506 intron suggests a slightly closer relationship to *O. crenatomarginata* (12.5 %, 14.5–15.5 % to *O. laevimarginata*). This high distance in the intron, compared to only 2–4 % among the three *O. laevimarginata* strains, suggests that the North American strain belongs to a different species. Further collections and sequences are needed, in particular from North America and from eastern Asian records in which the apothecia possess distinct marginal teeth.

Ecology. *O. laevimarginata* was found on rotten wood and bark of hygric angiosperm branches in southern China. Collections are predominantly from subtropical humid (winter-dry) broad-leaved evergreen forests, those from Kunming and Yuxi being mainly composed of *Quercus* trees and that from Dali of *Castanopsis* etc. The collection from Xishuangbanna was made in a tropical rainforest. The not included American samples are from cold-temperate humid mixed oak forests on granite and Devonian sediment.

Map 82. Known distribution of *O. laevimarginata* in southeastern Asia.

Specimens included. **CHINA**: **Yunnan**, **Kunming**, 18 km NW of Anning, 6 km NE of Qinglongzhen, Qinglongxia (Yu'an Shan), 1900 m, branch of *Quercus*, on bark & wood, 3.XI.2004, Z.F. Yu (ex Z.F.Y. qlx-1, ex H.B. 7667, M-0276498, **holotype**). – 9 km WNW of Kunming, Bamboo temple (Qiongzhushi, Yu'an Shan), 2150 m, on wood of *Quercus*, VII.2005, Y. Zhang (Y.Z. ya-17, YMFT 1.01833, anam. cult.; sq.: DQ512890). – **Yuxi**, Yimen, 54 km NW of Yuxi, ?3 km NW of Fangtunxiang, Dalongkou, Longquan, ?1750 m, on wood of *Quercus*, VIII.2006, Z.F. Yu & S.F. Li (Z.F.Y. ym-87, YMFT 1.01869, anam. cult.; sq.: GQ351279). – ibid., VIII.2007 (Z.F.Y. ym3-52, YMFT 1.03013, anam. cult.; sq.: KM252677). – **Dali**, 42 km NNE of Dali, Jizushan Nature Reserve, 2700 m, branch of ?*Fagus*, on bark, 20.X.2008, X.M. Gao et al. (Z.F.Y. jz-8, YMFT, H.B. 8978b). – **Chuxiong**, 12.5 km WSW of Chuxiong, S of Jiguang temple, Zixishan, 2155 m, on indet. woody substrate, X.2004, ?Z.F. Yu (?Z.F.Y. xz-1, YMFT ø). – **Xishuangbanna**, around Jinghong, 1000 m, unidentified wood, 9.XI.2002, B. Liu et al. (B.L. 6220, HMAS 139521 incl. culture, doc. vid.; sq.: DQ656627).

Not included (with prominent marginal teeth): **CHINA**: **Yunnan**, **Yuxi**, Yimen, 54 km NW of Yuxi, 3 km NW of Fangtunxiang, Dalongkou, Longquan, 1750 m, branch of indet. angiosperm, on bark, VI.2007, S.F. Li & J.W. Guo (J.W.G. lq2–54, YMFT, H.B. 8744). – ibid., on indet. wood (J.W.G. lq2-68, YMFT, H.B. 8693). — **USA**: **Massachusetts**, 19 km SE of Boston, ~2.5 km NNE of Hingham, World's End peninsula, ~5 m, log of *Quercus*, on bark, 29.IX.2013, D. Haelewaters (bhi-F121b, H.B. 10168; sq.: MN339157, MN339159). – **New York**, 19 km NE of Ithaca, 2 km SW of McLean, Fall Creek, 330 m, *Quercus* bark, 15.V.1894, G.F. Atkinson, vid. B. Spooner (Disc. Exsicc. 22, non vid.).

Orbilia scolecospora (G.W. Beaton) Baral, in Liu et al., Fungal Diversity 22: 117 (2006) — Pls 463–464

≡ *Hyalinia scolecospora* G.W. Beaton, in Beaton & Weste, Trans. Br. Mycol. Soc. 70: 77, fig. 1 (1978) [non *Calloria scolicospora* Rehm 1878, nom. inval.]

Etymology: named after the worm-shaped (scoleciform) ascospores.

Typification: Australia, Victoria, Portland, bark of *Eucalyptus*, 3.V.1964, G. Beaton (Beaton 186, MEL, holotype).

Description: — **TELEOMORPH**: **Apothecia** fresh/rehydrated (0.3–)0.5–1(–1.4) mm diam., 0.1–0.2(–0.3) mm high (receptacle 0.11–0.12 → 0.06–0.08 mm), whitish or cream-dull, to pale yellow-ochre, ± translucent, round, scattered to gregarious; disc slightly concave to flat, margin dentate, with ~7–16 distinct triangular teeth of 30–55 × 80–140 µm with obtuse or blunt ends, teeth protruding ~15–50 µm beyond disc; sessile on a ± narrowed base or obconical stipe (0–60 × 100–250 µm), superficial. **Asci** *28–30 {Yunnan} or 40–56 {Tenerife} × 3.3–4.5 µm {2}, †(24–)27–40(–53) × (2.7–)3–4 µm {4}, 8-spored, pars sporifera *10.5–12.5 µm long (†14–21 µm), spores †2–4-seriate, spirally twisted, ~4 lower spores inverted {3}; **apex** (†) medium truncate (not indented, laterally not inflated); **base** with short to long, ± thin, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(7–)8–9(–10.5)((–11)) × 0.9–1.2(–1.3) µm {3} (~8–12 µm actual length), †6.5–10 × 0.8–1 µm {3}, narrowly fusoid-clavate, apex obtuse to acute, base strongly attenuated, tail-like or with a distinct tail 0.2–0.6 µm thick, rather strongly curved (helicoid, in profile view S- or sickle-shaped), especially in lower part; **SBs** 2.2–3.7 × (0.2–)0.3–0.5(–0.7) µm {4}, subulate to narrowly tear-

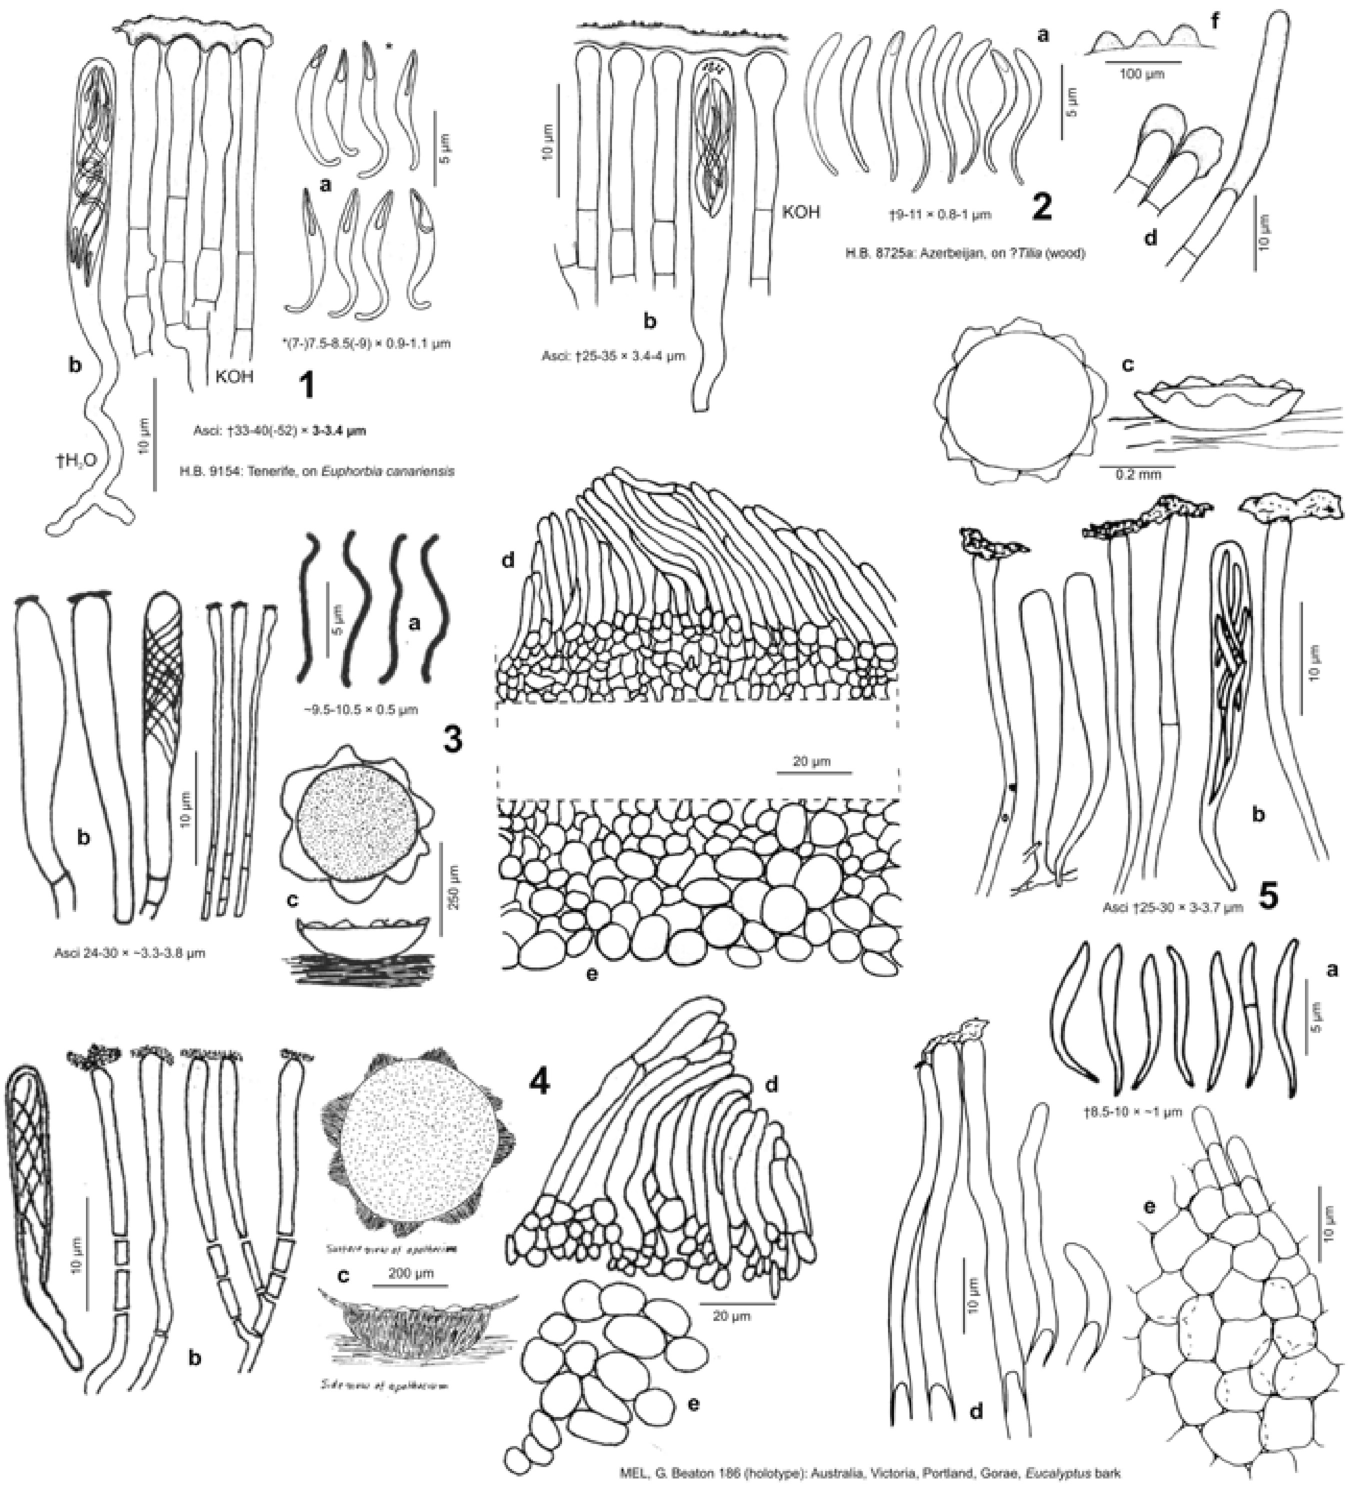

Plate 463. **1**, **3–5**: *Orbilia scolecospora*; **2**: *O.* cf. *scolecospora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. apothecia with dentate margin; **d**. marginal cortical cells with long glassy processes; **e**. excipular cells at flanks; **f**. marginal teeth. — **3–5** from type material: **3**. after Beaton & Weste (1978: 78); **4**. original drawing on herbarium label; **5**. after Spooner (1987: 188).

shaped, apically narrowed to a small point, sometimes slightly flexuous. **Paraphyses** apically uninflated or slightly to medium clavate-capitate, terminal cell †13–21(–24) × (1.7–)2–3.3(–4) µm {3}, lower cells †(2.5–)4–7(–12) × (1.2–)1.5–2.5(–3) µm {2}; never branched at upper septum. **Medullary excipulum** 45–75(–125) µm thick, upper part of small-celled dense textura intricata-angularis, lower part of larger-celled t. globulosa-angularis, indistinctly delimited from ectal excipulum. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, irregularly oriented t. globulosa-prismatica from base to mid flanks, 30–120 µm thick near base, cells *(9–)11–20(–22.5) × (7–)8–14(–16) µm {1}; 20–40 µm thick at flanks, 12–15 µm at margin, inner part of t. angularis oriented at 70–80°, outer part of t. porrecta at 10–20°, marginal cortical cells †9–11 × 2.2–2.8 µm {1}; **glassy processes** 8–55 or 100–200 × (2–)2.5–3.5(–4) µm {2}, refractive, not distinctly stratified, coherent to form distinct, often upwards curved teeth. **Anchoring hyphae** sparse to medium abundant, †1.5–3(–3.5) µm wide, wall 0.2 µm thick. **SCBs** in paraphyses globose to elongate, also crystalloid: filiform to C-shaped, in ectal excipulum ring- to lasso-shaped, 2–5.5 × 2–4 µm {2}. **Exudate** over paraphyses 1–2 µm thick, cloddy-continuous, hyaline to pale yellow, loosely to firmly attached. **— ANAMORPH**: unknown.

Habitat: on the ground, usually on branches and logs of *Eucalyptus* sp. {T}, *Euphorbia canariensis* {6}, *Quercus* sp. {1}, indet. angiosperm {1}, on medium to strongly decayed, fallen bark (detached, inner surface)

{T} or on decorticated wood {5}. **Associated**: *Orbilia crenatonemaspora* {1}. **Desiccation tolerance**: some excipular cells and many spores viable after 3 months. **Altitude**: 120–350 m a.s.l. (Macaronesia), ~80 m (Australia), 1750–3100 m (China). **Geology**: mafic volcanic basaltic & trachybasaltic flow, metamorphic rock. **Phenology**: II, VI–VII, XII (N-hemisphere, perhaps throughout the year).

Taxonomic remarks. *Orbilia scolecospora* is very similar to *O. crenatomarginata*, as already noted by Spooner (1987: 188, the latter as *Hyalinia crystallina*). It differs in slightly longer and distinctly wider ascospores with much longer SBs, also in a more (sub)tropical distribution. *O. vermiformis* (series *Xanthoguttulatae*) differs from *O. scolecospora* in wider marginal cortical cells without glassy processes, and in longer asci and spores. A collection from subtropical China mentioned under *O. pseudobrevistipitata* (series *Xanthoguttulatae*; Pl. 453: 2; 454: 2) differs in narrower spores and in the upper spores being inversely oriented.

Variation. The here figured collections from Macaronesia (Tenerife, on *Euphorbia* wood, treated in detail in Quijada et al. 2016) and China (Tibet, on *Quercus* wood, Liu 2006; Yunnan, on indet. angiosperm wood, Z.F. Yu pers. comm.) included in *O. scolecospora* correspond rather well to the characteristics of the Australian type specimen (on *Eucalyptus* bark) as redescribed by Spooner. Beaton & Weste (1978) and Spooner gave the number of teeth in the type as up to 9, and also Liu et al. (2006b: 108) reported 9 teeth in his Tibetan sample, whereas those from Tenerife have around 9–16 teeth. In the latter, however, the teeth are often confluent to form fewer and larger teeth (see Quijada et al. 2016, fig. 6: 1a–e), for which reason the authors gave only a number of 5–8(–10). The apothecia vary in colour from whitish (Tibet, Tenerife) to yellowish-ochraceous (Australia, Tenerife). In the type the apothecia were smaller (~0.3–0.5 mm diam. fide Beaton & Weste; 0.25–0.45 mm fide Spooner, probably rehydrated) than in the other specimens (mostly 0.5–1 mm). Macaronesian specimens have distinctly longer asci (†33–53 × 2.7–3.5 µm), whereas the Chinese specimens are with †24.5–33 × 3–4 µm in the range of the type and also the two not included samples.

Spore length in the specimens from Tenerife was intermediate between the sample from Yunnan (*6.7–7.6 × 1.1–1.3 µm, Pl. 464: 2d) and that from Tibet (*7.8–10.4 × 1–1.3 µm, Pl. 464: 3b). SB size concurs between those from Tenerife and Yunnan, while the rather short and wide SBs in the Tibet sample (1–1.8 × 0.4–0.6 µm) might refer to overmature spores. In spore shape the Macaronesian specimen has more distinct and narrow tails.

Type studies. The holotype of *O. scolecospora* could not be studied because it was lost during delivery to Europe. N. Middleton (pers. comm.) kindly forwarded a scan of the herbarium label which bears a handwritten description and drawing, also the collection data. These documents deviate from the protologue in several points (Pl. 463: 3–4), and Spooner's (1987: 188) redescription of the holotype again differs hereof. Beaton & Weste (1978) described the spores as 15 × 0.5 µm, narrowly filiform, flexuous (Fig. 3a), and stated that they could not find any free spores. Obviously they measured the actual length, because on their published drawing the spores in situ are only ~9.5–10.5 µm long. The very narrow spore width is in conflict with Spooner's observation of a few free spores which were narrowly clavate-fusoid, often somewhat sigmoid and spirally arranged, sometimes apparently with a median septum (Fig. 5a). We assume that Beaton & Weste's spore description is inexact.

Beaton & Weste (l.c.) and Spooner (l.c.) gave the ascus size as 24–30 × 2.5–3 µm (on the label 20–27.5 × 2–2.5 µm) and 25–30 × 2.5–3(–3.5) µm, but the asci in their drawings are about 3.3–3.8 and 3–3.7 µm wide, respectively. Also the tips of paraphyses were drawn by Beaton & Weste much too narrow (Pl. 463: 3b, evaluated as 0.9–1.2 µm). On the herbarium label paraphysis width is correctly stated as 1.5–2 µm, which fits Spooner's drawing (evaluated as 1.7–2.2 µm).

Not included collections. Two specimens that were only studied in the dead state are not included in the description of *O. scolecospora*. The sparse collection from Caucasus on *Tilia* bark (Pl. 463: 2) differs in slightly longer spores (†9–11 × 0.8–1 µm), apothecia with ± convex, light yellow disc and smaller, especially narrower teeth (20–30 × 40 µm), and a temperate occurrence. The few apothecia in this sample should have possessed around 50–100 teeth according to their large size of 0.8–1.5 mm diam., but were already somewhat distorted when received. This might instead belong in the scope of *O. crenatonemaspora* (series *Xanthoguttulatae*).

A collection from Argentina on bark of *Eucalyptus* (see Fig. 164) could belong in the same relationship. It was reported by Romero (1987, 1994) under the name *Hyalinia scolecospora*, but deviates from the present concept of the species in yellow apothecia and narrowly filiform spores of †10–15 × 0.5 µm (actual length, in situ only ~9 × 0.5 µm as evaluated from drawing). The spores well correspond to the protologue of *H. scolecospora* Pl. 463: 3a, but not to the much wider, heteropolar spores in Spooner's redescription of the holotype (Pl. 463: 5a). The asci measured 25–35 × 3–5 µm (~25 × 3 µm on the drawing), and the spores are intertwined in the asci by forming one bundle (pars sporifera ~9–10 µm long). 14–16 teeth were drawn in the provided illustration. A recent reexamination of Romero's sample by L. Quijada (pers. comm.) confirmed her description of free spores but did not clearly show spores from inside the asci. Also the number of marginal teeth is confirmed, but only when counting confluent aggregates of small teeth as one.

Phylogeny. Sequences gained from apothecia of five samples of *O. scolecospora* were available: four from Tenerife (ITS, once also SSU and LSU) and one from Tibet (ITS+LSU). The four from Tenerife are completely identical except for 1 nt in the ITS1 of TFC Mic. 24450 (L. Quijada pers. comm., not shown in Phyl. 16), while a very high distance of 17.4–17.6 % is observed in the entire ITS region between the Tibetan strain and those from Tenerife. Also in the LSU the distance between the Tibet and Tenerife sample is high (3.5 %, 409 nt), therefore, two different species must be involved. The S1506 intron is absent in the four Macaronesian strains, while the Tibetan strain is incomplete at the 5'-end of ITS1. To *O. crenatomarginata* and *O. laevimarginata* the distance of *O. scolecospora* s.l. lies in the range of 17–22 % in the ITS, and to *O. crenatomarginata* 6–7 % in the LSU.

The two *O. scolecospora* taxa do not even form a clade in our analyses of ITS+LSU, ITS, or LSU (Phyls 13, 16, S15, S16). Whether or not the Australian type of *O. scolecospora* is conspecific with one of these specimens cannot be clarified at present. We assume that the Macaronesian samples belong to a different, undescribed, highly host-specific species. Further molecular data, particularly from other geographical regions, are needed, also from re-collections at the type locality in Australia. The Macaronesian genotype is planned to be described as a new species in a separate paper (Quijada et al. ined.).

Ecology. *O. scolecospora* differs from the desiccation-sensitive *O. crenatomarginata* in a slight drought tolerance of its apothecia, based on observations from the Macaronesian samples. The collective species is at present known from fallen, hygric bark of *Eucalyptus* and wood of *Quercus*, and from mesic branches of *Euphorbia canariensis*. The southeastern Australian collection was from a warm-temperate humid eucalypt open forest in the Victorian Volcanic Plain ecoregion, and the Asian ones from an orotemperate altimontane) humid (winter-dry), continental floodplain forest in eastern Himalaya and from a subtropical humid (winter-dry) mountain forest in Yunnan. Collections from Tenerife (Macaronesia) were in inframediterranean semihumid to mainly lower semiarid to arid xerophytic cardonal scrublands (*Periploco laevigatae-Euphorbietum canariensis*). Here the apothecia developed on *Euphorbia* branches with contact to the soil, mainly on the shaded lower side and only after long periods of rain, though later falling dry for some time. The not included samples are from warm-temperate humid Caucasus and subtropical humid South America.

Specimens included. **MACARONESIA**: **Canary Islands**, **Tenerife**, Buenavista del Norte, 5.2 km WSW of Buenavista del Norte, 3 km NW of Teno Alto, Punta de Teno, 122 m, on branches of *Euphorbia canariensis*, on wood, 16.VI.2009, L. Quijada, C. Quijada & E.V. Rodríguez (TFC Mic. 22307, H.B. 9154; sq.: KM248770; TFC Mic. 22289, 22290, 22297, 22305, non vid.). – ibid., 28.II.2010, L. Quijada, R. Castro & E.V. Rodríguez (TFC Mic. 22872, 22873, non vid.). – ibid., El Draguillo, 130 m, on *E. canariensis*, 5.VI.2009, L. Quijada, C. Quijada & E.V. Rodríguez (TFC Mic. 22235, non vid.). – La Laguna, Anaga, 6 km NE of Tegueste, 1.2 km NW of Chinamada, Andén de la Cruz, 340 m, on *E. canariensis*, 29.XII.2013, L. Quijada & E.V. Rodríguez (TFC Mic. 24450, doc. vid., sq.: UDB0777920). – Fasnia, 7.5 km SSW of Güímar, 1.5 km NE of Fasnia, La Morra los Cardones, 346 m, on *E. canariensis*, 18.XII.2013, L. & C. Quijada (TFC Mic. 24423, doc. vid., sq.: UDB0777921). – ibid. (TFC Mic. 24479, sq.: UDB0777922). — **AUSTRALIA**: **Victoria**, Victorian Volcanic Plain, 12 km NW of Portland, Gorae, State Forest Road, near stream, ~80 m, ?log of *Eucalyptus*, on bark, 3.V.1964, G. Beaton (Beaton 186, MEL, **holotype**, doc. vid., specimen lost). — **CHINA**: **Tibet**, **Nyingchi** (Linzhi), 36 km ESE of Bomê (Bomi), 1.3 km ENE of Songzong, 3100 m, on wood of *Quercus*, 16.VII.2004, B. Liu & X.Z. Liu (HMAS 132094, doc. vid.; sq.: DQ656628, DQ656687). – **Yunnan**, **Yuxi**, Yimen, 54 km NW of Yuxi, 3 km NW of Fangtunxiang, Dalongkou, 1750 m, branch of indet. angiosperm, on wood, VII.2007, S.F. Li & J.W. Guo (J.W.G. ym3-7, YMFT, H.B. 8694b ø, doc. vid.).

Not included. **AZERBAIJAN**: **Shaki-Zaqatala**, Caucasus Mts., ?4 km NE of Zakatala, 'Kordon', 800 m, log of *Tilia*, on wood, 9.VIII.1974, B. Kullman (TAAM 68123, as *Orbilia* sp., H.B. 8725a ø). — **ARGENTINA**: **Buenos Aires**, 21.5 km WNW of San Pedro, 7.5 km N of Gobernador Castro (Rio Paraná), 200 m, on bark of *Eucalyptus viminalis*, XI.1982, A.I. Romero et al. (BAFC 30457, doc. vid.).

Orbilia crenatofalcata Baral & S. Tello, **sp. nov.**, MB 813765 — Pl. 465

Etymology: named after the crenulate margin and falcate ascospores.
Typification: Spain, Andalucía, Cazorla, log of *Populus nigra*, 19.X.2013, S. Tello (JA-CUSSTA 7771, holotype; sq.: KM248769).

Latin diagnosis: Similis Orbiliae crenatomarginatae *sed ascosporis falcatis, dentibus marginalibus apotheciorum minoribus differt. Habitat ad lignum putridum ramorum uvidorum* Populi nigrae *in zona suprasub ad supramediterranea Europae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.27–)0.33–0.6(–0.7) mm diam., in total 0.11–0.16 mm high (receptacle 0.09–0.11 → 0.05–0.07 mm), watery greyish-white to pale cream, strongly translucent, round, subgregarious; disc flat or slightly convex, margin denticulate to dentate, with ca. 30–40 small {T} or 10–20 large teeth {1}; sessile or with a low and broad stipe up to 0.06 × 0.2 mm, superficial; dry pale yellowish-cream or slightly rosaceous. **Asci** *30–33 × 3.2–3.4(–3.7) µm {T}, †25–35 × 2.8–3.3 µm {2}, 8-spored, spores 4–8-seriate, slightly spirally twisted within the living asci, pars sporifera *10–12 µm, †17–18 µm, ~4 lower spores inversely oriented (never mixed); **apex** (†) slightly to strongly truncate (never indented or inflated); **base** with very short to medium long, thick or thin, flexuous stalk, L-, T- or h-shaped. **Ascospores** *8–9.5(–9.8) × 0.8–0.9(–1) µm {T} (~8.5–10 µm actual length), †7.5–10 × 0.6–0.8 µm {2}, very narrowly fusoid, widest part closer to apex, apex subacute, base gradually attenuated, never tail-like; (*/†) slightly to medium curved (falcate, sometimes very slightly helicoid); **SBs** 2–3 × 0.4–0.5 µm, subulate. **Paraphyses** apically cylindrical or very slightly (rarely medium) capitate, terminal cell *11.5–15.5 × 2–2.5 µm, †1.5–2 µm wide, lower cells *3.5–4 × 1.6–2.1 µm, unbranched at upper septum. **Medullary excipulum** ~40–60 µm thick in centre, of dense textura globulosa-angularis, not sharply delimited from ectal excipulum. **Ectal excipulum** of thin-walled t. globulosa-angularis from base to margin, 60–90 µm thick at base, cells *12–17 × 9–16 µm, †10–15 × 9–13 µm, 20–40 µm thick at lower flanks, externally covered by a single layer of hyphoid elements, 20 µm thick at mid flanks and margin, oriented at a high angle, marginal cortical cells †8–12 × 3–7 µm, curved upwards at tip; **glassy processes** 5–10 {T} or 20–40 {1} × 2–4 µm {2}, low- to high-refractive, stratified, conglutinate to form indistinct or distinct teeth. **Anchoring hyphae** sparse, †1.5–3 µm wide, walls 0.2 µm thick. **SCBs** globose, highly refractive, in terminal cells of paraphyses 1 per cell (sometimes cylindrical), in lower part of ectal excipulum 1 or more per cell, 1.2–2.3 µm diam., in apices of marginal cortical cells 1.8–3 µm diam.; crystalloid SCBs in both terminal and lower cells of paraphyses and in ectal excipulum from base to margin {2}, medium to strongly refractive, in paraphyses rhomboid to rod-shaped, in excipulum ring- to C-shaped, 4–7 µm diam., also plate-shaped; **VBs** absent. **Exudate** over paraphyses continuous to cloddy, hyaline or pale yellowish, 0.5–1.8 µm thick, externally rough to granular, loosely attached; over margin and flanks finely granular, ~0.5 µm thick. — **ANAMORPH**: unknown.

Habitat: underside of 15–20 cm thick, decorticated logs of *Populus nigra* {2} lying on moist ground, on very decayed wood {2}. **Associated**: none observed. **Desiccation tolerance**: dead in all parts when examined after 3 weeks. **Altitude**: 490–810 m a.s.l. **Geology**: Jurassic dolomite, Tertiary limestone, marl, clay, sandstone. **Phenology**: VIII, X.

Taxonomic remarks. *Orbilia crenatofalcata* strongly concurs with *O. crenatomarginata* in most features. It differs in consistently falcate ascospores which are only very slightly helicoid and always lack a tail-like base, and contain longer SBs. Macroscopically, the smaller, more numerous marginal teeth might be diagnostic, but in the second collection they were larger and fewer. A similar deviation in ascospore curvature is noted in the possibly heterogeneous Asian *O. crenatonemaspora* (series *Xanthoguttulatae*) which has typically helicoid spores but in some specimens falcate spores very similar to *O. crenatofalcata* though distinctly longer.

Variation. In the specimen from Navarra the apothecia have distinctly longer glassy processes (20–40 vs. 5–10 µm), resulting in larger marginal teeth of only about half the number per apothecium.

Phylogeny. Sequences were taken from apothecia of the holotype from Andalucía and the paratype from Navarra, comprising ITS and in the Navarra strain also LSU (the S1506 intron is absent in both). In the ITS region the two strains are completely identical. *O. crenatofalcata* clustered in the strongly supported *Hyalinia* clade (Phyls 13, S15–S16), though with a high ITS distance of 16–18% to *O. laevimarginata*, *O. crenatomarginata*, and *O. scolecospora*. Also in the LSU the distance to *O. crenatomarginata* and *O. scolecospora* is rather high (5.5–6.5%). 6 deviations in the LSU are unique within section *Aurantiorubrae*: pos. 127 **A** vs. **G** or exceptionally **T**, pos. 178 C**A**GT vs. **G** (**A** only *O. tianmushanensis* of section *Helicoon*), pos. 259 **A**TCGA vs. **T**, pos. 296 AA**C**GG vs. **T**, pos. 317 AA**G**GC vs. **A**, pos. 327 **G**GGC vs. **T** (verified from chromatogram).

Ecology. *O. crenatofalcata* was twice collected on rotten wood of *Populus nigra* in a suprasubmediterranean humid riparian forest with *Populus*, *Salix*, *Alnus*, *Acer*, *Cornus* etc. in the western Pyrenees (Navarra), and in a supramediterranean semihumid forest with *Populus* and *Pinus halepensis* in a valley between Sierra de Cazorla and Sierra de Segura (Andalucía).

Specimens included. **SPAIN**: **Navarra**, western Pyrenees, 12 km NE of Pamplona, W of Akerreta, 490 m, log of *Populus nigra*, on wood, 13.VIII.2014, F.J. Balda (H.B. 9926; sq.: KT222398). – **Andalucía**, **Jaén**, Sierra de Cazorla, 17.5 km NE of Quesada, 8.5 km NE of Cazorla, N of Arroyo frío, 810 m, log of *Populus nigra*, on wood, 19.X.2013, S. Tello (JA-CUSSTA 7771, **holotype**; H.B. 9852, **isotype**; sq.: KM248769).

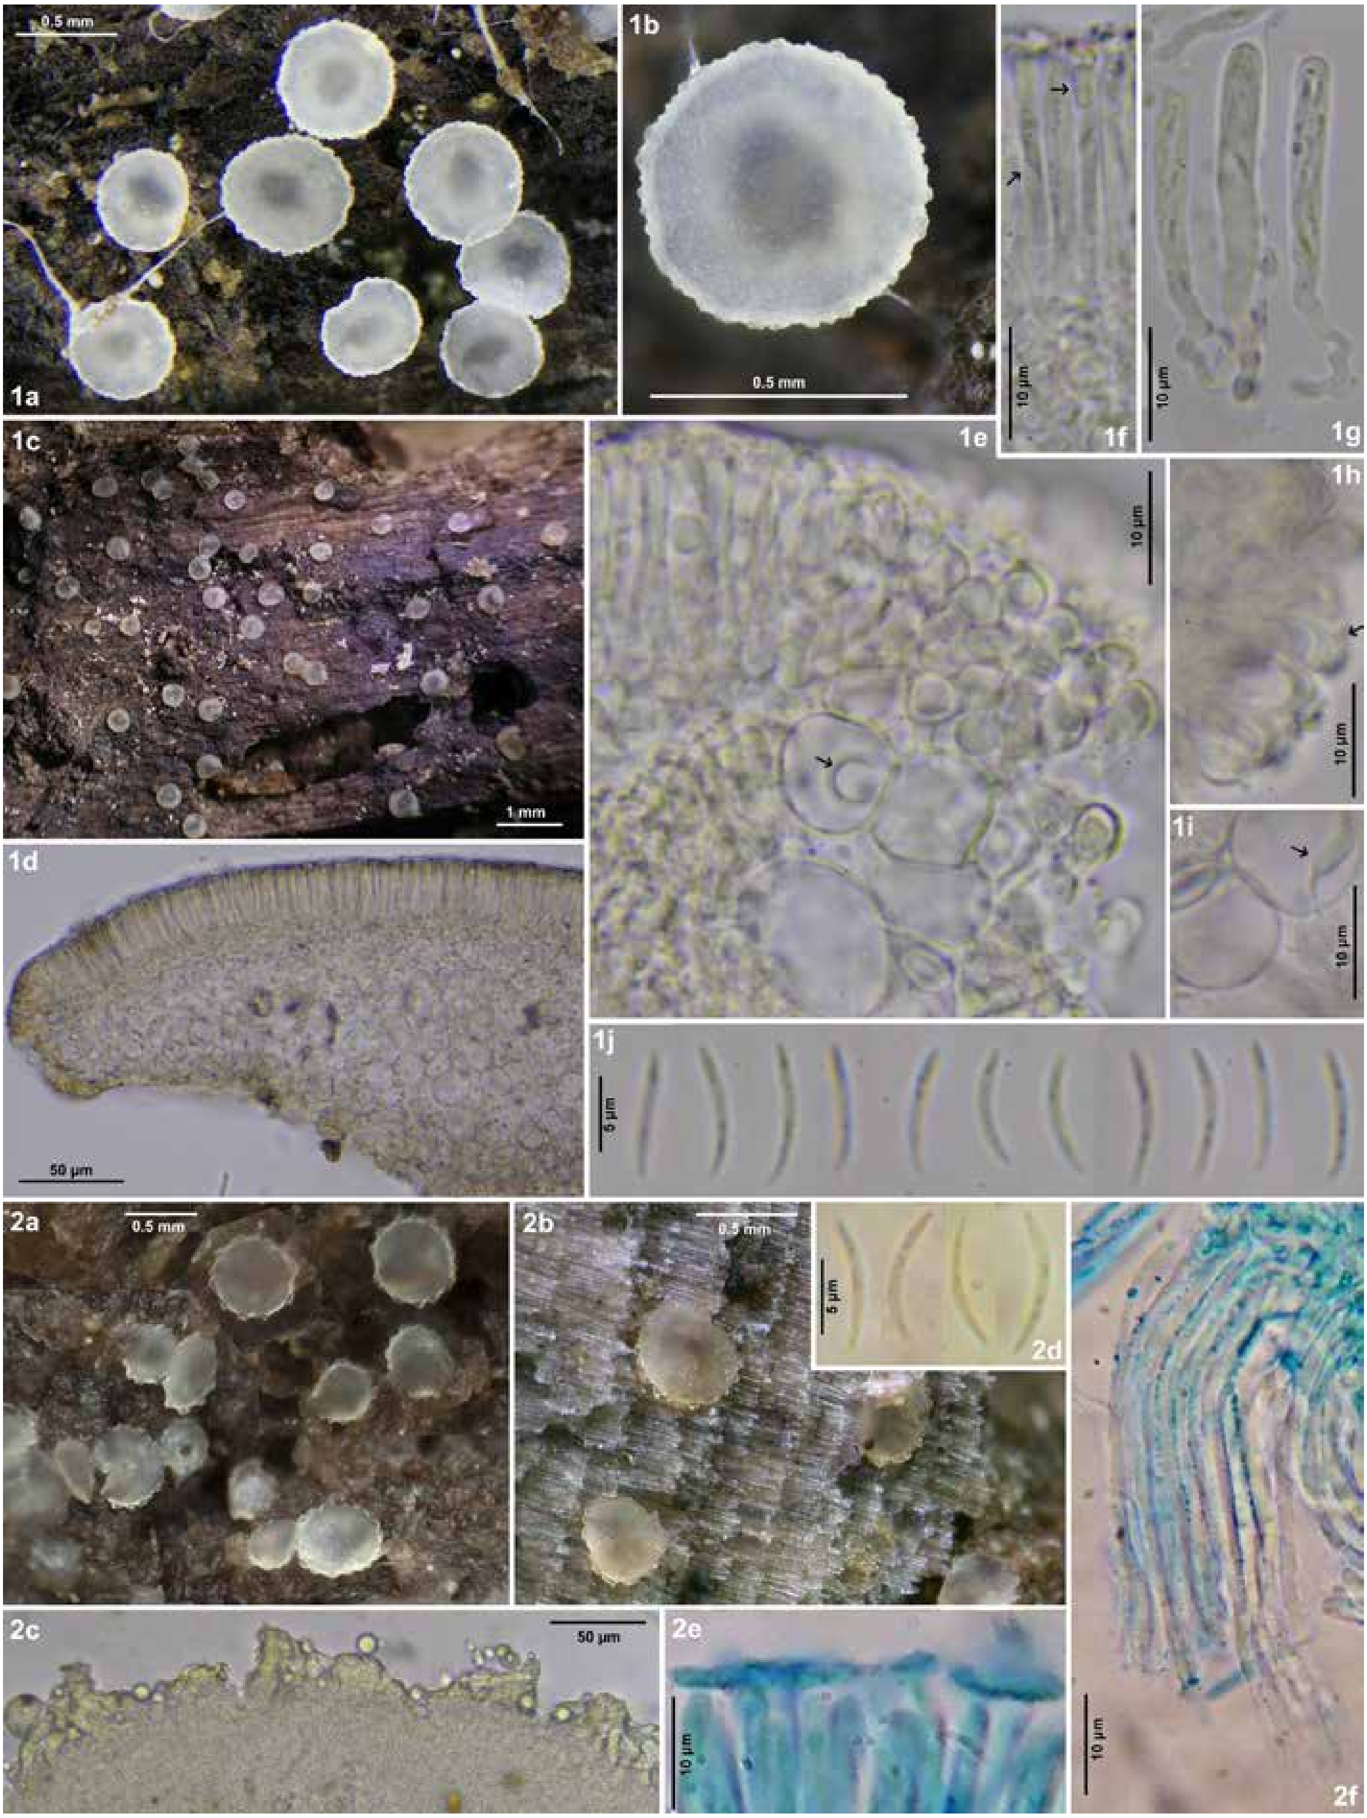

Plate 465. **1–2**: *Orbilia crenatofalcata*. – **1a–b**, **2a**. fresh apothecia; **2b**. rehydrated apothecia. **1c**. rehydrated piece of wood with apothecia; **1d**. apothecium in median section; **1e**. id., marginal region, with crystalloid SCBs (arrow); **1h**. marginal cortical cells with short glassy processes (arrow); **2f**. glassy processes; **1i**. crystalloid SCBs in ectal excipular cells (arrow); **2c**. dentate margin in top view; **2e**. upper part of hymenium with exudate; **1f**. paraphyses with elongate cylindrical SCB (right arrow) rhomboid crystalloid SCBs (left arrow); **1g**. mature asci; **1j**, **2d**. ascospores. – Living state, except for **1h** & 2 asci in **1g** (in H_2O), **2d–f** (**e–f** in CRB). – phot. S. Tello (except for **1c** & **2b–c**). — **1a–j**. JA-CUSSTA 7771, H.B. 9852 (type): Spain, Andalucía, Jaén, on *Populus*; **2a–f**. H.B. 9926: Navarra, Pamplona, on *Populus*.

Series *Abutilones*

Orbilia subgenus ***Habrostictis*** section ***Aurantiorubrae*** series ***Abutilones*** Baral & E. Weber, **ser. nov.**, MB 815013 –
Type species: *Orbilia abutilonis* E.K. Cash

Etymology: named after the type species, *O. abutilonis.*

Latin diagnosis: *Seriei* Aurantiorubrae *similis sed paraphysibus apice pro parte majore spathulatis vel lageniformibus, ascosporis ad basim non raro constrictis et saepe valde geniculatis, conidiis staurosporis (typo* Dicranidion*) differt.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–1.5(–2) mm diam., pale to bright cream, yellow-ochre to orange- or carmine-rose, margin smooth or pruinose to prominently hairy, sessile or with ± distinct short stipe. **Asci** *37–62(–69) × 3.7–5 µm, 8-spored, lower or upper 3–5(–6) spores inverted; **apex** (†) slightly to strongly truncate, rarely indented, laterally not or sometimes slightly inflated; **base** T-, L- or Y-, h-, rarely H-shaped **Ascospores** *(4.8–)6–11(–12) × (0.6–)0.8–2(–2.3) µm, narrowly (cylindric-)fusoid(-clavate) to fusiform(-clavate), apex acute to acuminate, rarely obtuse to subacute, base hardly to strongly attenuated, sometimes tail-like or with a ± strong subbasal constriction, straight or often slightly to strongly curved (falcate), at base often slightly to very strongly geniculate, sometimes (sub)helicoid; **SBs** 1.5–4(–5.5) × 0.2–1.1 µm, filiform to subulate or tear-shaped, apically narrowed to a small point. **Paraphyses** (uninflated to) slightly to strongly inflated at the apex, spathulate-lageniform or clavate-capitate, terminal cells (1–)1.5–3(–4)× longer than lower cells. **Ectal excipulum** cells near base *(6–)10–20(–30) × (4–)7–15(–20) µm; **glassy processes** absent, rarely 2–15 µm long, **hairs** often present, 15–65 µm long, thin- to thick-walled, septate, also as short, hair-like protrusions. **SCBs** absent, rarely globose or crystalloid; **VBs** absent, rarely present, low-refractive. **Exudate** absent or 0.2–1(–2) µm thick, continuous-rough to cloddy, firmly (or loosely) attached, hyaline or pale yellowish. — **ANAMORPH**: dicranidion-like (*O. abutilonis*, *O. ficicola*, *O. siculispora*). **Conidiophores** short (4–6 µm). **Conidia** staurosporous, maniform, mostly 4-armed by repeated branching, also 2–3-armed, *35–52 × 13–25 µm, arms parallel, in a plane; exceptionally with some unbranched conidia.

Habitat: wood and bark of angiosperms or on herbaceous stems, boreal to tropical, humid to semiarid, always ± desiccation-tolerant.

Recognized species: 14, plus 1 unnamed species ('affinis').

Taxonomic remarks. Morphologically the species of series *Abutilones* resemble those of series *Aurantiorubrae* in having similar ascospores with very acute apices and not or only slightly attenuated, often strongly geniculate bases, but they mainly lack crystalloid SCBs and frequently possess spathulate to mammiform paraphyses and constricted spore bases.

Species delimitation. Many of the species included in series *Abutilones* appear to be easily recognizable, whereas *O. abutilonis*, *O. ficicola*, and *O. siculispora* form a morphologically very difficult species complex. However, *O. abutilonis* and also *O. rosella* would perhaps better be characterized if their vital features were known. *O. milinana* showed some variation which might point to heterogeneity of the included specimens. *O. rosella* and *O. paravitalbae* seem sharply separated from *O. ebuli*, but can be confused with species of other series because the spores lack the basal constriction typical of many species of series *Abutilones*.

This often strong but variable constriction at the more or less geniculate spore base occurs in *O. abutilonis*, *O. ficicola*, *O. siculispora*, and *O. lobeliae*, and less pronounced in *O. subsiculispora*, *O. milinana*, *O. somedana*, and *O. ebuli*. In *O. lobeliae* and *O. milinana* the spore orientation deviates from the others by showing a strong predominance of the upper spores being inverted within the asci. Inverted upper spores were also seen in some asci of *O. abutilonis*, *O. ficicola*, *O. siculispora*, and in *O. carminorosea*.

Six species (*O. abutilonis*, *O. ficicola*, *O. siculispora*, *O. somedana*, *O. suberis*, *O. subsiculispora*) are exceptional in their filiform to narrowly subulate SBs, mostly spathulate-lanceolate to lageniform-mammiform paraphyses (except *O. somedana*), and septate, thin-walled, appressed or projecting marginal hairs (because of lacking vital studies, the SBs of *O. abutilonis* and *O. carminorosea* are unknown, while those of *O. rosella* are probably strongly inflated at their base). *O. ebuli* resembles *O. aurantiorubra* in spore and SB shape, except that the spores of *O. ebuli* are usually not or only slightly curved.

A tendency to short, hair-like projections forming a pruinose to crenulate margin is typical of *O. ebuli*, *O. rosella*, *O. carminorosea*, and *O. rehmii*. Glassy processes are mostly absent or very short, rarely up to 15 µm long (*O. rehmii*). *O. ebuli* and *O. aethiopica* are characterized by tear-shaped SBs with a subulate upper part. *O. milinana*, *O. lobeliae*, *O. ebuli*, *O. rosella*, and *O. somedana* deviate from the remaining species in capitate(-clavate) paraphyses, the former two also in the total absence of marginal hairs. *O. aethiopica* is outstanding in its short and broad, straight spores with a subacute, flat-conical apex, and lanceolate paraphyses. Crystalloid SCBs were only observed in *O. subsiculispora*.

Anamorph. Only from *O. siculispora* an ascospore isolate was gained. It formed (2–)4-armed, maniform, stipitate, dicranidion-like conidia with parallel arms. In *O. abutilonis*, *O. ficicola*, *O. suberis*, and *O. carminorosea* conidia were only found on the natural substrate. They are also 2- or 4-armed but differ in diverging arms and resemble those of *O. fissilis* of series *Orbilia*. In *O. rosella* very different, narrow, vermispora-like conidia were seen on the natural substrate, but their connection to this species, which is only tentatively placed here, is quite uncertain.

Phylogeny. Despite a close morphological similarity to series *Aurantiorubrae*, series *Abutilones* is situated in our analyses unresolved within section *Aurantiorubrae* and very distant from series *Aurantiorubrae*. It forms a strongly supported clade when analysing ITS+LSU or ITS (Phyls 13, S15), though with a high distance among the included species. The concept of series *Abutilones* is mainly based on our sequence data, which were available for *O. aethiopica*, *O. carminorosea*, *O. ebuli*, *O. ficicola*, *O. milinana*, and *O. siculispora*. Placement of *O. aethiopica* in this clade is surprising because of its morphological dissimilarity.

Specific nucleotide positions. Three nucleotides in the 5.8S region are characteristic of series *Abutilones*: pos. 30 is TTC**C**CGC and pos. 140 & 144 A**C**GTC**C**G compared to other members of section *Aurantiorubrae* which have TTC**T**CGC and A**T**GTC**T**G. As an exception, one of the two strains of *O. milinana* (B.L. X098) has TTC**T**CGC, and *O. poitevinica* A**C**GTC**T**G. In the LSU D1–D2 domain pos. 332 is highly diagnostic for the group, showing GGCG**G**GAGAC whereas all other members of subgenus *Habrostictis* have GGCG**A**GAGAC (though also *O. paravitalbae*). However, the motif of series *Abutilones* is shared by the genera *Mycoceros* and *Hyalorbilia*, and within *Orbilia* by section *Ovoideae*, *O. dryadum*, and section *Arthrobotrys* p.p.maj.; pos. 487–491 is G**GG**GG unlike any other *Orbilia* spp. which mostly have G**CA**GG or more rarely G**CG**GG or G**TG**GG (pos. 488 is unique within series *Abutilones*).

Ecology. All included species are more or less desiccation-tolerant. They have been collected on wood and bark of

Key to species of series *Abutilones*

1. Spores *4.8–6.3 × 1.8–2.5 µm, with a flat-conical, subacute apex forming a > 90° angle; paraphyses (sub)lanceolate, also ± uninflated; apothecia yellowish-ochre, margin rough; angiosperm bark, mesotemperate humid northeastern Africa .... ***O. aethiopica***, p. 912
1. Spores *6.5–12 × 0.6–1.8(–2) µm, apex acute to acuminate, rarely obtuse, forming a < 90° angle; paraphyses with rounded apex, cylindrical, capitate or lageniform-mammiform, also lanceolate 2

2. Apices of paraphyses distinctly ellipsoid-spathulate to lanceolate or mammiform, exceptionally uninflated 3
2. Apices of paraphyses clavate-capitate, sometimes ellipsoid or uninflated 8

3. Spores without subbasal constriction, *~ 1–1.3 µm wide 4
3. Spores with slight to strong subbasal constriction, *~ 1.1–1.5(–1.7) µm wide; marginal hairs without glassy processes 5

4. Spores †(6.5–)7–7.5(–8) × (0.9–)1–1.2 µm, fusiform, base strongly attenuated, tail-like; hairs absent or 12–30 µm long, tipped by 1–15 µm long glassy processes; bark of *Malus*, cold-temperate humid central Europe .... ***O. rehmii***, p. 904
4. Spores *6.5–9 × 1–1.2 µm, base not attenuated; hairs 25–65 µm long, without glassy processes; bark of *Quercus suber*, mesomediterranean semihumid southern Europe .... ***O. suberis***, p. 895

5. Spores with slight subbasal constriction, *8.5–10.5 × 1.4–1.7 µm; asci *53–69 µm long; paraphyses with crystalloid SCBs; bark of *Artemisia filifolia*, cold-temperate subhumid western North America .... ***O. subsiculispora***, p. 890
5. Spores with slight to strong subbasal constriction, *6.5–10.5 × 1.1–1.6 µm; asci *37–58 µm long; paraphyses and excipular cells without crystalloid SCBs (unknown in *O. abutilonis*) 6

6. Disc orange-ochraceous; hairs broad up to the apex, upper cell *3–5.5 µm wide, thin-walled; conidia with (2–)4 parallel, 3.8–5.5 µm wide arms; spores *(6.5–)7–9(–10) µm long; bark & wood of *Populus*, *Ulmus*, cold-temperate humid Europe..... ***O. siculispora***, p. 886
6. Disc usually pinkish, rarely ochraceous; hairs partly distinctly narrower in upper part, upper cell *2.5–3.3 µm wide, thin- to thick-walled; conidia with 2–4 strongly diverging, outwards curved, *3.5–4.3 µm wide arms; spores *(7.5–)8–10(–10.5) µm long 7

7. Basal inflation of */†spores max. 2 × thicker than connecting part; hair cells 5–14 µm long; apothecia pinkish; bark of *Ficus*, *Populus*, *Tilia*, *Ulmus* etc., submediterranean semihumid to cold-temperate (thermophilous) humid Europe .... ***O. ficicola***, p. 892
7. Basal inflation of †spores > 4 × thicker than connecting part; hair cells 10–18 µm long; apothecia ochraceous to pinkish; bark of *Abutilon*, tropical semihumid Hawaii .... ***O. abutilonis***, p. 890

8. Upper spores inverted within asci; spore base consistently (very) strongly and sharply reflexed and ± constricted 9
8. Lower spores mostly inverted within asci; spore base straight to strongly curved but not sharply reflexed, rarely constricted 10

9. Spores *7–10.5 × 0.9–1.3 µm, inflated basal part below constriction bent forwards; wood and bark of *Juglans*, *Euphorbia* etc., cold-continental to tropical (semi)humid Asia, Middle America, Macaronesia .... ***O. milinana***, p. 897
9. Spores *7–8 × 0.6–0.8 µm, inflated basal part below constriction bent backwards; bark of *Lobelia*, warm-temperate humid northeastern Africa .... ***O. lobeliae***, p. 899

10. Spores †6.5–7.5(–8) × 1.2–1.3(–1.4) µm, base strongly attenuated (tail-like) and quite strongly curved; apothecia bright carmine-rose, thick-fleshed, margin whitish powdered; wood of *Adansonia*, tropical subhumid western Australia .... ***O. carminorosea***, p. 906
10. Spores straight or only slightly to medium curved; apothecia light rose-orange-cream, margin ± crenulate by short agglutinated hairs; boreal to mediterranean Europe 11

11. Spores */†(7–)7.5–9(–9.8) × (1.5–)1.6–1.8(–2) µm, cylindrical to fusoid, apex obtuse (to rounded), base never with a tail 12
11. Spores mainly *1.3–1.6 µm wide, fusoid to fusiform, apex acute (to acuminate), base often with a sometimes slightly constricted, 2–3.7 µm long tail 13

12. Spores fusoid, apex obtuse (to subacute), base often ± strongly attenuated, almost tail-like; stems of *Atropa*, temperate humid Europe ***O. rosella***, p. 908
12. Spores ± cylindrical, apex rounded to obtuse; bark of *Daphne*, stem of *Helleborus*, orosubmediterranean humid to mesomediterranean semihumid southern Europe .... ***O. paravitalbae***, p. 910

13. SBs with filiform upper part and swollen, ellipsoid to tear-shaped, 0.7–1.1 µm wide lower part; spores *(8–)9–11(–12) × 1.3–1.6(–1.7) µm, tail *0.5–0.8(–1) µm wide; herbaceous stems, petioles of deciduous trees, thermoboreal to (oro)temperate humid and mesomediterranean semihumid Europe .... ***O. ebuli***, p. 900
13. SBs filiform to subulate, 0.2–0.4 µm wide; spores *(7.8–)8.2–9.2(–9.7) × 1.2–1.5 µm, tail *0.8–1.1 µm; bark of *Rhamnus*, *Fagus*, orotemperate humid southern Europe .... ***O. somedana***, p. 904

angiosperms and on herbaceous stems. Records derive from various climatic regions: from temperate to tropical and from humid to semiarid, and the distribution is worldwide: Europe, Africa, North America, Hawaii, Asia, and Australia.

Orbilia siculispora Baral, E. Weber, Friebes & G. Marson, **sp. nov.**, MB 825634 — Pls 466–468

Etymology: named after the spores reminding a curved dagger (Latin *sicula*).
Typification: Germany, Baden-Württemberg, Tübingen, trunk of *Ulmus laevis*, 20.VI.2004, H.O. Baral (ex H.B. 7526b, M-0291766, holotype).

Latin diagnosis: *Similis* Orbiliae abutiloni *et* O. ficicolae *sed brachia conidiae latiora et parallela differt. Habitat ad corticem et lignum putridum ramorum vel truncorum siccorum* Populi *et* Ulmi *in zona temperata humida Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–1.3(–1.7) × 0.4–1.1 mm, (0.11–)0.14–0.2(–0.38) mm high (receptacle 0.06–0.15 mm), light to bright orange-ochraceous, not or slightly translucent, round to broadly elliptical, also irregular or strongly compressed, scattered to subgregarious, also densely gregarious in small groups; disc young strongly concave, mature slightly concave to flat, margin distinct, 0–30 µm protruding (10–50 µm including hairs), with prominent hairs forming ± distinct, whitish, teeth-like fascicles; sessile or with a more or

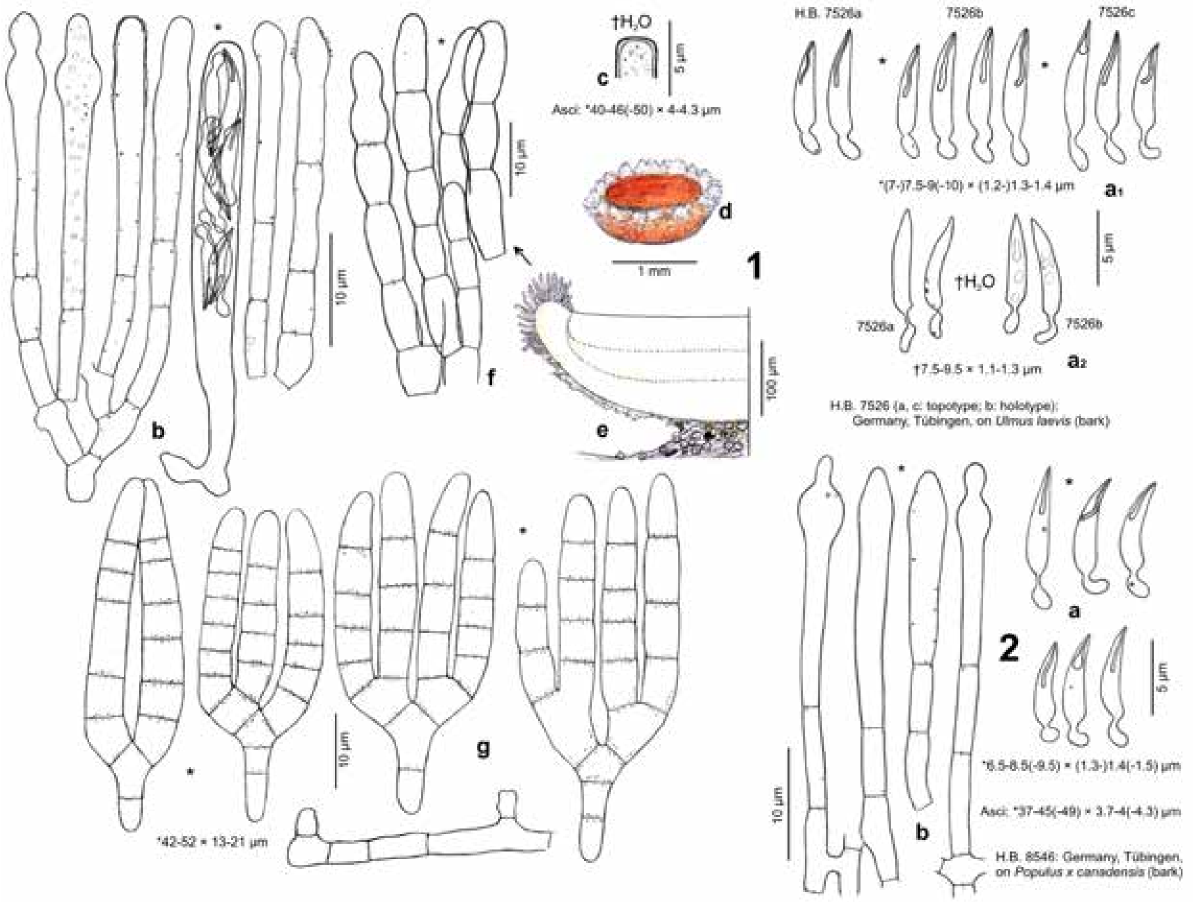

Plate 466. **1–2**: *Orbilia siculispora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium with hairy-dentate margin; **e**. apothecium in median section; **f**. marginal hairs; **g**. conidia (from culture).

less distinct obconical stipe up to 0.25 × 0.35 mm, superficial or slightly erumpent from small alveoles of bast, also immersed in narrow clefts; dry partially to completely closed by the incurved margin and white teeth, light orange. **Asci** *(37–)40–50(–58) × 3.7–4.3 µm {3}, †35–45(–50) × 3.2–3.7 µm {1}, 8-spored, spores *2–3-seriate, 3–4(–6) spores inverted {4}, mostly strongly mixed, often 1–3 of the lower spores inverted but often also 1–2 of the upper ones, pars sporifera *18–25 µm long; **apex** (†) medium to strongly truncate (not indented, laterally scarcely inflated); **base** with short to long, ± thin, flexuous stalk, L- or T-shaped. **Ascospores** *(6.5–)7–9(–10) × (1.2–)1.3–1.4(–1.5) µm {4}, †7.5–9.5 × 1.1–1.3 µm {1}, subulate, very slightly to medium curved, apex strongly acute to acuminate, with abrupt tail of 1.7–2.6 × 0.7–1 µm (†0.6–0.8 µm wide), with mostly strong constriction, ± geniculate (reflexed and bent forward), inflated part cylindric-ellipsoid (appendage-like); **SBs** *3–4(–4.5) × 0.2–0.4 µm {3}, filiform to subulate, straight or often ± flexuous, overmature tear-shaped, 2–2.5 × 0.5–0.6 µm. **Paraphyses** apically spathulate to lageniform, lanceolate or mammiform, with beaks of *2–4 × 1.3–2.7 µm, exceptionally cylindrical or capitate, terminal cells *(15–)17–24(–26) × (2–)2.8–4 µm {2}, exceeding the dead asci by 2–8 µm, lower cells *6–10 × (1.3–)1.5–3(–3.5) µm {2}; branched only near base, hymenium pale yellowish-orange. **Medullary excipulum** pale yellowish, 10–50 µm thick, of dense, apparently non-gelatinized textura intricata with scattered inflated cells, medium sharply delimited from ectal excipulum (mainly at lower flanks) by a parallel 10–25 µm thick layer of pale orange t. porrecta. **Ectal excipulum** hyaline, with pale to light yellowish cortex, of (†) thin-walled, irregularly oriented (10–30 to 45–90°) t. globulosa-angularis-prismatica from base to mid flanks, 40–100(–250) µm thick at base, cells *8–20(–30) × (5–)7–13(–15.5) µm {3}; 20–25 µm thick at mid flanks, irregularly horizontally oriented (10–30°), at margin 20–50 µm thick, of t. prismatica(-angularis) or t.porrecta oriented at a ~10–40° angle, marginal cells forming free to scarcely agglutinated **hairs** *(15–)30–40(–45) × (2.2–)2.8–5(–5.5) µm {4}, (0–)1–4-septate, cylindrical to moniliform, thin- to firm-walled, hyaline, individual cells *(5–)7–12(–14.5) µm long, without **glassy processes**. **Anchoring hyphae** sparse to very abundant, */†(1.5–)2–3(–4) µm wide {2}, walls 0.2 µm thick {2}. **SCBs** in paraphyses and ectal excipulum absent; light golden-yellow **LBs** (carotenoids) in cells of ectal excipulum at base and flanks 0.3–2.2 µm diam. {1}; **VBs** absent {4}, or present in paraphyses as numerous, small to large, globose, medium refractive guttules {1}. **Exudate** over paraphyses absent or 0.1–0.3 µm thick, finely rough or continuous, firmly attached, very inconspicuous; over hairs and excipular cells of margin and flanks absent or forming a thin, pale to light yellow, granular-cloddy covering layer. **— ANAMORPH**: dicranidion-like (from ascospore isolate {1} and natural substrate {2}). **Conidiophores** reduced. **Conidiogenous cells** *4–6 × 3 µm. **Conidia** fork-shaped or like fingers of a hand (maniform), mostly 4-armed by dichotomous branching, also 2–3-armed, arms parallel, in one plane or sometimes somewhat contorted, total size *35–52 × 13–25 µm {2}, stipe *7–11 × 2.5–3.5 µm, (0–)1–2-septate, arms *(11–)14–38 × 3.8–5.5 µm, (2–)3–7-septate; exceptionally unbranched conidia seen.

Habitat: collected 0.3–3 m above the ground, on 15 mm thick, corticated or decorticated, still-attached or fallen dead branches or 30–100 cm thick living trunks or dead logs of *Populus alba* {1}, *P.* × *canadensis* {2}, *Ulmus laevis* {2}, on slightly to strongly decayed bark (bast) {4} or wood {2}, on outer surface of partially detaching or ± loosely adhering bark, also hidden in cracks or behind detaching periderm, not or slightly to medium greyed, with very few to many green algae. **Associated**: *Amandinea punctata* {1}, *Lecanora conizaeoides* {1}, *Nectria peziza* {1}, *Orbilia aurantiorubra* {1}, *O. carpoboloides* {1}, *O. ficicola* {1}, *Orthotrichum* sp. {1}, *Peniophora lycii* {1}, *Phaeophyscia orbicularis* {1}, *Physcia tenella* {2}, *Strossmayeria basitricha* {1}, *Xanthoria parietina* {2}, *Xanthoriicola physciae* {1}, indet. coelomycete {1}. **Desiccation tolerance**: fully viable for at least 3 months, many paraphyses and immature asci still alive after 4 months. **Altitude**:

126–333 m a.s.l. **Geology**: Russia: Upper Devonian sediment, central Europe: alluvial deposits from Keuper etc. **Phenology**: IV–VIII, XI–XII (throughout the year, long-lived).

Taxonomic remarks. *Orbilia siculispora* is characterized by its remarkable ascospores with acute apex and knob-like basal inflation formed by a strong subbasal constriction, together with rather large apothecia with prominent thin-walled hairs in fascicles, also by dicranidion-like conidia with parallel, mainly 4 arms. However, *O. abutilonis* and *O. ficicola* more or less share the same characters of the teleomorph (see there), whereas the North American *O. subsiculispora* differs in spores with only a slight subbasal constriction and in crystalloid SCBs in the paraphyses (see below). *O. suberis* seems also closely related, but differs in non-constricted, more curved spores and yellow-ochraceous apothecia. *O. milinana* differs in consistently geniculate and hooked, hardly constricted spore bases, consistently inverse orientation of the upper spores, a tendency to capitate paraphyses, and absence of hairs.

Variation. The spores of *O. siculispora* vary between medium to very strongly constricted near the base (Pl. 466: a_1). This subbasal constriction is more prominent in dead spores, and one may easily get confused to consider the basal appendage-like inflation as a conidium. Yet, this constriction does not lead to disarticulation. The varying strength of constriction in *O. siculispora* in living spores with fully developed SBs, in comparison to spore shapes of closely related species with only slight or even absent constriction leave no doubt that this feature is a characteristic of the mature, not overmature ascospore.

Among the collections from Tübingen, those on *Populus* showed the paraphysis apices more lanceolate or mammiform (Pl. 466: 2) compared to spathulate or lageniform on *Ulmus* (Pl. 466: 1), and the apothecia were bright ochre (Pl. 468: 1) compared to ochre-orange on *Ulmus* (Pl. 467). Also in the Russian sample on *Ulmus* the apothecia were more orange (Pl. 468: 3), but the paraphysis shape was not noted. An ochre colour showed also the Slovakian sample on *Populus*, but here the paraphyses were only indistinctly lanceolate or even cylindrical. Unlike the German samples, the paraphyses were here filled with numerous conspicuous globose VB-guttules (IVV: 17.XI.2019),

Plate 468. **1–3**: *Orbilia siculispora*. – **1a**. dead, attached, corticated, 15 mm thick branch of *Populus* × *canadensis*; **1b**, **2a**. detail of xeric *Populus* branches (rehydrated), bark covered by algae, *Xanthoria* and *Peniophora*; **1c–e**, **3a–b**. rehydrated apothecia; **1f**, **2b**. apothecia in median section; **1g–h**. id., marginal ectal excipulum; **1i**. ascospores; **1j**. conidia (from substrate). – Living state. – **3**: phot. E. Popov. — **1a–j**. H.B. 8546: Germany, Tübingen, Kirchentellinsfurt, on *Populus*; **2a–b**. H.B. 8728: ibid.; **3a–b**. LE 247566: Russia (West), Nasva, on *Ulmus*.

and these guttules occurred also in an associated rose-coloured population tentatively referred here to *O. ficicola*.

Anamorph. Among the two known species of *Dicranidion* with more than two arms, the conidia of *O. siculispora* resemble those of *D. incarnatum*, a species known from branches of *Opuntia* from Galapagos Islands which deviates in 3–8 arms. The anamorph of *O. fissilis* differs in much smaller conidia with diverging arms. Similar, but larger and more slender dicranidion-like conidia with diverging arms distinguish the closely related *O. ficicola* (Pls 472: 1m; 473: 1g).

Phylogeny. A sequence was taken from apothecia of one of the samples on *Ulmus* from Tübingen (H.B. 8121), comprising SSU (V6–V9, incomplete near 3’-end), ITS (incomplete near 5’-end), and a fragment of LSU (parts of D1 and D2). The S1506 intron region was not covered. Another three sequences were taken in II.2020 from apothecia of the *Populus* sample from Bratislava (A.P. 19/36b). They comprise SSU V9, S1506 intron, ITS, and LSU D1 and partial D2, and differ from the preceding merely in 1 nt and 1 gap in ITS1 and 2 nt in ITS2.

The distance to other members of series *Abutilones* lies in the ITS region at 13.3–25 %, the lowest percentage being to *O. ficicola* (13.3–14 %), with which it forms a strongly supported clade in our analyses (Phyls 13, S15–S16), the next close being *O. ebuli* (17.5 %), and in the LSU (325 nt) at 1.5–4.5 %, the lowest again to *O. ficicola*, the next close 3.3 % to *O. aethiopica* (*O. ebuli* 4.5 %).

Ecology. *O. siculispora* was found on ± rotten bark or wood of xeric, dead or sometimes living branches and trunks of *Populus* and *Ulmus* in riparian forests in humid, cold-temperate subcontinental central Europe and hemiboreal continental eastern Europe. The two collections on elm were on *Ulmus laevis*, a typical representative of floodplain forests, which shows the highest resistance against the elm disease, but also against prolonged flooding.

One of the sites where *O. siculispora* was found in abundance was an about 160 years old living *Ulmus* tree inside the town of Tübingen close to university buildings of a similar age (Pl. 467: 1a–b). The apothecia have been collected there between 2004–2009 on detaching chips of bark on the 1 m thick trunk at a height of 1–3 m above the ground, but only on the south-oriented half of the trunk, especially on its (south-)east- but also southwest-exposed side. Mainly those chips were colonized which could easily be removed from the bark layers beneath. Lichens nearly exclusively occupied the northwestern side of the trunk. Therefore, they almost never occurred close to the *Orbilia*, which appears to prefer areas being most protected against rain falls, remaining dry for rather long periods of time. Bark pieces which superficially looked empty showed immature apothecia deeply hidden in clefts, along with abundant dicranidion-like conidia.

Specimens included. **GERMANY**: **Baden-Württemberg**, Tübingen, Neue Aula, Gmelinstraße, 333 m, trunk of *Ulmus laevis*, on bark, 20.V.2004, H.O. Orbilia subsiculispora G. Marson & Baral, **sp. nov.**, MB 813766 — Pl. 469

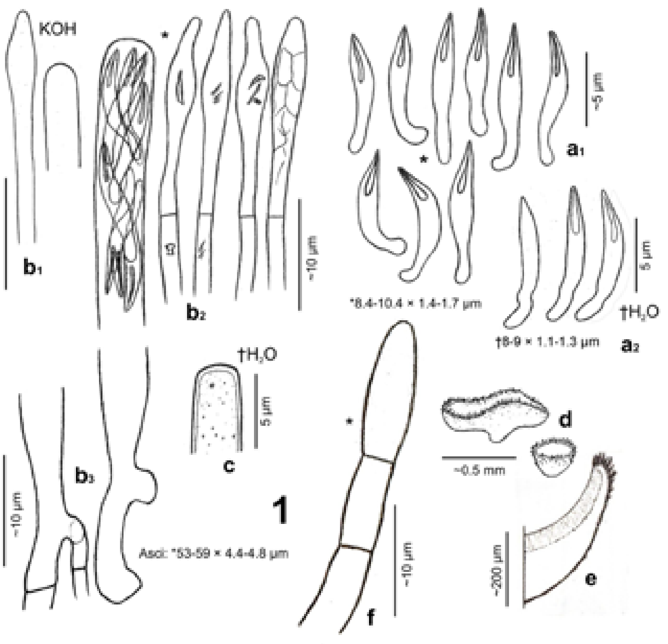
Etymology: after the similarity with *O. abutilonis*.
Typification: USA, Colorado, Cortez, branch of *Artemisia filifolia*, 31.V.1996, G. Marson (ex H.B. 6276a, M-0276590, holotype).

Latin diagnosis: *Similis* Orbiliae abutiloni *sed ascosporae basaliter minus constrictae, cellulae vivae excipuli et paraphysium corpuscula crystalloidea continentes. Habitat ad corticem putridum rami sicci* Artemisiae filifoliae *in zona supratemperata subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.65 mm diam., light orange-rose, round to slightly undulating, disc strongly concave, margin crenulate to hairy; subsessile to short stipitate. **Asci** *53–69 × 4.4–4.8 µm, †45–50 × 3.5–3.8 µm, 8-spored, spores *4-seriate, 3 lower spores inverted; **apex** (†) slightly to medium truncate; **base** short-stalked, Y- to h-shaped. **Ascospores** *8.5–10.5 × 1.4–1.7 µm, †8–9 × 1.1–1.3 µm, ± fusiform, apex acute to acuminate, base medium attenuated in a thick, tail-like, often basally somewhat knob-like end, slightly to distinctly helicoid, near base partly distinctly 2 × geniculate; **SBs** ~3–4 × 0.3–0.6 µm, subulate. **Paraphyses** apically lageniform to spathulate-lanceolate, terminal cell *~18 × 2.6–2.9 µm, †2–2.7 µm wide, exceeding the dead asci by 4–8 µm. **Medullary excipulum** not examined. **Ectal excipulum** not examined; hairs 2-septate, ?30 × 4 µm, without **glassy processes**, free or slightly coherent. **Anchoring hyphae** not examined. **SCBs** in paraphyses crystalloid, filiform to plate-like. **Exudate** absent on paraphyses, present over ectal excipulum. — **ANAMORPH**: unknown.

Habitat: collected 0.1–0.6 m above the ground, corticated, 12 mm thick branch of *Artemisia filifolia*, on medium decayed bark (periderm). **Associated**: *Orbilia mesaverdiana*, *O. ocellata*, *O. plurilentiformis*. **Desiccation tolerance**: fully viable for probably at least 6 months. **Altitude**: 2290 m a.s.l. **Geology**: Upper Cretaceous sedimentary rock. **Phenology**: long-lived.



H.B. 6276a (holotype): USA, Colorado, on *Artemisia filifolia* (bark)

Plate 469. **1**: *Orbilia subsiculispora*. – **1a**. ascospores (**a**$_1$ living state, **a**$_2$ dead in H_2O); **1b**. upper part of asci and paraphyses, dead (**b**$_1$) and living state (**b**$_2$), ascus bases (**b**$_3$); **1c**. ascus apex; **1d**. apothecia with fimbriate margin (rehydrated); **1e**. apothecium in median section; **1f**. marginal hair.

Taxonomic remarks. *Orbilia subsiculispora* is very close to *O. abutilonis* and related species, from which it differs in only slightly constricted ascospores and in the presence of crystalloid SCBs in the paraphyses. It is also similar to *O. aurantiorubra* (series *Aurantiorubrae*), from which it mainly differs in lanceolate-lageniform paraphyses and a hairy apothecial margin. *O. somedana* has similar but ± straight ascospores and differs by paraphyses with capitate-clavate apices.

Ecology. *O. subsiculispora* was collected on medium rotten bark of xeric branches of *Artemisia filifolia* in the cold-temperate subhumid sagebrush desert scrub of the Colorado Plateau in the southwest of Northern America. The collection consisted of only two apothecia which were used up during this study.

Specimens included. **USA**: **Colorado**, Canyonlands, 15.5 km SSE of Cortez, Mesa Verde, 5 km NNW of Spruce Tree House, 2290 m, branch of *Artemisia filifolia*, on bark, 31.V.1996, G. Marson (ex H.B. 6276a, M-0276590, **holotype**).

Orbilia abutilonis E.K. Cash, Mycologia 30: 101 (1938) — Pls 470–471

Etymology: named after the host genus in the type collection, *Abutilon*.
Typification: Hawaii, Honolulu, branch of *Abutilon grandifolium* (as *A. molle*), 18.I.1928, C.L. Shear & N.E. Stevens (Shear & Stevens 552, BPI, holotype).
Misinterpretation: Friebes (2011: 13), = *O. ficicola*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1.3 × 0.5–1 mm, 0.09–0.12 mm high, receptacle ~0.06–0.08 mm, light ochraceous, (Cash: pale ochraceous buff to pinkish buff), slightly translucent, round to broadly elliptical, often with irregular outline, subscattered to densely gregarious in smaller or larger groups; disc slightly to medium concave, finally flat, margin distinct, 10–40 µm protruding (including hairs), distinctly crenate (denticulate) by forming whitish-yellowish teeth; broadly sessile, superficial or slightly erumpent to entirely immersed in small or large alveoles of bast; disc dry partly closed by the incurved margin, light ochraceous salmon to avellaneous (Cash). **Asci** †34–55 × 2.7–3.5 µm, 8-spored, basal 4(–6) spores inverted, often strongly mixed; **apex** (†) medium to strongly truncate (not indented, laterally scarcely inflated); **base**

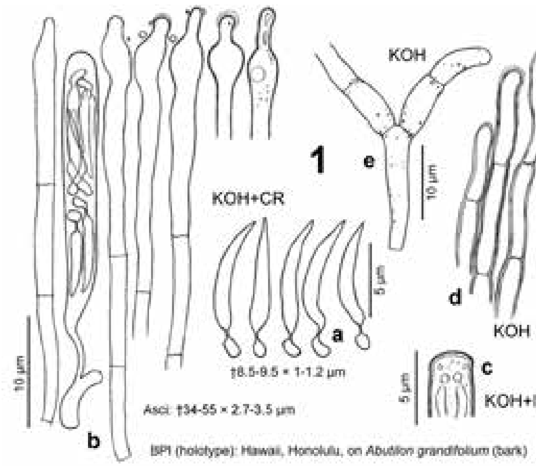


Plate 470. **1–2**: *Orbilia abutilonis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. marginal hairs; **e**. conidium from substrate.

with short to long, ± thin, flexuous stalk, L- or T-shaped. **Ascospores** †8.5–9.5 × 1–1.2 µm, subulate, very slightly to medium curved, apex strongly acute to acuminate, with abrupt tail of 1.7–2.3 × 0.7–0.8 µm, strongly constricted, straight to ± geniculate, inflated part cylindric-ellipsoid (appendage-like); **SBs** not seen. **Paraphyses** apically lanceolate or mostly lageniform to mammiform, with beaks 2–4 µm long, terminal cells †15–25 × 2–2.7(–3) µm, exceeding the dead asci by 2–4 µm, lower cells †8.5–11 × 1.3–1.6 µm; branched only near base. **Medullary excipulum** hyaline, 10–30 µm thick, of dense textura angularis-intricata, sharply delimited from ectal excipulum at flanks. **Ectal excipulum** pale yellowish, of (†) thin-walled, irregularly horizontally oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 25–30 µm thick at base, cells †10–15 × 5–9 µm; 15–20 µm thick at margin, of t. prismatica-porrecta oriented at a ~30–40° angle, marginal cells running out in **hairs** of †~20–40 × 2.5–3 µm, (1–)2-septate, cylindrical, slightly flexuous, wall 0.2–0.4 µm thick, hyaline, individual cells 10–18 µm long, without **glassy processes**, ± agglutinated by forming distinct teeth-like fascicles. **Anchoring hyphae** very abundant, †1.3–2 µm, walls 0.2 µm thick, forming a 20–60 µm thick layer of rather dense t. intricata. **SCBs** unknown. **LBs** unknown. **Exudate** over paraphyses absent or as scattered granules; over hairs and excipular cells of margin and flanks forming a thin, pale yellow, indistinctly rough covering layer by simulating a 0.5–1 µm thick hair wall. — **ANAMORPH**: dicranidion/trinacrium-like (presumed, from natural substrate). **Conidia** Y-shaped, †28 × 25 µm, stipe 13.5 × 3 µm, 0-septate, arms 15.5 × 3.5 µm, 1-septate, curved outwards.

Habitat: on 7–8 mm thick, corticated stem of *Abutilon grandifolium*, on strongly decayed bark (in alveoles of bast, periderm partly removed), also on periderm, no algae seen. **Associated**: ?*Diaporthe* sp. ?*Nectria* sp. **Desiccation tolerance**: unknown, but probably tolerant. **Altitude**: unknown (probably between 1–600 m a.s.l.). **Geology**: volcanic rock (tephrite). **Phenology**: I.

Taxonomic remarks. The Hawaiian *O. abutilonis* fits in most respects *O. ficicola* and *O. siculispora*. Especially ascospore size and shape is very much alike, although the spores of *O. abutilonis* are narrower than in *O. ficicola* when compared in the dead state, while *O. siculispora* lies between them. The ochraceous to pinkish buff original colour of the disc of *O. abutilonis* is in contrast to a more rose or orange-ochraceous disc of *O. ficicola* and *O. siculispora*. In *O. abutilonis* the anchoring hyphae formed a thick, subiculum-like layer which was also stressed by Cash, but which was often less developed in the other two species. *O. abutilonis* concurs with *O. ficicola* in hair morphology and in the presumed anamorph, whereas *O. siculispora* distinctly differs in both features.

For a long time we considered *O. abutilonis* and *O. siculispora* to belong to one species, for which reason Friebes (2011) used the name *O. abutilonis* for his Austrian collections.

Type studies. *O. abutilonis* was very misleadingly described as having uniseriate, allantoid to nearly globose spores measuring 2 × 1.5–1.7 µm. No doubt, Cash (1938) saw the spores only within the asci and there only the knob-like spore bases by overlooking the subulate upper part of the spores. The rather abundant and large apothecia looked macroscopically homogeneous so that a mixture seems to be quite improbable. Three apothecia of the holotype were examined in the present

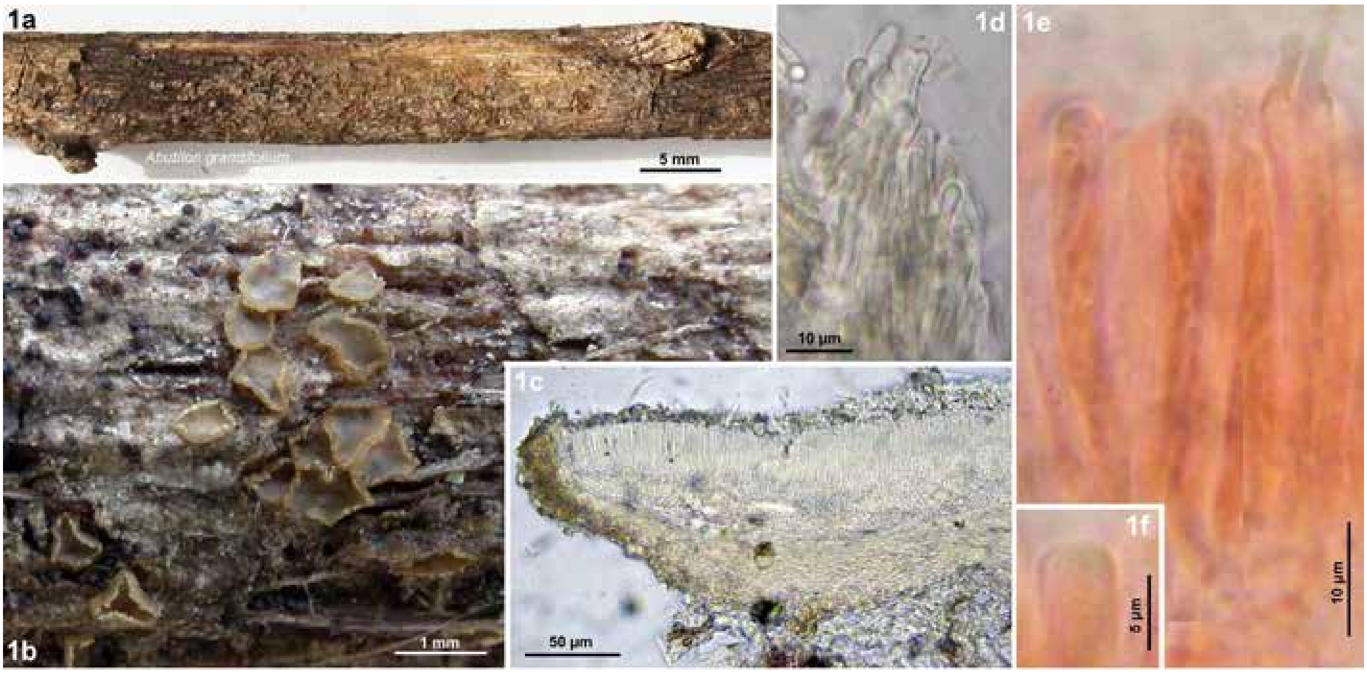

Plate 471. **1**: *Orbilia abutilonis*. – **1a**. dead, corticated branch of *Abutilon grandifolium*; **1b**. rehydrated apothecia; **1d**. apothecium in median section; **1c**. marginal hairs in squash mount; **1e**. asci and paraphyses; **1f**. ascus apex in front view. – Dead state (**1c–d** in KOH, **1e–f** in KOH+CR). —**1a–f**. BPI: Hawaii, Honolulu, on *Abutilon* (holotype).

study. Although Cash described the margin as crenulate, she did not report the hairs and their structure.

Anamorph. A single 2-armed conidium was found in an apothecium of the holotype, which closely resembles 2-armed conidia of *O. ficicola*, except for its small size (Pl. 470: 1e).

Ecology. The type collection was on bark of thin branches of *Abutilon* in the southwest exposed slopes in one of the islands of tropical semihumid (summer-dry) Hawaii. Cash (1938) did not provide ecological data apart from the substrate, and also the exact locality was not stated. *Abutilon grandifolium* is not native to Hawaii but was naturalized there, where it grows in waste areas and especially in rather dry southwest-exposed lowland regions up to 600 m a.s.l. (G. Wong pers. comm.).

Specimens included. **HAWAII**, **O'ahu**, ('N.') Honolulu, [?Kalihi valley,] branches of *Abutilon grandifolium* (as *A. molle*), on bark, 18.I.1928, C.L. Shear & N.E. Stevens (Shear & Stevens 552, BPI, **holotype**, H.B. 7600 ø, anam. substr.).

Orbilia ficicola G. Marson, Baral & E. Weber, **sp. nov.**, MB 825633 — Pl. 472–473, Map 83

Etymology: named after the host genus *Ficus* of the submediterranean collections.

Typification: France, Ardèche, Vallon-Pont-d'Arc, branch of *Ficus carica*, 12.IX.2016, G. Marson (ex G.M. 2016-09-12.1 & ex H.B. 10138a, M-0291756, holotype; sq.: MH221053 [from apothecia], MK473415 [from conidial isolate]).

Misapplied names: Friebes (2011: 13), as *O. abutilonis*.

Latin diagnosis: *Similis* Orbiliae abutiloni *sed ascosporae leniter latiores, conidia majora, 2–4-brachia. Habitat ad corticem vel lignum putridum ramorum siccorum* Fici caricae *in zona submediterranea semihumida Europae meridionalis, etiam* Populi, Tiliae, Ulmi etc. *in zona temperata humida Europae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.4–1.5(–2)((–2.8)) × 0.3–1.2(–1.8)((–2.4)) mm, 0.1–0.14 mm high (receptacle 0.075–0.09 mm), pale to light pinkish-rose(-orange) {∼12}, slightly to medium translucent, round to broadly elliptical, scattered to subgregarious; disc young slightly concave, mature flat, margin distinct, (20–)50–70 µm protruding, with agglutinated hairs forming ± distinct white teeth-like fascicles; sessile or with a broad, indistinct obconical stipe, superficial; dry ± closed by the incurved margin and white teeth. **Asci** *42–48 × 3.7–4.5 µm {3}, †34–45 × (3.1–)3.5–4 µm {2}, 8-spored, spores *2–3-seriate, 3–5 spores inverted {3} (lower or upper spores, often mixed); **apex** (†) slightly to medium truncate (not indented, laterally uninflated); **base** with short to long, thin or thick, flexuous stalk, L-shaped. **Ascospores** *(7.5–)8–10(–10.5) × (1.1–)1.2–1.5(–1.6) µm {10}, †(7–)8.5–10.5(–11.5) × (1–)1.2–1.4(–1.5) µm {2}, subulate, with acute apex, straight to slightly curved, with abrupt, slight to medium inflated, often ± geniculate tail of 1.7–2.6 × 0.6–1 µm, inflated part of tail cylindric-ellipsoid (appendage-like); **SBs** *3–5.2 × 0.4–0.7 µm {5}, subulate, basally inflated, straight to slightly flexuous. **Paraphyses** apically lanceolate or mostly lageniform to mammiform, with beaks of *2–3 × 1.2–1.8 µm (†1.5–3 × 1.2–1.5 µm), also almost cylindrical, terminal cells */†13–20 × 2.2–3.5(–4) µm {3}, exceeding the dead asci by 4–7 µm, lower cells †6–11 × 1.5–1.8 µm {2}; branched only near base, hymenium pale rose-orange. **Medullary excipulum** 20–40 µm thick, pale rose, of dense textura intricata with scattered inflated cells, medium to sharply delimited from ectal excipulum by a 20–30 µm thick layer of pale to light yellow-orange t. porrecta with many inflated cells. **Ectal excipulum** hyaline, of (†) thin-walled, irregularly oriented t. angularis-prismatica from base to mid flanks, 30–50 µm thick at base, cells */†7–20(–25) × 5–13(–17.5) µm {2}; 20 µm thick at mid flanks, horizontally oriented t. angularis(-prismatica), at margin 10–15 µm thick, of t. prismatica oriented at a ∼0–10° angle, marginal cells forming agglutinated **hairs** */†(25–)30–50(–70) × 3–5.5 µm {4}, in upper part 2–3.3 {3} or 3.8–5 {1} µm wide, ∼1–2-septate, cells *(5–)7–14 µm long, cylindrical to slightly moniliform, straight to often ± flexuous, thin- to thick-walled, hyaline, without **glassy processes**, agglutinated to form 20–30 µm thick teeth of 40–80 × 40–80(–150) µm which have inwards curved lageniform paraphysis-like elements at their inward side. **Anchoring hyphae** abundant, */†1.5–3 µm wide, walls 0.2(–0.3) µm thick {T}. **SCBs** in paraphyses and ectal excipulum absent. **VBs** absent {5}, or present in paraphyses as numerous, small to large, globose, medium refractive guttules {1}. **Exudate** over paraphyses absent; over hairs and excipular cells of margin and flanks forming a thin, pale to light yellow covering layer. **— ANAMORPH**: dicranidion/trinacrium-like (from natural substrate {8}, molecular data from conidial isolate {1}). **Conidiophores** not observed. **Conidia** 2- or more often 3–4-armed by dichotomous branching, arms diverging though subparallel at the base, gradually taperings towards apex, outer arms often outwards curved, all arms apparently in one plane or somewhat contorted, total size *(45–)50–62(–70) × (37–)45–62(–90) µm when 3–4-armed, *54–60 × 15–25(–45) µm when 2-armed, stipe *15–24 × 2.5–3.5 µm, (1–)2–3-septate, arms *(24–)30–40(–55) × 3.5–4.3 µm, 3–6(–7)-septate {T}.

Habitat: collected 0–3 m above the ground, on 4–40 mm thick, ± corticated or decorticated, still-attached branches but also 25–30 cm thick trunks of *Euonymus europaeus* {1}, *Ficus carica* {6}, *Hibiscus syriacus* {1}, *Juglans regia* {2}, *Magnolia* sp. {1}, *Populus* sp. {2}, *P. alba* {1}, *Sambucus nigra* {1}, *Tilia* sp. {3}, *Ulmus laevis* {2}, on slightly to strongly decayed bark (periderm & bast) {14} or wood {6}, on outer surface or in cracks of periderm, partly close to old immersed pyrenomycete, green algae sparse to abundant. **Associated**: *Capronia pilosella* {1}, *Helminthosporium velutinum* {2}, *Hohenbuehelia cyphelliformis* {1}, *Letendraea helminthicola* {1}, *Nectria peziza* {1}, *Orbilia comma* {2}, *O. eucalypti* {1}, *O. ?fraxini* {1}, *O. pilifera* {1}, *O. siculispora* {1}, *O. vitalbae* {1}, *Patellaria atrata* {1}, *Strossmayeria basitricha* {1}, *Xanthoria parietina* {2} and other lichens. **Desiccation tolerance**: a few ectal excipular cells and some conidia still viable after 1.5 years. **Altitude**: 83–413 m a.s.l. **Geology**: alluvial deposits from Upper Jurassic, Cretaceous & Tertiary lime- & marlstone, flysch, Tertiary molasse. **Phenology**: IV, VI–VII, IX–I (throughout the year, long-lived).

Taxonomic remarks. *Orbilia ficicola* closely resembles *O. siculispora*, the Hawaiian *O. abutilonis*, and the North American *O. subsiculispora* in shape of ascospores and other elements of the teleomorph. The mostly striking difference in the fresh apothecial colour permits macroscopical distinction between *O. ficicola* (pinkish-rose) and *O. siculispora* (orange-ochraceous) which in one Slovakian sample even grew on the same branch. However, for *O. abutilonis* both colours are mentioned in the protologue, and for *O. subsiculispora* the orange-rose colour seems to be intermediate between *O. ficicola* and *O. siculispora*.

O. siculispora and *O. subsiculispora* appear to differ from *O. ficicola* and *O. abutilonis* in the marginal hairs which are in the latter two species distinctly narrower in their upper part and more flexuous and agglutinated by yellowish exudate. However, one of the two Austrian samples tentatively referred here to *O. ficicola* (from Fernitz) was described by Friebes (2011, as *O. abutilonis*) with orange- to wine-reddish apothecia (more pinkish on the photo, IVV: G.F. 20090004) and straight untapered hairs, and also the other (from Halbenrain, data on hairs unavailable) shows pinkish apothecia (Pl. 473: 4).

Two samples on *Juglans* (Serbia, IVV: 27.IX.2019; Slovakia, IVV: 25.XII.2019) fit *O. ficicola* in their rosaceous disc, spore length, and hair morphology. Based on their apothecial colour we have also tentatively considered Austrian collections on *Populus* and *Ulmus* as belonging to *O. ficicola*. The taxonomic value of disc colour is supported by DNA data

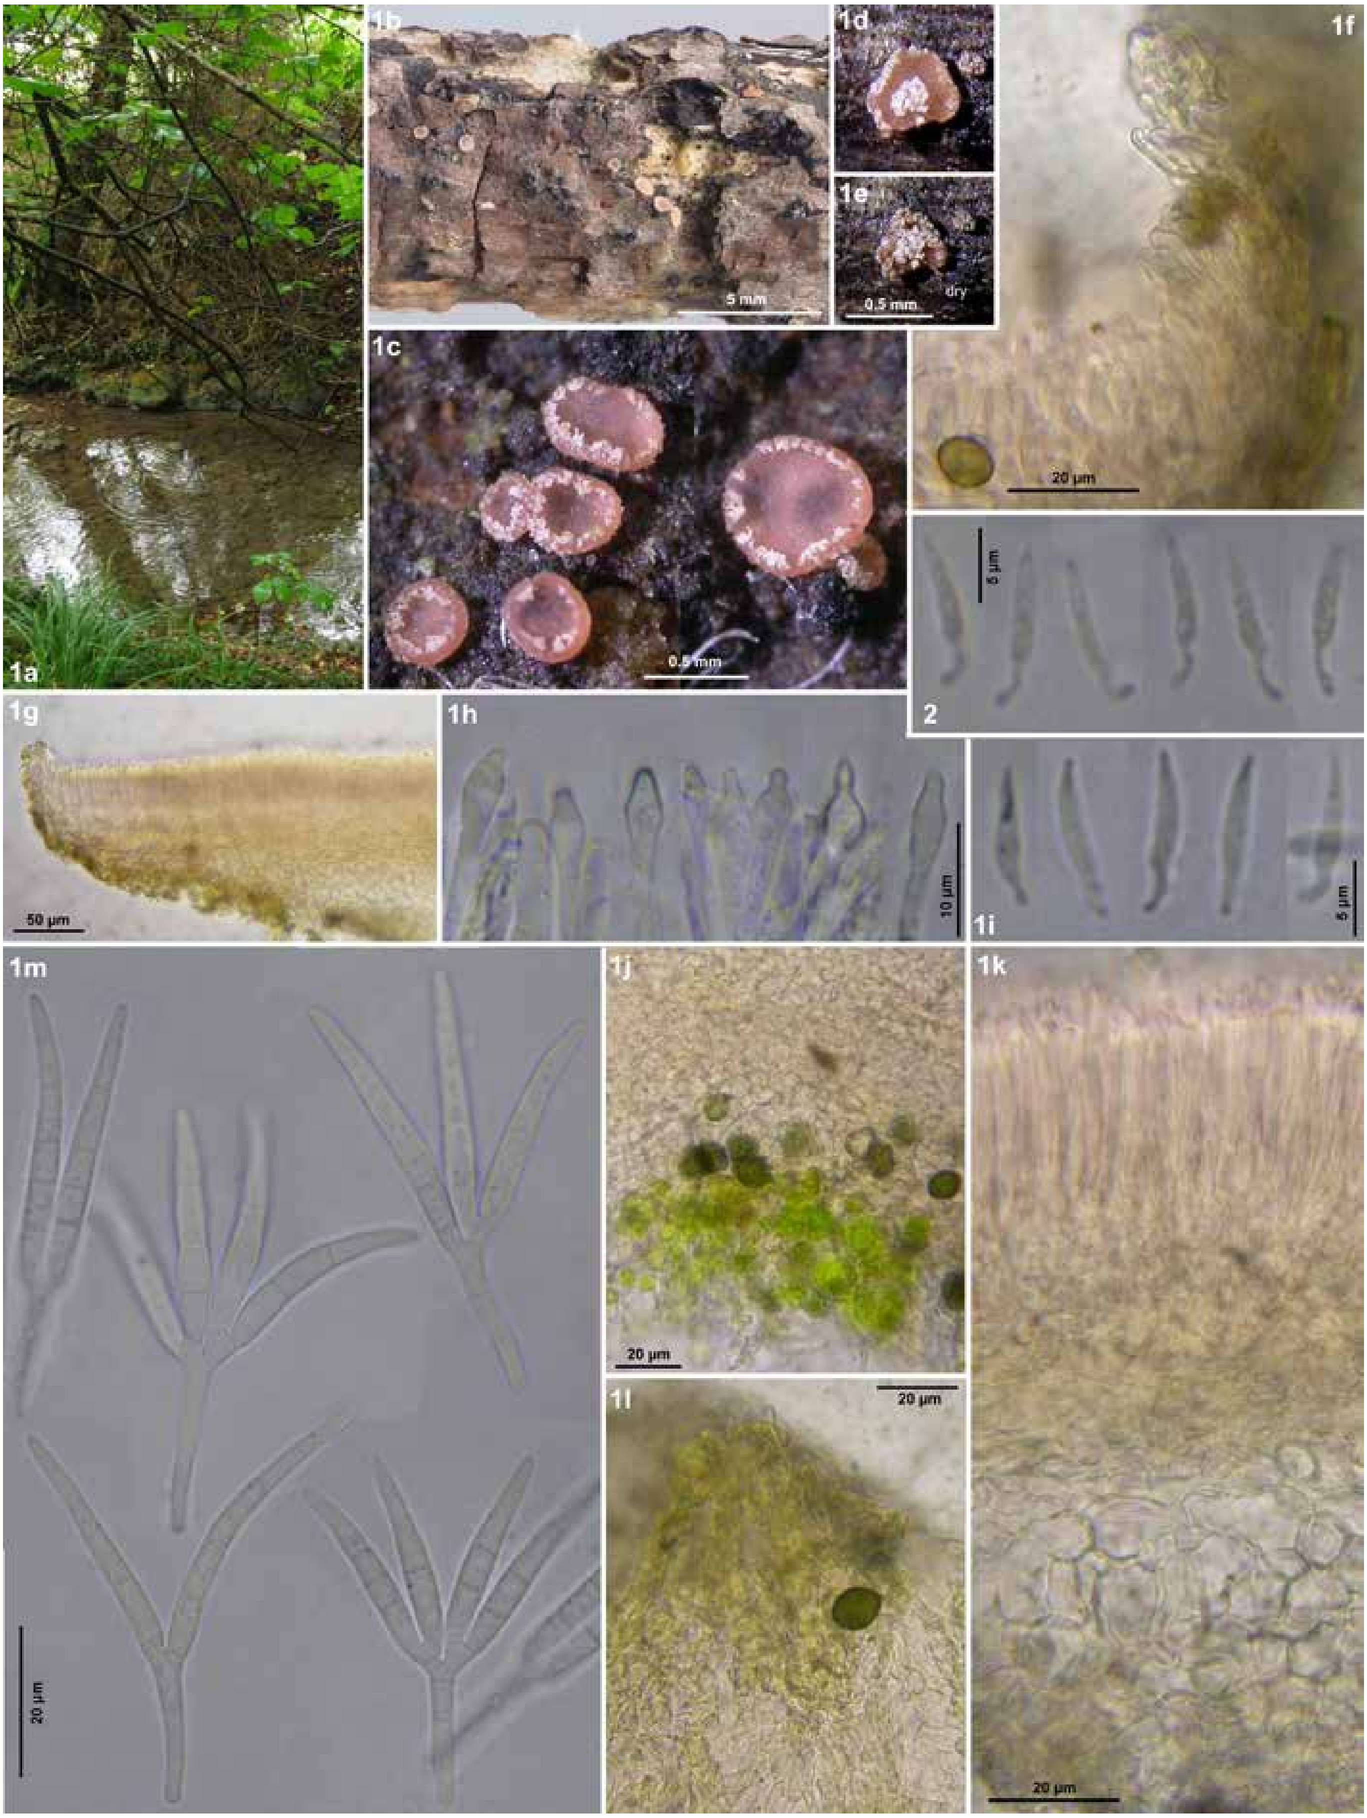

Plate 472. **1–3**: *Orbilia ficicola* (France, on *Ficus*). – **1a**. from a Slovakian sample on a *Populus* branch in which both species co-occur as populations with sharply different colour (IVV: 17.XI.2019, A.P. 19/36a/b).

The observed severe differences in both conidial shape and rDNA data prompted us to distinguish *O. ficicola* from *O. siculispora*. *O. abutilonis* appears to be very close to *O. ficicola*, from which it is tentatively separated by narrower spores with a stronger subbasal constriction and perhaps by conidial shape. Since no conidia and rDNA data were available for most of the Austrian samples, their correct identity remained uncertain.

Variation. The hairs are usually somewhat flexuous and taper in their upper half (observed on *Ficus*, *Tilia*, and *Populus*), sometimes also straight and tapering only at apex of terminal cell (on *Populus*, Friebes 2011: fig. 4e). In the former case they resemble those of *O. abutilonis*, otherwise those of *O. siculispora*. Because many samples were not examined for this character, the taxonomic value of hair shape remains tentative.

In the Slovakian sample on *Populus* the paraphyses were only indistinctly lanceolate or even cylindrical and filled with numerous conspicuous globose VB-guttules (IVV: 17.XI.2019). These guttules occurred also in the associated ochre-coloured population of *O. siculispora*. The Hungarian sample was said to have rather short spores of only 6.5–8 × 1.5 µm (in KOH).

Anamorph. Dicranidion/trinacrium-like conidia were observed near apothecia in all French samples on *Ficus* and in the Austrian collections on *Tilia* and *Hibiscus* (Pls 472: 1m; 473: 1g). In their thinner, outwards curved arms they resemble the single conidium observed in *O. abutilonis*. Their strongly diverging arms sharply separate these two taxa from the anamorphs of *O. siculispora* in which the conidial arms are wider, straight and ± parallel (Pls 466: 1g; 467: 4; 468: 1j). No conidia developed in the ascospore isolate of *O. ficicola*, but a pure culture gained from conidia from the natural substrate proved to belong to the teleomorph based on molecular data gained from it.

Not included collections. Two Austrian samples from Steiermark on *Juglans* (ascospores *8–10 × 1–1.5 µm, IVV: 18.II.2017, 24.XI.2018) were not included in either description, because their orange-ochraceous discs point to *O. siculispora*.

Phylogeny. A sequence covering the almost entire rDNA derives from an ascospore isolate of the holotype of *O. ficicola* on *Ficus*. Further sequences were gained from a conidial isolate of the holotype and from apothecia of the Austrian sample on *Tilia*, three Slovakian ones on *Euonymus*, *Juglans* and *Populus*, and one from Hungary on *Sambucus*. All comprise S1506 intron, ITS, and LSU D1–D2, two Slovakian ones LSU D1–D5. The sequences of these six samples are fully identical in their overlapping part, except for 1 deviating nt in the ITS2 and one in LSU D1 of the Hungarian sample. When analysing ITS+LSU or LSU alone, *O. ficicola* clustered with *O. siculispora* (distance 15.5% in intron, 12% in ITS, 1.5% in LSU D1) and *O. ebuli* (11% in intron, 15% in ITS, 4% in LSU D1–D2) in a strongly supported clade (Phyls 13, S16). Also in the intron it clustered with medium support with *O. ebuli* in a clade (10.5% distance, S14).

Ecology. In southern Europe, *O. ficicola* was collected on rotten bark of xeric branches of *Ficus carica*, mainly in small dense mixed angiosperm woodlands with *Fraxinus*, *Ulmus* etc. along rivulets and close to roads, once also on a free-standing tree, at six different calcareous sites in the suprasub- to mesosubmediterranean semihumid lower Rhône valley in southern France. Further collections were on xeric wood and bark of twigs, branches, and trunks of *Euonymus*, *Juglans*, *Populus*, *Sambucus*, *Tilia*, and *Ulmus* in thermophilous forests of cold-temperate humid eastern Austria, southwestern Slovakia, northern Hungary, and northern Serbia. The vegetation includes floodplain forests with *Acer campestre*, *Fraxinus*, *Sambucus*, *Populus alba*, *Prunus padus* etc. along rivers (Graz and Bratislava), but also rich oak forests with *Quercus cerris*, *Sambucus nigra*, *Crataegus monogyna*, and *Pyrus pyraster* (Vértes Mt.), or *Querco-Carpinetum* with *Acer*, *Corylus*, *Fagus*, *Fraxinus ornus*, *Tilia tomentosa*, and *Staphylea pinnata* (Fruška Gora). The samples on twigs of *Magnolia* and *Hibiscus* are from a village garden near Graz.

Specimens included. **FRANCE**: **Rhône-Alpes**, **Ardèche**, 1.5 km SSE of Vallon-Pont-d'Arc, S of La Combe St.-Pierre, 90 m, branches of *Ficus carica*, on bark, 12.IX.2016, G. Orbilia suberis Baral & R. Galán, **sp. nov.**,
MB 813767 — Pls 474–475

Etymology: referring to the substrate, *Quercus suber*.

Typification: Spain, Málaga, Ronda, trunk of *Quercus suber*, 26.II.2003, F. Prieto & A. González (AH 7564, holotype).

Latin diagnosis: *Apothecia rehydratata 0.8–2 mm diam., vivide lutea ad aurantio-ochracea, sessilia, margine valde fimbriato. Ascosporae *6.5–9 × 1–1.2 µm, cylindricae, apice (sub)acutae, basi rotundatae, ad basim non vel leniter et gradatim inflatae, leniter vel valde curvatae, in statu vivo corpusculum refringens filiformem vel subulatum continentes. Paraphyses ad apicem vix inflatae, spathulatae-sublanceolatae. Margo excipuli pilis longis, tenuitunicatis, 1–2-septatis, absque processis vitreis. Habitat ad corticem putridum in trunco sicco* Quercus suberis *in zona mesomediterranea semihumida Europae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated (0.5–)0.8–1.7(–2) mm diam., 0.3–0.4 mm high (receptacle 0.13 → 0.07 mm), light to bright yellow- to orange-ochraceous, non-translucent, round, moderately gelatinous, subgregarious in small groups; disc slightly to medium concave, margin distinctly hairy-fimbriate; sessile on a broad obconical base, superficial; dry bright orange-red.

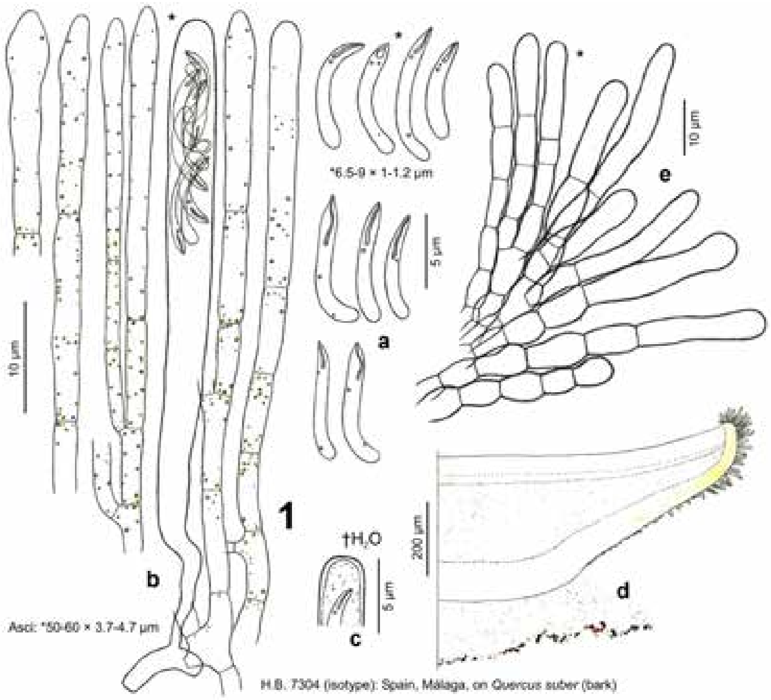

Plate 474. **1**: *Orbilia suberis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. apothecium in median section; **e**. id., marginal ectal excipulum with hairs.

Asci *50–60 × 3.7–4.7 µm, †45–61 × 3–3.5 µm, 8-spored, spores *3–4-seriate, 3–4 lower spores inverted (very often mixed, partly also only upper spores inverted), pars sporifera *17–21 µm long; **apex** (†) medium truncate (never indented, laterally not widened); **base** with medium to very long, thin, flexuous stalk, T- to L-shaped. **Ascospores** *6.5–9 × 1–1.2 µm (~7.5–10 µm actual length), cylindrical, apex subacute to acute, base rounded, often very slightly and gradually widened, slightly to strongly curved, subhelicoid; **SBs** *1.7–3.3 × 0.2 µm in situ, filiform to narrowly subulate, straight to ± flexuous; SBs in aged spores tear-shaped, 1.3 × 0.5 µm. **Paraphyses** apically uninflated or mostly slightly (to medium) spathulate or obtusely lanceolate, terminal cells *(10–)18–28 × 2–4 µm, ± equalling the living asci, lower cells *6–11(–18.5) × 2–2.6 µm; unbranched at upper septum, hymenium pale yellow. **Medullary excipulum** hyaline, 100–200 µm thick, of very loose textura intricata without inflated cells, hyphae *1.5–2.5 µm wide, embedded in ample non-refractive gel, very sharply delimited from ectal excipulum, subhymenium 20–30 µm thick, of dense, pale yellowish-orange t. intricata. **Ectal excipulum** very pale yellowish-orange near base, of (*) thin-walled to slightly gelatinized, vertically oriented t. globulosa-angularis-prismatica from base to lower flanks, 70–100 µm thick near base, cells *7–16(–25) × 5–12 µm; 30–60 µm thick at lower flanks, 25–30 µm at mid flanks and margin, here of bright yellowish-orange t. prismatica, cells *7.5–11 × 4–6(–7) µm, oriented at a 50–80° angle to the surface, containing many small yellow LBs, marginal cortical cells running out into free, non-agglutinated **hairs** *25–65 × 5–6.3(–7) µm, 1–2-septate, cylindrical, smooth, thin-walled (wall *0.2–0.3 µm thick, at base of hair up to 0.4 µm); **glassy processes** absent. **Anchoring hyphae** very abundant, *1.5–4 µm wide, walls 0.2–0.3 µm thick, partly with inflated, ± moniliform elements *5–7 µm wide, embedded in thick non-refractive gel, forming a very loose, ~100–250 µm thick hyaline t. intricata. **SCBs** in paraphyses and ectal excipulum absent; paraphyses with quite many minute, light yellow **LBs** (carotenoids). **Exudate** over paraphyses and excipulum absent. — **ANAMORPH**: unknown (but see below).

Habitat: collected 1.75 m above the ground, on uneven exterior of 7 years old, undetached bark (cork) of a living, ~1 m thick trunk of *Quercus suber*, strongly decayed, ± greyed, without algae. **Associated**: none observed. **Desiccation tolerance**: a few excipular cells still viable after 10 months. **Altitude**: 675 m a.s.l. **Geology**: Tertiary clay, marl, lime- & sandstone. **Phenology**: II (but long-lived).

Taxonomic remarks. Macroscopically *O. suberis* is characterized by rather large, yellow-ochraceous, hairy apothecia and herein much resembles *O. pilifera*. Even the hairs are of the same type. Yet, *O. suberis* greatly differs in much narrower, strongly curved ascospores with filiform SBs. More closely related to *O. suberis* seem to be species around *O. abutilonis*, which differs in basally constricted, less curved spores. *O. suberis* further differs from these two taxa in not or hardly lageniform paraphyses.

Extraordinary in this species is the gel which forms thick sheaths over the anchoring hyphae and the hyphae of the medullary excipulum, and which is responsible for

Plate 475. **1**: *Orbilia suberis*. – **1a–e**. rehydrated apothecia; **1f**. dry apothecia (H.B. 7304, isotype); **1g–h**. fresh apothecia (AH 7564, holotype, phot. R. Galán). — **1a–h**. Spain, Málaga, on *Quercus suber*.

the gelatinous consistency of the apothecia. Due to its low refraction, the gel is quite invisible, but can be visualized by staining bright lilac in CRB.

Anamorph. A single Y-shaped, dicranidion-like conidium (*16.5 × 10.5 µm, IVV: H.B. 7304) was seen near the apothecia, which might represent the anamorph of *O. suberis*.

Ecology. The rich collection of *O. suberis* was made on rotten xeric bark still-attached to the living trunk of *Quercus suber* in a mesomediterranean semihumid mixed forest of *Quercus suber* and *Q. faginea* var. *canariensis* on a southwest-exposed slope in the Serranía de Ronda, a part of Sistema Bético, at the eastern end of Sierra de Grazalema in southern Spain. The old cork oak trees were perhaps not planted but are protected in order to extensively harvest the cork every 10 years at a height of 0.5–2.5 m above the ground. The *Orbilia* grew on the newly formed bark 7 years after the last harvest.

Specimens included. **SPAIN**: **Andalucía**, **Málaga**, Sistema Bético, Sierra de la Sanguijuela, 7 km WNW of Ronda, Puerto de la Calerilla, 675 m, trunk of *Quercus suber*, on bark, 26.II.2003, F. Prieto & A. González (AH 7564, **holotype**; H.B. 7304, **isotype**).

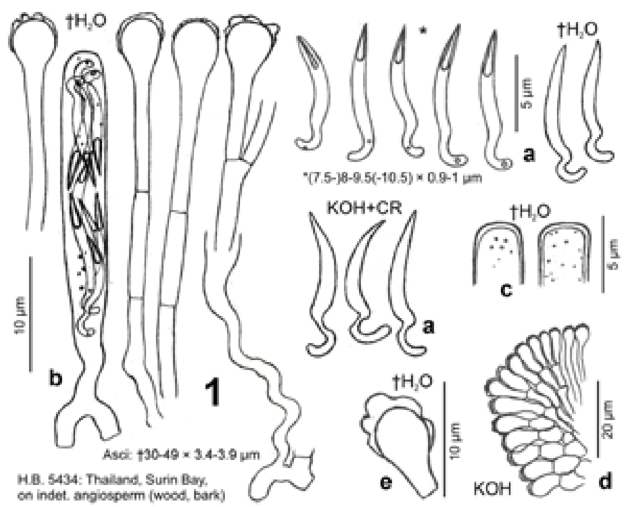

Plate 476. **1**: *Orbilia milinana*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section; **e**. cortical cell with exudate.

Orbilia milinana Bin Liu, Xing Z. Liu, W.Y. Zhuang & Baral, Fungal Diversity 22: 113 (2006) — Pls 476–477

Etymology: named after the collection site (Milin, Tibet) where the holotype was found.

Typification: China, Tibet, Zhaxiraodengxiang, wood of *Juglans regia*, 21.VII.2004, B. Liu & X.Z. Liu (HMAS 96813, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–1.2 mm diam., 0.1–0.27 mm high, (very) pale yellow {2} or light cream {1} or pale to light rose-red {2}, semitranslucent, ± round, scattered; disc flat, margin indistinct, not protruding, smooth; sessile on a broad base, superficial; dry light yellow to orange-buff or rose-red. **Asci** *43–50 × 3.5–4 µm {1}, †(30–)33–45(–49) × (3–)3.4–4 µm {2}, 8-spored, spores (*/†) 4-seriate, 3–4 upper spores inverted (not or sometimes mixed) {3}, pars sporifera *19 µm long; **apex** (†) medium to strongly truncate (not indented, laterally not or scarcely widened); **base** with short to long, thin, flexuous stalk, T-, Y-, also H-shaped. **Ascospores** *(7–)7.5–9(–10.5) × 0.9–1.3 µm {6} (~8–11 µm actual length), †7.5–9.5 × 0.8–1 µm {1}, narrowly fusiform, apex gradually strongly acute († also acuminate), upper part slightly to medium curved (falcate, very slightly helicoid), lower ~1/4 of spore abruptly ± strongly reflexed and slightly to medium († more strongly) constricted by forming a short tail of 2–2.7(–3.3) × 0.7–0.8 µm which is mostly strongly bent forward to form a hook; **SBs** *(2.3–)2.5–3.5(–4) × (0.3–)0.5–0.7(–0.9) µm {3}, narrowly tear-shaped to subulate {1} or divided into a tear-shaped lower part and a short filum {T}. **Paraphyses** apically uninflated or slightly to medium clavate (to spathulate) {2}, or medium to strongly clavate-capitate {1}, terminal cells *17–26 × 2–3.3 µm {2}, †12–18 {1} × †2.5–3.1 {T} or (2.5–)3.5–4.5(–5) µm {1}, exceeding the dead asci by 3–7 µm, lower cells †7–9 × 1.2–2(–3) µm {1}, sometimes branched at upper septum. **Medullary excipulum** 15–30 µm thick, of (medium) dense, non-gelatinized textura intricata with many inflated cells, sharply or indistinctly delimited. **Ectal excipulum** of thin-walled, vertically oriented t. globulosa-angularis from base to margin, 40–100 µm thick near base, cells */†12–18 × 10–18 µm {1}; at flanks of t. angularis, cells *5–10 × 4–6 µm {1}, †5.5–13 × 4–11 µm {2}, 15–30 µm thick near margin, oriented at a 70–90° angle to the surface, marginal cortical cells *5–8 × 4–5.5 µm {1}, †6–12(–15) × 3–4.5 µm {2} (4–6 µm wide at submargin); **glassy processes** absent {4}. **Anchoring hyphae** abundant, 2–2.5(–3.2) µm wide, walls 0.2 µm thick {3}, forming a loose t. intricata. Living paraphyses without obvious inclusions {2} or containing globose **SCBs** {2} along with elongate, medium refractive **VBs** {2}. **Exudate** over paraphyses, margin and flanks rough-cloddy, (0.2–)0.5–1(–2.2) µm thick, forming isolated, firmly attached caps on each cell; at margin 0.2–1 µm thick, ± warted-cloddy. — **ANAMORPH**: unknown.

Habitat: lying on ground or 0.5–2 m above the ground, corticated, 7–15 mm thick branches or trunks of *Euphorbia canariensis* {1}, *Juglans regia* {T}, *Malus domestica* {1}, indet. angiosperm trees {2}, on medium decayed wood {3} and bark {2} (periderm), partly at splitted or broken end of branch, bark detaching; on petiole of *Arecales* {1}; ungreyed, partly covered by abundant green algae. **Associated**: ?*Opegrapha* sp. {1}, ?*Thaxteriella pezizula* {1}. **Desiccation tolerance**: basal ectal excipular cells and ascospores still viable for at least 2.5 weeks. **Altitude**: 15–2950 m a.s.l. **Geology**: China: Jurassic-Cretaceous sedimentary rock; Serbia: sericitic shale & quartzite, phyllite (near limestone); Tenerife: basaltic flow. **Phenology**: III, VII, XI (apparently throughout the year).

Taxonomic remarks. *Orbilia milinana* is characterized by very peculiar ascospores with acute apices and strongly geniculate, hooked bases (with the hook pointing forward, i. e., away from the curved dorsal side), also by the inverse orientation of the upper spores within the asci. In spore morphology the species closely resembles *O. abutilonis*, *O. ficicola*, and *O. siculispora*, which differ in less hooked spore bases and particularly in septate hairs at the margin and paraphyses with lageniform (beaked) apices.

O. lobeliae from Ethiopia might belong in the scope of *O. milinana*, judging from spore shape, especially when comparing the Chinese samples. However, its spores are distinctly narrower, and the SBs much smaller, especially shorter. Contrary to *O. milinana*, the basal spore hook points backward. Moreover, the rose-orange apothecia and the absence of VBs in the living paraphyses differ from *O. milinana* which has a yellowish-cream colour when fresh (seemingly whitish on the photo, Pl. 477: 2a).

Variation. The holotype from Tibet (Pl. 477: 2) concurs rather well with samples from Thailand (Pl. 476), Macaronesia, Puerto Rico, and Serbia (L. Quijada and D. Savić pers. comm., IVV: TFC Mic. 23222, 15.VII.2018, 29.XI.2019), also with a collection from Yunnan (Pl. 477: 3) studied by Y. Zhang and Z.F. Yu (pers. comm.), in which the paraphyses tend to have a slightly conical, spathulate apex. The sparse collection from Thailand differs in rather narrow spores and slightly shorter SBs, perhaps also in the SBs being subulate and attached without a distinct filum, moreover in more inflated paraphyses

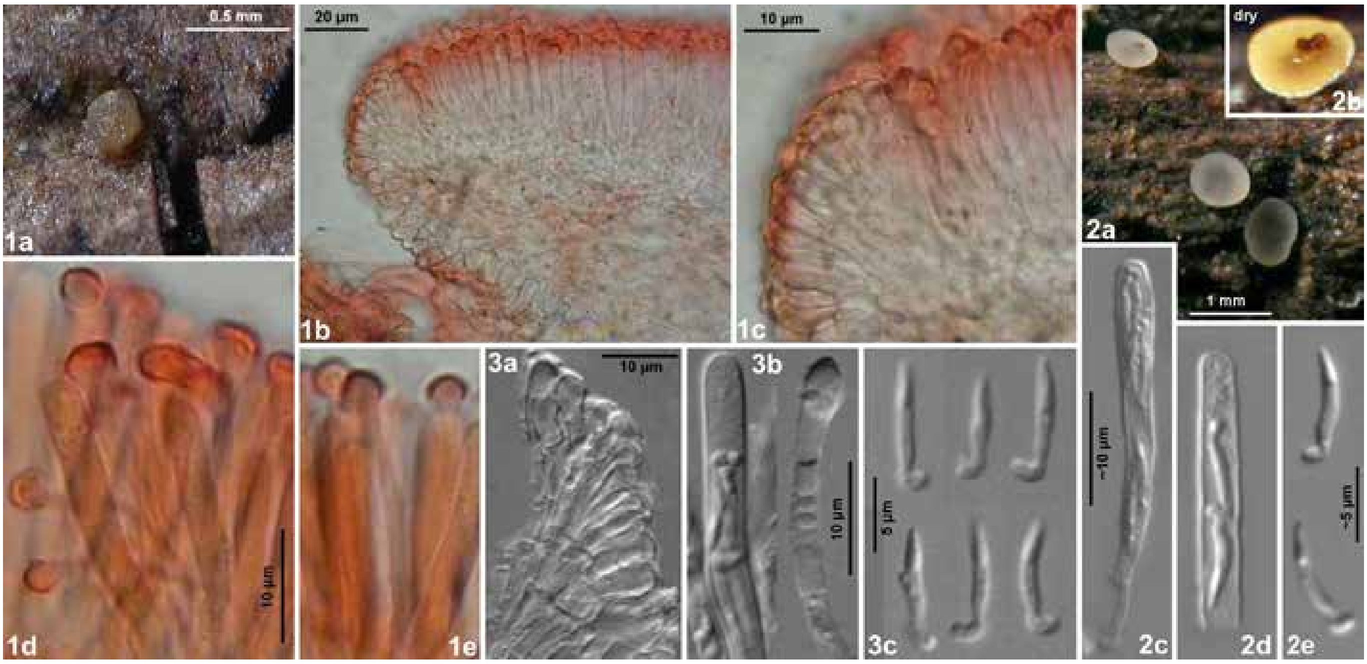

Plate 477. **1–3**: *Orbilia milinana*. – **2a**. fresh apothecia; **1a**. rehydrated apothecium; **2b**. dry apothecium (magnified), **1b**. apothecium in median section; **1c**, **3a**. id., marginal ectal excipulum; **1d–e**, **3b**. asci and paraphyses; **2e**, **3c**. ascospores. – Living state, except for **1b–e** (KOH+CR), **3a**, asci in **2c–d**. – **2a–e**: from Liu et al. (2006b, DIC), **3a–c**: phot. Z.F. Yu (DIC). — **1a–e**. H.B. 5434: Thailand, on indet. angiosperm; **2a–d**. HMAS 96813 (holotype): China, Tibet, on *Juglans* (Liu et al. 2006b); **3a–c**. Y.Z. pe-37: China, Yunnan, on indet. angiosperm.

and in smaller, more reddish apothecia, yet, short SBs and reddish apothecia were also observed in the Serbian sample. In the collections from Yunnan and Macaronesia some of the living paraphyses showed inconspicuous VBs, a feature typical of desiccation-sensitive species, but no such VBs were seen in the samples from Puerto Rico and Serbia. However, only a few living paraphyses were seen. The collection from Macaronesia fits well those from China, but in the narrower spores it concurs more with that from Thailand. The spores in the Serbian sample closely resemble those of *O. ficicola* and *O. siculispora*. An error must be mentioned for the scale bar of fig. 3 F in Liu et al. (2006a, b) which should be about 30 % longer.

Spore orientation could more or less be ascertained in five of the included samples. It remained uncertain in that from Puerto Rico, in which it is possible that the lower sp. were inverted and the upper spores not.

Not included collections. Another specimen from Yunnan (Xishan, IVV: ne4-1) differs in distinctly lanceolate paraphyses and herein strongly resembles the North American *O. subsiculispora*. However, that species has distinct marginal hairs, which are entirely absent in *O. milinana*, also the spores of *O. subsiculispora* are mostly only slightly bent at the base, and the lower spores are inversely oriented within the asci. However, in the specimen from Yunnan also some of the lower spores appear to be inverted.

A briefly studied specimen from northern Africa on wood of *Ulmus* (Maire 3055, MPU, IVV: H.B. 5602) might be conspecific. It shows the spore orientation and curved spore base of *O. milinana*, but free spores were not seen.

Phylogeny. Sequences were available for the Macaronesian sample (TFC Mic. 23222, from apothecia, S1506 intron and ITS) and the holotype from Tibet (ITS and LSU, presence of intron unclear). Although they form a strongly supported clade (Phyl. S15), the two strains surprisingly differ by 12 % in the ITS region. The ITS distance to other members of series *Abutilones* lies between 15.5–17.5 % to *O. carminorosea* and 23–24 % to *O. siculispora*. The intron shows a distance of ~ 18–24 % to other species of section *Aurantiorubrae*, and in the LSU (D1–D2) the lowest distance is 6.5 % to *O. siculispora* and *O. ficicola*, and 7.5 % to *O. carminorosea*.

Ecology. *O. milinana* s.l. was collected on rotten substrate of various angiosperms and from very different parts of the world. The holotype was from eastern China (Tibet) on wood of *Juglans regia* in an altimontane (orotemperate), cold-continental humid floodplain forest in the eastern Himalaya. The two south Chinese collections (Yunnan) on hygric branches were from montane subtropical humid (winter-dry) evergreen broad-leaved forests: one in the Xiaoheijiang Forest Park at the southern end of Hengduan Shan, a southeastern extension of Himalaya, and the other from a plateau near Kunming, east of Hengduan Shan. The sample from Thailand was on a xeric branch of a free-standing small tree close to the rocky coastline of the Phuket island, and that from Puerto Rico (Greater Antilles) on a xeric palm petiole, both with a tropical humid monsoon climate.

The European sample was from a living *Malus* tree on the trunk 2 m above the ground on dead wood of a scar where a dead branch broke down, in a supratemperate humid site on Fruška Gora in the suprasubmediterranean Vojvodina in northern Serbia. The sample from Macaronesia was on rotten xeric parts of *Euphorbia canariensis* in an inframediterranean semiarid xerophytic scrubland (cardonal, *Periploco laevigatae-Euphorbietum canariensis*). The not included northwestern African collection was from a subtropical semihumid forest close to the Mediterranean see.

Specimens included. **CHINA**: **Tibet** (Xizang), **Nyingchi**, Mainling, 56 km SW of Nyingchi, 2 km S of Zhaxiraodengxiang, N of Yaluzhangbu River, ~2950 m, on wood of *Juglans regia*, 21.VII.2004, B. Liu & X.Z. Liu (B.L. X098, HMAS 96813, **holotype**, doc. vid., DQ 656631, DQ656685). – **Yunnan**, **Pu'er**, Ning'er, 64 km N of Puér, ~25 km SE of Jinggu, Xiaoheijiang, ~1300 m, indet. branch, VII.2005, Y. Zhang & M. Qiao (Y.Z. pe-37, OT0001, YMFT, doc. vid.). — **THAILAND**: **Southern Thailand**, **Phuket**, Surin Bay, near coastline, 15 m, branch of indet. angiosperm, on bark & wood, 10.III.1996, C. Peller (H.B. 5434). — **MACARONESIA**: **Canary Islands**, **Tenerife**, La Matanza de Ajentejo, 8.5 km NE of Puerto de la Cruz, 1.1 km W of La Matanza de Acentejo, NW of Jagre, Puntillo del Sol, 95 m, on remnants of *Euphorbia canariensis*, 26.VII.2011, L. Quijada (TFC Mic. 23222, doc. vid.; sq.: KF696674). — **SERBIA**: **Vojvodina**: Fruška Gora, 18 km SW of Novi Sad, 2.7 km NNW of Bešenovački Prnjavor, Jabuka, 432 m, branch of *Malus domestica*, on wood, 29.XI.2019, D. Savić (doc. vid.). — **PUERTO RICO**: San Juan, Parque Nacional Julio Enrique Monagas, 37 m, indet. *Arecales*, on petiole, 15.VII.2018, L. Quijada (doc. vid.).

Not included. **ALGERIA**: **Algiers**, 63 km WSW of Algiers, 2 km NW of Hadjout ('Marengo'), forêt de Hadjout (Sidi Slimane), 60 m, on wood of *Ulmus campestris*, 14.I.1915, R. Maire (3055, MPU, as '*O. rubella* var.', H.B. 5602 ø). — **CHINA**: **Yunnan**, **Kunming**, ~12 km SW of Kunming, Xishan, ~1900 m, on indet. branch, S.F. Li and J.W. Guo, VII.2007 (J.W.G. ne4-1, YMFT, doc. vid.).

Orbilia lobeliae Baral, **sp. nov.**, MB 813769 — Pls 478–479

Etymology: named after the substrate of the type, *Lobelia giberroa*.

Typification: Ethiopia, Addis Ababa, Menagesha Suba, branch of *Lobelia giberroa*, 26.III.2010, U. Lindemann (ex H.B. 9318, M-0276501, holotype).

Latin diagnosis: *Differt ab* O. milinana *ascosporis ad basim abrupte et valde reflexis, corpusculis refringentibus brevioribus. Habitat ad corticem putridum siccum* Lobeliae giberroae *in zona mesotemperata humida afromontana Africae septentrio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1 mm diam., 0.12–0.15 mm high, light rose-orange, medium translucent, round, scattered or in small groups; disc slightly concave to flat, margin distinct, 5–10 µm protruding, smooth; ± broadly sessile, superficial; dry bright brick-orange. **Asci** *40–47 × 3.8–4.3 µm, †33–45(–50) × 3–3.5 µm, 8-spored, spores *4-seriate, 4–5 upper spores inverted (sometimes mixed); **apex** (†) medium to strongly truncate (not indented, laterally not or slightly inflated); **base** with medium to very long, thin, flexuous stalk, L-shaped. **Ascospores** *7–8 × 0.6–0.8 µm (~8.5–9.5 µm actual length), †7–7.5 × 0.5–0.7 µm, narrowly fusiform, apex acute to acuminate, slightly to medium curved (falcate), tail 2–2.5 × 0.6–0.7 µm, with ± strong constriction and reflexed (hook-like), ± cylindrical inflated part pointing backward; **SBs** *1.5–2 × 0.3–0.4 µm, subulate, straight. **Paraphyses** apically slightly to medium clavate-capitate, terminal cells *16–18 × (2.5–)3–4 µm, lower cells *6–12.5 × 1.5–1.8 µm; unbranched at upper septum, hymenium pale rose. **Medullary excipulum** pale rose, 50–70 µm thick, of medium dense, (†) medium to strongly gelatinized textura intricata with horizontal orientation, with many indistinctly inflated cells, medium sharply delimited. **Ectal excipulum** pale rose, of (†) thin-walled (to slightly gelatinized), vertically oriented t. globulosa-angularis from base to mid flanks, 30–40 µm thick near base, cells *10–20(–28) × 8–18 µm; 15–20 µm thick near margin, of t. prismatica oriented at a 40–60° angle to the surface, marginal cortical cells *5–10 × 3–4 µm; **glassy processes** absent. **Anchoring hyphae** abundant, †1.5–2.5 µm wide, walls 0.2 µm thick, forming a loose hyaline t. intricata 15–50 µm thick. **SCBs** in paraphyses and ectal excipulum absent; **VBs** absent. **Exudate** over paraphyses 0.3–1(–1.5) µm thick, irregularly granular-cloddy, hyaline, firmly attached, over margin and flanks 1–2 µm thick, hyaline to pale yellowish. — **ANAMORPH**: unknown.

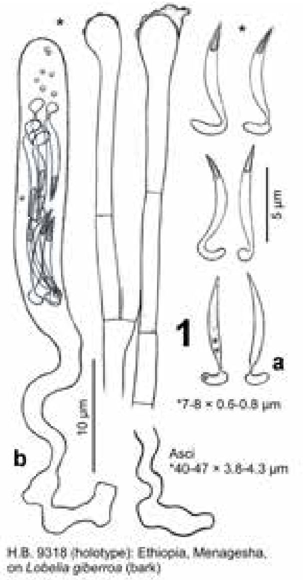

Plate 478. **1**: *Orbilia lobeliae*. – **a**. ascospores; **b**. ascus and paraphyses.

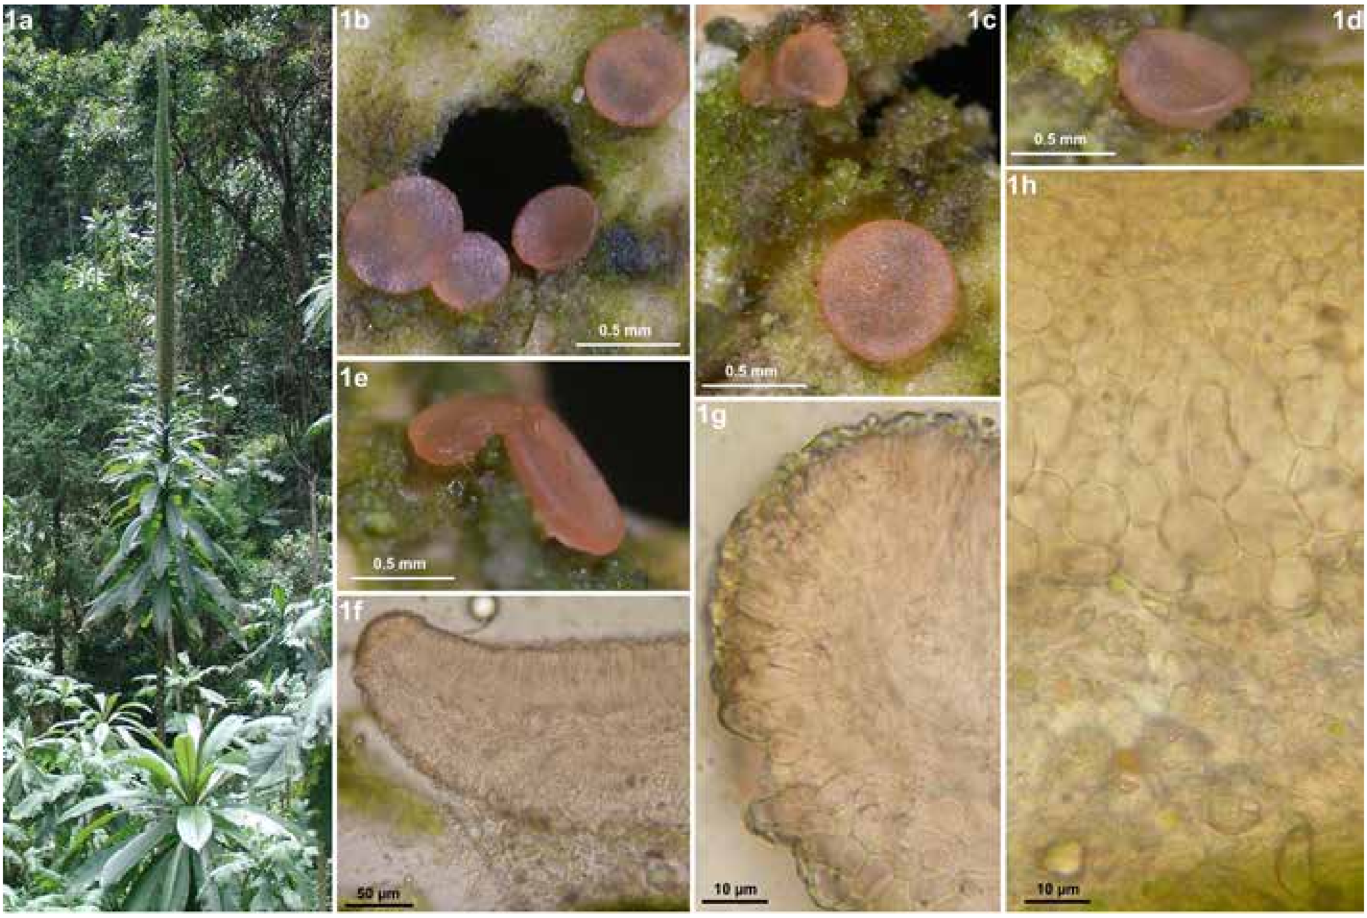

Plate 479. **1**: *Orbilia lobeliae*. – **1a**. warm-temperate afromontane forest with *Lobelia giberroa*; **1b–e**. rehydrated apothecia; **1f**. apothecium in median section; **1g**. id., marginal ectal excipulum; **1h**. id., basal excipulum and anchoring hyphae. – Living state. – **1a**: phot. U. Lindemann. — **1a–h**. H.B. 9318 (holotype): Ethiopia, Menagesha Suba, on *Lobelia*.

Habitat: on a standing, corticated, ?4 cm thick branch of *Lobelia giberroa*, on medium decayed bark (periderm), with many green algae and some black yeasts. **Associated**: *Hyalorbilia brevistipitata* (on separate branch). **Desiccation tolerance**: ± fully viable for at least 1.5 months. **Altitude**: 2520 m a.s.l. **Phenology**: III (but rather long-lived).

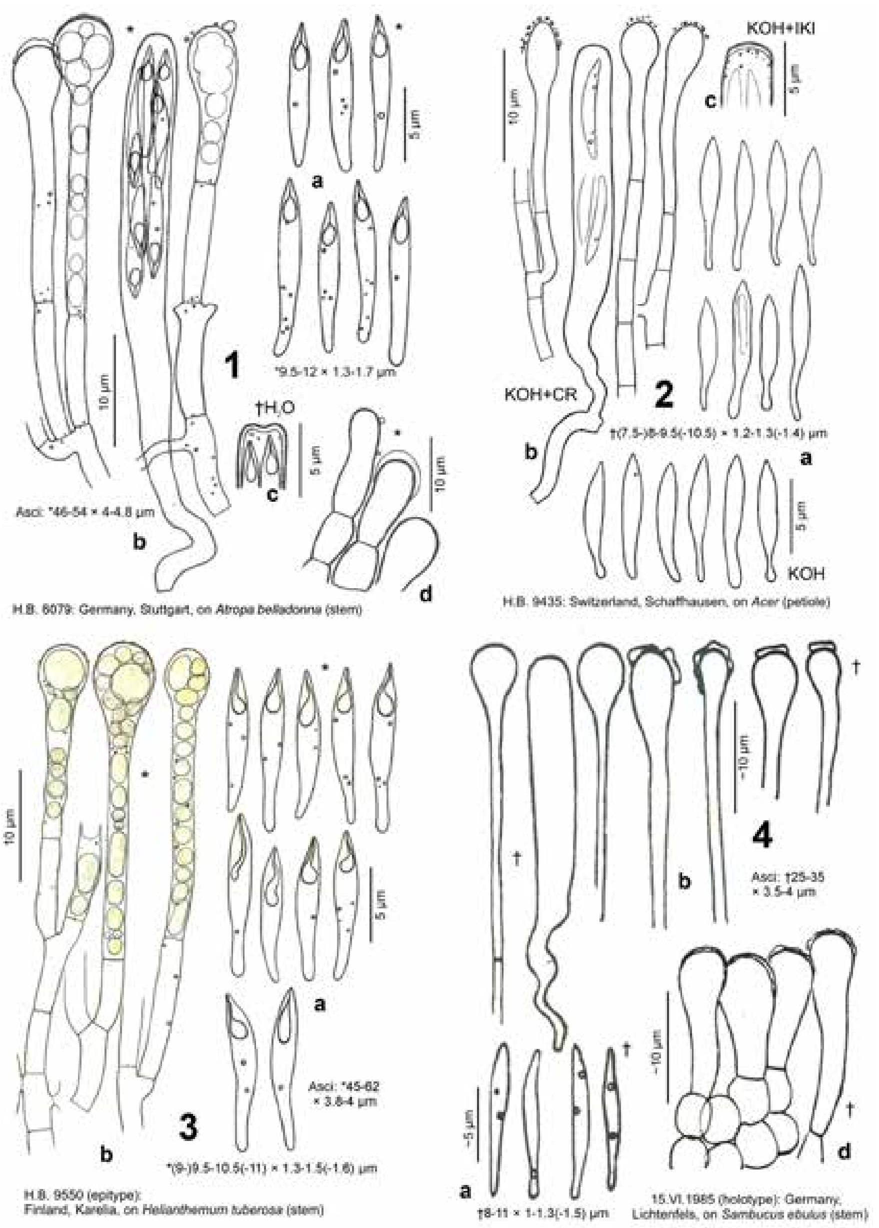
Taxonomic remarks. *Orbilia lobeliae* is easily recognized by its narrow falcate ascospores with a subbasal constriction and a sharply reflexed, ± cylindrical inflated basal end which points in backward direction, also in the upper spores being quite consistently inverted. Species with similar spores (*O. milinana*, *O. abutilonis*, *O. ficicola*, *O. siculispora*, *O. subsiculispora*) differ in the basal end being bent in a forward or ± downward direction, and in distinctly longer SBs.

Ecology. *O. lobeliae* was collected on bark of a xeric branch of *Lobelia* in a warm-temperate humid (somewhat winter-dry), evergreen, predominantly broad-leaved afromontane forest at the western slope of an old volcano in the central plateau of the Ethiopian highlands.

Specimens included. **ETHIOPIA**: **Oromia**, 22 km WSW of Addis Ababa, 10 km NW of Sebeta, southern part of Menagesha Suba State Forest, 2520 m, branch of *Lobelia giberroa*, on bark, 26.III.2010, U. Lindemann (U.L. 0310-22, **isotype**; ex H.B. 9318, M-0276501, **holotype**).

Orbilia ebuli Svrček, Česká Mykol. 41: 22 (1987) — Pls 480–481, Map 84

Etymology: after the host plant, *Sambucus ebulus*. **Typification**: Germany, Oberfranken, Serkendorf, stem of *Sambucus ebulus*, 15.VI.1985, H. Engel (holotype: illustration in Svrček 1987a: fig. 2.4). — Finland, Outokumpu, stems of *Helianthus tuberosus*, 28.V.2011, M. Pennanen (ex H.B. 9550, M-0276476, epitype, designated here, MBT202372; sq.: KT222425).



H.B. 6079: Germany, Stuttgart, on *Atropa belladonna* (stem)

H.B. 9435: Switzerland, Schaffhausen, on *Acer* (petiole)

H.B. 9550 (epitype): Finland, Karelia, on *Helianthemum tuberosa* (stem)

15.VI.1985 (holotype): Germany, Lichtenfels, on *Sambucus ebulus* (stem)

Plate 480. **1–4**: *Orbilia ebuli*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. marginal cortical cells of ectal excipulum. – **4**: from Svrček (1987a).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.5(–0.8)((–1)) mm diam., 0.09–0.2 mm high, (very) pale to light rose-cream (to rose-orange), medium to strongly translucent, ± round, scattered to ± gregarious; disc flat, margin 0–10 µm protruding, finely pubescent or mostly distinctly crenulate to subdenticulate {5}; broadly sessile, seemingly superficial but apparently partly erumpent from splits in epidermis; dry contracted or not, light cream-rose to bright orange-red. **Asci** *45–55(–62) × 3.8–4.8 µm {2}, †(31–)35–46(–52) × (3.1–)3.5–4(–4.3) µm {4}, 8-spored, spores *3–4-seriate, 4–5 lower spores inverted {2} (sometimes strongly mixed), pars sporifera *20–25 µm long; **apex** (†) slightly to strongly truncate (not or slightly to distinctly indented, laterally not widened); **base** with medium to long, thin, flexuous stalk, T- or L-shaped. **Ascospores** *(8–)9–11(–12)((–13)) × 1.3–1.6(–1.7) µm {5}, †(7.5–)8–10.5(–11.3) × (1.2–)1.3–1.5(–1.6) µm {2}, narrowly fusoid(-clavate), often with cylindrical middle part, apex (subacute to) acute (to acuminate), base slightly to strongly attenuated, often forming a tail *2–3.7 × 0.5–0.8(–1) µm, †0.4–0.5(–0.8) µm wide (sometimes with a bulbous base and subbasal constriction), straight to (very) slightly curved near base; **SBs** *2.7–4(–5.5) × 0.7–1.1 µm {4}, divided into an abruptly or gradually swollen, ellipsoid to tear-shaped lower part and a filiform upper part of equal length or slightly shorter, rarely subulate, straight or medium flexuous. **Paraphyses** apically slightly to very strongly capitate(-clavate), rarely spathulate, terminal cells *(14–)17–29 × (2.5–)3.5–5(–5.5) µm {2}, lower cells *5–14 × 1.8–2.7 µm {2}, rarely branched at upper septum. **Medullary excipulum** 20–50 µm thick, of dense textura intricata with indistinct inflated cells, sharply delimited. **Ectal excipulum** of thin-walled, indistinctly oriented t. globulosa-angularis from base to margin, 20–70 µm thick near base, cells *(7–)10–20(–25) × (6–)9–14(–17) µm {3}, †7–15 × 5–8(–13) {1}; 10–20 µm thick near margin, of. t. prismatica-porrecta oriented at a 10–40° angle to the surface, marginal cortical cells *(9–)11–14(–19) × (3.5–)4–5(–6.5) µm {2}, †6–10 × 3–4.5 µm {2}, ± thin-walled, sometimes hair-like but usually coherent to form small teeth; **glassy processes** absent {6} or sometimes present, 2–4 × 2.5–3 µm {1}. **Anchoring hyphae** abundant, */†2–3 µm wide, walls 0.2(–0.3) µm thick {2}, often forming a dense t. intricata 20–70 µm thick at the base, gelatinized or not, sometimes also with globular cells, over flanks and margin sometimes forming a 5–7 µm thick yellowish layer. **SCBs** in paraphyses and ectal excipulum absent {3}; **VBs** absent {1} or abundant in terminal cells of paraphyses {2}, low-refractive, hyaline to pale yellow, deep red-brown in IKI. **Exudate** over paraphyses, margin and flanks 0.1–0.2 µm up to 0.4–1 µm thick, rough to granular, firmly or loosely attached, on marginal cells sometimes cap-like, yellowish. — **ANAMORPH**: unknown.

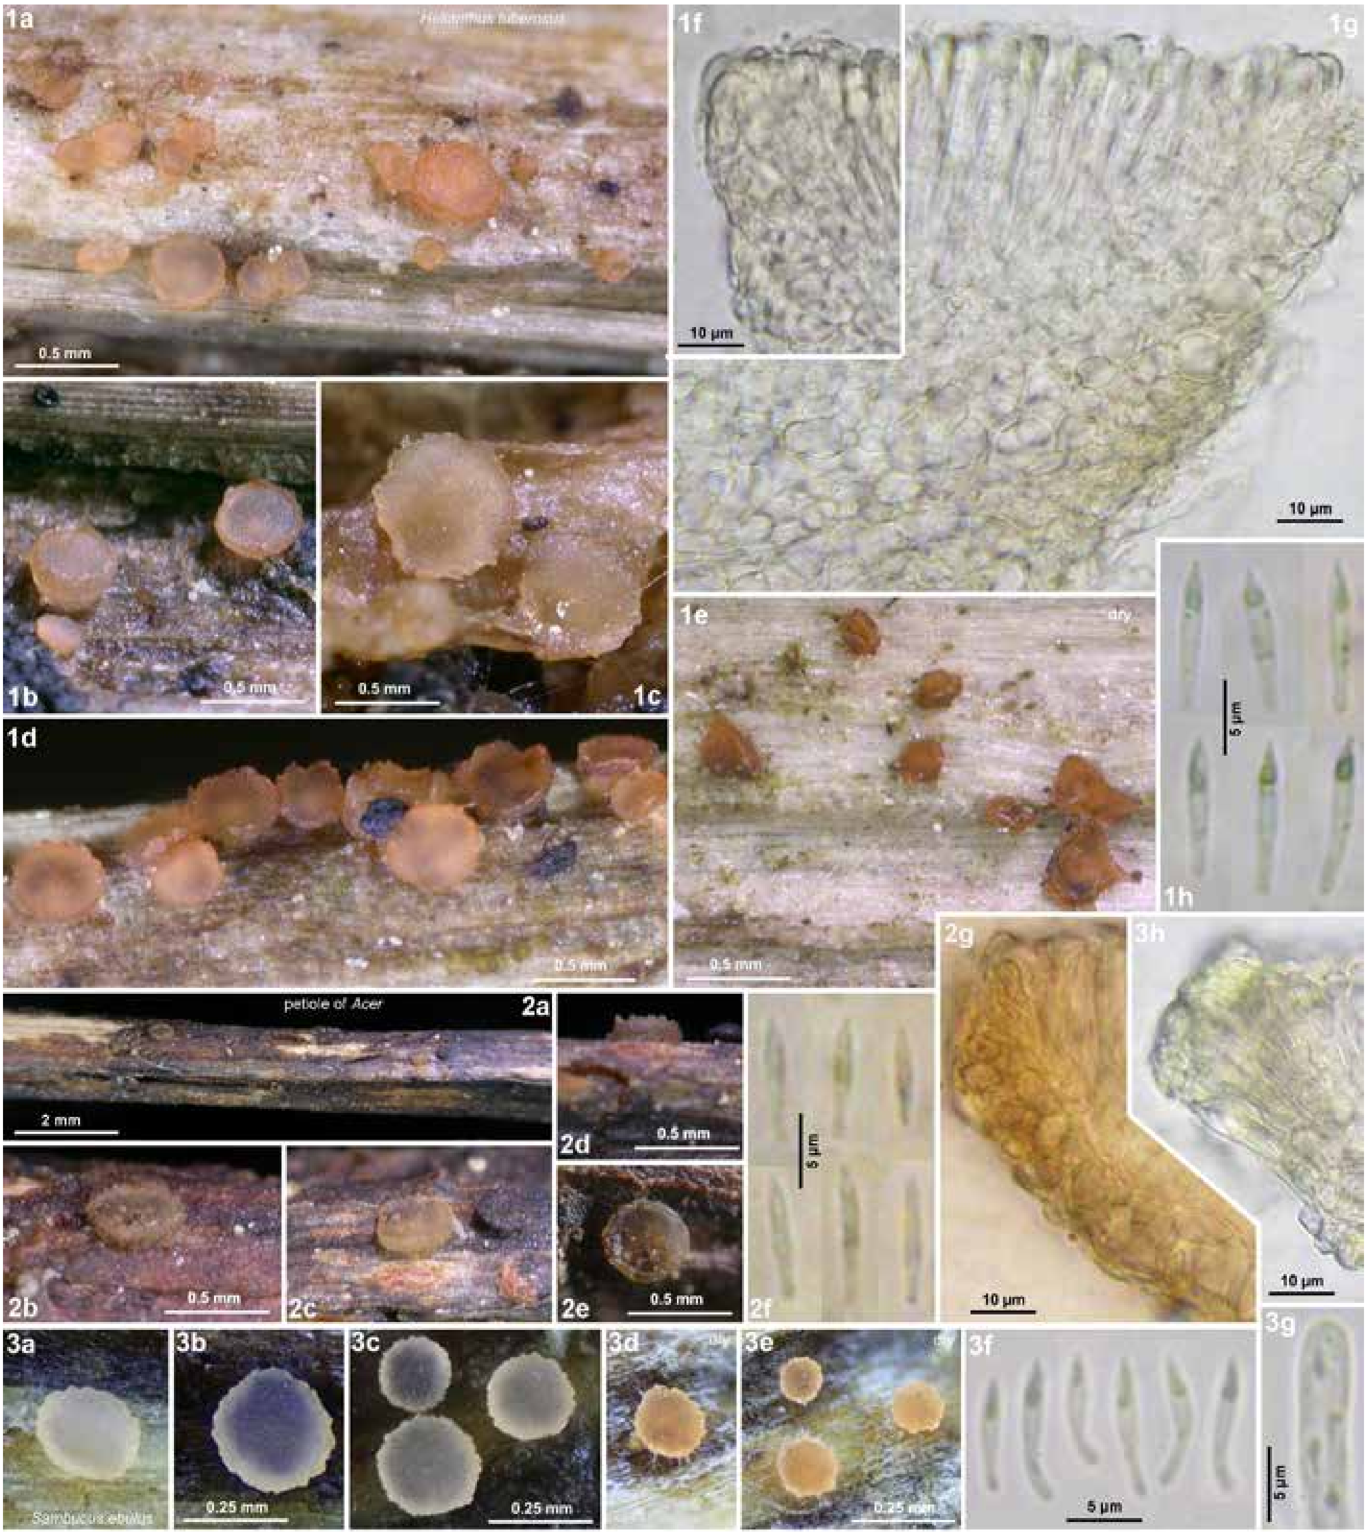


Plate 481. **1–3**: *Orbilia ebuli*. – **1a–d**, **2a–e**, **3a–c**. rehydrated apothecia (**2**: after 24 years); **1e**, **3d–e**. dry apothecia; **1f**, **2g**, **3h**. apothecia in median section (marginal region); **3g**. apex of mature ascus with spores; **1h**, **2f**, **3f**. ascospores. – Living state, except for **2f**, **3h**, ascus in **3g** (in H_2O), **2g** (in KOH). – **3a–g**: phot. S. Tello. — **1a–h**: H.B. 9550 (epitype): Finland, on *Helianthus*; **2a–g**: H.B. 9435: Switzerland, Schaffhausen, on *Acer*; **3a–h**. Spain, Jaén, on *Sambucus ebulus*.

Habitat: on previous year's stems of *Apiaceae* sp. {1}, *Atropa belladonna* {1}, *Helianthus tuberosus* {2}, *Sambucus ebulus* {3}, petiole of *Acer* sp. {1}, ungreyed, sometimes blackened, no algae. **Associated**: *Calycina drosodes* {1}, *Cyathicula ?cyathoidea* {1}, *Pirottaea* sp. {1}, *Pyrenopeziza atrata* {2}, *Trichopeziza mollissima* {1}, *Urceolella crispula* {1}. **Desiccation tolerance**: basal excipular cells and many immature asci still alive after 4 weeks, a few spores after 8 weeks. **Altitude**: 125–1630 m a.s.l. **Geology**: Muschelkalk, Middle & Upper Jurassic limestone, Cretaceous flysch, Pleistocene calcareous sand (moraine), travertine tuff; granite, granodiorite, schist, serpentinite, gabbro, basalt. **Phenology**: III–VI (but rather long-lived).

Taxonomic remarks. *Orbilia ebuli* closely resembles *O. rosella* and was once even recorded on the same substrate (*Atropa*). It differs hereof and also from *O. paravitalbae* mainly in narrower ascospores with ± acute instead of obtuse apices and partly distinct basal tails. The occasional presence of short glassy processes was observed in both species. For the similar but lignicolous *O. somedana* (p. 904) and *O. rehmii* (p. 904) see there. With its rather large, tear-shaped SBs attached by a narrow upper part, *O. ebuli* resembles species of series *Aurantiorubrae* but also section *Helicoon*.

Variation. Apothecia varied in the intensity of the rose-cream colour, also in size. On the type substrate, *Sambucus ebulus*, the specimen from Spain showed the smallest apothecia (0.13–0.31 mm diam.), whereas in the holotype from Germany they were said to be 0.4–1 mm large. The collection on *Acer* showed a tendency of the spore tails to be constricted similar as in the type on *Sambucus*, but this constriction is apparently mainly present in the dead state. In the samples on *Atropa* and *Helianthus* the asci were longer than in the other ones, while the length given in the protologue might not include the entire ascus stalk. In that on *Atropa* the SBs are ± straight (Pl. 480: 1a), whereas in those on *Helianthus* (Pls 480: 3a; 481: 1h) and *Sambucus ebulus* they are partly distinctly flexuous. Indented ascus apices were seen in the *Atropa* collection but never in those on *Acer* and *Helianthus.* Short glassy processes at the margin were only observed in the Spanish specimen (Pl. 481: 3h).

Type studies. Authentic material of *Orbilia ebuli* could not be located in Svrček's herbarium, nor in the herbarium of PRM (M. Chlebická pers. comm.). The protologue, which was based on a single collection, mentions a duplicate in Heinz Engel's private herbarium, but also there no type material could be found (H. Engel pers. comm.). In the lack of a voucher specimen, the illustration added to the protologue, from which a few details are included in the above description, must serve as holotype (Arts 8.1, 40.4 ICN). For a more precise typification we here designate a rich collection on *Helianthus* from Finland (ex H.B. 9550), studied in the living state and well corresponding to the original description (Fig. 4), as **epitype** of *Orbilia ebuli* (Pl. 480: 3). The epitype concurs morphologically also well with a recent Spanish sample on the type substrate, *Sambucus ebulus* (Pl. 481: 3).

Although a photo of a paratype collection of *O. ebuli* (Engel et al. 1987: 67, pl. 55 fig. 213) shows whitish apothecia, Engel & Hanff (1987: 67), Engel et al. (1987: 67) and Svrček (1987a) described them as rose or grey-rose when fresh, 0.4–1 mm diam., turning orange(-yellow) when dry, with a 'finely and indistinctly subdenticulate margin'. The paraphyses are described as apically oblong-clavate to subglobose-capitate, 3–5 µm wide, and the (dead) spores 8–11 × 1–1.3(–1.5) µm, inequilaterally fusiform, with both ends attenuated (but the lower part sometimes with a minute clavate inflation), partly with 1–2 small guttules (see Pl. 480: 4). Neither distinct hairs nor glassy caps are reported. Ascus size is given much shorter (25–35 × 3.5–4 µm, 'non bifurcato') than in the present observations, perhaps because the asci were broken below.

Svrček believed *O. ebuli* to be very closely related to *O. luteorubella* and to differ, e. g., in the guttulate spores, i. e., in the presence of a few small oil drops. He was unaware, however, of the characteristic spore bodies in *Orbilia*, for instance the rather long and narrow SBs in *O. luteorubella* which, contrary to *O. ebuli*, get tear-shaped only when overmature. Since no information on spore bodies of living spores is available for the original collections of *O. rosella* and *O. ebuli*, their separation remains somewhat tentative for the time being.

Not included collection. An old sparse specimen from Czechia on *Sambucus ebulus* under the name *Calloria vinosa* in M (herb. G. Niessl) was examined. It differs by rather wide, fusiform spores (†8–9.5 × 1.6–1.7 µm) with obtuse apices which would also fit *O. rosella* or a species of series *Helicoon*.

Phylogeny. A sequence taken from apothecia of the epitype of *O. ebuli* (SSU, S1506 intron, ITS, LSU) shows an ITS distance of 14% to *O. carminorosea*, 15% to *O. ficicola*, and > 18% to other species. In the LSU (D1–D2) the minimum distance is 4% to *O. ficicola* (4.5% to *O. carminorosea*), and in the intron 11% to *O. ficicola*. When analysing ITS+LSU or LSU, *O. ebuli* clustered with *O. siculispora* and *O. ficicola* in a strongly supported clade (Phyls 13, S16).

Map 84. Known distribution of *O. ebuli* in Europe (yellow = not included collection).

Ecology. *Orbilia ebuli* is only known from a few collections on herbaceous stems of different plants lying in moist or dry leaf litter, also on petioles. It was found in subcontinental, humid to rarely semihumid sites under very diverse thermotypes: in cold-temperate central and thermoboreal northern Europe but also in orosub- and mesomediterranean southern Europe, e. g. in a rather shady conifer forest rich in mosses, among garden trash (on *Helianthus*, Finland), or in a *Quercus rotundifolia*-*Q. coccifera*-*Q. faginea* shrubland on dry ground with *Rubus ulmifolius* (on *Sambucus ebulus*, Spain). Because of low-refractive VBs in the paraphyses, and the position of the substrate on the moist ground, the species probably shows an only moderate desiccation tolerance.

Specimens included. **FINLAND**: **North Karelia**, 42 km WNW of Joensuu, 0.8 km WNW of Outokumpu, Raivionmäki, 140 m, stems of *Helianthus tuberosus*, 28.V.2011, M. Pennanen (ex H.B. 9550, M-0276476, **epitype**; sq.: KT222425; **isoepitype**s in JOE and M.P. 110502). – 14 km WNW of Outokumpu, 1.5 km WSW of Rikkaranta, 125 m, stems of *H. tuberosus*, 18.V.2013, M. Pennanen (H.B. 9827). — **GERMANY**: **Bayern**, **Oberfranken**, 8.5 km SE of Lichtenfels, 1.5 km ESE of Serkendorf, Röderitz/Hoher Bühl, 530 m, stem of *Sambucus ebulus*, 15.VI.1985, H. Engel (**holotype** [illustration], doc. vid.). – **Baden-Württemberg**, Obere Gäue, 6 km W of Herrenberg, 2 km NNE of Oberjettingen, Herrenplatte, 575 m, stem of *Atropa belladonna*, 30.III.1998, A. Gminder (H.B. 6079). — **SWITZERLAND**: **Schaffhausen**, 4.5 km NE of Schaffhausen, 1.8 km NE of Herblingen, Rohrbühl, Herblinger Weiher, 500 m, petiole of *Acer*, 1.IV.1986, P. Blank (P.B. 165, H.B. 9435 ø). — **SERBIA**: **Vojvodina**, Fruška Gora, 13 km SSW of Novi Sad, 1 km E of Brankovac, 430 m, stem of *Sambucus ebulus*, 4.III.2019, D. Savić (FG-1019, doc. vid.). — **SPAIN**: **Aragón**, **Huesca**, 9 km SW of Benasque, 1.5 km WNW of Villanova, Chia Plan, 1630 m, on stem of indet. *Apiaceae*, 2.V.2016, R. Blasco (R.B. 02-05-16-918-CH, doc. vid.). – **Andalucía**, **Jaén**, Sistema Bético, 20 km S of Jaén, SW of Valdepeñas de Jaén, 913 m, on stems of *Sambucus ebulus*, 11.IV.2013, S. Tello (JA-CUSSTA 7565, H.B. 9776).

Not included. **CZECHIA**: **South Moravia**, Blansko, 12 km NNE of Brno, Adamov, ~270 m, on stem of *Sambucus ebulus*, 10.VI.1866, G. Niessl v. Mayendorf (herb. G. Niessl, M, as *Calloria vinosa*).

Orbilia somedana Baral & E. Weber, **sp. nov.**, MB 825636 — Pl. 482

Etymology: after the geographical origin, National Park of Somiedo, Asturias.
Typification: Spain, Asturias, Pola de Somiedo, collado La Farrapona, branch of *Rhamnus alpina*, 4.VI.2017, H.O. Baral (ex H.B. 10084e, AH 52845, holotype).

Latin diagnosis: Orbiliae ebuli *similis sed corpuscula refringentia ascosporarum multo angustiores, apices paraphysium leniter inflatae. Habitat ad corticem et lignum putridum siccum* Fagi sylvaticae *et* Rhamni alpinae *in zona orotemperata humida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.22–)0.3–0.45(–0.55) mm diam., 0.9 mm high (receptacle 0.08–0.09 mm), light to bright cream-orange, medium translucent, round, scattered to subgregarious; disc flat, margin 10 µm protruding, almost smooth to finely and irregularly crenulate; broadly sessile, seemingly superficial; dry ± strongly contracted, light to bright orange to brick-red, partly with whitish marginal tufts. **Asci** *45 × 3.5–4.2 µm {T}, †33–46 × 3–3.7 µm {2}, 8-spored, spores *~2–4-seriate, 2–4 lower or sometimes upper spores inverted {1} (sometimes mixed), pars sporifera *23 µm long; **apex** (†) strongly truncate (not indented, laterally not or hardly widened); **base** with short to long, thin to thick, ± flexuous stalk, T-, L- to Y-shaped. **Ascospores** *(7.8–)8.2–9.2(–9.7) × 1.2–1.5 µm {2}, †7.5–9.5 × 1.1–1.4 µm {2}, narrowly fusoid, apex acute, base slightly to medium attenuated, often forming a tail of *2–3.2 × (0.8–)0.9–1.1 µm {2} with sometimes a slight subbasal constriction, straight to very slightly curved near base; **SBs** *(3–)3.5–4(–4.3) × 0.2–0.3(–0.4) µm {2}, filiform to subulate, straight to often medium flexuous. **Paraphyses** apically slightly to medium capitate-clavate, terminal cells *~18–22 × 2.5–3.5 µm {T}, †11–18 × 2–3(–3.5) µm {2}, lower cells *3–13 × 2–2.7 µm {T}, †4–12 × 1.3–2 µm {2}, di- to trichotomously branched below. **Medullary excipulum** 20–25 µm thick at lower flanks, of dense textura intricata-porrecta with inflated cells, sharply delimited. **Ectal excipulum** of (†) thin-walled, indistinctly vertically oriented t. globulosa-angularis from base to margin, 20–25 µm thick at base and lower flanks, cells *6–17 × 6–13 µm {2}; 15 µm thick at mid flanks and margin, of. t. angularis-prismatica to t. porrecta oriented at a 0–20(–70)° angle to the surface, marginal cortical cells forming appressed **hairs** of *20–50 × 3–4.7 µm {1}, firm-walled (0.3–0.4 µm), 1–4-septate, ± agglutinated to form irregular, 30–50(–80) × 30–70 µm {2} large teeth; **glassy processes** absent {2}. **Anchoring hyphae** sparse, †1.7–3.3 µm wide, walls 0.2–0.3 µm thick {T}. **SCBs** in paraphyses and ectal excipulum absent {2}; **VBs** in paraphyses not observed {2}. **Exudate** over paraphyses, margin and flanks 0.1–0.2 µm thick, rough, firmly attached. **— ANAMORPH**: unknown.

Habitat: 0.3–2 m above the ground, ~5 cm thick, standing trunk of *Fagus sylvatica* {1}, 2 cm thick, horizontal branch of *Rhamnus alpina* {T}, dead, partially decorticated, on medium to strongly rotten bark (bast) {2}, on inner surface of detaching bark {1} or on outer surface (periderm removed) {T}, no algae. **Associated**: *Cyathicula* sp. {1}, *C. hysterioides* {1}, *Orbilia subtrapeziformis* {2}, *Karstenia* sp. {1}, *Parmelia sulcata* {1}, *Usnea* sp. {1}. **Desiccation tolerance**: excipular cells, a few immature asci and many spores still alive after 3 weeks. **Altitude**: 1350–1650 m a.s.l. **Geology**: Silurian-Devonian sediments: Saliencia: elution from sand and slate with limestone above, La Peral: dolomite. **Phenology**: VI (but probably long-lived).

Taxonomic remarks. The ascospores of *Orbilia somedana* closely resemble those of the caulicolous *O. ebuli*, but differ in containing much narrower SBs. They also resemble those of *O. abutilonis*, *O. ficicola*, *O. siculispora*, and especially *O. subsiculispora*, but in these four species the spores are more curved and in the former three also more constricted near the base. All of them have larger apothecia with concave disc and more protruding margin, and paraphyses with lanceolate-lageniform or mammiform apices, whereas *O. somedana* resembles *O. ebuli* in flatter apothecia and capitate paraphyses, those of *O. somedana* being apically less inflated than in *O. ebuli*.

Variation. The two included collections hardly show any deviation, except that the apothecia in the paratype are smaller and their colour slightly paler.

Ecology. *Orbilia somedana* is so far only known from two collections made at orotemperate humid sites in the Somiedo National Park in the atlantic Cantabrian Mountains of Asturias. The holotype grew on xeric bark of *Rhamnus alpina* in a subalpine shrubland with *Erica arborea* and *E. australis*, whereas the paratype was on xeric, detaching bark of *Fagus sylvatica* in a montane, rocky beech forest, in a small clearing where many fallen beech trees were lying upon each other. At both collection sites *Orbilia subtrapeziformis* grew in association.

Specimens included. **SPAIN**: **Asturias** 13.5 km ESE of Pola de Somiedo, W of collado La Farrapona, 1650 m, branch of *Rhamnus alpina*, on bark, 4.VI.2017, H.O. Baral (ex H.B. 10084e, **holotype**, AH 52845). – 6 km S of Pola de Somiedo, SSW of La Peral, 1350 m, trunk of *Fagus sylvatica*, on bark, 7.VI.2017, H.O. Baral (H.B. 10104a).

Orbilia rehmii Baral, **sp. nov.**, MB 813770 — Pls 483–484

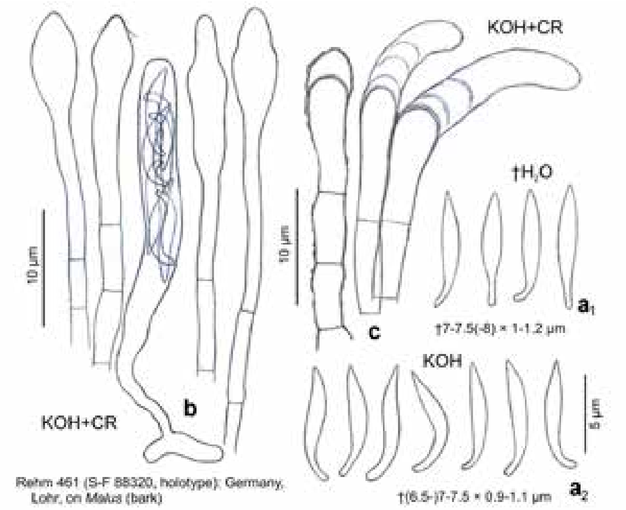
(?)= *Calloria scolicospora* f. *minor* Rehm, Ascomyceten, fasc. 10: no. 461 (1878), nom. inval., ICN Art. 38.1(a)
≡ *Calloria rubella* f. *minor* Rehm, Ber. Naturhist. Vereins Augsburg 26: 112 (1881)
≡ *Orbilia rubella* var. *minor* (Rehm) Sacc., Syll. Fung. 8: 621 (1889)

Etymology: named after the collector, H. Rehm.
Typification: Germany, Unterfranken, Lohr a. Main, bark of *Malus*, winter 1877–78, H. Rehm (ex Rehm Ascom. 461, S-F 88320, holotype).
Misapplied names: Karsten (1885: 142) & Rehm (1891: 458), as *O. rubella*; Nannfeldt (1932: 252, p.p.), as *Hyalinia rubella.*

Latin diagnosis: *Similis* Orbiliae ebuli *sed paraphysibus plerumque spathulatis, ascosporis minoribus, processis vitreis marginalibus saepe praesentibus differt.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.28–0.43 mm diam., 0.11 mm high, carneous to dark red (fide Rehm), ± round, scattered or in small groups; disc slightly concave to flat, margin 10–20 µm protruding, finely whitish crenulate; broadly sessile, superficial. **Asci** †(30–)35–53 × 3–3.5 µm, 8-spored, spores †2–3-seriate, ~3–5 spores inverted (lower or upper spores, strongly mixed); **apex** (†) medium to strongly truncate (not indented or laterally inflated); **base** with short to very long, thin, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** †(6.5–)7–7.5(–8)((–9.5)) × (0.9–)1–1.2 µm, fusiform, apex acute, base medium to mostly strongly attenuated, tail-like or with a sometimes very slightly bulbous tail of 1.2–1.5 × 0.3–0.7 µm, medium to strongly curved, especially near base, sometimes slightly helicoid, rarely straight; **SBs** not seen. **Paraphyses** apically slightly to strongly inflated, spathulate to lageniform, terminal cells *18–23(–26) × (2–)3–3.8(–4.5) µm, lower cells *4.5–8 × 1.3–2.2 µm; unbranched at upper septum, hymenium amber-yellow (fide Rehm). **Medullary excipulum** 30 µm thick, of dense textura intricata, indistinctly delimited. **Ectal excipulum** of (†) thin-walled, horizontally oriented t. angularis from base to mid flanks, 20 µm thick at base and flanks, cells †4–8 × 3–6 µm; 15–20 µm thick near margin, of a light yellow t. porrecta oriented at a 10–20° angle, partly projecting as fascicles of agglutinated hyphae, marginal cortical cells †5.5–12 × 2.5–4 µm, sometimes forming 12–30(?–60) µm long, thin-walled, 2–3-celled, ± free hair-like projections; **glassy processes** 1–15 × 3–5 µm, refractive, pale yellowish, slightly stratified. **Anchoring hyphae** sparse, †1.5–3 µm wide, walls 0.2 µm thick. **SCBs** no data available. **Exudate** over paraphyses absent, over margin and hairs forming 0.2 µm thick firmly attached granules. **— ANAMORPH**: unknown.

Habitat: on a ?standing corticated ?trunk of *Malus domestica* {1}, on inner surface of detaching bark, medium decayed, slightly greyed, algae not observed. **Associated**: ?*Nitschkiaceae*. **Desiccation tolerance**: probably tolerant. **Altitude**: ~200 m a.s.l. **Geology**: Buntsandstein. **Phenology**: winter (but presumably long-lived).



Pl. **483**. **1**: *Orbilia rehmii*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. marginal hair-like cells tipped by glassy processes.

Taxonomic remarks. *Orbilia rehmii* closely resembles *O. ebuli* and *O. somedana* in the ascospores, also in the marginal textura porrecta oriented at a low angle and running out into hair-like projections which form a crenulate margin. It differs in more curved spores and often spathulate though also clavate paraphysis apices, whilst in *O. ebuli* and *O. somedana* the spores are ± straight and the paraphyses capitate-clavate or only exceptionally spathulate (Pl. 480: 2). A more protruding margin and the partial occurrence of up to 15 µm long glassy processes, together with slightly smaller spores are further features that deviate from *O. ebuli* and *O. somedana*. The Australian *O. carminorosea* has very similar spores and paraphyses, but seems to deviate in wider marginal cortical cells running at a higher angle, larger excipular cells at lower flanks (but see below), slightly wider spores, and larger apothecia with a carmine-rose colour. *O. subsiculispora* has wider, more constricted spore tails and lacks glassy processes, and *O. rubella* (series *Rubellae*) obtuse to subacute spore apices and thick-walled hairs with longer glassy processes.

Variation. In the isotype specimen from M the spores were found to be partly longer (7–9.5 µm) than in the holotype (6.5–8 µm), also the curved base was more distinctly inflated (knob-like). No drawing or photos were made when the specimen from M was studied.

Nomenclature and type studies. Rehm's (1878 in sched.) label of Ascomyceten no. 461 bears the name *Calloria scolicospora* Rehm f. *minor* on the printed label but no diagnosis. Since this combination was not published elsewhere, it is not validly published. A handwritten description is included in the duplicate S-F 88320, suggesting that this was Rehm's personal specimen. Rehm (1881) validly published this taxon at the rank of a forma of *Calloria rubella* and Saccardo (1889) raised it to a variety of *Orbilia rubella*, whereas Karsten (1885: 142), Rehm (1891: 458), and Nannfeldt (1932: 252) listed it as a synonym of *O. rubella*. It remains unclear which collection Rehm intended under the epithet *scolicospora* (not to be confused with *Hyalinia scolecospora* G.W. Beaton), which could not be detected in later publications, so it appears that it has never been validly published and must be regarded as a nomen nudum.

Rehm's handwritten description includes a sketch of two falcate spores and a clavate paraphysis. The spores are drawn with an obtuse upper end and resemble those of *O. auricolor*. Unexplainably, Rehm (1881) cited as exsiccata for *C. rubella* f. *minor* Karsten FFE 831 instead of Ascomyc. 461. This is a misprint for FFE 834, which Karsten cited under *O. rubella* and was referred to *O. phragmotricha* in the present study, whereas FFE 831 is *Niptera graminis* in the list of FFE (S. Huhtinen & T. Pertti pers. comm.). Since Rehm's (1881) diagnosis was clearly taken from the handwritten one in Ascomyc. 461 (S-F 88320), the type of *C. rubella* f. *minor* is Rehm Ascomyc. 461.

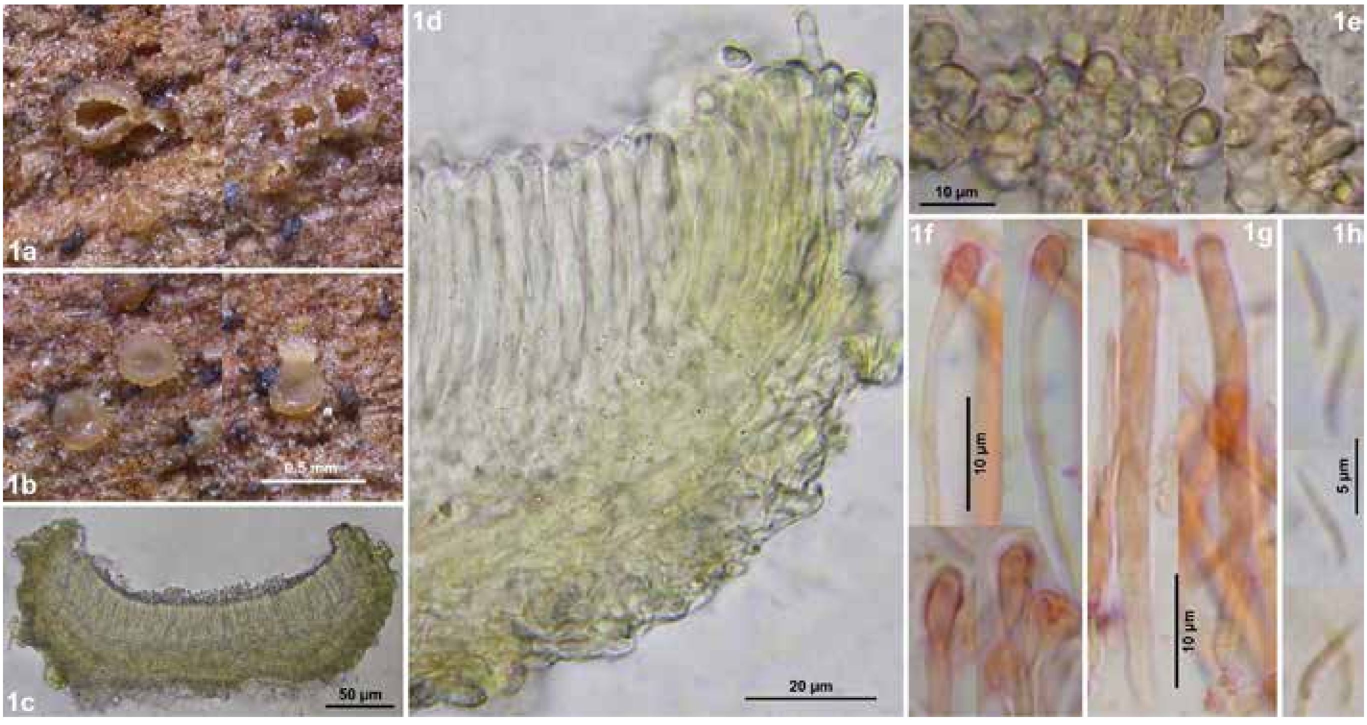


Plate 484. **1**: *Orbilia rehmii*. – **1a–b**. rehydrated apothecia; **1c**. apothecium in median section; **1d**. id., marginal region; **1e**. marginal glassy processes (squash mount); **1f**. paraphyses; **1g**. asci; **1h**. ascospores. – Dead state (**1c** in H2O, **1d** in KOH, **1e–h** in KOH+CR). — **1a–h**. S-F 88320, H.B. 9838 ø (holotype): Germany, Lohr, on *Malus*.

In his Kryptogamen-Flora, Rehm (1891) cited only Ascomyc. 461 as exsiccata, which served as the basis for his description of *O. rubella*, for which he only gave apple bark and Lohr as collection data.

Rehm's handwritten diagnosis includes asci of 30–45 × 5 µm and spores of 6–8 × 1 µm. Later, Rehm (1881) shortened these measurements to –45 × 5 µm and –8 × 1 µm, and Saccardo (1889) again changed them to 40–45 × 5 µm and 7–8 × 1 µm. Rehm's (1891) description of the same collection, now under the name *O. rubella*, gives a further variant, 30–45 × 4–5 µm and 6–12 × 1 µm, because he included also data from Karsten's description of '*O. rubella*'. The apothecia are there described as 0.2–1.5 mm diam., with a finely fimbriate margin, carneous to dark red, hymenium amber-yellow [in transmitted light], data which do not appear on the handwritten note, while his statement 'spores apically blunt, tapered and slightly curved below, intertwined within the asci' might have been taken from there. Although Nannfeldt (1932) included Rehm Ascomyc. 461 in his concept of *Hyalinia rubella*, he said that his redescription of excipular structures was solely based on the specimen from Karsten's herbarium (FFE 834).

The holotype collection of *O. rehmii* revealed ascospores very different from Rehm's description and drawing, though they concur in size. Also Rehm's (1891) remark of a large-celled ectal excipulum is in strong contrast to the present fungus. Rehm's omission of spathulate paraphyses, on the other hand, can be explained by the frequent occurrence of clavate paraphyses along with spathulate ones in the present specimen. Nevertheless, a mixed collection cannot be excluded, e. g., with a species of section *Arthrobotrys*, and the apothecial size and colour given by Rehm (1891) might partly refer to such an associated species. In any case, the here redescribed fungus differs from all other collections examined by us, therefore, it is described as a new species.

Ecology. *O. rehmii* was collected on the inner surface of detached, projecting bark of *Malus*, possibly from a standing, living trunk, at the eastern foothills of Spessart, a mountain range of acidic soil in cold-temperate humid northwestern Bayern (Germany).

Specimens included. **GERMANY**: **Bayern**, **Unterfranken**, Spessart, ~35 km NW of Würzburg, Lohr a. Main, ~200 m, bark of *Malus*, winter [1877–]1878, H. Rehm (Rehm Ascomyc. 461, as *Calloria scolicospora* f. *minor*, S-F 88320 **holotype**, H.B. 9838 ø; **isotypes** in M-0206541, M-0206542).

Orbilia carminorosea Baral, **sp. nov.**,
MB 813771 — Pls 485–486

Etymology: named according to the spectacular, comparatively large, bright carmine-rose apothecia.

Typification: Western Australia, Derby, branch of *Adansonia gregorii*, 1.XI.2007, G. Marson (ex H.B. 8777a, MEL 2389260, holotype; sq.: KT222423).

Latin diagnosis: *Apothecia rehydratata 0.6–1 mm diam., vivide carmino-rosea, sessilia, margine incrassato, albido aspero ad pulverulento. Ascosporae †6.5–8 × 1.1–1.4 µm, fusiformes, apice acutae, ad basim valde attenuatae, subcaudatae, modice vel valde curvatae. Paraphyses ad apicem non inflatae vel modice spathulatae. Margo excipuli pilis agglutinatis, septatis, subcrassitunicatis compositus, absque processis vitreis. Habitat ad lignum putridum rami sicci* Adansoniae gregorii, *in zona tropica subhumida Australiae septentrio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1 mm diam., 0.17–0.22 mm high (receptacle 0.16 → 0.08 mm), (light to) bright crimson- or carmine-rose, non-translucent, ± round, scattered or in densely aggregated pairs; disc slightly concave to flat, margin thick, 10–40 µm protruding, rough to whitish pruinose, somewhat longitudinally ribbed; broadly sessile, superficial; dry bright carmine, only slightly contracted. **Asci** †30–40 × 3–3.7(–4) µm, 8-spored, spores †2–3-seriate, ~3–5 lower spores inverted (strongly mixed, sometimes upper spores inverted and lower not); **apex** (†) strongly truncate (never distinctly indented, laterally hardly inflated); **base** with short to long, thin, flexuous stalk, T-, L- or h-shaped. **Ascospores** †6.5–7.5(–8) × 1.2–1.3(–1.4) µm (~7.5–9 µm actual length), fusiform, apex acute, base strongly attenuated, tail-like, medium to mostly strongly curved near base (falcate but straight or only slightly curved in middle part); **SBs** ?2 µm long, ?elongate tear-shaped, hardly visible as a faint region in a few spores. **Paraphyses** apically uninflated or slightly to medium inflated, spathulate (to lageniform), terminal cells *(12.5–)15–22 × 2.3–3.5(–4) µm, lower cells *4–10 × 2–2.5(–3) µm; unbranched at upper septum, hymenium pale rose. **Medullary excipulum** hyaline to pale rose, 30–60 µm thick, of medium dense textura intricata(-angularis), ± horizontally oriented, indistinctly to medium sharply delimited. **Ectal excipulum** at base hyaline to pale rose, of (†) slightly gelatinized, vertically oriented t. (prismatica-)angularis from base to mid flanks, 80–120 µm thick near base, cells *(10–)15–25(–30) × (8–)11–16(–18) µm; 50 → 30 µm thick at flanks, 20–35 µm near margin (including hair-like cell rows), submargin of t. globulosa-prismatica oriented at a 50–80° angle to the surface, upper margin of t. prismatica oriented at 20–60°, sometimes forming agglutinated, firm-walled cell rows, marginal cortical cells †5–10 × 3–5.5 µm, sometimes forming 9–14 µm long, ± free hair-like projections; **glassy processes** absent. **Anchoring hyphae** medium abundant, *2.5–3.5 µm wide, walls 0.2 µm thick, below basal excipulum forming a medium dense prismatic texture of *4–6 µm wide hyphae. **SCBs** in paraphyses and ectal excipulum absent. **Exudate** over paraphyses 0.1–0.2(–0.4) µm thick, finely rough, firmly attached to apex and subapex, at margin forming 0.3–1.5 µm thick caps on terminal cells. — **ANAMORPH**: dicranidion/trinacrium-like (presumed, from natural substrate, on apothecium). **Conidiophores** not observed. **Conidia** 3-dimensional, 4-armed by dichotomous branching, total size †26 × 16 µm, stipe †9 × 3.3 µm, non-septate, arms †8–14 × 2.7–3.2 µm, 0(–1)-septate, diverging, straight, gradually tapering towards apex {only 1 conidium seen}.

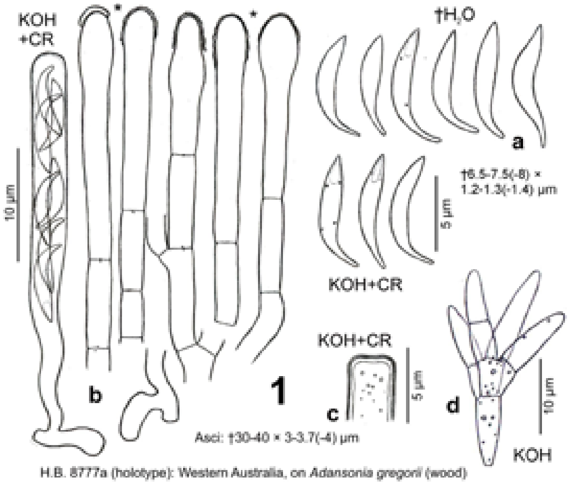

Plate 485. **1**: *Orbilia carminorosea*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. conidium.

Habitat: collected 2–3 m above the ground, decorticated, 20–25 mm thick branch of *Adansonia gregorii*, excavated by termites or ants, on 0.1–0.3 mm deep strongly decayed wood, greyed, no algae. **Associated**: *Orbilia brachychitonis*, *O. euphorbiae*. **Desiccation tolerance**: only paraphyses and excipular cells viable after 4 months. **Altitude**: 20 m a.s.l. **Geology**: Cenozoic red-brown gravel. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia carminorosea* is remarkable due to its rather large, bright carmine-rose apothecia with a whitish pruinose margin made up of distinct cell rows, and small, somewhat falcate spores with acute apex and tail-like base. Based

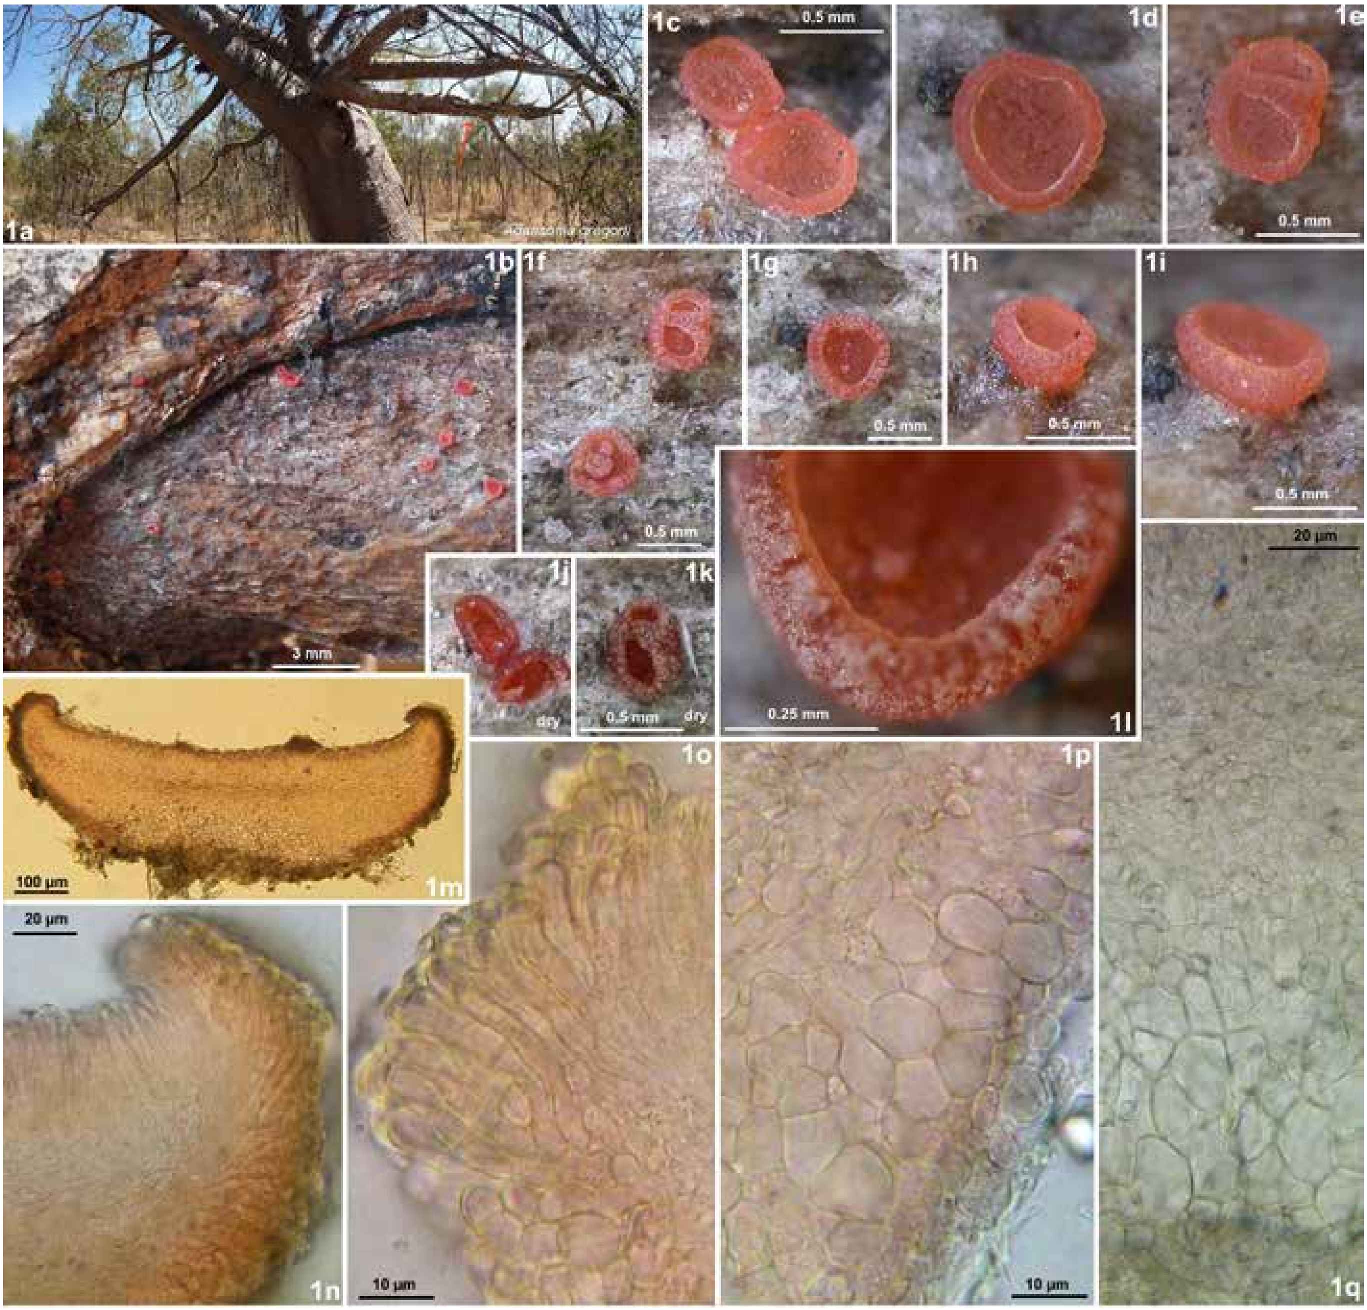

Plate 486. **1**: *Orbilia carminorosea*. – **1a**. tropical semiarid Eucalypt woodland with *Adansonia gregorii* in foreground; **1b–i**, **l**. rehydrated apothecia; **1j–k**. dry apothecia; **1m**. apothecium in median section; **1n–o**. id., ectal excipulum near margin; **1p**. id., lower flanks; **1q**. id., basal region showing ectal and medullary excipulum. – Living state. — **1a–q**. H.B. 8777a (holotype): Western Australia, Kimberley Mts., on *Adansonia*.

on its morphology, the species is difficult to place. The marginal cell rows resemble the free hairs of *O. phragmotricha* (series *Rubellae*) but are more thin-walled and always conglutinate to form a compact tissue, similar as observed in *O. fraxini*, a species assigned to series *Neodactylella* of section *Arthrobotrys*. The spathulate paraphyses with thin exudate would fit series *Rubellae* but are also similar in *O. abutilonis* and similar species. For the similar *O. rehmii* see p. 904. *O. carminorosea* resembles *O. aurantiorubra* in the acute spore apex and a strongly bent base, and an apparently elongate tear-shaped spore body. *O. aurantiorubra* differs in longer spores with thicker tail-like bases, and a marginal excipulum that lacks distinct cell rows. Mature asci were only sparsely seen in *O. carminorosea*, and all asci and spores were dead when examined 4 months after collecting.

Anamorph. A single staurosporous (4-armed) dicranidion-like conidium was seen on an apothecium (Pl. 483: 1d), showing a branching mode similar as in *O. siculispora* and *O. ficicola*.

Phylogeny. A sequence gained from apothecia of the holotype (SSU without S1506 intron, ITS, LSU) shows a minimum ITS distance of 14% to *O. ebuli* and 16% to *O. aethiopica* in (3.5–4.5% in LSU D1–D2).

Ecology. *O. carminorosea* grew on rotten wood of a xeric branch of baobab (*Adansonia gregorii*) in a tropical subhumid eucalypt open woodland (savannah, wet and dry) at the southern border of the Kimberley plateau adjacent to the Great Sandy Desert (Pilbara) in the Dampierland ecoregion of northwestern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Dampierland, SW-border of Leopold Ranges (Kimberleys), 47 km SSW of Derby, 12 km WNW of Willare Bridge over Fitzroy River, 20 m, branch of *Adansonia gregorii*, on wood, 1.XI.2007, G. Marson (ex H.B. 8777a, MEL 2389260, **holotype**; sq.: KT222423; anam. substr.).

Orbilia rosella (Rehm) Sacc., Syll. Fung. 8: 623 (1889) — Pls 487–488

≡ *Calloria rosella* Rehm, Hedwigia 23: 56 (1884)
≡ *Laetinaevia rosella* (Rehm) Nannf. in Kanouse, Pap. Mich. Acad. Sci. 21: 100 (1936)

Etymology: named after the rose colour of the apothecia. **Typification**: Germany, Sachsen, Nossen, stems of *Atropa belladonna*, VIII.1883, K.W. Krieger (Rehm 720, M-0206546, lectotype, designated here, MBT392868). **Misinterpretation of *O. rosella***: Baral (1992, fig. 37d, as '*O.* cf. *rosella*'), = *O. caulicola*; Bommer & Rousseau (1890: 227), = ?*Calloriaceae*; Feltgen (1901: 37), on *Angelica* = *O. auricolor*, on *Knautia* = *O. flavida*.

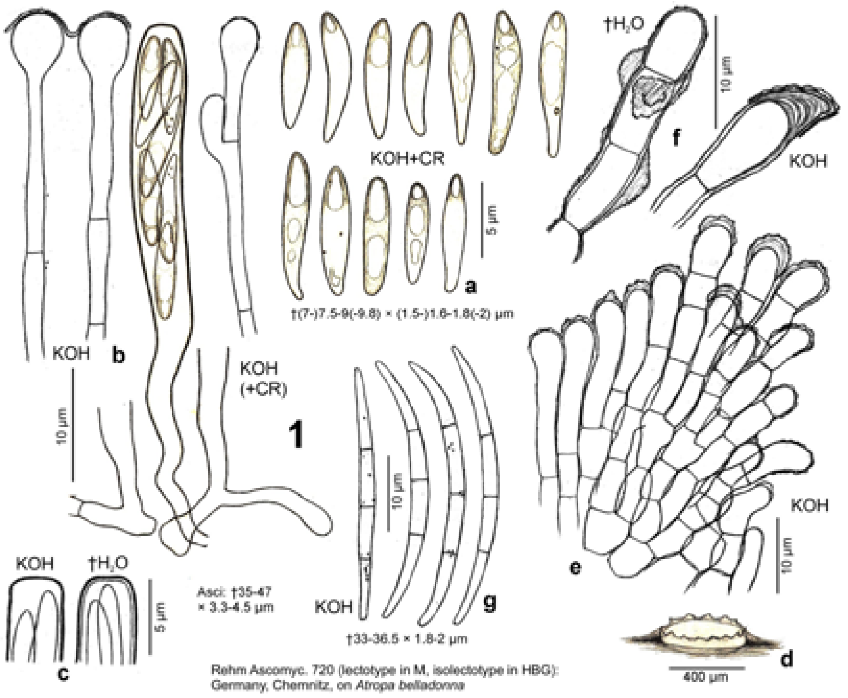

Plate 487. **1**: *Orbilia rosella* (lecto- and isolectotype). – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium with dentate margin (rehydrated); **e**. median section of marginal ectal excipulum; **f**. id., cortical cells, with or without glassy processes; **g**. conidia from natural substrate. **a–d**, **f**: M-0206546 (lectotype, H.B. 4670a); **a–b** (only SBs in spores), **g**, **e**: HBG (isolectotype H.B. 4670b).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.6 mm diam., 0.08–0.15 mm high (receptacle 0.06–0.09 mm), pale cream (Rehm: rose-red, later brownish-red), ± translucent, round to somewhat elliptical, medium gregarious; disc concave to flat, margin 10–20 µm protruding, distinctly crenulate with small teeth; broadly sessile, erumpent from slits in epidermis; dry light yellowish-ochraceous(-orange) (Rehm: rose-red), margin rolled inwards. **Asci** †(35–)40–47(–52) × (3.3–)3.7–4.5 µm {2}, 8-spored, spores †~3-seriate, 4(–5) lower spores inverted (not mixed), pars sporifera †28 µm long; **apex** (†) strongly truncate (± not indented, laterally not or scarcely widened); **base** with medium to long, thin, flexuous stalk, L- or Y- to h-shaped. **Ascospores** †(7–)7.5–9(–9.8) × (1.5–)1.6–1.8(–2) µm {T}, fusoid-clavate, apex ± obtuse (to somewhat subacute), base slightly to strongly attenuated, straight to slightly curved (entirely or near base); **SBs** †1.3–1.8 or sometimes 3–4.5 × 0.5–1.1 µm {T}, ± tear-shaped, faintly visible as a transparent region. **Paraphyses** apically (slightly to) medium to very strongly capitate-clavate, terminal cells †(10.5–)18–25 {T} × (2–)3.5–4.7 µm {2}, lower cells †~9–15 × 1.2–1.6 µm {T}, sometimes branched at upper septum. **Medullary excipulum** 10–50 µm thick, of medium loose or dense t. intricata with many inflated cells, indistinctly or sharply delimited. **Ectal excipulum** of slightly gelatinized, indistinctly oriented t. globulosa-angularis from base to margin, 30–50 µm thick near base, cells 15–24(–32) × 10–19(–23) µm {T}; 15–25 µm thick near margin, oriented at a 10–40° angle to the surface, margin with or without protruding, 2–3-celled, 15–30 µm long **hairs**, thick-walled (0.2–0.8 µm), coherent to form indistinct teeth, terminal cells †4–12 × (3–)3.5–5(–6) µm {T}, sometimes tipped by **glassy processes** up to 3–4.5 × 4–5 µm, low-refractive, stratified. **Anchoring hyphae** not examined. **SCBs** and **VBs** unknown. **Exudate** over paraphyses, margin and flanks 0.2–0.4 µm thick, rough, continuous, firmly attached. **— ANAMORPH**: unknown (but see below).

Habitat: previous year's stems of *Atropa belladonna* {3}, on outer and partly also inner surface of hollow stems, ungreyed, no algae, closely **associated** with an old subepidermal pyrenomycete. **Desiccation tolerance**: unknown (probably tolerant). **Altitude**: ~300–380 m a.s.l. **Geology**: Germany: dolerite (diabase), Czechia: mica and biotite gneiss. **Phenology**: IV, VIII (but probably rather long-lived).

Taxonomic remarks. *Orbilia rosella* is characterized by narrowly fusoid ascospores with obtuse apices and attenuated, slightly bent bases, and by apothecia with a finely denticulate margin made up of short hairs which sometimes carry small glassy caps. The species deviates from members of series *Aurantiorubrae* in its rather straight spores which more resemble those of series *Rubellae*, also in the sparse and thin exudate. For the very similar *O. ebuli* see p. 900.

O. rosella resembles *O. rectispora* and *O. cardui* in some macro- and microscopical aspects, but differs in the formation of short, septate hairs forming distinct small teeth at the margin, in wider and partly longer spores with never rounded apices and longer SBs, and in strongly capitate paraphyses, their lower cells being not much shorter than the terminal cells, finally in a reddish colour of the partly erumpent apothecia. In its fusoid to fusiform spores *O. rosella* also resembles *O. caulicola*, which differs in a smooth margin lacking septate hairs or glassy caps, and in shorter spores with shorter SBs.

O. paravitalbae (Pls 489–490) differs from *O. rosella* in distinctly longer SBs (except for *O.* cf. *paravitalbae* Pl. 489: 2) and usually wider, basally never strongly tapered spores. *O. vitalbae* (section *Habrostictis*) has similar spores (e.g., Pl. 696: 1, *O.* cf. *vitalbae*), but the apothecial margin is only minutely crenulate and lacks protruding hair-like elements. Vital characters and molecular data are required to solve the position of *O. rosella*.

Variation. A specimen from Czechia on the type substrate under the name *O. rosella* (M, herb. T. Kupka) appears to be conspecific according to its apothecia being erumpent through a slit, with ~15 µm long marginal hairs, though spores could not be seen. Also in its ascus size and paraphysis diameter it fits well the type.

A collection on *Atropa* (Bayern, Oberfranken, Lichtenfelser Forst, 4.V.1982) reported by Engel et al. (1982: 54) under the name *O. rosella* might be correctly identified, but was inadequately described. The fusoid spores measured 7–9.5(–10.8) × 1.3–1.8 µm, with obtuse ends, but one end partly acute. No SBs were seen, therefore, the upper and lower spore end cannot be recognized.

Nomenclature and type studies. Rehm (1884) described the spores of ***O. rosella*** as 'fusiform, subacute, [..], 5–6 × 1–1.5 µm' and later (Rehm 1891: 460) as '5–7 × 1–1.5 µm'. The present reexamination of one of five syntypes of Rehm Ascomyc. 720

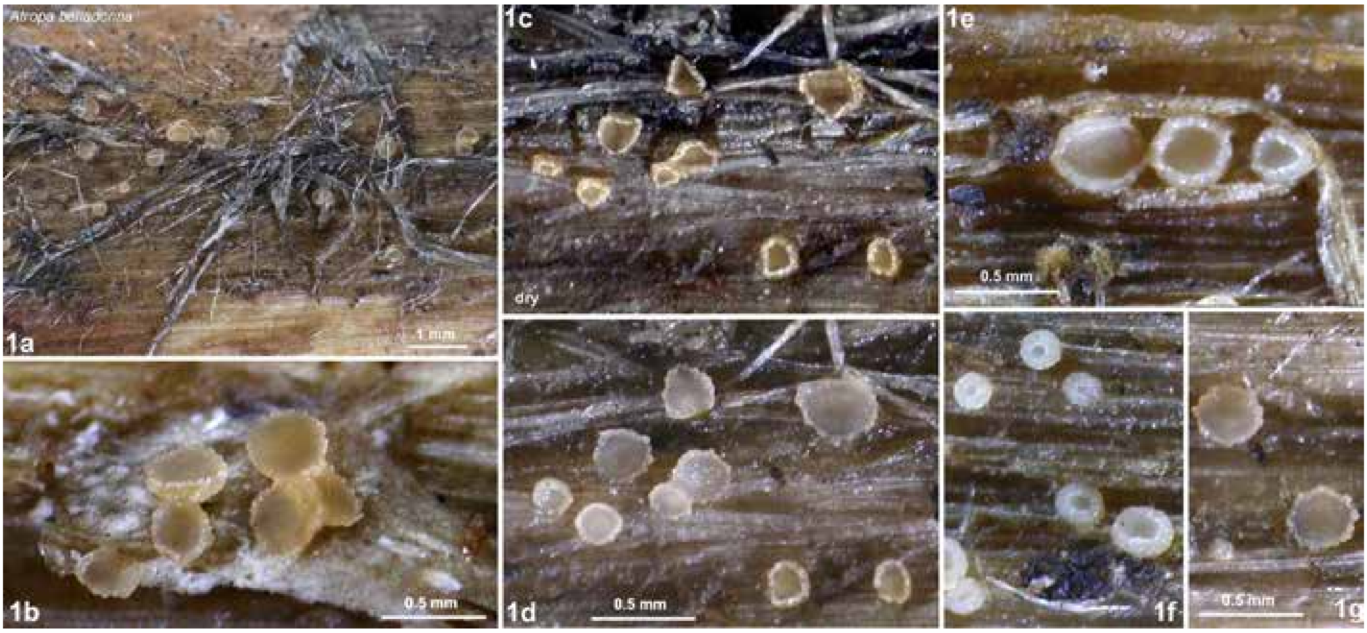

Plate 488. **1**: *Orbilia rosella*. – **1a–b**, **d–g**. rehydrated apothecia; **1c**. dry apothecia. — **1a–g**. Rehm Ascom. 720 (syntype, HBG): Germany, Nossen, on *Atropa*.

(VIII.1883, K.W. Krieger) in M and one of three syntypes in HBG revealed distinctly larger spores with more obtuse apices (Pl. 487: 1a). Rehm (1884) believed that *O. rosella* was closely related to *O. vinosa*, but later he considered a possible relationship to *O. rozei*, a helotialean species tentatively placed in synonymy of *Psilachnum rubicundum* in our list of excluded taxa (see p. 1683).

The rich type collection of *Orbilia rosella* (Germany, Sachsen, Nossen, *Atropa belladonna*, K.W. Krieger, Rehm Ascomyc. 720) was distributed as a set of exsiccata to various herbaria. A specimen with handwritten notes exists among the five syntypes in S (S-F9977, I. Olariaga pers. comm.), while syntype specimens in M and HBG did not carry handwritten notes of the protologue. On the convolutes in M and HBG, Rehm's number 720 appears not only with August 1883 as collection date, but also as 'Aug. 1883. April 1884' (M-0206548, HBG). These must be considered as topotypes, because they were collected by K.W. Krieger presumably after the manuscript was finished (the volume of Hedwigia bears the date April 1884). Three other syntypes were distributed by Rabenhorst, Fungi Eur. Exs. 3067, and the topotype by Krieger Fungi Saxon. Exs. 36.

However, we have not studied any of the specimens in S. Since specimen M-0206546 was studied in detail (Pl. 487: 1a–d, f), this is designated here as **lectotype** of *O. rosella*.

Patouillard (1886: 213, pl. 492) briefly redescribed a syntype specimen of *O. rosella*, with minute wine-rose apothecia, fusiform spores (no size stated), and apically very slightly inflated paraphyses, although Rehm reported the latter as filiform, inflated to a 5 µm wide capitate apex.

The combination *Laetinaevia rosella* (Rehm) Nannf. was published in Kanouse (1936), who reported a collection from Michigan on wet, hygric stems of *Impatiens* sp. (without microscopic data). From Kanouse's note this combination is clearly based on *Calloria rosella* Rehm (see also Seaver 1951: 161), not on *Pseudopeziza rosella* Rehm to which Hein (1976: 34) erroneously referred it. Kanouse relied on Nannfeldt (1932: 192) who listed the former under the name *Orbilia rosella* (Rehm) Sacc., besides many other taxa, as 'very probably belonging to *Laetinaevia*'.

Misapplication. Feltgen (1901: 37) reported under the name *O. rosella* two collections from Luxembourg, with ellipsoid-fusoid spores (4.5–5 × 2 µm). Reexamination of the specimen on stems of *Angelica sylvestris* revealed *O. auricolor*, and that on *Knautia arvensis O. flavida*. Also a sample on *Atropa* referred to *O. rosella* by Bommer & Rousseau (1890: 227; Belgium, Namur, Hastière, X.1890, BR) was reexamined and found to belong to an unidentified helotialean taxon with amyloid apical rings, perhaps a member of *Aivenia* (*Calloriaceae*, IVV: H.B. 8791). Not examined was a collection on *Atropa* from Bayern (Enzenauer Kopf, Bad Tölz, northern Alpine foothills), which Kirschstein (1938: 390, without microscopic data) assigned to *O. rosella* despite its golden yellow apothecia. A spore drawing in Baral (1992: fig. 37d) under the name '*O.* cf. *rosella*' represents *O. caulicola*.

A collection on *Symphytum* from Belgium reported by (Declercq & Leysen 2017), with shorter, fusiform-clavate spores of *5.5–8 × 1.5–2 µm with strongly conical apex containing several ?LBs (B. Declercq pers. comm.), requires reexamination.

Anamorph. On the substrate of the type collection we detected some slender, slightly curved phragmoconidia (†33–36.5 × 1.8–2 µm, 3-septate, Pl. 487: 1g). It is, however, not clear whether they belong to the anamorph of *O. rosella*.

Ecology. *O. rosella* is only known with certainty from the type locality in central Sachsen and a Czechian collection from the southern foothills of Erzgebirge in subcontinental, colline, cold-temperate humid central Europe. At both sites it grew on previous year's stems of *Atropa*. The species is possibly slightly desiccation-tolerant, considering the erumpent growth and rose-red colour.

Specimens included. **GERMANY**: **Sachsen**, Mittelsächsisches Lößhügelland, ~35 km NE of Chemnitz, Nossen, 'at a hill', ~300 m, stems of *Atropa belladonna*, VIII.1883, K.W. Krieger (Rehm 720, M-0206546, **lectotype**, H.B. 4670a ø; **isolectotypes** & topotypes in M-0206547, 206549, 206550, 206551, 206552, non vid.; HBG, H.B. 4670b ø; S-F9977, 9978, 88309, 88311, 88312, non vid.). – ibid., VIII.1883 & IV.1884, K.W. Kupka (herb. T. Kupka, M).

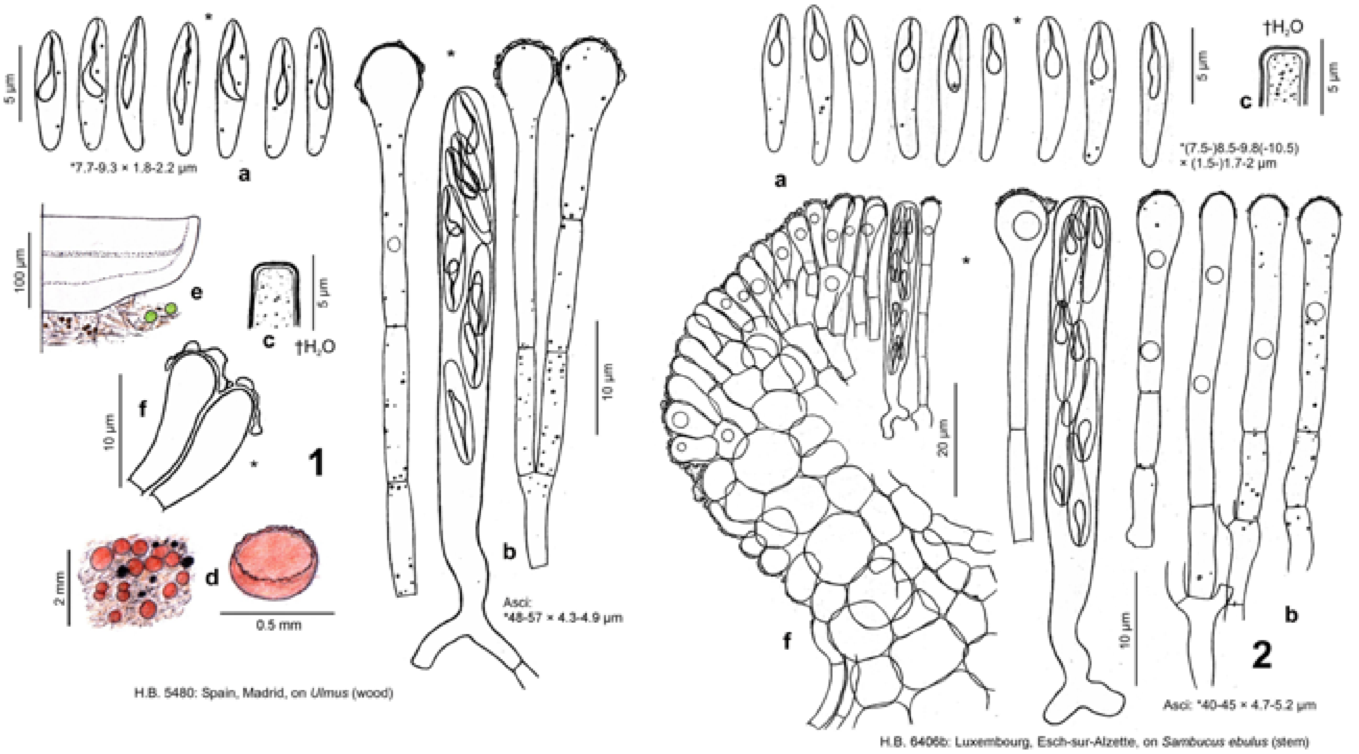

Plate 489. **1**: *Orbilia paravitalbae*; **2**: *O.* cf. *paravitalbae*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., ectal excipulum at margin and flanks.

Orbilia paravitalbae Baral, E. Weber, Priou & R. Tena, **sp. nov.**, MB 825635 — Pls 489–490

Etymology: named after the similar but distantly related *O. vitalbae*.

Typification: Spain, Murcia, Bullas, branches of *Daphne gnidium*, 10.V.2015, J.P. Priou (ex J.P.P. 15119 & ex H.B. 10081, TAAM 198539, holotype; sq.: MG372375).

Latin diagnosis: Orbiliae vitalbae *similis sed ascosporae subcylindricae vel leniter fusoideoclavatae, cellulae apicales paraphysium longiores. Habitat ad corticem et lignum putridum siccum* Daphne gnidii *et* Ulmi *vel caules* Hellebori *in zona meso- ad orosubmediterranea humida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5(–0.6) mm diam., 0.13–0.18 mm high (receptacle 0.1 mm), pale to bright (vinaceous-)rose to pink, ± translucent, round, very scattered to ± gregarious; disc flat, sometimes finally slightly convex, margin finely to distinctly crenulate, 0–0.5 µm protruding; sessile on a stipe-like base, superficial to slightly immersed in biofilm; dry light to deep rose or pink-red. **Asci** *48–57 {1} × 4–5 {2} µm → 5.2–5.5 µm wide, †43–50 × 3.3–3.7 µm {T}, 8-spored, spores *2-seriate, 2–5 lower spores inverted {2} (not mixed), pars sporifera *21–25 or 26–33 → 17–21 µm long; **apex** (†) strongly truncate (not indented, laterally not inflated); **base** with short to long, ± thin, flexuous stalk, L- to Y-shaped. **Ascospores** *(6.8–)7.5–9(–10) {3} × 1.5–1.7 {T} or 1.8–2(–2.2) µm {2}, †7.5–9.2 {2} × 1.4–1.6 {T} or 1.7–2 {1}, subcylindrical to slightly fusoid-clavate, apex rounded to obtuse, rarely subacute, base not or slightly attenuated, straight to slightly inequilateral; **SBs** *(3.5–)4–4.5(–5) {2} or 4.5–5.5(–6.8) {1} × 0.5–0.8(–1) µm {3}, divided into a ± abruptly swollen, tear- to stomach-shaped or ellipsoid to fusoid lower part and a filiform or continuously thickened upper part of about the length of the inflated part, narrow part slightly to strongly flexuous, wide part often oblique. **Paraphyses** apically (slightly) medium to strongly capitate(-clavate), terminal cells *16–27 {1} × (3–)4–5(–6) µm {2}, †17–25 × (3–)4–4.5(–5.5) µm {2}, lower cells *8–14 × 1.5–2.3 µm {1}, †8 × 1.2–2 µm {T}; unbranched at upper septum, hymenium pale rose. **Medullary excipulum** pale rose, 25–50 µm thick, of ± dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** hyaline, towards margin pinkish, of (†) thin-walled t. globulosa-angularis from base to flanks or submargin, 30–60 µm thick near base, cells *(6–)8–14 × (4.5–)6–10 µm {2}, †8–15 × 5–8 µm {T}; 20 µm thick at margin, of t. porrecta oriented at a 20–40° angle to the surface, marginal cortical cells *13 × 3.8–4.6 µm {1}, †6–12 × 3–4 µm {T}, ± flexuous, forming ± free hair-like protrusions, or agglutinated as teeth, **glassy processes** absent. **Anchoring hyphae** medium abundant, *2.5–3.5(–4) µm wide {1}, †1.5–2.5 µm {1}, walls 0.2–0.4 µm thick {2}. **SCBs** in paraphyses and ectal excipulum globose {2}, 1.2–2.5 µm diam., or absent {1}. **Exudate** over paraphyses 0.2–1(–1.5) µm thick, granular-cloddy to continuous, firmly attached, pale yellowish; over margin and flanks 0.2–2 µm thick, cloddy to granular. **— ANAMORPH**: unknown.

Habitat: collected 0.5–2 m above the ground, ± corticated to partially decorticated, 14–15 mm thick, dead branches of *Daphne gnidium* {T}, *Ulmus* sp. {1}, medium to strongly decayed wood {1} and bark (periderm & bast) {1}, on boring dust in beetle galleries {1}; herbaceous stem of *Helleborus nitidus* {1} on the ground; slightly to strongly greyed or darkened, with a few green algae. **Associated**: *Allophylaria* sp., ?*Dothideomycetes*, *Orbilia* sp. **Desiccation tolerance**: fully viable for at least a few days. **Geology**: sandy to clayey or marly deposits from calcareous hills nearby. **Altitude**: 577–1635 m a.s.l. **Geology**: Triassic & Jurassic gypsum, sandstone & dolomite, Quaternary gravel, sand & clay. **Phenology**: II & V (but probably long-lived).

Taxonomic remarks. *Orbilia paravitalbae* is characterized by ± subcylindrical ascospores with rounded to obtuse ends containing flexuous SBs composed of a narrow filiform upper part and an inflated, ± stomach-shaped lower part, also by rose-coloured apothecia with a denticulate margin due to hair-like projections. *O. ebuli* differs in spores with acute apices and tail-like bases, also in lacking any SCBs. *O. rosella* has more fusoid-clavate spores with shorter SBs. *O. vitalbae* (section *Habrostictis*) differs in ellipsoid to fusoid-clavate spores and shorter terminal cells of paraphyses, but a sharp separation from *O. paravitalbae* based on morphology is very difficult. A mediterranean collection from Croatia referred to *O. obtusispora* (section *Habrostictis*) has similar subcylindrical spores with

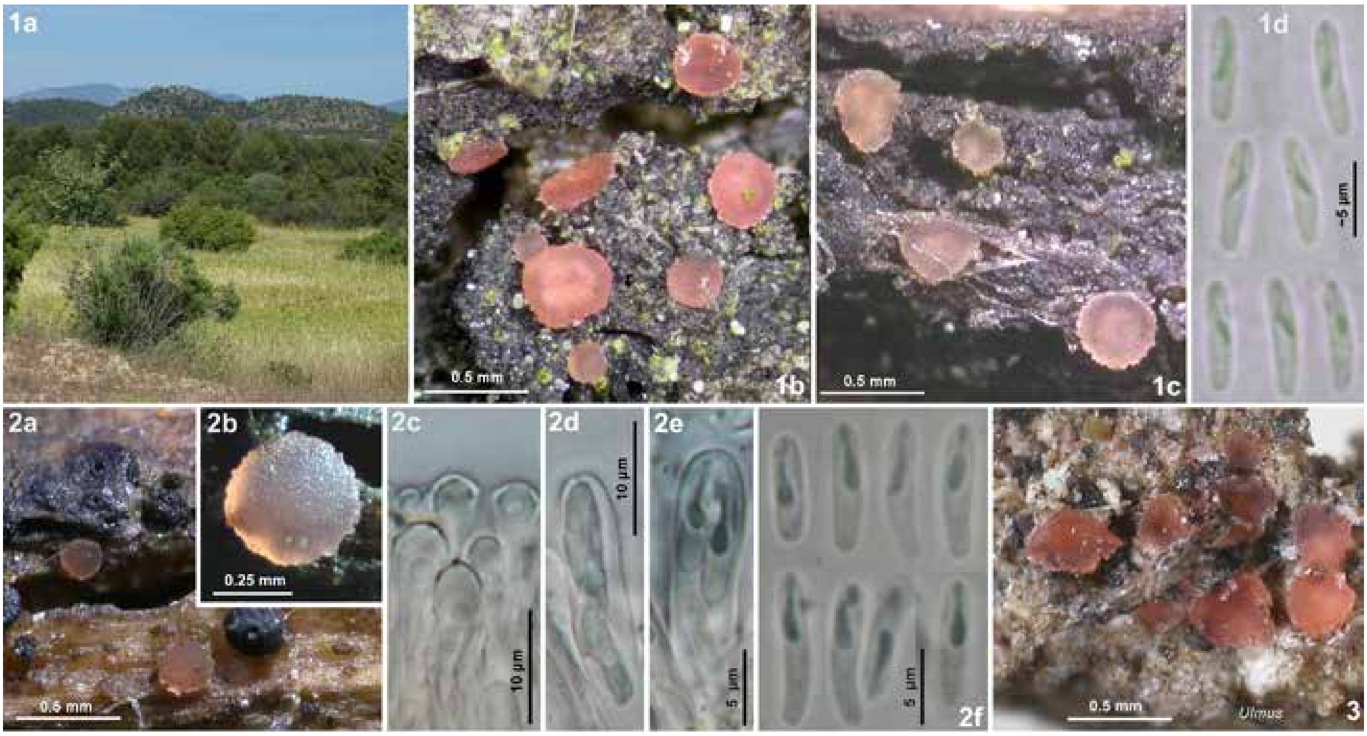

Plate 490. **1–3**: *Orbilia paravitalbae*. – **1a**. supramediterranean semihumid grassland with bushes of *Daphne gnidium* and *Juniperus phoenicea*; **1b–c**, **2a–b**, **3**. rehydrated apothecia; **2d–e**. asci with mature spores; **2c**. apices of paraphyses; **1d**, **2f**. ascospores. – Living state (**2d**: fully turgescent). – **1a–b**, **d**: phot. J.P. Priou, **2b–f**: phot. R. Tena. — **1a–d**. H.B. 10081 (holotype): Spain, Murcia, on *Daphne*; **2a–f**. H.B. 9681: Spain, Teruel, on *Helleborus*; **3**. H.B. 5480: Spain, Madrid, on *Ulmus*.

rounded to obtuse apices (e.g., Pl. 596: 3), which differ from *O. paravitalbae* in being slightly longer and in containing narrower SBs that are more gradually thickened towards their base, also in shorter terminal cells of paraphyses.

Variation. The holotype on bark of *Daphne gnidium*, Pl. 490: 1) closely resembles the other two included collections in spore and SB shape, except that the spores are distinctly narrower (*7–9 × 1.5–1.7 µm). The SBs vary between shorter and longer than half the spore length, but are never shorter in the collection on *Ulmus*, which also differs in a longer pars sporifera and in slightly more fusoid spores similar as in *O. vitalbae*.

Not included collections. A sample on herbaceous stems of *Sambucus ebulus* from Luxembourg (Pl. 489: 2) closely resembles the type of *O. paravitalbae* in shape of spores and SB which are only slightly larger, but the apothecial margin was smooth.

A collection from Tenerife mentioned in Quijada et al. (2016, fig. 8) under the name *O. vitalbae* (IVV: TFC Mic. 23937) resembles *O. paravitalbae* in spore and SB shape except for slightly shorter spores of *6.5–7.2(–8) × 1.6–2.1 µm. Because we felt unable to decide to which of the two species this collection belongs, we preferred not to include it in either description.

A collection from mediterranean Islas Baleares on bark of *Juniperus phoenicea*, studied by I. Olariaga (IVV: 6.XII.2018), deviates in shorter and wider, distinctly clavate spores (*5.7–6.4 × 2.3–2.5 µm) and shorter SBs (3 × 0.7 µm), and in prominent glassy processes. From *O. poitevinica* it differs in shorter spores and SBs, in seemingly lacking crystalloid SCBs, and in downwards curved glassy processes. Based on its deviating DNA data (see below) this represents a species of its own which is referred to as *O.* aff. *paravitalbae* here.

Phylogeny. Sequences of ITS and LSU were gained from the holotype on *Daphne* (S1506 intron absent) and from the Balearean sample on *Juniperus* (S1506 intron present). Both form a strongly supported clade in a combined ML analysis (ITS+LSU, not shown). *O.* aff. *paravitalbae* deviates from *O. paravitalbae* by 6% in ITS and 0.5% in LSU D1–D3. In comparison, *O. poitevinica* differs from both by 17% in ITS and 4.3% in LSU D1–D3.

The position of *Orbilia paravitalbae* s.l. within section *Aurantiorubrae* is problematic. A close relationship to *O. vitalbae* can be excluded based on a high distance in both gene regions. Analyses of LSU (Phyl. S16) placed *O. paravitalbae* in a weakly supported sister position to series *Piliferae*, whereas analyses of ITS (Phyls 13, S15) or SSU+ITS+LSU (Phyl. 7) left it unresolved. Because of the morphological similarity to *O. rosella* we here treat *O. paravitalbae* for the time being as a member of series *Abutilones*.

Ecology. Samples on woody plants were on attached branches, whereas that on *Helleborus* was on the underside of a stem lying on moist ground. In the holotype the apothecia grew on bast, but sometimes on wood of *Daphne* and also on old perithecia of a dothideomycete in a mesomediterranean semihumid (dry) grassland. The sample on *Ulmus* was in a mesomediterranean floodplain, and that on *Helleborus* in an orosubmediterranean *Juniperus oxycedrus* woodland. Among the not included samples, the one on *Sideritis* from Tenerife was in the south-exposed mesomediterranean semihumid *Sideritido solutae-Pinetum canariensis* on trachybasalt, that on *Juniperus* from Islas Baleares a thermomediterranean, almost semiarid, dense forest with *Pinus halepensis*, *Pistacia lentiscus* and *Juniperus phoenicea* along a ravine, and that on *Sambucus ebulus* from Luxembourg in a cold-temperate humid dwarf elder population adjacent to a small angiosperm forest.

Specimens included. **SPAIN**: **Aragón**, **Teruel**, Sierra de Javalambre, 24 km SSE of Teruel, 4 km E of Camarena de la Sierra, 1635 m, stem of *Helleborus foetidus*, 26.II.2012, R. Tena (R.T.L. 12022601, H.B. 9681). – **Murcia**, 4.3 km NW of Bullas, 3.3 km SSW of Chaparral, 577 m, branches of *Daphne gnidium*, on bark, 10.V.2015, J.P. Priou (ex J.P.P. 15119, ex H.B. 10081, TAAM 198539, **holotype**; sq.: MG372375). – **Madrid**, 32 km ENE of Madrid, 4 km ENE of Alcalá de Henares, rio Henares, 595 m, branch of *Ulmus*, on wood, 19.V.1996, H.O. Baral (H.B. 5480).

Not included. **LUXEMBOURG**: **Gutland**, **Esch-sur-Alzette**, 2.5 km W of Esch-sur-Alzette, Belval Usines, 303 m, stems of *Sambucus ebulus*, 10.VI.1999, G. Marson (H.B. 6406b). — **SPAIN**: **Islas Baleares**, **Formentera**, 3.3 km WSW of Sant Francesc, Canal de Cala Saona, 10 m, branch of *Juniperus phoenicea*, on bark, 6.XII.2018, M. Prieto & I. Olariaga (ARAN-F 11430, doc. vid., sq.: MN151401). — **MACARONESIA**: **Canary Islands**, **Tenerife**, Vilaflor, 1.3 km N of Vilaflor, Lomo Gordo, 1600 m, twigs of *Sideritis soluta*, on bark, 9.III.2013, L. & C. Quijada (TFC Mic. 23937, doc. vid.).

Orbilia aethiopica Baral & U. Lindem., **sp. nov.**,

MB 813772 — Pls 491–492

Etymology: named after the geographical origin, Ethiopia.

Typification: Ethiopia, Addis Ababa, Menagesha Suba, branch of indet. angiosperm, 22.XII.2009, U. Lindemann (ex H.B. 9246a, M-0276430, holotype; sq.: KT222424).

Latin diagnosis: *Apothecia rehydratata 0.3–0.55 mm diam., subluteo-ochracea, disco conspicue concavo, margine breviter fimbriato. Asci 8-spori. Ascosporae *4.8–6.3 × 1.8–2.5 µm, cylindrico-clavatae, apice perlate subacutae. Paraphyses ad apicem plerumque sublanceolatae, exsudato tenui. Pili marginales breves, 8–15 µm longi, aseptati, subluteo-ochracei. Habitat ad corticem putridum subsiccum arboris angiospermae in zona mesotemperata humida afromontana Africae septentrio-orientalis.*

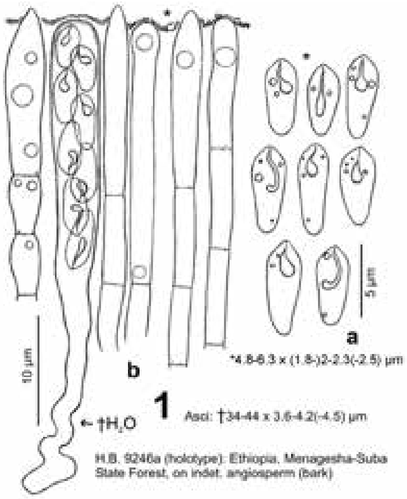

Plate 491. **1**: *Orbilia aethiopica*. – **a**. ascospores; **b**. ascus and paraphyses.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.55 mm diam., 0.14–0.19 mm high (receptacle 0.09–0.14 → 0.07–0.11 mm), pale to light yellowish-ochre, slightly translucent, round, scattered to subgregarious; disc deeply concave, margin 10–30 µm protruding, rough to warted; sessile on a narrowed base, superficial; dry with distinctly narrower aperture, bright ochre-brownish, without or with distinct

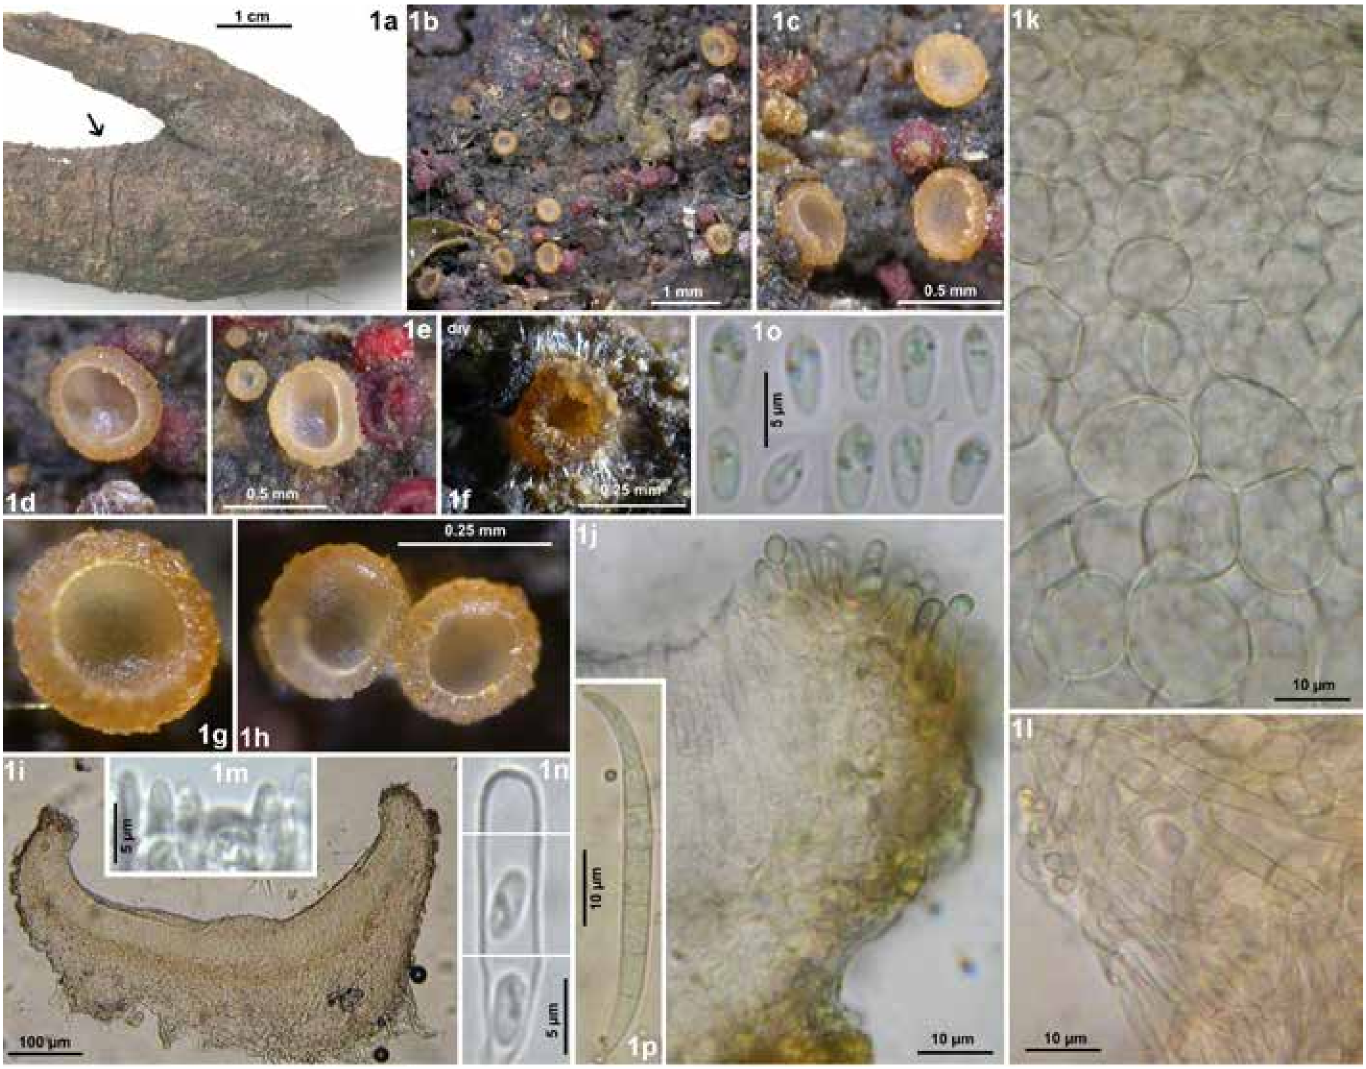

Plate 492. **1**: *Orbilia aethiopica*. – **1a**. dead, corticated, mesic branch; **1b–e**, **g–h**. rehydrated apothecia (with *Cosmospora* sp.); **1f**. dry apothecia; **1i**. apothecium in median section; **1j**. id., marginal region; **1k**. id., basal ectal excipulum; **1l**. anchoring hyphae; **1m**. paraphysis apices; **1n**. parts of basally broken ascus; **1n–o**. ascospores; **1p**. conidium (from substrate). – Living state, except for ascus in **1n** and upper cell in **1p**. – **1m–n**: phot. U. Lindemann. — **1a–p**. H.B. 9246a (holotype): Ethiopia, on indet. angiosperm.

whitish subiculum. **Asci** *4–5 µm wide, †34–44 × 3.6–4.2(–4.5) µm, 8-spored, spores †(sub)biseriate, ~3–4 lower spores inverted; **apex** (†) medium to strongly truncate (not indented, laterally not inflated); **base** with short to long, thin to thick, ± flexuous stalk, L-shaped. **Ascospores** *4.8–6.3 × (1.8–)2–2.3(–2.5) µm, cylindric-clavate, apex subacute at a wide angle (flat-conical), base very slightly to medium attenuated, straight to slightly inequilateral; **SBs** *2.2–3(–3.5) × 0.5–0.8 µm, with a usually strongly swollen, ± tear-shaped lower part and often a subulate upper part of varying length, apically narrowed to a short filum, mostly slightly to strongly flexuous. **Paraphyses** apically uninflated to slightly or medium lanceolate, terminal cells *(12–)15–20(–24) × 2–2.6(–3.7) µm, exceeding the dead asci by 0–3 µm, lower cells *(5.5–)7–9 × 1.8–2.2(–3) µm; unbranched at upper septum. **Medullary excipulum** pale cream, 30–40 µm thick, of dense, small-celled textura globulosa-intricata, somewhat horizontally oriented, sharply delimited. **Ectal excipulum** hyaline to pale yellowish, of (†) thin-walled, indistinctly oriented t. globulosa-angularis from base to margin, 80–120 µm thick near base, cells *13–20(–30) × 10–15(–16.5) µm; 10–20 µm thick at flanks and margin, cells at flanks *5–10 × 4–8 µm, at submargin and margin with protruding, non-septate **hairs** *8–15 × 3–4(–5) µm with 0.2–0.3(–0.5) µm thick smooth walls, surface yellowish-ochraceous; **glassy processes** absent. **Anchoring hyphae** abundant, *2–3(–3.5) µm wide, walls 0.2 µm thick, partly forming strands. **SCBs** in paraphyses and at flanks of ectal excipulum globose, (1–)1.5–2 µm diam. **Exudate** 0.2–0.5 µm thick, continuous to somewhat cloddy, over paraphyses ± firmly attached, subhyaline, at margin and flanks light yellowish-ochraceous. **— ANAMORPH**: unknown (but see below).

Habitat: lying on the dry ground, corticated, 18 mm thick mesic branch of unidentified angiosperm tree, on medium decayed bark (periderm), partly on old perithecia of *Cosmospora*; somewhat blackened, no algae. **Associated**: *Cosmospora* sp., *Hyalorbilia herbicola*, *Lanatonectria flocculenta*, ?*Nectriopsis* sp. **Desiccation tolerance**: excipulum and paraphyses still viable after at least 3 weeks. **Altitude**: 2520 m a.s.l. **Phenology**: XII (but rather long-lived).

Taxonomic remarks. *Orbilia aethiopica* is characterized by cupulate apothecia with short hair-like marginal projections, more or less lanceolate paraphyses, and particularly by short, cylindric-clavate ascospores with a seemingly rounded apex that is, in fact, subacute under a wide angle. The species is difficult to place based on its morphology alone. Due to the shape of the SBs, *O. aethiopica* is similar to series *Habrostictis* in which, however, the paraphyses are apically consistently inflated and often beaked. Because of similarities in the yellowish exudate, *O. aethiopica* resembles species of section *Helicoon*, such as the eastern Asian *O. hoana*. The neotropical *O. martinicensis*, assigned to series *Helicoon*, has a similar shape of spores and particularly SBs, but differs in larger, flat apothecia with glassy processes instead of short hairs at the margin. In some of its features *O. aethiopica* resembles species such as *O. cupularis* (section *Ovoideae*), *O. fraxini*, and *O. lamarcheae* (section *Arthrobotrys*), except for characters of the spores which have a very different shape and contain globose SBs.

Anamorph. Two phragmoconidia (*50 × 3.8–4.5 µm) with medium curved ends (vermispora-like) were detected on the substrate near the apothecia (Pl. 492: 1p).

Phylogeny. A sequence taken from apothecia of the holotype (SSU without S1506 intron, ITS, LSU) shows a minimum ITS distance of 16% to *O. carminorosea* (3.5% in LSU D1–D2), and 18.5% to *O. ebuli* (4.3% in LSU). In our analyses of ITS+LSU or ITS (Phyls 13, S15), *O. aethiopica* clustered strongly supported in series *Abutilones*, whereas in the LSU (S16) it clustered unresolved.

Ecology. *O. aethiopica* was detected on ± rotten periderm of a corticated mesic branch in close association with a *Cosmospora*, in a warm-temperate humid (somewhat winter-dry), evergreen, predominantly broad-leaved afromontane forest at the western slope of an old volcano in the central plateau of the Ethiopian highlands.

Specimens included. **ETHIOPIA**: **Oromia**, 22 km WSW of Addis Ababa, 10 km NW of Sebeta, southern part of Menagesha Suba State Forest, 2520 m, branch of indet. angiosperm, on bark, 22.XII.2009, U. Lindemann (ex H.B. 9246a, M-0276430, **holotype**; sq.: KT222424).

Series *Poitevinicae*

Orbilia subgenus ***Habrostictis*** section ***Aurantiorubrae*** series ***Poitevinicae*** Baral, **ser. nov.**, MB 815014 – Type species: *Orbilia poitevinica* Baral

Recognized species: *O. poitevinica*.

Orbilia poitevinica Baral, **sp. nov.**, MB 813773 — Pls 493–494

Etymology: named after the site of the type collection, Marais Poitevin (W-France).
Typification: France, Charente-Maritime, Niort, branches of *Fraxinus excelsior*, 25.IV.2006, H.O. Baral & N. Van Vooren (ex H.B. 8131, M-0276566, holotype).

Latin diagnosis of series and species: *Apothecia rehydratata 0.3–1.5 mm diam., rosea, margine subtiliter vel conspicue albido-crenulato. Asci 8-spori. Ascosporae *6–9 × 2.2–3 µm, subcylindricae vel fusoideo-clavatae, in statu vivo corpusculum vermiformem, basaliter lacrimiformem, ad apicem filo minuto affixum continentes. Paraphyses ad apicem leniter capitato-clavatae. Cellulae vivae excipuli et paraphysium corpuscula crystalloidea continentes. Habitat ad corticem ramorum siccorum* Fraxini excelsioris *in zona meso ad supratemperata atlantica ad subcontinentali Europae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–1(–1.5) mm diam., 0.14–0.2 mm high, light (brick-)rose, round to

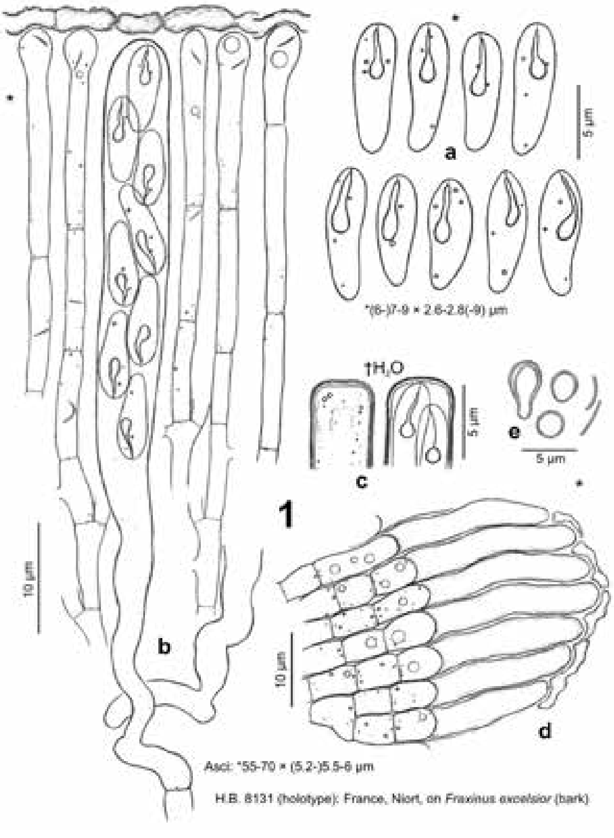

Plate 493. **1**: *Orbilia poitevinica*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section, cortical cells with glassy processes; **e**. SCBs in cells of ectal excipulum (lower flanks).

somewhat undulating, scattered to gregarious in small groups; disc flat to slightly convex, margin 0–10 µm protruding, finely to distinctly whitish crenulate or toothed; broadly sessile, superficial; dry light to bright rose-orange to orange-red. **Asci** *55–70 × (5.2–)5.5–6 µm {2}, †50–60 × 4.3–5.4 µm {1}, 8-spored, spores (*) biseriate, 3–5(–6) lower spores inverted {2} (rarely or sometimes mixed), pars sporifera *30–38 µm long; **apex** (†) medium to strongly truncate (not indented, laterally scarcely inflated); **base** with medium long and thick, flexuous stalk, L- to Y-shaped. **Ascospores** *(6–)7–8(–9) {2} × 2.2–2.6 {1} or 2.6–2.8(–3) µm {T}, subcylindrical to clavate or fusoid-clavate, apex rounded, more rarely obtuse, base not or slightly to medium attenuated, straight to slightly inequilateral; **SBs** *(3–)3.7–4.4(–4.7) × (0.7–)0.8–1(–1.2) µm {2}, divided into an ellipsoid to tear-shaped lower and a vermiform to subulate upper part, straight to ± flexuous; overmature with long filum and abruptly globose lower part. **Paraphyses** apically uninflated or often slightly (to medium) capitate-clavate, terminal cells *(9–)16–21(–23) × (2–)2.3–3.3 µm {T}, lower cells *(6–)9–14(–17) × (1.4–)1.6–2(–2.2) µm {T}; never branched near apex, hymenium pale rose. **Medullary excipulum** very pale rose, 50–100 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale rose (only near margin), of thin-walled († slightly gelatinized), vertically oriented t. angularis(-prismatica) from base to mid flanks, 30–45 µm thick near base, cells *(8–)10–15(–20) × (6–)7–10(–12.5) µm {2}; 20–25(–35) µm thick near margin, of strictly parallel t. prismatica oriented at an 60–80° angle to the surface, marginal cortical cells *4–8(–12) × 2.7–4.5 µm {T}; **glassy processes** (5–)10–20(–40) × (2.5–)3–3.5(–4) µm {2}, low- to high-refractive, not or only sparsely stratified, ± straight or slightly downwards curved (those at mid flanks slightly upwards), coherent to form indistinct teeth, **hairs** absent. **Anchoring hyphae** abundant, *2–2.7(–4) µm wide, walls 0.2–0.3(–0.5) µm thick {T}, forming a 25 µm thick layer. **SCBs** in paraphyses forming thin rods, in ectal excipulum (only at lower and mid flanks) rod- or ring-shaped, 2–5.3 × 2–2.8 µm {2}, hyaline. **Exudate** over paraphyses 1.5–2.5 µm thick, cloddy-continuous, hyaline to very pale yellowish, loosely attached; over margin and flanks ~1–1.5 µm thick. — **ANAMORPH**: vermispora-like (presumed, from natural substrate {2}). **Conidiophores** not seen. **Conidia** phragmosporous, *44–58 × (4.5–)5–6(–6.5) µm, 11–15-septate {2}, slightly to strongly curved at both ends, mostly ± straight in middle part, with a few small LBs especially at the septa, sometimes also with 1–2 larger LBs in each cell (0.8–1.2 µm diam.).

Habitat: collected 1–4 m above the ground, corticated to nearly decorticated, 14–60 mm thick branches and trunks of *Fraxinus excelsior* {2}, on medium to very rotten bark (bast or over cracks in periderm) {2}, also on old boring dust of a bark beetle {1}, slightly greyed, partly blackened, sparsely to strongly covered by green algae. **Associated**: *Orbilia phragmotricha* {1}, *Orthotrichum* sp. {1}, *Peniophora* sp. {1}, *Physcia* sp. {1}, *Xanthoria parietina* {1/1}. **Desiccation tolerance**: fully viable for at least 4 weeks. **Altitude**: 4–333 m a.s.l. **Geology**: France: Holocene alluvial peaty clay adjacent to Middle & Upper Jurassic limestone, Luxembourg: Lower Jurassic sandstone. **Phenology**: IV (but rather long-lived).

Taxonomic remarks. *Orbilia poitevinica* is extraordinary within section *Aurantiorubrae* because of its rather short and wide ascospores with elongate spore bodies which resemble those of section *Habrostictis*. Judging especially from its SBs, *O. poitevinica* was first thought to belong to that section close to *O. vitalbae* or *O. trapeziformis*. However, *O. poitevinica* possesses conspicuous glassy processes that form ± distinct teeth at the margin, a character unknown in section *Habrostictis*. Similar spores are found in *O. aethiopica*, which differs, e. g., in yellowish-ochre apothecia, short marginal hairs instead of glassy processes, partly ± lanceolate paraphyses, and in lacking crystalloid SCBs.

Variation. In the holotype the apothecia were predominantly smaller [0.3–0.5(–1.3) mm] than in the specimen from Luxembourg [0.5–1(–1.5) mm], and the spores were wider [Luxembourg: *(6.5–)7–8(–9) × 2.2–2.6 µm].

Anamorph. Vermispora-like conidia were observed on the substrate near apothecia in both collections (Pl. 494: 1j, 2j). However, conidia did not develop in pure culture.

Phylogeny. A sequence gained from apothecia from the Luxembourg specimen comprises ITS and LSU (the S1506 intron is absent). Analyses of (SSU+)ITS+LSU, ITS, or LSU (Phyls 7, 13, S15–S16) placed *O. poitevinica* unresolved in the genus *Orbilia*. In Phyl. 7 *O. paravitalbae* was associated with low support with *O. poitevinica*.

In the ITS region the lowest distance was 18–19 % to *O.* cf. *paracaudata* and *O. pilifera* (series *Piliferae*) and 19 % to *O. albidorosea* and *O. albovinosa* (series *Albovinosae*), and in the LSU (D1–D2) around 2.5–3 % to *O. ovalis*, *O. albidorosea*, and *O. phragmotricha*.

Specific nucleotide positions. *O. poitevinica* concurs with series *Abutilones* at pos. 140 of the 5.8S (GGCA**C**GTCTG), by which it differs from all other series of subgenus *Habrostictis* which generally have GGCA**T**GTCTG. Similarities to series *Piliferae* can be seen in the alignment of the ITS2 region, but further characteristic nucleotides could not be found in the ITS or LSU.

Ecology. *O. poitevinica* was collected on decayed bark and bark beetle boring dust of xeric branches of *Fraxinus excelsior* in atlantic and subcontinental, warm- to cold-temperate humid western and central Europe. The type location is part of a large area of cultivated marshland with mesosubmediterranean influence (with *Fraxinus*, *Salix aurita*, *Populus* and some *Quercus pubescens*), a remnant of the former Gulf of Poitou in western France. The paratype was detected in a small moist depression with dead young ash trees surrounded by young spruce trees in a deciduous forest between airport and highway in temperate Luxembourg.

Specimens included. **FRANCE**: **Poitou-Charentes**, **Deux-Sèvres**, Poitou, 21 km W of Niort, 4 km NW of St.-Hilaire-La-Palud, Marais Poitevin, 4 m, branches of *Fraxinus excelsior*, on bark & boring dust, 25.IV.2006, H.O. Baral & N. Van Vooren (ex H.B. 8131, **holotype**, M-0276566, anam. substr.). — **LUXEMBOURG**: **Gutland**, **Luxembourg**, 4 km ENE of Luxembourg, NW of Kalchesbrück, E of Findel, 333 m, branch and trunk of *Fraxinus excelsior*, on bark, 4.IV.2013, G. Marson (G.M. 2013-04-04.2; sq.: KT380079).

Series *Piliferae*

Orbilia subgenus ***Habrostictis*** section ***Aurantiorubrae*** series ***Piliferae*** Baral, **ser. nov.**, MB 815015 – Type species: *Orbilia pilifera* Baral & R. Galán

Etymology: named after the type species, *O. pilifera*.

Latin diagnosis: *Apothecia ochracea, aurantiaca vel testaceo-rubra, fimbriata vel glabra, guttulae luteae carentes, ascosporae apice rotundatae ad obtusae, raro subacutae, basaliter plerumque breviter caudata, plerumque rectae vel leniter curvatae, status anamorphicus conidiis staurosporis (typo* Trinacrium incurvum*).*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.3–1.5(–1.8) mm diam., pale to bright ochre-orange to brick-red, somewhat urceolate to flat, margin smooth to crenulate or whitish fimbriate, sessile or with a short stipe. **Asci** *(36–)40–71 × (3.5–)4–5.5(–6) µm, 8-spored, lower (1–)3–6(–7) spores inverted; **apex** (†) medium to strongly truncate, not or slightly indented and laterally inflated; **base** T-, L- to Y- or h-shaped. **Ascospores** *(5–)6–11(–12.5) × (1–)1.3–2.5(–3) µm, subcylindric- to ellipsoid- or fusoid-clavate, apex rounded to obtuse, rarely subacute, base often tail-like or with a distinct short tail, straight to slightly, sometimes medium curved or geniculate near base, **SBs** (1.2–)1.5–3(–4.2) × (0.3–)0.5–1(–1.3) µm, globose to tear-shaped or ampulliform to rod-shaped, apically untapered or narrowed to a small or wide point, rarely with a short filum, straight, sometimes medium flexuous. **Paraphyses** slightly to strongly clavate-capitate or spathulate to mammiform or lageniform at the apex, terminal cells 1– 3 × longer than lower cells. **Ectal excipulum** cells near base *(6–)8–20(–30) × (5–)7–15(–19) µm; **glassy processes** absent, rarely 5–10 µm long (*O. caudata*), **hairs** absent or ~ 10 µm up to 35–55(–80) × (3–)3.5–6.5(–8) µm, thin-walled, (2–)3–6-septate. **SCBs** absent or sometimes line- to ring-shaped, rarely globose (small); **VBs** consistently absent. **Exudate** over paraphyses and margin absent or up to 1–2(–3) µm thick, rough, cloddy or often cap-like, firmly attached. **— ANAMORPH**: trinacrium incurvum-like. **Conidiophores** short (7–20 µm). **Conidiogenous cells** monoblastic or sympodial. **Conidia** staurosporous, T-shaped (2-armed), *26–43 × 17–49 µm, the two arms curved downwards.

Habitat: on bark (exceptionally wood) of twigs and branches of angiosperms, rarely herbaceous stems, humid to semiarid, temperate to tropical, always desiccation-tolerant.

Recognized species: 7, plus 4 unnamed species ('affinis').

Taxonomic remarks. Series *Piliferae* is defined by its characteristic trinacrium-like conidia with curved arms in combination with molecular data. Although typified by *O. pilifera*, a species with prominent, septate, thin-walled hairs, the apothecia in a majority of the included species have a more or less smooth margin. In two taxa tentatively placed here (*O. caudata*, *O.* aff. *caudata*) short glassy processes occur at the margin in some specimens. As a characteristic of most of the included taxa, the spores tend to have a more or less defined, short and thick tail, also the spore apex is predominantly rounded to obtuse. Spore bodies are always visibly attached to the spore apex but vary between subglobose, tear-shaped, rod-shaped, and ampulliform. Species with elongate, apically strongly narrowed spore bodies may be confused with members of section *Habrostictis*, but also series *Ovales* (section *Lentiformes*) or series *Commatoideae.*

Series *Piliferae* is placed here in section *Aurantiorubrae* mainly because of a partial similarity of *O. pilifera* with *O. suberis* of series *Abutilones*. *O. pilifera* resembles also members of series *Albovinosae* in spore body shape, but that series is characterized by rather prominent glassy processes at the margin and by conidia with longer and thinner arms. In the marginal hairs and lageniform-mammiform paraphyses *O. pilifera* strikingly resembles *O. carpoboloides* of series *Habrostictis*. However, strong differences in the shape of SBs and conidia suggest that the two species are not closely related.

Four of the included species (*O. caudata*, *O. floridensis*, holotype collections of *O. paracaudata* and *O. farnesianae*) were first thought to belong to series *Ovales* of section *Lentiformes*, mainly because of spore bodies similar as in the type species, *O. ovalis*. On the other hand, *O.* cf. *paracaudata* and the paratype of *O. farnesianae* were first believed to belong to series *Habrostictis* (section *Habrostictis*) close to *O. mammifera*, based on partly mammiform paraphysis apices and rather long and narrow SBs. These four species share indeed some similarities, including lageniform to mammiform paraphyses in some of them, or a similar shape of ascospores and SBs, besides their characteristic trinacrium-like conidia and molecular data. *O. bannaensis* was at first tentatively affiliated in section *Helicoon* based on morphological similarities, including the unbranched conidia of its presumed anamorph.

Species delimitation. Rather strong variation was noted between populations of *O. farnesianae* (from the same site and substrate), *O. paracaudata*, and *O. caudata*, which raises the question as to whether these species are heterogeneous. The independency of *O.* aff. *farnesianae* is supported by molecular data.

Anamorph. Except for *O. bannaensis* and *O. amarilla*, quite charateristic trinacrium incurvum-like conidia with curved-down arms, resembling an anchor, were observed in all taxa of series *Piliferae*, though mostly only on the natural substrate. They were obtained in pure culture in *O. pilifera* and in two undescribed Chinese taxa here referred to as *O.* aff. *farnesianae* (Liu 2006, as *O. brasiliensis*) and *O.* aff. *bannaensis* (Guo et al. 2013, as *Orbilia* sp.). The presence of these conidia in *O. floridensis* (holotype), *O. farnesianae* (paratype), *O. caudata*, and *O.* cf. *paracaudata* and their almost exclusive appearance in one clade gave the impetus to place all these species in series *Piliferae*.

The anchor-like conidia are a main difference between series *Piliferae* and the remaining series of section *Aurantiorubrae*, in which trinacrium-like anamorphs almost never occur with certainty, except for two species of series *Albovinosae* in which the conidial arms are also curved down- or outwards but arms and stipes are more slender. Series *Piliferae* concurs with section *Habrostictis* in possessing a trinacrium-like anamorph, but in that group the two conidial arms are always straight and project upwards. Although series *Habrostictis* resembles *O. pilifera* in teleomorph characteristics, it sharply differs in vermispora-like conidia.

The observed conidia do not significantly differ among the taxa of series *Piliferae* and fit more or less *Trinacrium incurvum*, a species that was described from two isolates [Taiwan, on bark, Matsushima 1980: 75, paratype; Peru, Rio Monanti, on twig of broad-leaved tree, Matsushima 1993, holotype; see Pl. 22: d]. In the holotype the stipes are reported as 3–4-septate, whereas in the paratype they are longer and 3–6-septate. In comparison to the here reported anamorphs of series *Piliferae*, Matsushima's two strains have somewhat shorter arms with only 0–2 septa. Matsushima reported unbranched conidia in the holotype, which were also seen in B. Liu's culture of *O.* aff. *farnesianae* and a single time on the natural substrate in a collection of *O. pilifera* studied by us (H.B. 7095a). No sequence is available for Matsushima's strains, therefore, the identity of *T. incurvum* remains unclear and we refrained from adopting that name for any of our taxa.

Phylogeny. In an analysis of the LSU region by Liu et al. (2006a), *O.* aff. *farnesianae* formed with *Orbilia* sp. (both as '*O. brasiliensis*') a paraphyletic sister group to section *Helicoon*, whereas members of section *Aurantiorubrae*, represented by *O. milinana*, *O. scolecospora*, *O. bomiensis*, and *O. nemaspora*, clustered distant from those (no member of section *Habrostictis* was available).

Our molecular analysis of (SSU+)ITS+LSU or each region alone placed *O. pilifera*, *O. farnesianae*, *O.* aff. *farnesianae*, *O. amarilla*, and *O.* cf. *paracaudata* in a strongly (ITS+LSU, ITS) or medium (LSU) supported monophyletic clade distant from other taxa (Phyls 7, 13, S15–S16). Also *O. bannaensis* clustered within this clade when analysing ITS, but unresolved in the combined analysis (Phyls 13, S15), perhaps because it lacks LSU. In the S1506 intron (S14) *O. piliferae* and *O.* cf. *paracaudata* form a strongly supported (NJ analysis, not shown) or unsupported (ML, S14) clade, whereas *O.* aff. *farnesianae* clustered unresolved in section *Aurantiorubrae*. The clade indeed occupies a rather isolated position within subgenus *Habrostictis*, where it clustered in the analysis of Baral et al. (2017b) unsupported sister to section *Helicoon*.

Specific nucleotide positions. Series *Piliferae* shows in the ITS2 region a highly conservative string of 87 nt which is consistent in all five species, except for 2 variable positions: TTAAAGTTGACGTTCTGTGTGGTACTCATCCTTACCTTCCGTAGTAATTTACTTTAT*S*ACTGTTCGTT*W*GGATTTGGCACGCACCTG. Other series of section *Aurantiorubrae* are rather variable in this region. In the ITS1 no such regular pattern is observed. Pos. 295 of LSU D1 is diagnostic for series *Pilifera*, showing TCAAA**T**TG, whereas all other groups of subgenus *Habrostictis* show TCAAA**A**TG or rarely TCTAA**A**TG or TCAAA**A**CG.

At pos. 98 of the 5.8S region series *Pilferae* has CATCGA**A** except for *O. bannaensis* which has CATCGA**G**, the current motif in *Orbilia*, but CATCGA**A** also occurs in a few *Orbilia* spp. and in most basal genera.

Ecology. Probably all included species are more or less desiccation-tolerant. They grew on bark of angiosperms, rarely on wood or herbaceous stems. Records derive from warm-temperate to tropical, humid to arid regions of Europe, Macaronesia, Asia, Australia, and North America.

Key to species of series *Piliferae*

1. Inflated apex of paraphyses at least partly mammiform or lageniform (beaked); septate hairs present or absent, glassy processes always absent 2
1. Inflated apex of paraphyses capitate, never beaked; septate hairs always absent, glassy processes present or absent 7

2. Marginal excipular cells terminated by 35–55 µm long, 2–6-septate, thin-walled hairs; spores *(5–)6–8(–9.2) × (2–)2.2–2.5(–2.7) µm, with tail-like base; SBs broadly tear-shaped to subglobose; bark of *Ulmus*, cold-temperate to supramediterranean humid to semihumid, mainly western and southern Europe, also northeastern North America .... ***O*. *pilifera***, p. 918
2. Marginal excipular cells without hairs 3

3. Spores *11.5–20.5 × 2.4–3.5 µm, subcylindrical to narrowly fusoid-clavate; SBs consistently absent (living state!); wood of *Euphorbia*, subtropical (semi)arid Macaronesia .... ***O*. *asomatica*** (section *Arthrobotrys*), p. 1487
3. Spores *5.5–12.5 µm long, fusoid-clavate; SBs present in living mature spores 4

4. Spores consistently ellipsoid-fusoid, apex obtuse to subacute, base always with a short tail 5
4. Spores often cylindrical, if ellipsoid-fusoid then < *2 µm wide, apex rounded to obtuse, base attenuated, tail-like or with a short tail 6

5. Spores *(5.8–)6.4–7.3(–8) × (1.9–)2.2–2.3(–2.4) µm; SCBs ring- to S- or rod-shaped (line- to plate-like); branch of *Euphorbia*, subtropical arid Macaronesia .... ***O*. *amarilla***, p. 921
5. Spores †(7.5–)8–10 × 2.3–3 µm; data on SCBs unknown; twig of indet. angiosperm shrub, subtropical humid southern China .... ***O*. aff. *farnesianae***, p. 925

6. Spores *(5.5–)8–11(–12.5) × 1.7–2.5 µm; SBs 2–4.2 µm long; bark of *Vachellia*, subtropical arid western Australia ... ***O*. *farnesianae***, p. 923
6. Spores *6–7.5 × 1.4–1.8 µm; SBs 2–2.5 µm long; bark of woody climber, tropical semiarid western Australia.... ***O*. cf. *paracaudata***, p. 926

7. Spores *(3.7–)4.5–7.5 × 1.8–3.3 µm, ovoid, ellipsoid or fusoid, base sometimes tapered but never tail-like; conidia dicranidion-like (partly unknown) 8
7. Spores *5–8 or 7.5–12.5 × 1–2.3 µm, fusoid to subcylindrical, base partly tail-like or with distinct short tail; conidia trinacrium-like, with downwards curved arms (partly unknown) 9

8. Spores ellipsoid to ovoid, *3.7–7.5 × 2.2–3.3 µm; SBs ± ampulliform, with a rod-shaped upper part; margin without glassy processes; bark of angiosperms, Europe & North America .... see ***O*. *ovalis*** (section *Lentiformes*), p. 498
8. Spores ellipsoid-fusoid, †5–7.3 × 1.8–2.2 µm; SBs ?tear-shaped; margin with 2–5 µm long glassy processes; anamorph unknown; bark of *Cynanchum*, subtropical semiarid Pakistan .... ***O*. aff. *caudata***, p. 929

9. Spores *1.9–2.3 µm wide, with ± broad, ellipsoid-fusiform upper part; margin with or without short glassy processes 10
9. Spores *1–2 µm wide, with ± narrow, cylindric-fusoid upper part; margin without glassy processes 11

10. Spores *5–7.8 µm long; SBs tear- to rod-shaped; bark of angiosperms, herbaceous stems, (sub)tropical humid South America & eastern Asia .... ***O*. *caudata***, p. 928
10. Spores *(7–)8–9.5(–11) µm long; SBs broadly tear-shaped to globose; wood of *Euphorbia*, subtropical (semi)arid Macaronesia .... see ***O*. *pisciformis*** (series *Commatoideae*), p. 808

11. Spores *5.8–6.3 × 1.2–1.3 µm; indet. woody substrate, subtropical humid eastern Asia .... ***O*. aff. *bannaensis***, p. 932
11. Spores longer and partly wider 12

12. Spores *7–8.8 × 1–1.5 µm; asci †31–43 µm long 13
12. Spores *5.5–12.5 × 1.5–2.5 µm; asci †42–56 µm long 14

13. Spores *7–8.8 × 1.3–1.5 µm, SBs 1.2–1.8 µm long; bark of *Ficus*, tropical humid southeastern North America ... ***O*. *floridensis***, p. 927
13. Spores *7–8.5 × 1–1.3 µm, SBs 1.5–2.3 µm long; bark of *Broussonetia*, (sub)tropical humid eastern Asia .... ***O*. *bannaensis***, p. 930

14. Spores *5.8–8.5(–9.5) × (1.5–)1.6–1.8(–1.9) µm; SBs 1.5–2(–2.2) µm long; with inconspicuous crystalloid SCBs; bark of different climbers, tropical subhumid eastern & western Australia .... ***O*. *paracaudata***, p. 925
14. Spores *(5.5–)8–11(–12.5) × (1.7–)1.8–2(–2.5) µm; SBs (2–)2.3–3.2(–4.2) µm long; without crystalloid SCBs; bark of *Vachellia*, subtropical arid western Australia .... ***O*. *farnesianae***, p. 923

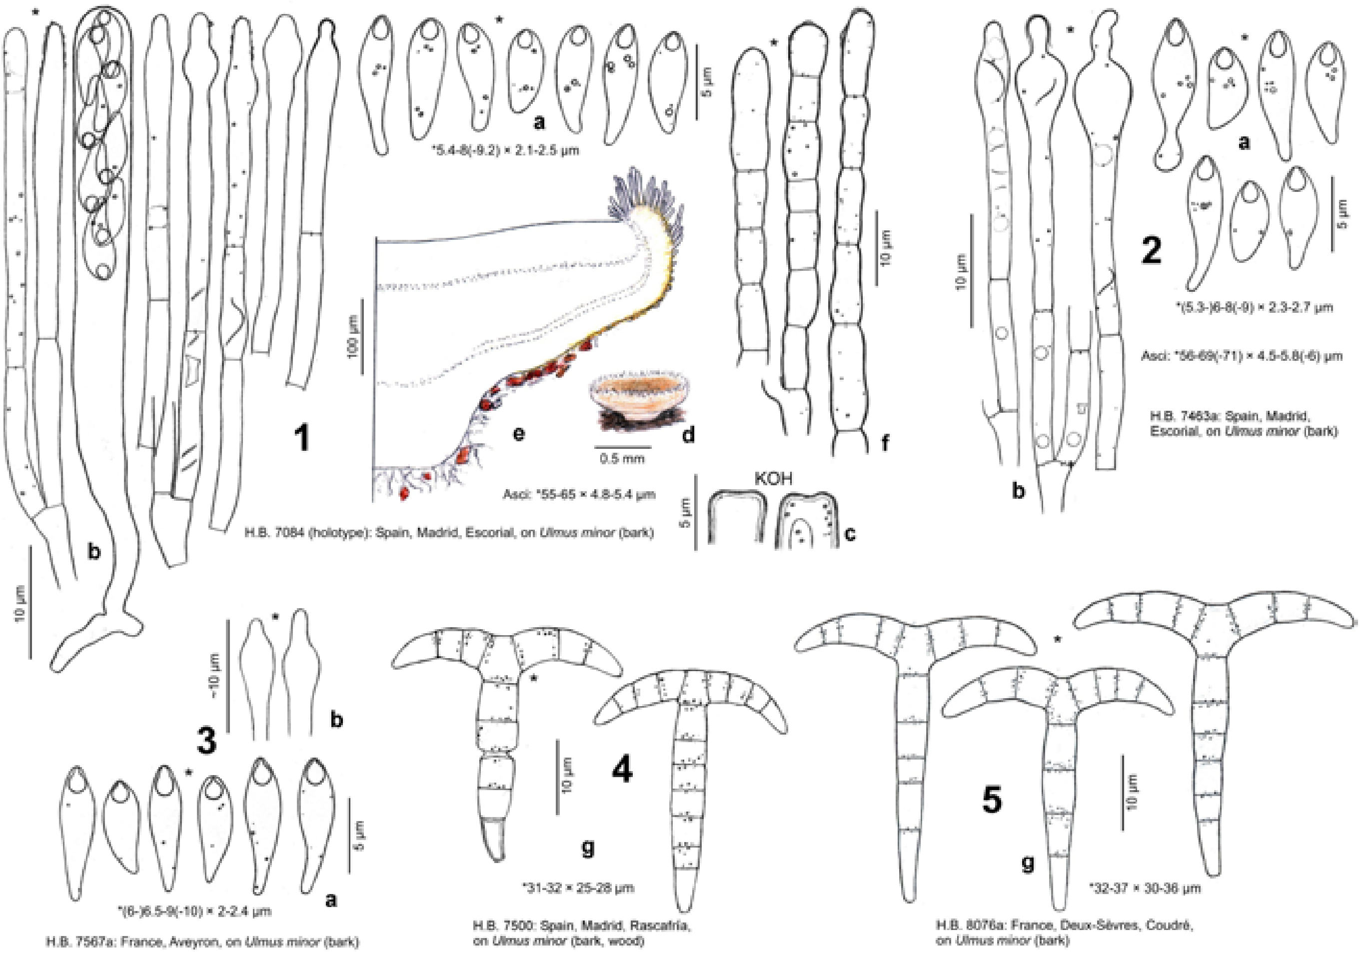

Plate 495. **1–5**: *Orbilia pilifera*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium with fimbriate margin; **e**. apothecium in median section; **f**. marginal hairs; **g**. conidia (**4** from substrate, **5** from culture).

Orbilia pilifera Baral & R. Galán, in Friebes, Joannea Bot. 9: 18 (2011) — Pls 495–497, Map 85

Etymology: referring to the hairy apothecial margin.

Typification: Spain, Madrid, Colmenarejo, trunk of *Ulmus minor*, 7.XII.2001, F. Prieto (ex H.B. 7084, M-0276554, holotype).

Misapplied name: García Alonso (2003: 228), as *O. luteorubella*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.5–1.5(–1.8)((–2.5)) mm diam., 0.15–0.25(–0.3) mm high (receptacle 0.14–0.15 → 0.08–0.11), light to bright (yellowish-)ochre(-orange), non- to semitranslucent (hygrophan), round, soft, non-gelatinous, gregarious in small groups or often large numbers; disc slightly to strongly concave, flat only when old, margin fimbriate to crenulate by prominent, 15–60 µm protruding whitish hairs; sessile or with an obconical base or short stipe 0.1 × 0.25–0.3 mm, ± superficial, sometimes erumpent from beneath bark tissue; dry light orange-ochre. **Asci** *(52–)55–71 × 4.5–5.5(–6) µm {4}, †45–64 × 3.8–4.8 µm {3}, 8-spored, spores (*) biseriate, (1–)2–**3**–**5**–6(–7) lower spores inverted (sometimes mixed) {10}, pars sporifera *(15–)20–31(–36) µm long; **apex** (†) strongly truncate (often slightly indented, laterally sometimes slightly inflated); **base** with medium to very long, thin, flexuous stalk, T- to L-shaped. **Ascospores** *(5–)6–8(–9.2)((–10)) × ((1.8–))(2–)2.2–2.5(–2.7)((–3)) µm {7}, †(6.8–)7.3–8.5(–9) × 2–2.3 µm {1}, ellipsoid- to fusoid-(or fusiform-)clavate, exceptionally ellipsoid-fusoid or with bulbous tail, apex obtuse, sometimes subacute, base mostly strongly attenuated in a tail-like end, straight or slightly curved near base; **SBs** *(1.2–)1.4–1.8 × 1–1.3 µm {5}, broadly tear-shaped to subglobose, attached by a ± small point. **Paraphyses** apically uninflated to narrowly lanceolate or mostly slightly to very strongly spathulate or lageniform to mammiform, terminal cells *(14–)17–30(–38) × (2–)2.5–4(–5.2) µm {5}, apical beak 1–4.5 × 1.3–2 µm, exceeding the living asci by up to 2–3 µm, the dead asci by 0–5 µm, lower cells *8–17 × 1.5–2.6 µm {3}, unbranched at upper septum, hymenium pale orange. **Medullary excipulum** very pale orange, 40–130 µm thick in centre, of dense textura globulosa-angularis, partly interrupted by loose t. intricata, near base indistinctly delimited from ectal excipulum, at flanks ± sharply so by a 5–40 µm thick, pale yellow-orange layer of t. porrecta. **Ectal excipulum** hyaline to very pale yellowish-orange, near cortex light golden yellow, of thin-walled, (irregularly) vertically oriented t. angularis-prismatica from base to margin, up to 110 µm thick in stipe, 30–60 µm near base, cells *6–16(–18)((–25)) × 5–11(–14) µm {3}, 20–40 µm thick at lower flanks, cells *7–13 × 4–9 µm, 15–30 µm thick near margin, of t. prismatica-porrecta oriented at a 10–45° angle to the surface, or of t. angularis-prismatica oriented at 45–80°, cells *7–17 × 2.5–5 µm; cortical cells terminating in thin-walled, **hairs** */†35–55(–80) × (3.5–)4.5–6.5(–8) µm {6}, (2–)3–6-septate, straight or often somewhat irregularly flexuous, cylindrical to medium moniliform, wall *0.2–0.4 µm thick, †0.3–0.5(–0.7) µm, smooth, free or slightly coherent to form indistinct teeth. **Anchoring hyphae** abundant, */†(1.5–)1.8–3(–5) µm wide, walls 0.2–0.3(–0.5) µm thick {5}, forming an up to 100 µm thick, loose hyaline texture on base and lower flanks, partly as hyphal strands. **SCBs** in paraphyses forming inconspicuous rod-shaped or filiform, partly circular structures {3}, also absent {2}; similar SCBs in ectal excipulum present {1} or absent {4}; **VBs** in young paraphyses present {1}, medium refractive. **Exudate** on paraphyses forming minute warts or often absent; at margin and lower flanks ~1 µm thick, light to bright golden-orange-ochre, cloddy; dead cytoplasm light golden yellow. — **ANAMORPH**: trinacrium incurvum-like (from ascospore isolate {1} and natural substrate {9}). **Conidiophores** short. **Conidia** T-shaped, the two arms bent downwards, total size *27–37 × 22–36(–40) µm, stipe *22.5–31 × 4–4.7 µm, 4–7-septate, arms tapering, *13.5–18 × 4.2–5 µm, (2–)3–4-septate {6}.

Habitat: collected on the ground or more often in 0.2–2(–3.5) m above the ground, on ~3–25 cm thick trunks (or stumps), also on 12–40 mm thick branches, of ?*Populus* sp. {1}, *Ulmus* sp. {15/1}, *U. laevis* {3}, *U. minor* {12/5}, on rather large pieces of bark {36}, rarely on wood {2}, bark usually more or less detaching from standing, dead trunks, also firmly attached, sometimes fallen to ground, on inner surface, also on edges and in smaller number on outer surface (then in crevices of bark or small holes of periderm), medium to strongly decayed, regularly around and partly in old galleries of a bark beetle (*Scolytus* sp.), ungreyed, no algae, trees probably killed by the elm disease. **Associated**: *Anthostoma gastrinum* {1}, *Arthonia cinnabarina* {1}, *Ceratocystis ulmi* {1}, *Cistella chlorosticta* {2}, *Hyalorbilia juliae* {1}, *Lachnella* ?*villosa* {1}, *Lecophagus subglobosus* {2}, *Nectria cinnabarina* {1}, *N. pseudopeziza* {5}, *Opegrapha* sp. {1}, *Orbilia aurantiorubra* {5}, *O. auricolor* {1}, *O. ficicola* {1}, *O. gambelii* (on wood) {1}, *O. quaestiformis* (on wood) {1}, *O. xanthoguttulata* {2}, several crustose and foliose lichens (on exterior of bark, e.g., *Parmelia*, *Physcia*, *Xanthoria parietina*, *Lecanora*) and bryophytes (*Frullania* etc.). **Desiccation tolerance**: fully viable for at least 2.5 months, a few ascospores and many excipular cells survived for nearly 7.5 years, conidia at least 20 days. **Altitude**: 5–560 m a.s.l. (central and western Europe), 173–1135 m (southern Europe), 85–90 m (hemiboreal North America). **Geology**: Canada: Middle Ordovician sedimentary rock; Europe: Lower to Upper Jurassic clay & limestone, Cretaceous calcareous marl, Tertiary clay, partly with andesite and quartz. **Phenology**: (VIII–)X–V (long-lived).

Phenology of *O. pilifera*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
4	2	8	6	6	0	0	1	0	2	2	6

Taxonomic remarks. *Orbilia pilifera* is characterized by rather large, ochraceous apothecia with prominent thin-walled, septate hairs without glassy caps, ellipsoid- to fusoid-clavate ascospores with broadly tear-shaped SBs, and a trinacrium incurvum-like anamorph.

O. pilifera resembles *O. carpoboloides* (section *Habrostictis*) which also often grows on bark of *Ulmus* and has similar lageniform-mammiform paraphyses, septate thin-walled hairs, a yellow exudate on the excipulum, and even a similar spore shape, though usually a more orange disc. *O. pilifera* sharply differs in its consistently subglobose to broadly tear-shaped SBs from the entire section *Habrostictis* which is characterized by vermiform, flexuous SBs. In the spores, *O. pilifera* also resemble some species of section *Ovoideae*. Moreover, *O. pilifera* could easily be mistaken for a *Lachnaceae* (*Helotiales*) if studied only in the dead state.

Since mycologists have rarely paid attention to spore bodies, *O. pilifera* may well have been recorded in the past under the name *O. carpoboloides* or any of its synonyms. Based on herbarium material the two species are in fact not easy to distinguish. Also the types of *O. decipiens* and *O. brasiliensis* (series *Habrostictis*) very closely approach *O. pilifera* in their persistent features, but differ in the ascospore having more tapered apices (see Pls 568–575). SB shape was hardly visible in the type of *O. brasiliensis*, therefore, the position of this taxon is somewhat uncertain. A similar uncertainty applies to some of the names mentioned as synonyms of *O. carpoboloides* (p. 1025). A taxon described under the name *O.* aff. *farnesianae* from China and Macaronesia (Pl. 501) differs from European *O. pilifera* in ± smooth apothecia and narrowly tear- to rod-shaped SBs (uncertain in the Chinese sample).

Variation. *O. pilifera* is a rather constant, easily recognizable species. Some variation concerns spore shape and size, but such diversity is generally seen within a single apothecium. The shape and size of the spore bodies was very uniform throughout the many fresh collections examined, with a large number of spores observed inside mature, living asci.

Misapplication. García Alonso (2003: 228, colour photo p.175) described *O. pilifera* under the name *O. luteorubella* on bark of 'probably *Genista patens*'. R. Tena (pers. comm.) reexamined this specimen and also a recent sample from the same locality, and confirmed identity with *O. pilifera*. The substrat turned out to be *Ulmus*.

Anamorph: With its trinacrium-like anamorph *O. pilifera* sharply differs from *O. carpoboloides* which forms phragmosporous conidia. *Trinacrium incurvum* fits quite well the present anamorph but also that of *O.* aff. *farnesianae* (Pl. 501) and several other taxa of this series.

Variation among populations of *O. pilifera* was observed in the depth of indentation between the two conidial arms above the central cell. Especially on the natural substrate this indentation was almost absent (Pl. 497: 2–3, partly in Pl. 495: 4), but also in the paratype of *T. incurvum* the indentation was partly only very slight. Conidia observed in Canadian specimens did not differ from European ones.

Phylogeny. Sequences were taken from apothecia of samples from Deux-Sèvres and Steiermark, comprising ITS, LSU D1–D2, and S1506 intron which is present in both. The two sequences differ by 4 nt in the intron, 3 nt in the ITS, and 1 nt in the LSU (that from France is incomplete in the intron and ITS1).

In the ITS region *O. pilifera* shows a distance of around 6.5–8.5 % to other members of the series, except for *O. bannaensis* which differs by 10–10.5 %. In the LSU (D1–D2) the distance is 1.5 % to *O. farnesianae* and 3 % to *O.* aff. *farnesianae*, *O. amarilla*, and *O.* cf. *paracaudata*. When analysing ITS+LSU, ITS, or LSU (Phyls 13, S15–S16), *O. pilifera* clustered unresolved in the series *Piliferae* clade.

Ecology. Judging from the available data, *O. pilifera* is a species of atlantic to subcontinental distribution, occurring in warm-temperate to mainly mesosubmediterranean (semi) humid western Europe and suprasubmediterranean to mainly supra- and mesomediterranean semihumid southern Europe, but also in cold-temperate southwestern and southern parts of Europe. It grows in riparian forests with *Fraxinus* and *Populus*, deciduous forest edges or hedge rows, or free-standing *Ulmus* trees. *O. pilifera* appears to be confined to ± rotten bark of *Ulmus* branches and trunks of usually dead trees. Collections were also made on *Ulmus* trunks in hemiboreal humid forests around Ottawa in southeastern Canada (J. Mack pers. comm.).

O. pilifera preferably inhabits large, ± rotten pieces of xeric bark detaching from standing, dead main trunks. The trees obviously die before the apothecia appear. The species usually occurs in great abundance, sometimes over a thousand of apothecia, on the inner surface of the often still-adhering bark, usually in or close to abundant galleries caused by a bark beetle (*Scolytus*), the vector agent of *Ceratocystis ulmi* which causes the elm disease. *O. pilifera* was also often found on corticated branches and in two collections on decorticated wood (Austria & Spain).

Specimens included. **AUSTRIA**: **Steiermark**, 8 km WNW of Bad Radkersburg, 4 km W of Halbenrain, SW of Unterpurkla, Donnersdorfer Au, 218 m, branch of *Ulmus laevis*, on bark, 24.I.2009, G. Friebes (G.F. 20090005, doc. vid.). – ibid., on wood, 12.XII.2009, G. Friebes (G.F. 20090146, doc. vid.). – ibid., trunk of *U. laevis*, on bark, 30.X.2011, G. Friebes (G.F. 20110193, non vid.; sq.: MK473413). — **FRANCE**: **Poitou-Charentes**, **Deux-Sèvres**, Poitou, 14 km WSW of Niort, 1.2 km NNE of Amuré, Marais Poitevin, Port Goron, 5 m, trunk of *Ulmus*, on bark, 15.IV.2008, J.P. Priou (ø). – 4.5 km NW of Chizé, 1.3 km SSE of Villiers-en-Bois, Forêt de Chizé, RBI-area, clearing, 72 m, branch of *Ulmus*, on bark, 27.IV.2011, P. Perz (P.P., doc. vid.). – 13.5 km N of Melle, 2 km SW of La Mothe-St.-Héray, La Dame de Chambrille, 103 m, branch of *Ulmus*, on bark, 17.IV.2008, H.O. Baral (H.B. 8814b). – 13 km ESE of Melle, Coudré, 158 m, trunk of *U.* (?)*minor*, on bark, 25.II.2006, B. Coué (M.H. 040206, J.P.P. 26051, H.B. 8076a, anam. cult., anam. substr.). – ibid., 25.X.2006, B. Coué (ø, non vid.). – trunk of *U.* (?)*minor*, on bark, 25.IV.2006, B. Coué (H.B. 8132b, anam. substr.). – 16 km ESE of Melle, 2 km ENE of Clussais-la-Pommeraie, E of Clussais, 130 m, trunk of *Ulmus*, on bark, 6.V.2006, B. Map 85. Known distribution of *O. pilifera* in Europe

Orbilia amarilla Quijada & H.O. Baral, Fungal Planet 853, in Crous et al., Persoonia 41: 238–417 (2018) — Pl. 498

Etymology: named after the orange apothecial colour, which coincides with the locality name Llanos de Amarilla.

Typification: Macaronesia, Tenerife, Montaña Amarilla, branch of *Euphorbia canariensis*, 16.XII.2012, L. Quijada & R. Castro (TFC Mic. 23767, holotype; sq.: MH221071).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.5–)0.8–1.8 mm in diam, up to 0.2 mm high (receptacle 0.17 mm), bright orange-yellow to vivid orange, non-translucent, round to slightly undulating, scattered to subgregarious; disc slightly concave to slightly convex, margin smooth, 0–8 µm protruding; broadly sessile, superficial. **Asci** *(49.5–)53–58(–61) × 4.5–5.5 µm, †(36.5–)39–46(–52) × 3.4–4.3 µm, cylindric-clavate, 8-spored, spores (obliquely) *2-seriate,

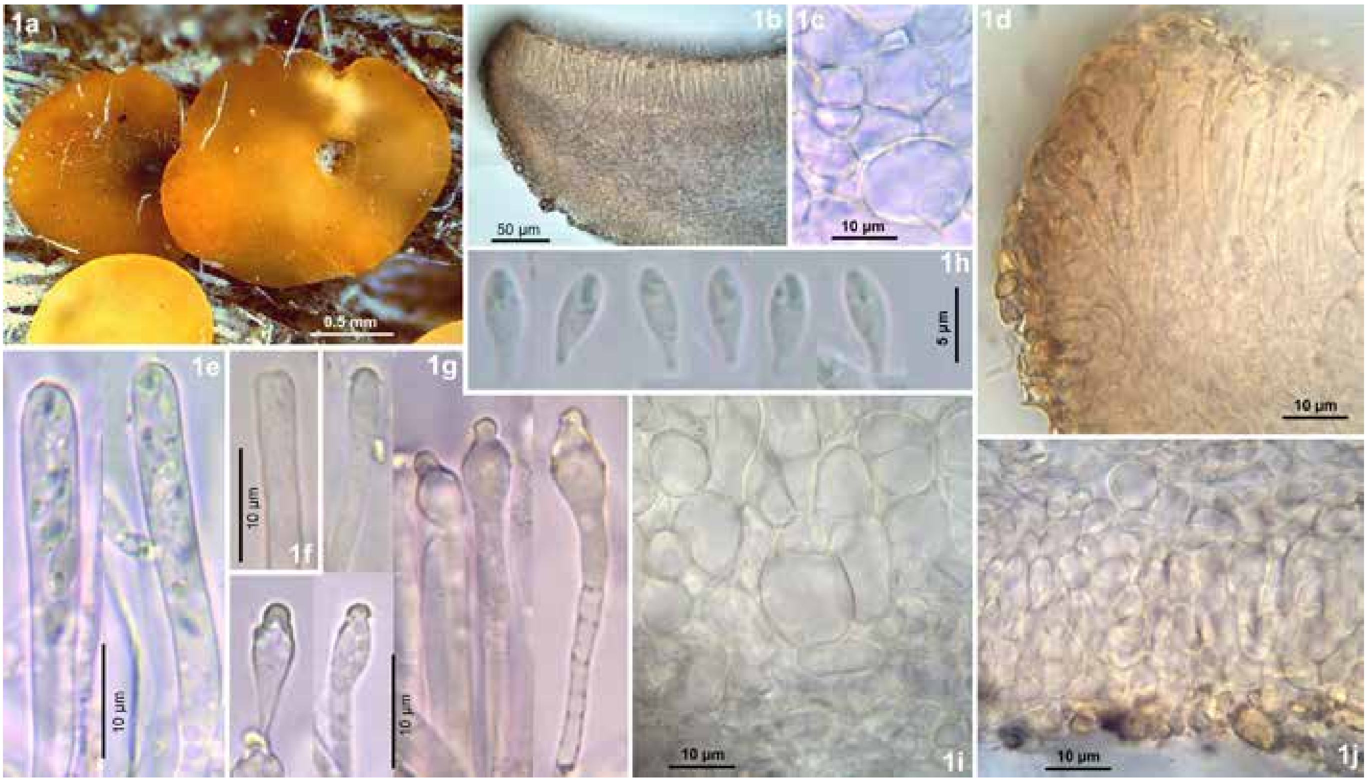

Plate 498. **1**: *Orbilia amarilla*. – **1a**. rehydrated apothecia; **1b**. apothecium in median section; **1d**. id., marginal ectal excipulum; **1i**. id., basal ectal excipulum, with anchoring hyphae; **1j**. id., at lower flanks **1c**. ring-shaped crystalloid SCBs in cells of ectal excipulum (flanks); **1e**. asci; **1f**. ascus apex (immature, dead state); **1g**. upper part of paraphyses; **1h**. ascospores. – Living state, except for **1f**. **— 1a–j**. phot. L. Quijada (p.p. from Quijada & Baral 2018), TFC Mic. 23767: Tenerife, on *Euphorbia*.

2–4(–6) lower spores inverted (usually mixed), pars sporifera *20–26 µm long; **apex** (†) strongly truncate (slightly indented, laterally hardly inflated); **base** with medium to long, thin, flexuous stalk, L- to Y-shaped. **Ascospores** *(5.8–)6.4–7.3(–8) × (1.9–)2–2.2(–2.4) µm, †4.3–6.8 × 1.6–2 µm, fusoid to fusiform-clavate, straight, apex obtuse to subacute, base with a straight to slightly curved tail of *0.7–1.8 × 0.5–0.9 µm, sometimes slightly to distinctly bulbous at base; **SBs** *1.7–2.1 × 0.6–0.8(–1) µm, plug- to rod-shaped with a slightly bulbous base, straight to slightly, rarely medium bent, apically slightly widened and broadly attached at spore apex, often obliquely oriented. **Paraphyses** apically slightly to very strongly spathulate to mammiform, terminal cell *(10–)14–19(–22) × 2.5–4.5 µm, apical beak 1.3–1.7 × 1.7–2.2 µm (including exudate), exceeding the living asci by up to 3–7 µm, lower cells *(9–)10–13.3(–14.7) × 1.5–2.3(–3) µm, unbranched at upper septum, hymenium pale orange. **Medullary excipulum** very pale orange, 120 µm thick in centre, of loose to dense textura intricata(-globulosa), at flanks sharply delimited from ectal excipulum (partly by an indistinct ~5–10 µm thick layer of t. porrecta). **Ectal excipulum** from base to mid flanks of thin-walled, t. globosa, at flanks and margin light yellow-orange, 50 µm thick at base, cells *(8–)11–20(–23) × (7–)10–15(–17) µm, 25–35 µm thick at flanks, of vertically oriented t. globulosa-angularis-prismatica, cells *3.5–8.5 × 3.5–7 µm, at margin of 17 µm thick t. prismatica-globulosa oriented at 80°, marginal cortical cells *4–9 × 3–5 µm. **Anchoring hyphae** 2.5–5 µm wide, thin-walled, forming a rather dense t. inricata-globulosa. **VBs** often abundant in terminal cells of paraphyses, ± globose, medium refractive, hyaline. **SCBs** line- or ring-shaped, in lower cells of paraphyses and in ectal excipulum at lower flanks. **Exudate** over paraphyses 0.5–1 µm thick, cloddy to cap-like, individually firmly attached on beak and also sublaterally (beak seemingly thick-walled), pale yellow, at margin and flanks 1–1.5 µm thick, yellow-brownish. **— ANAMORPH**: unknown.

Habitat: on superficially decayed, greyed wood of detached, branch of *Euphorbia canariensis* lying on the ground. **Associated**: *Orbilia asomatica*, *O. beltraniae*, *O. pisciformis*. **Desiccation tolerance**: examined a few days after collecting in dry state, but certainly highly tolerant. **Altitude**: 35 m a.s.l. **Geology**: volcanic basaltic flow. **Phenology**: XII (but long-lived).

Taxonomic remarks. *Orbilia amarilla* was only studied by L. Quijada (pers. comm.). It resembles *O. farnesianae*, from which it differs in shorter, fusoid-clavate, consistently tailed ascospores, also in having line- to ring-shaped crystalloid SCBs. From *O.* aff. *farnesianae*, which is only known in the dead state, it differs in distinctly smaller spores with shorter tails. In spore and SCB shape *O. amarilla* resembles *O. pisciformis* (series *Commatoideae*), which occurs in the same habitat, and in spore and SB shape it resembles *O. caudata*. These two species sharply differ, however, in having capitate paraphyses and partly glassy processes. *O. pilifera* and *O. pisciformis* differ in having tear-shaped, narrowly attached SBs.

Phylogeny. A sequence of *O. amarilla* comprising SSU, ITS, and LSU (S1506 intron absent) was taken from apothecia of the holotype. The species shows an ITS distance of 7–7.2 % to *O. farnesianae* and *O.* aff. *farnesianae* (1.3–1.5 % in LSU D1–D2) and 7.5 % to *O. pilifera* (3 % in LSU). When analysing ITS+LSU (Phyl. 13) it formed with them a strongly supported clade, while in the LSU (S16) only *O. amarilla* and *O.* aff. *farnesianae* form a supported clade.

Ecology. *O. amarilla* was collected on rotten wood of a detached, xeric branch of *Euphorbia canariensis* in an inframediterranean hyperarid *Ceropegio fuscae-Euphorbietum balsamiferae* xerophytic scrubland in the south of Tenerife.

Included specimen. **MACARONESIA**: **Canary Islands**, **Tenerife**, San Miguel de Abona, 4 km SSW of Las Chafiras, 1.5 km NE of Costa del Silencio, NNE of Montaña Amarilla, 35 m, branch of *Euphorbia canariensis*, on wood, 16.XII.2012, L. Quijada & R. Castro (TFC Mic. 23767, **holotype**; sq.: MH221071).

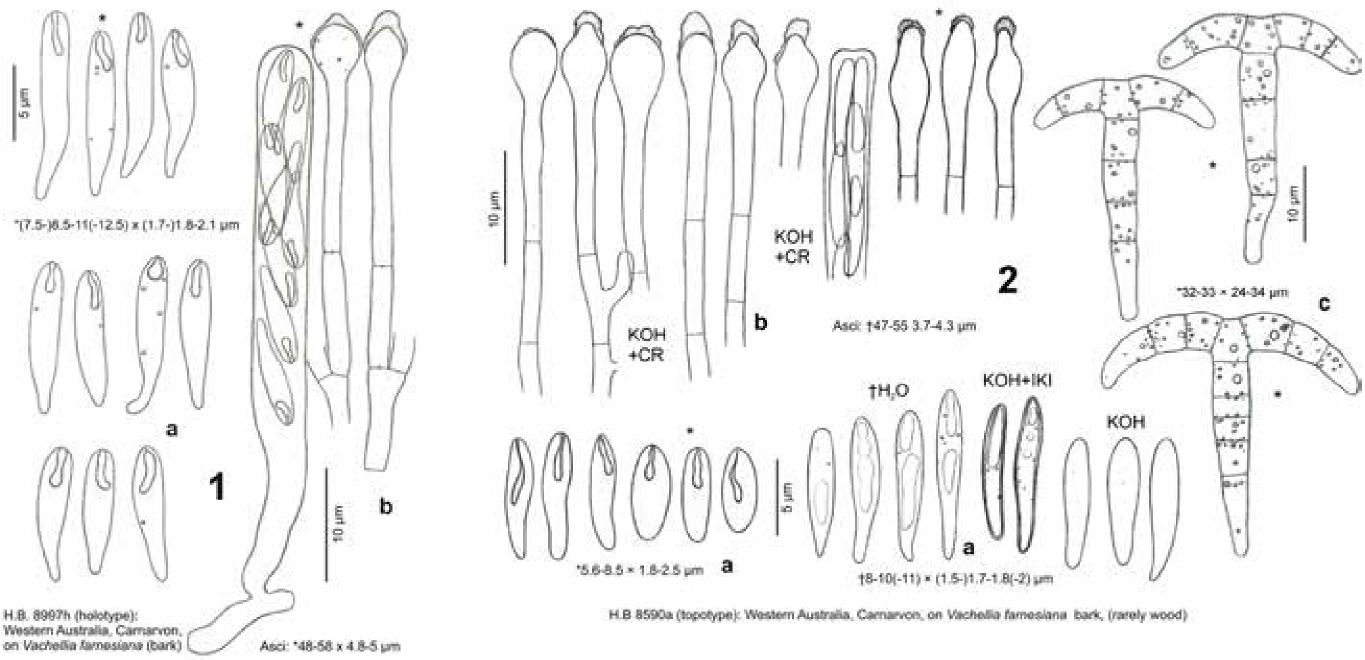

Plate 499. **1–2**: *Orbilia farnesianae*. – **a**. ascospores; **b**. asci and paraphyses; **c**. conidia (from substrate).

Orbilia farnesianae Baral, **sp. nov.**, MB 813774 **— Pl. 499–500**

Etymology: named after the host species, *Vachellia farnesiana*.

Typification: Western Australia, Minilya Roadhouse, branch of *Vachellia farnesiana*, 6.XI.2007, G. Marson (ex H.B. 8997h, MEL 2389271, holotype; sq.: KT222421).

Latin diagnosis: Orbiliae paracaudatae *similis sed ascosporae et corpuscula refringentia majores, corpuscula crystalloidea paraphysium et excipuli carentes. Habitat ad corticem putridum siccum* Vachelliae farnesianae *in zona subtropica arida Australiae septentrio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.45–1(–1.3) mm diam., 0.11–0.17 mm high (receptacle 0.08–0.12 mm), light to bright, partly dirty orange-ochraceous (brick-red), ± translucent, round to elongate, partly rather irregular, scattered to gregarious in small groups; disc flat, margin thin or thick, 0–12 µm protruding, finely rough; broadly sessile, superficial or immersed in cracks. **Asci** *48–58 × 4.8–5 µm {T}, †40–55 × (3.7–)4–4.5(–5) µm {2}, 8-spored, spores (*) 2–3-seriate, 4–5 lower spores inverted (not mixed), pars sporifera *26–33 µm long; **apex** (†) strongly truncate (slightly indented, laterally slightly inflated), hemispherical in side view, thin-walled; **base** with short to medium long, ± thin, flexuous stalk, L-shaped. **Ascospores** *(5.5–)8–11(–12.5) × (1.7–)1.8–2(–2.5) µm {2}, †(7–)8–10(–11) × (1.4–)1.6–1.8(–2) µm {2}, cylindric- to fusoid-clavate, rarely ellipsoid, apex rounded to obtuse, base medium to strongly attenuated (often tail-like or rarely with a basally slightly bulbous tail), straight to slightly (rarely medium) curved at base; **SBs** *(2–)2.3–3.2(–4.2) × (0.4–)0.5–0.6(–0.8) µm {2}, ± rod-shaped or sometimes dumbbell-shaped or subulate, apically untapered or narrowed to a point, sometimes with a short filum, straight to medium flexuous, overmature tear-shaped, 1.5–1.8 × 1–1.2 µm. **Paraphyses** apically medium to strongly clavate to spathulate or lageniform, terminal cells *19–21 × 3–4 µm {T}, †15–21 × (2.5–)3.5–4.5(–5.5) µm {1}, lower cells *9–11 × 1.8–2.5 µm {T}, †7.5–10 × 1.5–1.8 µm {1}; rarely branched near upper septum. **Medullary excipulum** 20–50 µm thick, of ± loose or dense textura intricata, with many inflated cells, horizontally oriented, sharply delimited. **Ectal excipulum** very pale rose, of (†) thin-walled, vertically oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 30–110 µm thick near base, cells *15–25(–30) × 10–18 µm {T}, †8–15 × 6–10 µm {1}; 20–25 µm thick at margin, of t. prismatica(-porrecta) oriented at a 30–90° angle to the surface, marginal cortical cells partly bent upwards to an angle of 10–20°, *8–12 × 4–5 µm {T}, †8–12 × 2.5–4 µm {2}; **glassy processes** absent {2}. **Anchoring hyphae** sparse to abundant, †2–3.5(–5) µm wide, walls 0.2 µm thick {2}, sometimes forming a 10–20 µm thick layer up to mid flanks. **SCBs** in paraphyses and ectal excipulum absent {T}. **Exudate** over paraphyses (0.3–)0.7–1.8 µm thick, hyaline to pale yellow-orange, forming individual, firmly attached caps, over margin and flanks 1–2(–3) µm thick, rough-cloddy. **— ANAMORPH**: trinacrium incurvum-like (presumed, from natural substrate {2}). **Conidiophores** not observed. **Conidia** T-shaped, the two arms ± bent downwards, *32–39 × 23–30(–34) µm, stipe *27–34 × 4.3–6.3 µm, 4–5(–6)-septate, arms *(10–)12–17 × 4.2–6.8 µm, 2–3-septate, distinctly bent downwards {2}.

Habitat: on corticated to partially decorticated, 4–15 mm thick branches of *Vachellia farnesiana* {2}, on 0.1–0.2 mm deep medium to very decayed, easily detaching bark (on bast or over splits in periderm) {2}, rarely on wood {1}, strongly greyed, no algae, often close to a black immersed ?pyrenomycete. **Associated**: *Hysterobrevium mori* {1}, *Orbilia corculispora* {2}, *O.* ?*myriella* {1}, *O. octocercocarpi* {1}, *O. pleioaustraliensis* {1}, *Patellaria* '*andina*' {1}, ?*Stictis* sp. {2}. **Desiccation tolerance**: ectal excipulum, some mature asci and paraphyses, and many spores viable after 20 months. **Altitude**: 13 m a.s.l. **Geology**: Cenozoic regolith (light brown soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia farnesianae* differs from *O. paracaudata* in wider ascospores and slightly longer SBs, also in the absence of crystalloid SCBs. From *O. mammifera* (section *Habrostictis*) the species differs in spores with obtuse to rounded apices and wider SBs, also in the paraphysis apices mostly lacking abrupt beaks. *O. farnesianae* also resembles *O. acaciae* and *O. dixiensis* (section *Habrostictis*), but also *O. rosella* (series *Abutilones*); from all these it differs in a clear tendency to spathulate paraphyses, also in larger apothecia.

Variation. When the topotype was still alive, it was only sketchily drawn, and much later it was restudied in more detail in the dead state. Only here, the paraphyses were sometimes found to be provided with a beak at the apex. The topotype further deviates from the holotype in somewhat larger apothecia, slightly wider paraphysis apices, and smaller basal excipular cells, but these features are quite variable. The spores of the topotype varied strongly in length and shape, and only some of them closely resemble those of

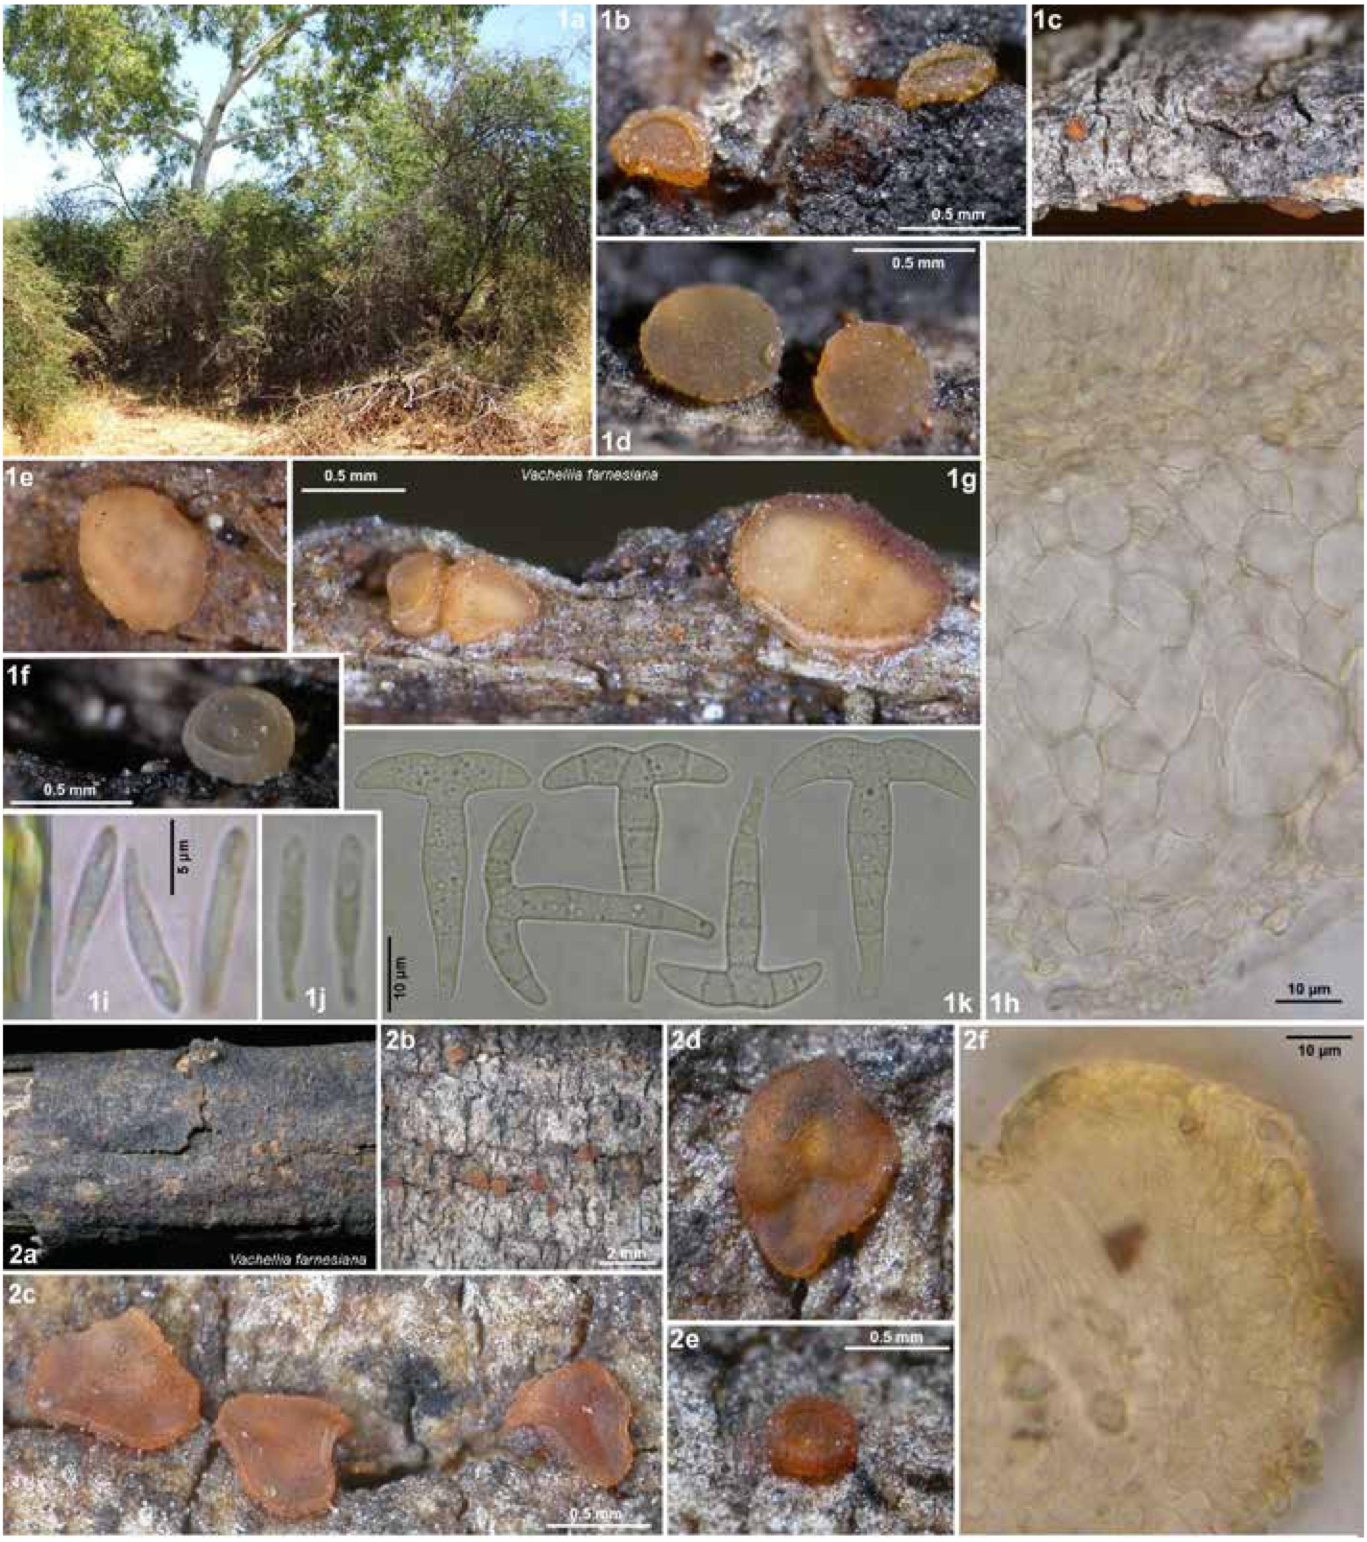

Plate 500. **1–2**: *Orbilia farnesianae*. – **1a**. subtropical arid acacia shrubland with *Eucalyptus* tree and *Vachellia* shrubs; **2a**. dead, corticated branch of *Vachellia*; **1b–g**, **2b–e**. rehydrated apothecia; **1h**. ectal excipulum in median section at flanks; **2d**. id., at margin; **1i–j**. ascospores; **1k**. conidia from substrate. – Living state, except for **1j** and **2f** (in KOH). — **1a–k**. H.B. 8997h (holotype): Western Australia, Carnarvon, Barrabiddy Creek, on *Vachellia farnesiana*; **2a–d**. H.B. 8590a: ibid., on *Vachellia farnesiana*.

the holotype. Also the SBs had a more consistent shape in the holotype. The observed rather short and wide ellipsoid spores are possibly abnormal, since such spores were no more seen during reexamination of the topotype.

Anamorph. The staurosporous trinacrium incurvum-like conidia were observed on the natural substrate near the apothecia in both collections (Pls 499: 2c; 500: 1k).

Phylogeny. A sequence comprising SSU, ITS, LSU (S1506 intron absent) was taken from apothecia of the holotype. In the ITS region it shows a distance of 4 % to *O.* aff. *farnesianae*, 7 % to *O. amarilla* and *O.* cf. *paracaudata*, and 9 % to *O. pilifera* and while in the LSU (D1–D2) the distance is 1.5 % to all of them.

Ecology. The two rather rich collections of *O. farnesianae* were on rotten xeric bark (rarely wood) of *Vachellia farnesiana* in a subtropical arid acacia shrubland 50 km from the coastline of western Australia. The first collection (topotype) was rather abundant. When revisiting the type locality 6 years later, only 1 branch of the very same shrub was found to carry apothecia referable to this species.

Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 117 km NNE of Carnarvon, 7 km SSE of Minilya Roadhouse, Barrabiddy Creek, 13 m, branches of *Vachellia farnesiana*, on bark & wood, 6.XII.2001, G. Marson (H.B. 8590a, anam. substr.). – ibid., branch of *Vachellia farnesiana*, on bark, 6.XI.2007, G. Marson (ex H.B. 8997h, MEL 2389271, **holotype**, anam. substr., sq.: KT222421).

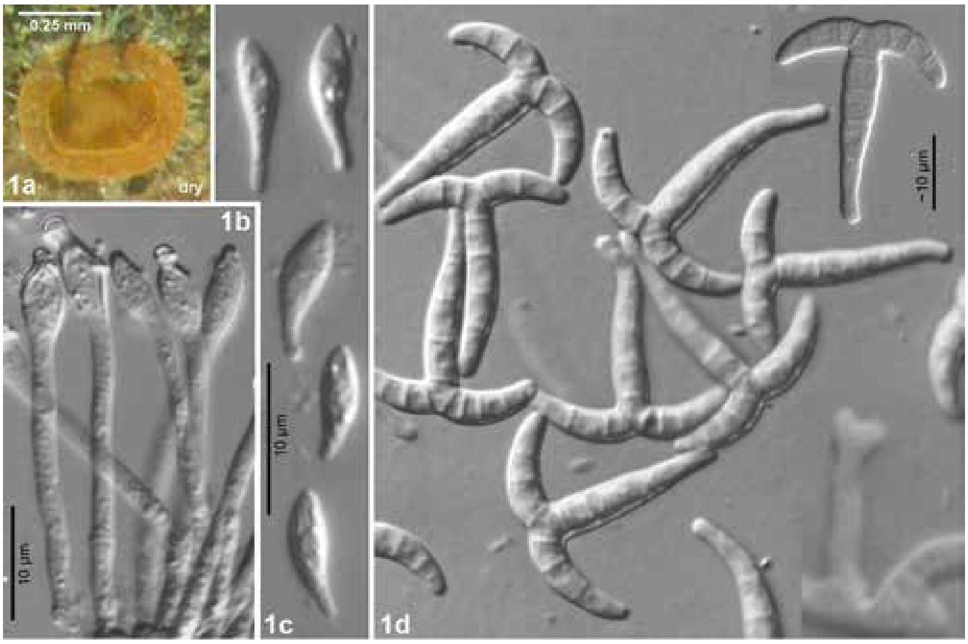

Plate 501. **1**: *Orbilia* aff. *farnesianae*. – **1a**. dry apothecium; **1b**. paraphyses; **1c**. ascospores; **1d**. conidia in pure culture. – Living state, except for **1b–c**. **— 1a–d**. from Liu (2006, fig. 17), HMAS 139700: China, Hunan, on indet. angiosperm.

Orbilia aff. *farnesianae* — Pl. 501

Misapplied name: Liu (2006: 59), Liu et al. (2006a), as *O. brasiliensis.*

Description: — **TELEOMORPH**: **Apothecia** 0.5–0.8 mm diam., round, orange to orange-red, translucent, scattered, sessile, margin ± smooth; dry with thick, protruding margin. **Asci** †38–49 × 3.5–5 µm, 8-spored, lower spores inverted; **apex** (†) truncate, hemispherical in side view, stalked, base h-shaped. **Ascospores** †(7.5–)8–10 × 2.3–3 µm, fusiform-clavate, apex subacute, base with a distinct, partly slightly constricted tail of 1.7–3 × 0.9–1.1 µm, straight to slightly curved; **SBs** ?broadly tear-shaped, †~1.5–2.3 × 0.8–1.2 µm. **Paraphyses** apically spathulate to mammiform, with a distinct beak, ~5–10 µm longer than asci, terminal cell †23–26 × 2.5–4 µm. **Ectal excipulum** of t. globulosa-angularis, at base 35–80 µm thick, at margin without any hairs or glassy processes. **— ANAMORPH**: trinacrium incurvum-like (from ascospore isolate). **Colonies** white to pale pink. **Conidiophores** branched or unbranched, 7–20 × 2.5–3 µm, conidia arising singly or sympodially. **Conidia** T-shaped, the two arms bent downwards, *26–31 × 22–31 µm {1}, stipe *22–26 × 4–5.5 µm, 4(–5)-septate, arms *7–15 × 3.5–5 µm, 2–4-septate; rarely unbranched conidia seen.

Habitat: on a xeric twig of an unidentified broad-leaved shrub. **Associated**: none observed. **Desiccation tolerance**: probably tolerant. **Altitude**: 600 m a.s.l. **Phenology**: IV (but presumably long-lived).

Taxonomic remarks. This species was studied by B. Liu (2006) and tentatively identified by him as *O. brasiliensis* (series *Habrostictis*, see also p. 1040), but it fits in series *Piliferae* because of its anamorph and molecular data. The apothecial margin is completely smooth similar as in *O. farnesianae* and *O. paracaudata*, from which it differs in broader, fusiform ascospores with subacute apices. Also from European *O. pilifera* it deviates in slightly larger spores with more subacute apices, besides the absence of hairs. The apothecia were studied in the dead state only, therefore, the SBs are hardly recognizable as broad, tear-shaped regions.

Anamorph. The trinacrium incurvum-like conidia obtained in pure culture match very well those of *O. pilifera*. Liu and Liu et al. (l.c.) referred to it as *Trinacrium incurvum*, but the identity of this anamorph remains unsettled (see also under *O. pilifera*, p. 920).

Phylogeny. A sequence of *O.* aff. *farnesianae* comprising S1506 intron, ITS, and LSU taken from pure culture by B. Liu shows an ITS distance of 4% to *O. farnesianae* as the closest match (1.5% in LSU), but 7% to *O. amarilla* and *O.* cf. *paracaudata* (1.3% and 2.2% in LSU D1–D2, respectively) and 9% to *O. pilifera* (3% in LSU). When analysing ITS+LSU or LSU (Phyls 13, S16), *O.* aff. *farnesianae* clustered with *O. amarilla* in a strongly supported clade, while in the intron region it clustered unresolved in section *Aurantiorubrae* (S14).

Another specimen identified by B. Liu as *O. brasiliensis* or *O. decipiens* (B.L. 4099, HMAS 139701), collected in the same area at the same day, clustered in analyses of ITS and LSU by Liu et al. (2006a) with high distance in a clade with the present taxon. However, the available members of section *Aurantiorubrae* were rather few in this study, and in our analyses it clustered distantly near *O. comma* (series *Commatoideae*, see p. 815).

Ecology. *O.* aff. *farnesianae* is from a subtropical humid, somewhat winter-dry mountainous area in southeastern China.

Included specimen. **CHINA**: **Hunan**, **Chenzhou**, 88 km S of Chenzhou, ~5 km ESE of Dashi Ling, Mangshan, 600 m, on unidentified angiosperm shrub, 7.IV.2002, W.Y. Zhuang, Y.H. Zhang & B. Liu (B.L. 4090, HMAS 139700, doc. vid., anam. cult.; sq.: DQ656643, DQ656688 [intron not uploaded]).

Orbilia paracaudata Baral & G. Marson, **sp**. **nov**., MB 813775 — Pls 502–503

Etymology: named after the similarity with *Orbilia caudata*.

Typification: Australia, Queensland, Mingela, branches of indet. climber, 17.X.1998, G. Marson (ex H.B. 6280d, BRI AQ799180, holotype).

Latin diagnosis: Orbiliae caudatae *similis sed ascosporae angustiores, subcylindricae, exsudatum crassius. Habitat ad corticem putridum rami sicci angiospermae volubilis in zona tropica subhumida Australiae septentrio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–1.1 mm diam., 0.14–0.18 mm high (receptacle 0.12 mm), scarcely translucent, round to often somewhat undulating to lobate, light orange, subgregarious; disc slightly concave to flat, margin distinctly raised, 10 µm protruding, finely rough; with an indistinct broad stipe, nearly superficial but emerging from cracks in periderm; dry ± deep (apricot-) orange. **Asci** *50–53 × 4–4.4 µm, †42–56 × 3.8–4.5 µm, 8-spored, spores (†) biseriate, 3–6 lower spores inverted, pars sporifera *30–34 µm long; **apex** (†) strongly truncate (slightly indented, laterally ± inflated); **base** with short to long, thin, flexuous stalk, L-shaped. **Ascospores** *5.8–8.5(–9.5) × (1.5–)1.6–1.8(–1.9) µm, narrowly ellipsoid to subcylindric, base with a distinct, thick, 1–3 µm long tail, also narrowly clavate with tail-like base, apex rounded to obtuse, slightly to medium curved near base; **SBs** *1.5–2(–2.2) × 0.5–0.7 µm, rod-shaped, partly slightly inflated

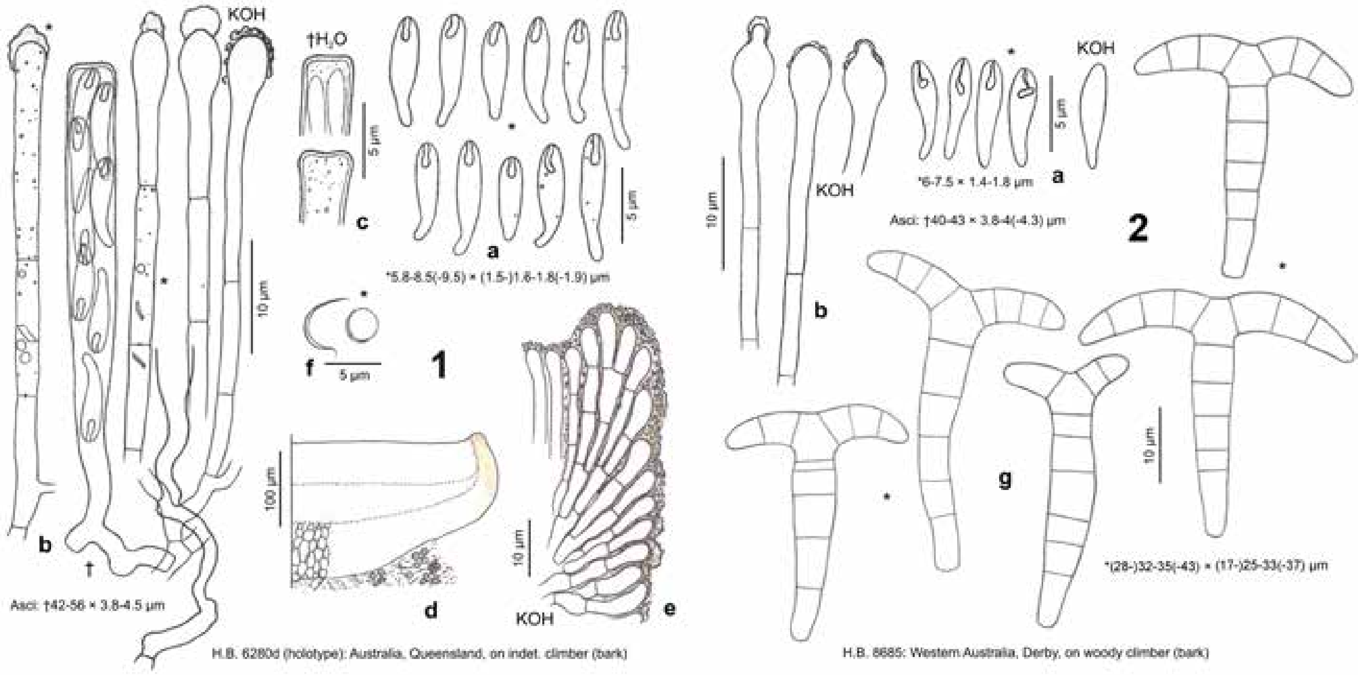

Plate 502. **1**: *Orbilia paracaudata*; **2**. *O.* cf. *paracaudata*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. crystalloid SCBs in cells of ectal excipulum at lower flanks; **g**. conidia from substrate.

at base (narrowly pyriform), apically untapered or narrowed to a ± wide point, straight to sometimes medium geniculate. **Paraphyses** apically slightly to medium clavate-spathulate, terminal cell *14–23 × 2.5–4 µm, lower cells *6–12 × 1.5–2.3 µm; hymenium pale yellowish. **Medullary excipulum** subhyaline (lower part pale orange), 30–50 µm thick, of dense textura angularis-intricata, horizontally oriented, sharply delimited. **Ectal excipulum** subhyaline, light orange near margin, of thin-walled, vertically oriented t. angularis(-prismatica) from base to mid flanks, 60–80 µm thick near base, cells *10–30 × 9–19 µm; 15–20 µm thick near margin, oriented at a 30–50° angle to the surface, marginal cortical cells †7–10 × 3–4(–5) µm; **glassy processes** absent. **Anchoring hyphae** abundant, *2–4 µm wide, walls 0.2–0.3 µm thick. **SCBs** in paraphyses and ectal excipulum forming thin rods or rings, also small globose SCBs in paraphyses. **Exudate** over paraphyses 1–3 µm thick, mostly forming firmly attached individual caps, pale yellowish-chlorinaceous; over margin and flanks 1–3 µm thick, granular, light orange-yellow. — **ANAMORPH**: trinacrium incurvum-like (presumed, from natural substrate). **Conidiophores** not seen. **Conidia** T-shaped, the two arms somewhat bent downwards, total size †25 × 21 µm, stipe †21 × 5 µm, 4-septate, arms †8–12 × 4 µm, 2-septate.

Habitat: collected 0.5–3 m above the ground, corticated to nearly decorticated, 9–13 mm thick branch of indet. climber, on medium to strongly decayed bark (periderm and bast), partly on clefts over old ?pyrenomycete, greyed, with green algae. **Associated**: *Corticiaceae*, *Hyalorbilia ?erythrostigma*, *Hysteropatella ?prostii*, *Orbilia mammifera*, *O. neocomma*, *O. scandens*, *O. subfabacearum*, *Rhytidhysteron ?rufulum*, some lichens. **Desiccation tolerance**: ectal excipulum still viable after 2 months, also some paraphyses and mature asci. **Altitude**: 286 m a.s.l. **Geology**: granite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia paracaudata* differs from *O. caudata* in the ascospores being narrower and more cylindrical instead of ellipsoid, in thick glassy caps of exudate on the paraphyses, and in a distinctly protruding apothecial margin. For the similar *O. farnesianae* see p. 923. *O.* aff. *farnesianae* differs in mammiform paraphysis apices and fusoid spores. *O. paracaudata* resembles also some members of series *Commatoideae*, e.g., *O. comma*, which features the same type of crystalloid SCBs, or *O. mali* of series *Regales*, but the SBs in these series have an inflated, broadly tear-shaped lower part or appear almost globose, while their attachment is very narrow. The unrelated *O. subclavuliformis* (section *Hemiorbilia*) has similar but much larger spores and strongly deviates in hemispherical, thick-walled ascus apices.

Not included collection. The western Australian specimen (Pl. 502: 2) was only sketchily documented. Merely the spores were studied in the living state, therefore the presence of crystalloid SCBs is unknown. The paraphyses are sometimes provided with a beak at the apex (mammiform), and are covered by a thinner exudate compared to the holotype. The spores are slightly smaller than in the holotype and more fusoid-clavate, and the SBs with a thinner, narrowly attached upper part.

Anamorph. The observed conidia of *O. paracaudata* (Pl. 503: 1j) are similar to those of other members of series *Piliferae*. The conidia of the western Australian specimen (Pl. 502: 2g) have a (3–)4–5(–6)-septate stipe of *23–29(–32) × 5–6 µm, and consistently downwards curved, (1–)2–4-septate arms of *(7–)10–16 × 4.8–5.2 µm.

Phylogeny. A sequence comprising SSU, S1506 intron, ITS, and LSU, taken from apothecia of *O.* cf. *paracaudata* from western Australia, shows an ITS distance of 7% to *O. farnesianae* and *O.* aff. *farnesianae* (1.5% and 2.2% in the LSU D1–D2, respectively). In the intron the distance is generally above 20%.

Ecology. The type collection of *O. paracaudata* was made on ± rotten bark of dead, hanging, xeric branches of an unidentified climber in a tropical subhumid (winter-dry, savannah climate) eucalypt open woodland in a dry riverbed in northeastern Australia east of Great Dividing Range, ca. 75 km from the coastline. The not included *O.* cf. *paracaudata* was on xeric bark of a different unidentified climber on Devonian sedimentary rock in a tropical savannah-like eucalypt woodland in the broad riverbed of the Windjana Gorge 140 km from the coastline in northwestern Australia, flanked on the plateau by acacia shrubland and tussock grassland.

Plate 503. **1**: *Orbilia paracaudata*; **2**: *O.* cf. *paracaudata*. – **2a**. tropical semiarid acacia shrubland at slope above gorge; **1a–b**, **2b**. dead, xeric branch of indet. climber (dry, **1a** with apothecia); **1c–i**, **2c–g**. rehydrated apothecia; **1j**. conidium from substrate. – Living state, except for **1j** (in H_2O). — **1a–j**. H.B. 6280d (holotype): Australia, Queensland, Mingela, on indet. climber; **2a–g**. H.B. 8685: Western Australia, Derby, Windjana Gorge, on indet. climber.

Specimens included. **AUSTRALIA**: **Queensland**, Einasleigh Uplands, 75 km SSW of Townsville, 2 km WSW of Mingela, 286 m, branches of indet. climber, on bark, 17.X.1998, G. Marson (ex H.B. 6280d, BRI AQ799180, **holotype**, anam. substr.).

Not included. **Western Australia**, Dampierland, 140 km E of Derby, 108 km NW of Fitzroy Crossing, Windjana Gorge, 115 m, branch of indet. climber, on bark (partly on *Diatrypaceae*), 2.XII.2001, G. Marson (H.B. 8685; sq.: KT222422).

Orbilia floridensis Baral, **sp. nov.**, MB 813776 — Pl. 504–505

Etymology: named after the geographical origin (Florida, USA).

Typification: USA, Florida, Homestead, branch of *Ficus*, ~12.IX.1998, L. Ferron (ex H.B. 6241b, M-0276483, holotype**)**.

Latin diagnosis: Orbiliae paracaudatae *similis sed ascosporae angustiores, asci minores. Habitat ad corticem putridum siccum* Fici ?benjamini *in zona tropica humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3 mm diam., 0.15 mm thick, pale yellowish-rose-cream, round, scattered; disc slightly concave, margin distinct, 10–20 µm protruding, smooth; sessile, superficial. **Asci** *~3.6–4.2 µm wide, †33–35 × 3.3–3.8 µm, 8-spored, lower spores inverted; **apex** (†) medium to strongly truncate (sometimes slightly indented, laterally not inflated), hemispherical in side view, thin-walled; **base** with long, flexuous stalk. **Ascospores** *7–8.8 × 1.3–1.5 µm, narrowly cylindric- to fusoid-clavate, apex rounded to obtuse, base medium attenuated, with or without a thick tail, slightly to medium curved near base; **SBs** *1.2–1.8 × (0.3–)0.4–0.6 µm, tear-shaped to ampulliform or rod-shaped, apically untapered or narrowed to a point, ± straight. **Paraphyses** apically slightly clavate-capitate to spathulate, terminal cells †15–21 × 2–2.5 µm, lower cells †3–8 × 1.3–1.6 µm; unbranched at upper septum, hymenium pale yellowish.

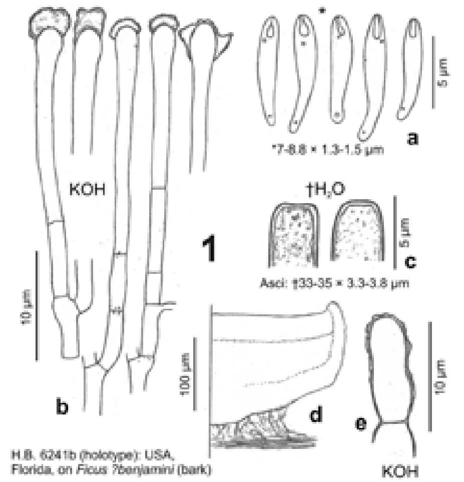

Plate 504. **1**: *Orbilia floridensis*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. hair-like cortical cell (lower flanks).

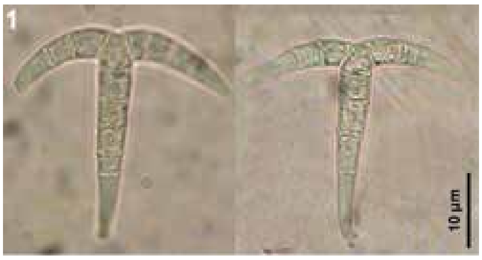

Plate 505. **1**: *Orbilia floridensis*. – Conidia from substrate (dead state). — **1**. H.B. 6241b (holotype): USA, Florida, on *Ficus*.

Medullary excipulum hyaline, 60 µm thick, medium sharply delimited. **Ectal excipulum** hyaline, of vertically oriented textura angularis from base to margin, 30 µm thick near base, cells *8–12 × 6–8 µm; 20 µm thick at flanks, 10 µm near margin, oriented at a 70–80° angle to the surface, cortical cells from lower flanks up to margin †9–11 × 3–4(–4.5) µm, sometimes ± free (hair-like); **glassy processes** absent. **Anchoring hyphae** abundant, *2–3 µm wide, walls 0.2–0.25 µm thick, forming a dense, 40 µm thick textura intricata-porrecta. **SCBs** in ectal excipulum not seen. **Exudate** over paraphyses 0.7–2 µm thick, pale golden yellow, cap-like, firmly attached on each paraphysis, over margin and flanks 0.2–0.4 µm, rough. **— ANAMORPH**: trinacrium incurvum-like (presumed, from natural substrate). **Conidiophores** not seen. **Conidia** T-shaped, the two arms bent downwards, total size †28–30 × 28–30 µm, stipe 23–25 × 4 µm, 4–5-septate, arms 12–14 × 3.5–3.8 µm, 3–4-septate.

Habitat: collected on hanging, mainly decorticated, 9 mm thick branch of *Ficus ?benjamini*, on strongly decayed bark (periderm). **Associated**: *Nectria* sp., *Orbilia neocomma*. **Desiccation tolerance**: after 2 weeks many immature asci still alive. **Altitude**: 1 m a.s.l. **Geology**: Quaternary sedimentary deposits. **Phenology**: IX (but probably long-lived).

Taxonomic remarks. *Orbilia floridensis* differs from the Australian *O. paracaudata* in distinctly narrower spores and smaller asci, also in smaller apothecia. Therefore, it is regarded to be a different species. For the differences to *O. bannaensis* see p. 831.

Anamorph. The trinacrium incurvum-like conidia (Pl. 505) found on the substrate are quite similar as in other species of this series.

Ecology. The collection was made on bark of a xeric branch of *Ficus* in the tropical humid, monsoon-influenced (winterdry) Everglades of Florida.

Specimens included. **USA**: **Florida**, southern part, 55 km SW of Miami, 12 km SW of Homestead, Everglades, ahead of entrance to national park, 1 m, branch of *Ficus ?benjamini*, on bark, ~12.IX.1998, L. Ferron (H.B. 6241b, M-0276483, **holotype**, anam. substr.).

Orbilia caudata Starbäck, Bih. K. Sven. Vetenskapsakad. Handl. 25: 8, pl. 1 figs 45–47 (1899) — Pls 506–507

Etymology: named after the ascospores provided with a tail.

Typification: Brazil, Rio Grande do Sul, near Cachoeira do Sul, branch of indet. angiosperm, 21.I.1893, G.A. Malme (Brasil. Regnell., I. Exped. Fungi No. 164, S-F41422, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.8(–1) mm diam., 0.08–0.14 mm high (receptacle 0.08–0.1 mm), pale to light cream-yellowish-orange to orange-red (Starbäck: brickred-orange), ± translucent, round to slightly undulating when large, scattered or usually (sub)gregarious; disc slightly concave to slightly convex, margin distinct, thin, slightly raised, 0–5 µm protruding, smooth or sometimes finely crenulate; broadly sessile but only centrally attached, superficial; in dry state a subiculum visible as white strands around some apothecia. **Asci** †32–44 {2} or 45–53 {T} × 3.5–4.2 µm {3}, 8-spored, spores †(sub)biseriate, (2–)3–6(–7) lower spores inverted {3} (sometimes mixed); **apex** (†) (medium to) strongly truncate (sometimes slightly indented and laterally inflated); **base** with short or mostly medium to very long, thin, flexuous stalk, Y- to L-shaped. **Ascospores** *5–7.8 × 1.9–2.3 µm {2}, †(4.5–)5–6.5(–7.5) × (1.7–)1.8–2(–2.2) µm {3}, ellipsoid-fusoid with a distinct tail, sometimes fusoid-clavate with a tail-like base, apex obtuse, tail *1–1.5 × 0.4–0.8 µm {1}, †1–2.3 × 0.4–0.6(–0.7) µm {2}, rarely with a slight basal inflation, straight or slightly (to medium) curved at base; **SBs** *(1–)1.4–1.8(–2) × 0.5–0.7(–0.9) µm {2}, rod-shaped to ± pyriform or tear-shaped to ampulliform, rarely ellipsoid, apically narrowed to a wide or narrow point, straight. **Paraphyses** apically medium to strongly capitate(-clavate), terminal cell †12–21 × 2.5–4.5 µm {3}, lower cells †4.3–9.5(–11) × (1.2–)1.4–1.8(–2.5) µm {3}; unbranched at upper septum. **Medullary excipulum** 20–30 µm thick, of dense textura intricata(-prismatica) with some or many inflated cells, medium to sharply delimited from ectal excipulum by a layer of t. porrecta. **Ectal excipulum** of thin-walled, ± vertically oriented t. globulosa-angularis(-prismatica) from base to mid flanks or margin, 15–60 µm thick near base, cells †(6–)7–13(–17) × 5–10 µm {2} or †10–24 × 9.5–16 µm {T}; 15–40 µm thick at flanks, 15–20 µm near margin, of t. prismatica(-angularis) oriented at a 50–90° angle to the surface, marginal cortical cells †4.5–10 × (2.5–)3.5–4.5(–5) µm {3}; **glassy processes** absent {2} or 6–10 × 2.5–3 µm {1}, low-refractive, stratified, outwards curved. **Anchoring hyphae** medium to very abundant, †1.5–2.5(–3) µm wide, walls 0.2(–0.3) µm thick {3}, sometimes forming a 10–20 µm thick t. porrecta at base and lower flanks, agglutinated by gel. **SCBs**: no data available. **Exudate** granular(-cloddy), over paraphyses 0.2–0.5(–1) µm thick, firmly attached, pale chlorinaceous-yellowish; over margin and flanks 0.2–1(–1.3) µm thick. **— ANAMORPH**: trinacrium incurvum-like (presumed, from natural substrate {1}). **Conidiophores** not seen. **Conidia** T-shaped, the two arms somewhat bent downwards, total size †38–42 × 40–49 µm, stipe †32–35 × 5–5.5 µm, 6-septate, arms tapering, †16–25 × 4.2–5 µm, 4–5-septate {1}.

Habitat: on moist ground or hanging in 1.5 m above the ground, corticated, 4–12 mm thick twigs and branches of indet. angiosperm trees {2}, on strongly decayed bark {2} (periderm {T} or bast {1}), on herbaceous, 2–3 mm thick stems of indet. climber {1}, on medium decayed epidermis or often on epidermis-free areas {1}, slightly greyed, no algae observed. **Associated**: ?*Peroneutypa scoparia* {1}, old black ?pyrenomycete. **Desiccation tolerance**: not tested, a few spores still alive after 8 months {Taiwan}. **Altitude**: ~100–1890 m a.s.l. **Phenology**: V–VI (N-hemisphere, but possibly long-lived).

Taxonomic remarks. *Orbilia caudata* is characterized by ellipsoid-fusoid ascospores provided with a short, ± distinct tail, and by rod-shaped to somewhat ampulliform SBs. For the similar *O. ovalis* (section *Lentiformes*), *O. mali* (series *Regales*), and *O. paracaudata* see there. *O. pisciformis* from Macaronesia (series *Commatoideae*, Pls 419–420) and a not included collection from Pakistan (Pl. 506: 4) have similar ascospores and possess short glassy processes at the margin. *O. pisciformis* closely resembles *O. caudata* in the distinct spore tails, but differs in much longer spores.

Variation. The collection from Taiwan (Pl. 506: 1) differs from the other two specimens in slightly longer spores and SBs. The holotype from Brazil (Pl. 506: 2) deviates from the two Asian collections in distinctly longer asci, a thicker ectal excipulum, and larger basal excipular cells. The Chinese collection (Pl. 506: 3) was presented in Zhang et al. (2009b). It differs from the other two in rather small and thin apothecia, and particularly in the presence of short glassy processes which are responsible for the crenulate margin. For the time being, all these differences are thought to lie within the scope of variation of *O. caudata*.

Type studies. The rather detailed original description by Starbäck (1899), repeated by Saccardo & Sydow (1902:

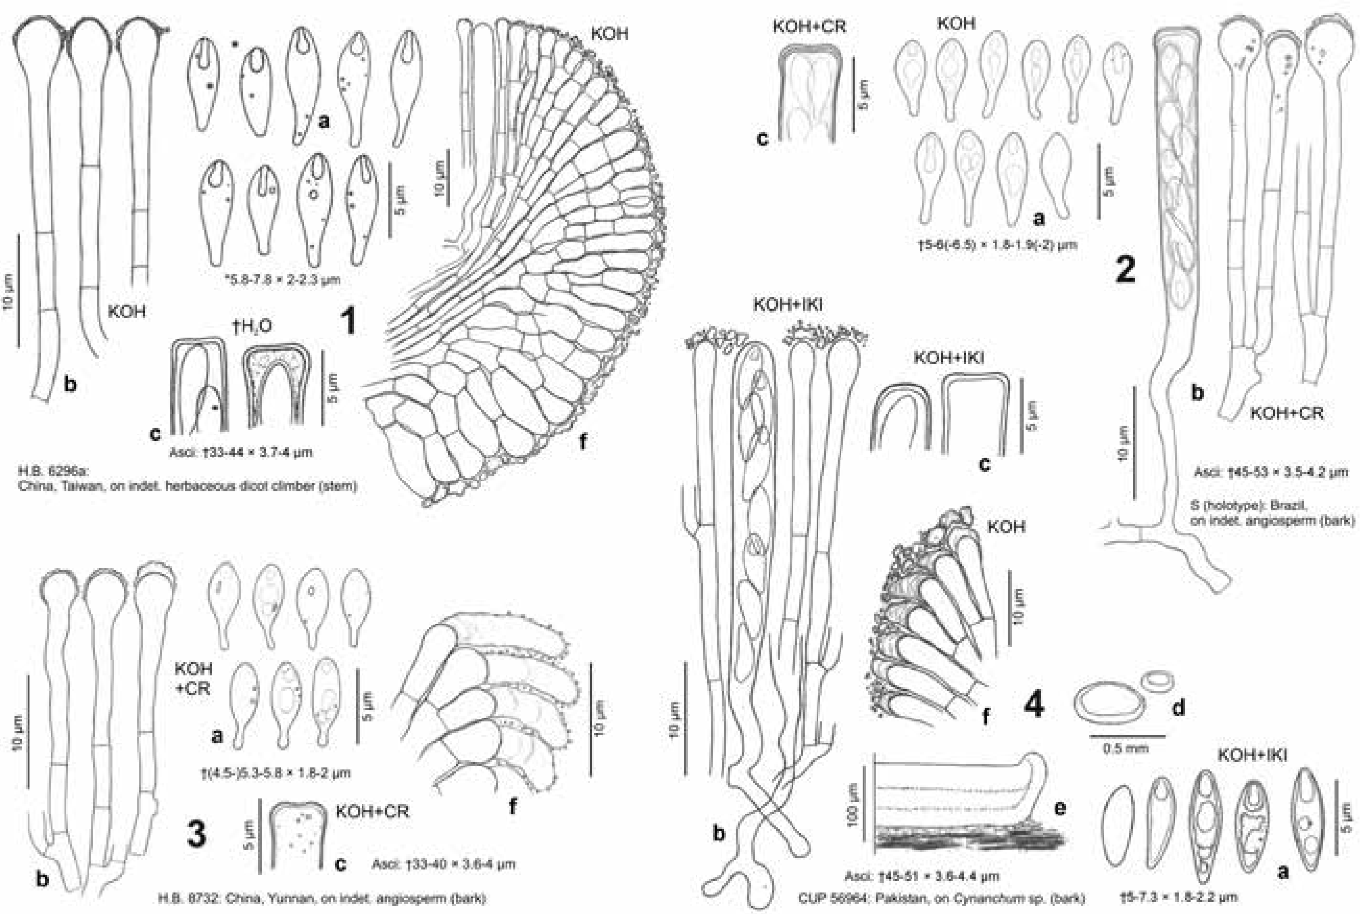

Plate 506. **1–3**: *Orbilia caudata*; **4**. *O.* aff. *caudata*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., ectal excipulum at margin and mid flanks.

768) and Rick (1932), fits well the microscopic features here evaluated from the well-preserved holotype in S. Two details in the protologue should be correct: the ascus tips are reported as very faintly amyloid, and all spores within the asci are depicted as pointing with their tails towards the ascus base. Starbäck gave the spore size as 5–6.5 × 1.5–2 µm, and described the tails as filiform, 0.5–1 µm wide, curved, acute (but he figured straight tails). The paraphyses are reported as abruptly inflated to a 4.5–6 µm wide, globose to obconical apex. Based on a similar spore shape, Starbäck compared *O. caudata* with *O. occulta*.

Not included collections. A sparse, partly immature sample from Ethiopia on stems of *Solanecio gigas* (IVV: H.B. 9240b) differs mainly in curved (comma-shaped) spore tails. It was only studied in the dead state and possibly represents an undescribed species. Vermispora-like conidia were observed on the substrate. Whether it is related to *O. caudata* or perhaps to *O. comma* remains uncertain. A collection from Northern Thailand on ?herbaceous stem referred by Ekanayaka et al. (2018) to *O. caudata* shows a very variable spore shape which only partly resembles the holotype, or the collection from China with which it was compared by the authors. The spores are given much longer and also partly narrower (*/†7–9 × 1.4–2 µm) than here described for *O. caudata*. The yellow-orange apothecia are up to 1 mm diam. according to the scale (0.2–0.7 mm in description). In the collection from Pakistan (Pl. 506: 4) the fusoid spores are consistently without tails. The spore body region suggests a relationship to series *Ovales*, but the elongate spores exclude *O. ovalis* and better fit the specimen from Taiwan (Pl. 506: 1).

Anamorph. The T-shaped trinacrium-like conidia found on the substrate of H.B. 6296a resemble those of *Trinacrium incurvum*, but have longer arms similar as in the other species of the series (Pl. 507: 2d).

Phylogeny. Sequences were only available for the not included sample from Thailand, comprising ITS and LSU. It falls in series *Regales* and here to *O. brachychitonis* with an 8.5 % ITS distance (1.2 % in LSU D1–D2), with which it forms a supported clade (Phyls 13, S16). Also a motif in the LSU (pos. 239–245, TT**TC**A**AT**) supports placement in this series (Tab. 68). This result suggests that it is probably not conspecific with the present concept of *O. caudata*.

Ecology. *O. caudata* was collected on rotten bark of hygric and xeric twigs and branches of unidentified angiosperm trees, also on herbaceous stems of a climber. The holotype locality is a subtropical humid lowland rainforest area at the Rio Grande river in southern Brazil, and the other two are in a subtropical humid (winterdry) monsoon rainforest in the Yunnan-Guizhou high plateau of southern China, and in a similar but tropical lowland rainforest at the southernmost end of Taiwan. In the Taiwan collection the substrate was hanging in 1.5 m above the ground. The apothecia of this population probably show some tolerance to drying, though growing under a rather high atmospheric humidity. The not included sample on *Cynanchum* is from a subtropical semiarid lowland floodplain of the Indus river, that on *Solanecio* from a warm-temperate humid, evergreen afromontane forest in the Ethiopian highlands, and that on indet. ?herbaceous plant in tropical humid (wet and dry) lowland of northern Thailand.

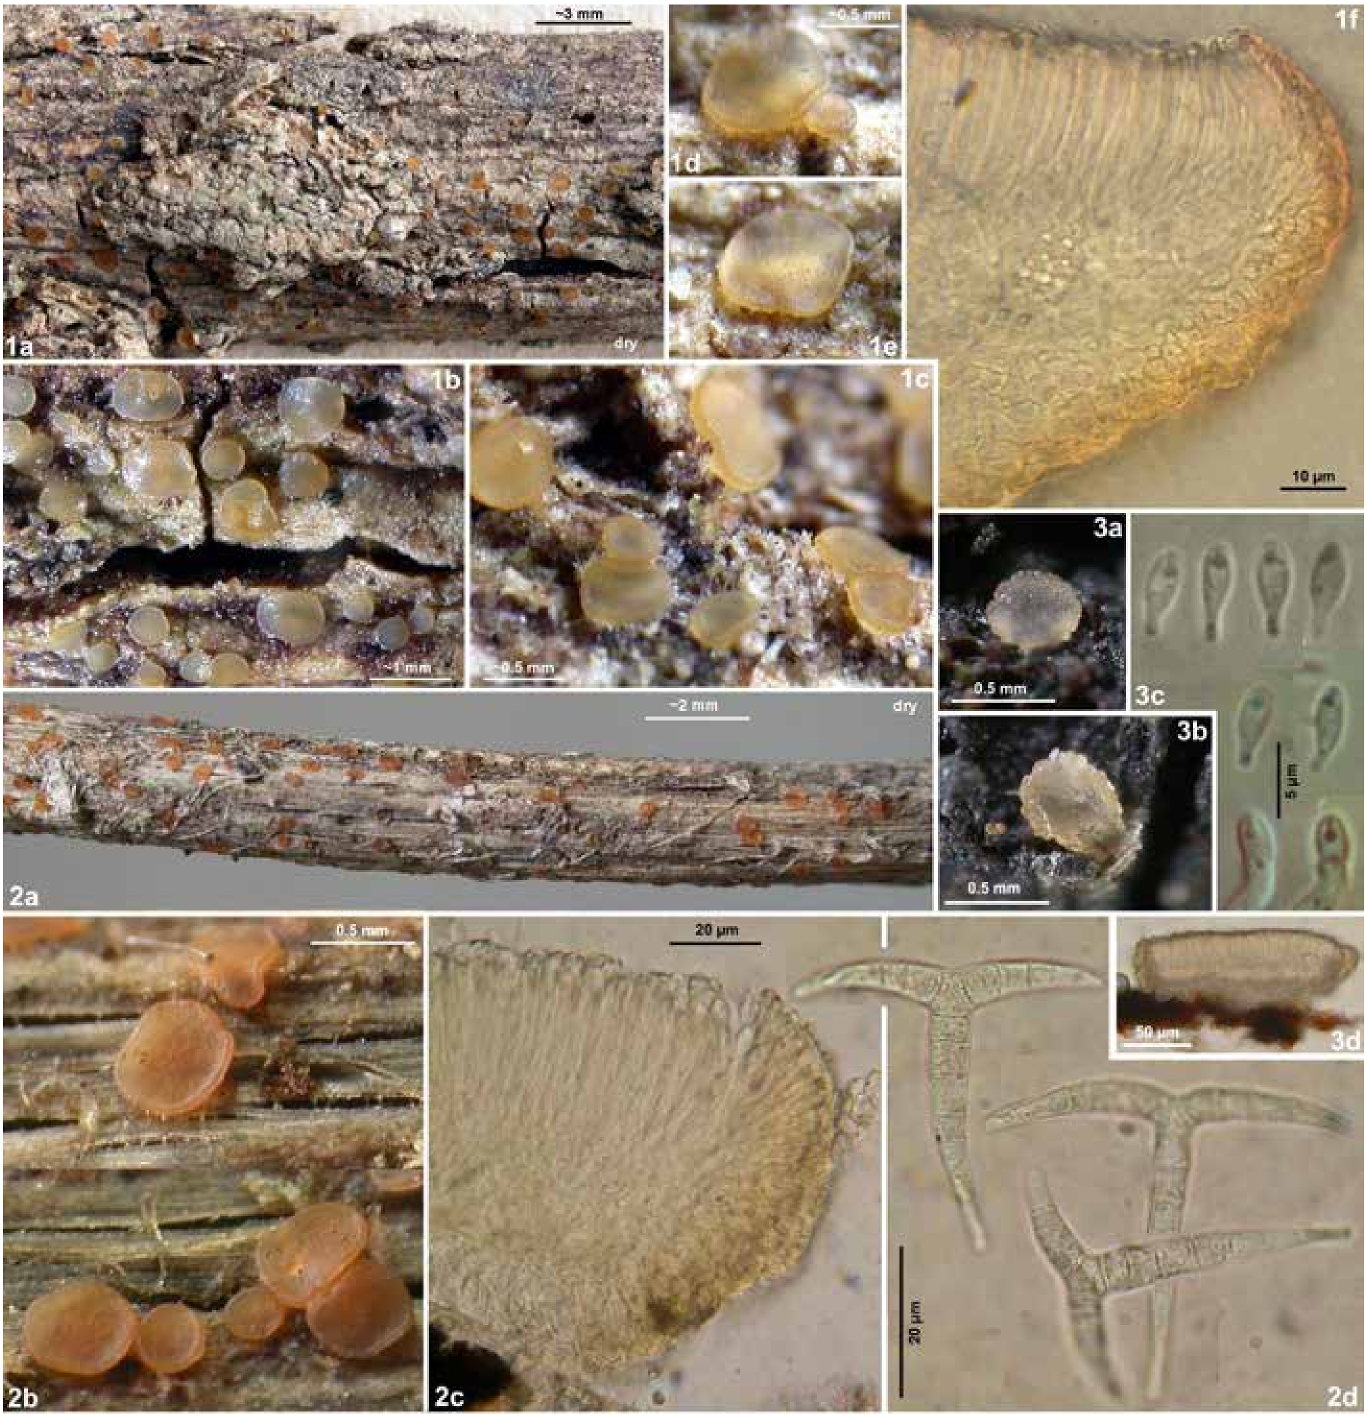

Plate 507. **1–3**: *Orbilia caudata*. – **1a**, **2a**. corticated, ?hygric branch and xeric herbaceous stem of angiosperms with dry apothecia; **1b–e**, **2b**, **3a–b**. rehydrated apothecia; **3d**. apothecium in median section; **1f**, **2c**. id., marginal region; **3c**. ascospores; **2d**. conidia from substrate. – Dead state (**2c–d** in water; **1f**, **2c** in KOH), except for **3c**. – **3c**: from Zhang et al. (2009b). — **1a–f**. S-F41422 (holotype): Brazil, Rio Grande do Sul, on indet. woody angiosperm; **2a–d**. H.B. 6296a: China, Taiwan, on indet. herbaceous dicot climber; **3a–d**. YMFT 033: China, Yunnan, on indet. woody angiosperm.

Specimens included. **BRAZIL**: **Rio Grande do Sul**, 200 km WNW of Porto Alegre, ~55 km NNW of Cachoeira do Sul, Colônia Santo Ângelo (now Agudo), ~100 m, branch of indet. angiosperm, on bark, 21.I.1893, G.A. Malme (Brasil. Regnell., I. Exped. Fungi No. 164, S-F41422, **holotype**, H.B. 7681,ø). — **CHINA**: **Yunnan**, **Yuxi**, Yimen, Central Highlands, 75 km SW of Kunming, 53 km NW of Yuxi, Longkou Forest Park, 1890 m, twig of indet. angiosperm, on bark, 27.VI.2006, Z.F. Yu (YMFT 033, H.B. 8732). – **Taiwan**, **Pingtung**, 70 km SSE of Pingtung, 9 km ESE of Hengchun, Kenting Botanical Garden, 300 m, stem of indet. herbaceous dicot climber, 25.V.1998, F. Oberwinkler & C.J. Chen (F.O. 47270, H.B. 6296a, anam. substr.).

Not included. **PAKISTAN**: **Punjab**, Indus River Plain, Lahore, ~220 m, ?woody stem of *Cynanchum*, on bark, 3.I.1954, collector unknown [?S. Ahmad] (Fungi of West Pakistan 9012, CUP-056964, as *Orbilia* sp., H.B. 5862 ø). — **ETHIOPIA**: **Oromia**, 22 km WSW of Addis Ababa, 10 km NW of Sebeta, southern part of Menagesha Suba State Forest, 2520 m, stem of *Solanecio gigas*, 22.XII.2009, U. Lindemann (U.L. 1209-7 ø, H.B. 9240b). — **THAILAND**: **Northern Thailand**, **Chiang Rai**, 16 km NNE of Chiang Rai, Mae Fah Luang University, 460 m, stem of herbaceous plant (?, as 'wood'), 18.III.2015, A.H. Ekanayaka (dh018, MFLU 16-0580; sq.: MG599271, MG599274).

Orbilia bannaensis Ying Zhang, Z.F. Yu & K.Q. Zhang in Zhang et al., Cryptog. Mycol. 27(4): 290 (2006) — Pls 508–509

Etymology: named after the geographical origin (Xishuangbanna County, Yunnan Province).

Typification: China, Yunnan, Menglunzhen, branch of *Broussonetia*, 20.VII.2004, Z.F. Yu (Z.F.Y. xsbn-1, OT003, YMFT, holotype; sq.: DQ512888).

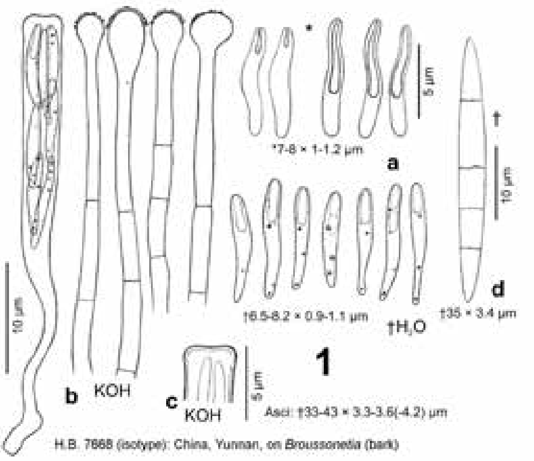

Plate 508. **1**: *Orbilia bannaensis* (from holotype). – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. conidium (from substrate).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.6 mm diam., 0.15–0.16 mm thick, light orange(-rose), medium translucent, round or slightly undulating, often gregarious; disc flat (to slightly convex), margin thick, hardly protruding, smooth; sessile on a ± broad base, superficial. **Asci** *~36–46 × 4.5–5 µm, †31–43 × 3.3–4.5 µm, 8-spored, spores *3–4-seriate, ~4 lower spores inverted (?somewhat mixed); **apex** (†) truncate (sometimes slightly indented and laterally inflated); **base** with short to long, thin or thick, flexuous stalk, L- to Y-shaped. **Ascospores** *7–8.5 × 1–1.3 µm, †6.5–8.2 × 0.9–1.1 µm, narrowly subcylindrical to mostly cylindric-clavate (to fusoid-clavate), apex rounded to obtuse, base slightly to medium attenuated, with or without a tail, slightly inequilateral to ± distinctly curved (helicoid); **SBs** *1.5–2.3 × 0.5–0.8 µm, ellipsoid or tear- to rod-shaped, apically narrowed to small point attached to the wider spore end [or *5–5.3 × 0.6–0.7 µm, subulate, flexuous, attached to the narrower end]. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cells †(11–)15–18 × 2.5–4(–4.3) µm, lower cells †5–9 × 1.3–1.7 µm, unbranched at upper septum. **Medullary excipulum** 15–40 µm thick, of dense textura intricata with some slightly inflated cells, medium sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, indistinctly oriented t. globulosa-angularis from base to margin, 50–60 µm thick near base, cells †10–15 × 8–12 µm diam.; 15–20 µm thick near margin, oriented at a 45–70° angle to the surface, marginal cortical cells †8–10 × 4–5 µm; **glassy processes** absent. **Anchoring hyphae** abundant, †1.7–2.5(–3) µm wide, wall 0.1–0.2 µm thick. **SCBs** and **VBs**: no data available. **Exudate** over paraphyses 0.2–0.3 µm thick, over margin 0.2–0.5 µm, granular to continuous, light yellowish-orange. — **ANAMORPH**: unknown (but see below).

Habitat: on a pile of logs near a house, medium decayed bark of *Broussonetia* sp., on outer surface of detached periderm, greyed, without algae. **Associated**: none observed. **Desiccation tolerance**: unknown, but some spores still viable after 6 months. **Altitude**: 1400 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: VII.

Taxonomic remarks. *Orbilia bannaensis* shows some similarities with series *Helicoon*. Because of its rather short SBs it resembles especially *O. yuanensis*, a species that differs in somewhat shorter and wider, more straight spores and in more whitish to yellow-cream apothecia. The contents of the dead paraphyses and cortical excipular cells in *O. bannaensis* show a light yellow-orange colour, therefore, the living cells might have contained hyaline or yellowish VBs similar as in *O. yuanensis*. However, our phylogenetic analysis showed that *O. bannaensis* is excluded from section *Helicoon* (see below).

Also *O. rectispora*, *O. cardui* and some further taxa of section *Arthrobotrys* have very similar spores but deviate in more globose SBs and are obviously not closely related. Zhang et al. (2006) compared with *O. bannaensis* another member of section *Arthrobotrys*, *O. quercus*, which differs in shorter spores and more roundish SBs, and whitish to pale yellowish apothecia. However, this species clustered very distantly in their phylogenetic tree. Also *O. ellipsospora* has very similar though distinctly smaller spores (4.5–7 × 1–1.2 µm). Like *O. quercus*, this species forms a dactylellina-like anamorph in pure culture. *O. kingsiana* was compared by Zhang et al. 2006 (as '*O. regalis* aff.') with *O. bannaensis*, but differs in spores with more curved bases and more globose SBs. It is affiliated here in series *Regales* although it lacks glassy processes.

Within series *Piliferae O. floridensis* is morphologically close to *O. bannaensis*. It has similar but somewhat wider spores with similar SBs, but differs in cap-like exudate over the paraphyses.

Variation. When a part of the type collection of *O. bannaensis* was studied in Jan. 2005, a few spores were still viable and contained mainly very long SBs (Pl. 508: 1a, above), also the spores were more distinctly curved (helicoid), and they were tapered above rather than below. Another apothecium was examined more than 3 years later: the dead spores were less curved and had ± tapered bases, and the region of the SBs was much shorter (1a, below). This better corresponds to the photos of living spores in the protologue, though the SBs were here still longer (2.2–3.3 µm) than in the protologue (1.5–2 µm). Spore size was given in the protologue as *7.5–9.5 × 1.5–1.8 µm. However, from the scale on the photo plate a spore size of *7.5–8.5 × 1.1–1.3 µm can be evaluated which is obviously more correct. Also the SBs are a bit narrower (~0.8 µm as a maximum) than indicated in the protologue (0.5–1 µm).

Although the observations by Zhang et al. (2006) are said to be based on living elements (asci, paraphyses, ascospores) in a tap water mount of a fresh specimen, a majority of their figures

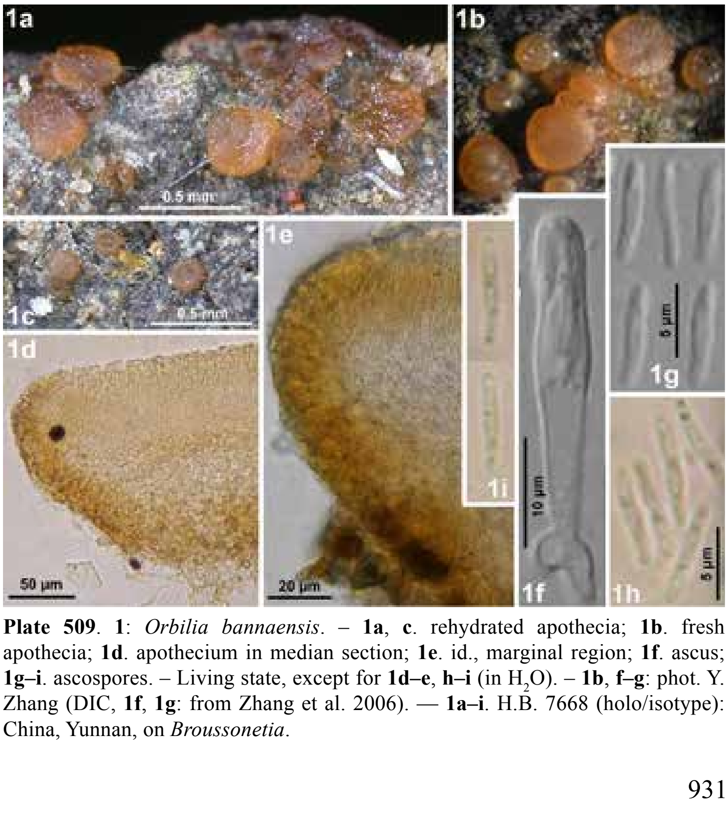

Plate 509. **1**: *Orbilia bannaensis*. – **1a**, **c**. rehydrated apothecia; **1b**. fresh apothecia; **1d**. apothecium in median section; **1e**. id., marginal region; **1f**. ascus; **1g–i**. ascospores. – Living state, except for **1d–e**, **h–i** (in H_2O). – **1b**, **f–g**: phot. Y. Zhang (DIC, **1f**, **1g**: from Zhang et al. 2006). — **1a–i**. H.B. 7668 (holo/isotype): China, Yunnan, on *Broussonetia*.

refer to dead cells, except for the spores (Pl. 509: 1g) and one of the asci (1f).

Not included collections. An unidentified species of *Orbilia*, here referred to as *O.* aff. *bannaensis*, was reported by Guo et al. (2013) from three localities in China. Regrettably, the authors described only its anamorph (see below). According to an unpublished plate of the teleomorph (see IVV), it differs from *O. bannaensis* in apically less inflated paraphyses and in shorter ascospores (*5.8–6.3 × 1.2–1.3 µm) without a tail-like base; the broadly cylindrical spore bodies measure 1.2–1.5 × 0.7–0.8 µm (both evaluated from scale).

A collection from Guizhou examined and cultured by M. Mo (pers. comm.) resembles *O. bannaensis* because of similar ascospores and conidia, but appears to belong near *O. rosea* (Pl. 533).

Anamorph. Zhang et al. (2006) did not obtain a culture of *O. bannaensis*. A single 4-septate conidium was found by us close to the apothecia in the isotype (Pl. 508: 1d), which resembles the dactylella-like conidia of *O.* cf. *rosea* obtained by M. Mo in pure culture (Pl. 533: 1e–f). In a Chinese collection of *O. rosea* from Henan a similar anamorph developed in pure culture, but its conidia are shorter and appear to represent microconidia of *O. rosea* (see Pl. 532).

Guo et al. (2013) reported under the name *Trinacrium incurvum* an anamorph (IVV: jhs-40) gained from an ascospore isolate of one of the three collections which we here identify as *O.* aff. *bannaensis*. The anamorph was believed by the authors to be the first record of a *Trinacrium* within China. Its conidia have about the same size and shape as those of *O.* aff. *farnesianae* in Liu (2006, as *O. brasiliensis*). No sequence was available of this isolate (J.W. Guo pers. comm.). Guo et al.'s observation raises the questions whether *O. bannaensis* might also possess a trinacrium incurvum-like anamorph.

Phylogeny. A sequence of the ITS region was gained from apothecia of *O. bannaensis* by Zhang et al. (2006). The S1506 intron is absent. In their phylogenetic analysis the species clustered with *O. sinensis* (as *O. luteorubella* and *O. vinosa*) in a clade. However, members of section *Aurantiorubrae* were not available for comparison at that time. In our analysis of ITS (Phyl. S15) it clustered in the strongly supported clade of series *Piliferae*, whereas a relation to section *Helicoon* was not confirmed. The distance in the entire ITS region is 8–12% to other members of series *Piliferae*, the lowest to *O.* cf. *paracaudata*, but ~20–22% to those of section *Helicoon*. The alignment of the ITS1 and ITS2 region actually shows great divergences between section *Helicoon* and *O. bannaensis*. Regrettably, Guo's isolates of *O.* aff. *bannaensis* were not investigated by molecular methods.

Ecology. *O. bannaensis* was found on rotten periderm of a semihygric log of *Broussonetia* (*Moraceae*) in a subtropical (almost tropical) humid (winter-dry, monsoon-influenced) rainforest in southernmost China. The three samples of *O.* aff. *bannaensis* Guo et al. (2013) originate from similar but subtropical forests in eastern and southern China.

Specimens included. **CHINA**: **Yunnan**, **Xishuangbanna**, 25 km SE of Menglunzhen, NE of Mengyuan, Mengyuan Rainforest, 1400 m, branch of *Broussonetia*, on bark, 20.VII.2004, Z.F. Yu (Z.F.Y. xsbn-1, OT003, YMFT, **holotype**; H.B. 7668, **isotype**; sq.: DQ512888).

Not included. **CHINA**: **Anhui**, Jiuhuashan, substrate not stated, 29.IX.2009, J.W. Guo (jhs-40, anam. cult.). – Further collections from **Jiangsu**, Nanjing, Zijinshan and **Yunnan**, Yuxi, Xinhua Forest Park (J.W. Guo pers. comm., not clear for teleomorph which collection is figured).

Series *Albovinosae*

Orbilia subgenus ***Habrostictis*** section ***Aurantiorubrae*** series ***Albovinosae*** Baral, **ser. nov.**, MB 815016 – Type species: *Orbilia albovinosa* Baral & G. Marson

Etymology: named after the type species, *O. albovinosa*.

Latin diagnosis: *Apothecia rosacea (ad aurantiaca), fimbriata vel dentata, corpuscula crystalloidea saepe praesentia, guttulae luteae carentes, cellulae marginales processis vitreis generaliter perlongis praeditae, ascosporae fusoideae vel fusiformes, raro subcylindricae, apice subacutae ad acutae, raro obtusae ad rotundatae, corpusculum lacrimiformem, raro globosum continentes, ad basim leniter ad valde attenuatae vel longe caudatae, rectae vel leniter curvatae, status anamorphicus conidiis staurosporis* (*typo* Trinacrium/Dicranidion *vel* Dwayaangam).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.6(–1) mm diam., pale to bright rose(-orange), margin pubescent or with prominent white hairs or teeth, sessile or with an ill-defined stipe. **Asci** *34–60(–70) × (4–)5–7(–7.5) µm, 8–32-spored, lower 0–5(–6) spores inverted when 8-spored, about 8 or 16 spores inverted when 16-/32-spored; **apex** (†) slightly to mostly medium to strongly truncate, thin-walled, not or sometimes distinctly indented and laterally inflated; **base** T-, L-, Y- or h- but never H-shaped. **Ascospores** *(4–)5–22(–25) × (1–)1.2–2.9(–3.3) µm, ellipsoid-fusoid to fusiform(-clavate), rarely subcylindrical, apex subacute to acute, rarely obtuse to rounded, base slightly to strongly attenuated, partly tail-like or with an abrupt, long, basally partly inflated tail, straight or slightly (rarely medium) curved in lower part; **SBs** 0.6–3.5 × (0.4–)0.6–1.5(–2) µm, broadly (rarely narrowly) tear-shaped to ampulliform, rarely globose, apically narrowed to a ± small point. **Paraphyses** not or slightly to medium inflated at the apex, spathulate-lageniform, also clavate(-capitate) or uninflated, terminal cells 1–2(–3)× longer than lower cells. **Ectal excipulum** cells near base *(6–)8–20(–27) × (4–)7–15(–20) µm; **glassy processes** 1–7 µm up to 100–250 µm long, **hairs** absent. **SCBs** globose, often mixed with crystalloid ones; **VBs** consistently absent. **Exudate** ± absent or 0.2–3 µm thick, continuous-cloddy to granular, ± firmly or loosely attached, hyaline to pale yellowish. **— ANAMORPH**: trinacrium/dicranidion- or dwayaangam- like. **Conidiophores** not observed. **Conidia** staurosporous, either Y- to T-shaped (2-armed), *35–74 × 39–73 µm, the two arms slightly to strongly curved out- or downwards, or dwayaangam-like (4-armed), *40–60 × 13–46 µm, arms straight or curved.

Habitat: on wood and bark of angiosperms, temperate to subtropical, humid to semiarid, on bark (exceptionally wood).

Recognized species: 8, plus 1 with a provisional name and 3 unnamed species ('affinis').

Taxonomic remarks. Series *Albovinosae* appears to form a rather natural group, being characterized by ± straight ascospores and often long glassy processes at the margin which are ± free or form prominent white hairy teeth. The rather large spores are mostly fusoid to fusiform and have ± acute apices which contain rather large, mostly broadly tear-shaped SBs. The asci are predominantly 8-spored, but in some taxa 16-spored, an exceptional feature within section *Aurantiorubrae*. The somewhat marginal species *O. gemma* deviates from the remaining of this series in 32-spored asci containing small, subcylindrical spores with rounded to obtuse apices with small, almost globose SBs.

O. pseudoaristata and *O. pseudoflagellispora* may easily be confused with *O. aristata* and *O. flagellispora* of section *Hemiorbilia*. However, their truncate, thin-walled ascus apices forbid placement in that series. Despite this fundamental difference, the spores closely resemble each other, and also the texture of the marginal excipulum carrying glassy processes is very much alike. Even the anamorph in *O. pseudoaristata* and the tendency that only very few basal spores are inverted within the asci coincides in both groups. *O. subalbovinosa* forms a transition in spore shape between *O. albovinosa* and *O. pseudoaristata*, and thus supports, along with molecular data, placement of these tailed-spored species in series *Albovinosae*. *O. pilifera* resembles series *Albovinosae* in its large, broadly tear-shaped SBs, but the marginal hairs are septate and without a solid part.

Species delimitation. Considerable variation is observed among the studied collections treated under *O. pubescens*, *O. albovinosa*, and *O. albidorosea*, e.g., in spore size or length of glassy processes, which questions the homogeneity of these taxa. Also the limits between *O. pubescens* and *O. albidorosea* are not fully clear.

Anamorph. Conidia were only observed in three of the nine accepted species. Accordingly, series *Albovinosae* is characterized by a staurosporous anamorph with either trinacrium/dicranidion-like conidia with down- or outwards-curved arms (*O. albovinosa*, *O. pseudoaristata*), or dwayaangam-like conidia with straight (*O. albidorosea*) or curved arms (exceptionally in *O. albovinosa*). With its trinacrium-like conidia series *Albovinosae* resembles the anamorph of series *Piliferae*, while sharply differing from the vermispora-like anamorph typical of the remaining series of section *Aurantiorubrae*.

Phylogeny. Sequences were available for six species of series *Albovinosae* (SSU+ITS+LSU: *O. albidorosea*, *O. albovinosa*, *O. navicularis*, ITS+LSU: *O. pleioalbidorosea*, *O. pseudoaristata*, *O gemma*). In combined analyses, *O. albidorosea* and *O. albovinosa* form a strongly supported clade in Baral et al. (2017b), in which also *O. navicularis* and *O. pleioalbidorosea* clustered and to which *O. pseudoaristata* formed with low support a sister clade (Phyls 7, 13). The morphologically somewhat different *O gemma* formed an unsupported sister clade to the core of series *Albovinosae* (Phyl. 13). The same tree topology was obtained when analysing ITS (Phyl. S15),

Key to species of series *Albovinosae*

1. Margin without glassy processes; apothecia ochre-orange .... ***O. pilifera*** (series *Piliferae*), p. 918
1. Margin with short to long glassy processes (sometimes at the tip of hairs); apothecia orange to rose, rarely with ochraceous tint 2

2. Asci 32-spored; spores *(4–)5–6(–8) × 1–1.3 µm, subcylindrical with rounded to obtuse apex, SBs globose; bark of *Lamarchea*, subtropical semiarid western Australia .... ***O. gemma***, p. 934
2. Asci 8–16-spored; spores longer or wider, fusoid with acute to subacute apex, SBs tear-shaped 3

3. Asci 8-spored 4
3. Asci 16-spored; spores *8.5–15 µm long 11

4. Spores †7–8 × 3–3.3 µm, fusiform-subclavate, without tail; glassy processes 30–70 µm long, curved inwards; bark of *Dodonaea*, subtropical semiarid western Australia .... ***O.* aff. *pubescens***, p. 938
4. Spores max. *3 µm wide 5

5. Spores *2.3–3 µm wide 6
5. Spores *1.2–2.4 µm wide 8

6. Spores fusoid, without distinct tail, *(8.5–)9–12(–13) × (2.3–)2.5–3 µm; bark of *Pistacia*, supramediterranean semihumid southern Europe .... ***O. navicularis***, p. 936
6. Spores divided into an ellipsoid-fusoid head and a ± abrupt, much thinner tail of at least about the same length, *14–25 µm long 7

7. Spores *13–19(–26.5) × 2.3–2.8(–3) µm, tail medium thick (0.5–1 µm), not or hardly inflated at base; SBs 2–3 × 1.2–1.5 µm; bark or wood of mainly *Salix* & *Cornus*, cold-temperate humid to mesomediterranean semihumid Europe, subtropical humid eastern Australia .... ***O. pseudoaristata***, p. 947
7. Spores *20–25 × 2.7–2.9 µm, with a very thin (0.2–0.4 µm) tail with distinctly bulbous base; SBs 2.8–3.5 × 1.4–2 µm; bark of *Lamarchea* & *Melaleuca*, subtropical semihumid to semiarid western Australia .... ***O. pseudoflagellispora***, p. 951

8. Spores *11–14 × 1.3–1.8 µm, base attenuated in a thick tail; SBs 0.5–0.8 µm wide; with crystalloid SCBs in paraphyses and excipulum; bark of ?*Eucalyptus*, subtropical semihumid western Australia .... ***O. subalbovinosa***, p. 946
8. Spores *7–19 × 1.5–2.4 µm; SBs 1–1.5 µm wide 9

9. Spores *16–19 × 2–2.4 µm, with long-cylindrical middle part; SCBs globose; paraphyses spathulate; glassy processes 25–80(–140) µm long; bark of *Lonicera*, mesosub- to mesomediterranean semihumid Europe & northern Africa.......... ***O. albovinosa***, p. 945
The included mesosubmediterranean collection on wood of *Ficus* has only 1–7 µm long glassy processes and non-spathulate paraphyses covered by distinct exudate. A similar sample on *Euphorbia* from Montenegro deviates by much shorter spores of *12–16 × 1.9–2.3 µm.
9. Spores 7–11 µm long, fusoid, only sometimes with short-cylindrical middle part 10

10. Spores *(5.5–)6–10(–11) × (1.3–)1.4–1.8(–2) µm; excipular cells and/or paraphyses with crystalloid SCBs; paraphyses with ± spathulate apex; glassy processes up to 100 µm long, forming distinct teeth; apothecial disc rose; wood & bark of *Acacia*, *Eucalyptus*, *Jacksonia*, (sub) tropical subhumid to semiarid western & eastern Australia, (sub)mediterranean semihumid southern Europe .... ***O. albidorosea***, p. 939
10. Spores *8.5–11 × 2–2.2 µm; excipular cells apparently without crystalloid SCBs; paraphyses lageniform with long apical beak; glassy processes up to 35 µm long, not forming distinct teeth; apothecial disc orange; wood of *Ribes*, bark of *Acer*, boreal to cold-temperate humid North America .... ***O. pubescens***, p. 936
A collection from semiarid Australia on bark of *Lamarchea* differs in †2.2–2.4 µm wide spores and in hairs with a basal lumen terminated by 3–15 µm long glassy processes (p. 939).

11. Spores *2–2.8 µm wide; bark of *Amelanchier*, *Pistacia* etc., supra(sub)mediterranean (semi)humid southern Europe ***O. pleioalbidorosea***, p. 943
A similar collection was on *Amelanchier* in cold-temperate semiarid western North America.
11. Spores *3–3.5 µm wide; branch of *Pinus ponderosa*, cold-temperate humid western North America .... ***O.* aff. *pleioalbidorosea***, p. 943

but here the core clade received strong support. When analysing LSU (Phyl. S15), series *Albovinosae* is paraphyletic by forming three unresolved clades: one contains *O. albidorosea*, *O. pleioalbidorosea*, and *O. navicularis*, another *O. albovinosa* and *O. pseudoaristata*, and a third *O. gemma*.

Series *Albovinosae* clustered weakly supported sister to the core clade of series *Aurantiorubrae* (Phyl. 13), or unresolved among members of section *Aurantiorubrae* and *Habrostictis* in Baral et al. (2017b). In our combined analysis of the entire genus *Orbilia* (Phyl. 7), however, the marginal *O. gemma* clustered weakly supported with series *Vibrioides* (section *Hemiorbilia*).

Specific nucleotide positions. Two nucleotides in the LSU D2 domain characterize series *Albovinosae* s.str. within sections *Aurantiorubrae* and *Helicoon*: at pos. 527 (G**A**GAA vs. G**G**GAA or A**G**GAA) and at pos. 559 (AGC**T** vs. AGC**C**). However, the two motifs of series *Albovinosae* are also highly diagnostic of the *Serpentinae-Habrostictis* clade of section *Habrostictis* and were otherwise only seen in *O. octocorculispora* and *O. microsoma*. *O. gemma* shows the more frequent versions A**G**GAA + AGC**C** that occur in this combination only in series *Regales* and *Xanthoguttulatae*.

Ecology. Probably all included species are more or less desiccation-tolerant. They grew on bark of angiosperms, rarely on wood or herbaceous stems. Records derive from temperate humid to subtropical semihumid (mediterranean) Europe and northern Africa, subtropical semiarid to tropical humid Australia, and cold-temperate semiarid to boreal humid North America.

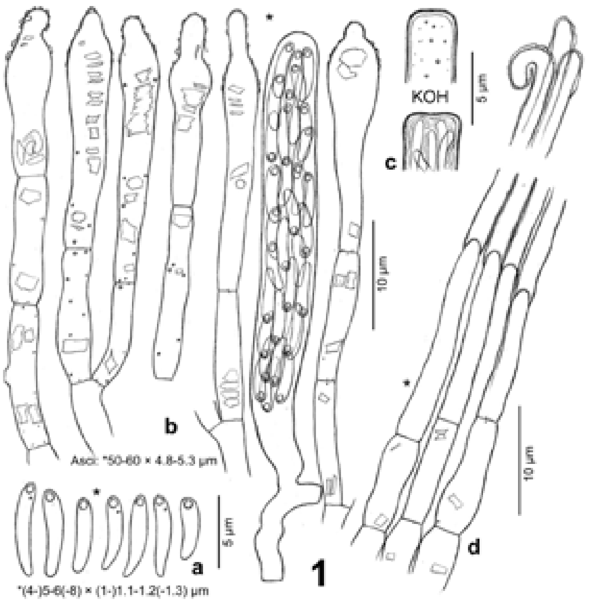
Orbilia gemma Baral & G. Marson, **sp. nov.**, MB 813777 — Pls 510–511

Etymology: resembling a gem (jewel).

Typification: Western Australia, Toolonga, twig and trunk of *Lamarchea hakeifolia*, 8.XI.2007, G. Marson (ex H.B. 9020a, MEL 2389273, holotype; sq.: KT222350).

Latin diagnosis: *Apothecia rehydratata 0.3–0.7 mm diam., vivide rosea, sessilia, margine exigue albido-dentata. Asci 32-spori. Ascosporae *4–8 × 1–1.3 µm, subcylindricae, basi partim leniter attenuatae, rectae vel saepe leniter curvatae, corpusculum refringens globosum vel late lacrimiforme, ad apicem cuspide brevissime affixum continentes. Paraphyses ad apicem distincte mammi- vel lageniformes, exsudato tenui tectae. Excipulum marginale processis vitreis perlongis hyalinis agglutinatis praeditum. Cellulae excipuli marginalis et paraphysium in statu vivo corpuscula crystalloidea continentes. Habitat ad corticem profusum putridum siccum rami et trunci vivi* Lamarcheae hakeifoliae *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.6(–0.7) mm diam. (0.35–0.8 mm incl. teeth), 0.11–0.16 mm high, light to bright rose-pink, indistinctly translucent, ± round, scattered; disc flat, margin 0–10 µm protruding (excl. teeth), with prominent, straight white teeth 100–250 × 40–100 µm; broadly sessile, superficial; dry ± completely closed by the teeth. **Asci** *50–60 × 4.8–5.3 µm, †49–59 × 4.3–4.7 µm, 32-spored (26–30 spores counted), spores *5–6-seriate, lower spores inverted (strongly mixed), pars sporifera *34–38 µm long; **apex** (†) strongly truncate (not or slightly indented and laterally inflated); **base** with short to long, thick or thin, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(4–)5–6(–8) × (1–)1.1–1.2(–1.3) µm, subcylindrical, apex rounded to obtuse, base not or slightly attenuated, straight to often slightly curved; **SBs** *0.6–0.8 × 0.4–0.6 µm, globose to broadly tear-shaped, apically narrowly attached. **Paraphyses** apically slightly or medium (rarely strongly) inflated, spathulate or mostly lageniform to mammiform, terminal cells *(12–)16–27 × 2.7–4.5 µm, beaks 2–6 × 1,6–2 µm, exceeding the dead or immature asci by 4–8 µm, lower cells *11–13(–18) × 1.8–3(–3.5) µm; never branched at upper septum, hymenium pale rose. **Medullary excipulum** hyaline, 20–40 µm thick, of dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a 5–10 µm thick layer of t. porrecta. **Ectal excipulum** hyaline to pale rose, of (†) thin-walled, irregularly vertically oriented t. angularis-globulosa(-prismatica) from base to mid flanks, 40–60 µm thick near base, cells *10–16(–19) × 6–10(–11.5) µm; 20–25 µm thick at flanks, 15–25 µm near margin, of t. prismatica oriented at a 40–70° angle to the surface, outer layer of t. porrecta oriented at 10–40°, marginal cortical cells *8–19 × 2–2.8 µm; **glassy processes** 100–250 × (1.8–)2.5–3(–4) µm, high-refractive, not stratified, ± straight, coherent to form distinct teeth, terminally sometimes strongly hooked (outwards, also inwards). **Anchoring hyphae** ± sparse, †2–2.5(–3.5) µm wide, walls 0.2(–0.3) µm thick. **SCBs** in paraphyses and entire ectal excipulum crystalloid, 2–4.5 × 1.5–3 µm in excipulum, hyaline. **Exudate** over paraphyses 0.l–0.4 µm thick, granular, hyaline, firmly attached, over glassy processes 0.3–1 µm thick. — **ANAMORPH**: unknown.



H.B. 9020a (holotype): Western Australia, Yalgoo, on *Lamarchea hakeifolia* (bark)

Plate 510. **1**: *Orbilia gemma*. – **a**. ascospores; **b**. ascus and paraphyses (containing crystalloid SCBs); **c**. ascus apices; **d**. marginal ectal excipulum in median section, cortical cells terminated by long glassy processes.

Habitat: collected 0.5–1.5 m above the ground, 3–5 mm thick dead twig or 10–18 cm thick living trunk of *Lamarchea hakeifolia*, on outer but sometimes also inner surface of paper-like, hanging bark being almost entirely detached, strongly decayed and greyed, no algae. **Associated**: *Capronia* spp. {2}, *Claussenomyces* sp., *Hyalorbilia pleioerythrostigma*, *Orbilia austroobtusispora*, *O. kingsiana*, *O. lamarcheae*, *O. myriolilacina*, *O. pseudoflagellispora*, *O.* ?*pubescens*, *Ostropales*, *Symbiotaphrina desertorum*, ?*Xerotrema* sp. **Desiccation tolerance**: fully viable for at least 17 months. **Altitude**: 190 m a.s.l. **Geology**: Cretaceous sedimentary rock (red-brown sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia gemma* is readily recognized by its apothecia with a pure rose-pink hymenium and very long, straight, white teeth which easily break off at their base, and microscopically by 32-spored asci, lageniform paraphyses, and small cylindrical ascospores with globose SBs.

With its rose colour, glassy processes, and spathulate-lageniform paraphyses containing crystalloid SCBs, *O. gemma* resembles members of series *Albovinosae*, except for its ascospores which are in the other species larger and apically consistently ± acute, containing larger, tear-shaped SBs. Species of series *Regales* concur with *O. gemma* in their lageniform paraphyses, glassy processes, and shape of spores and SBs. However, crystalloid SCBs as well as asci with more than 8 spores are so far unknown in that series.

In spore morphology *O. gemma* also resembles four species

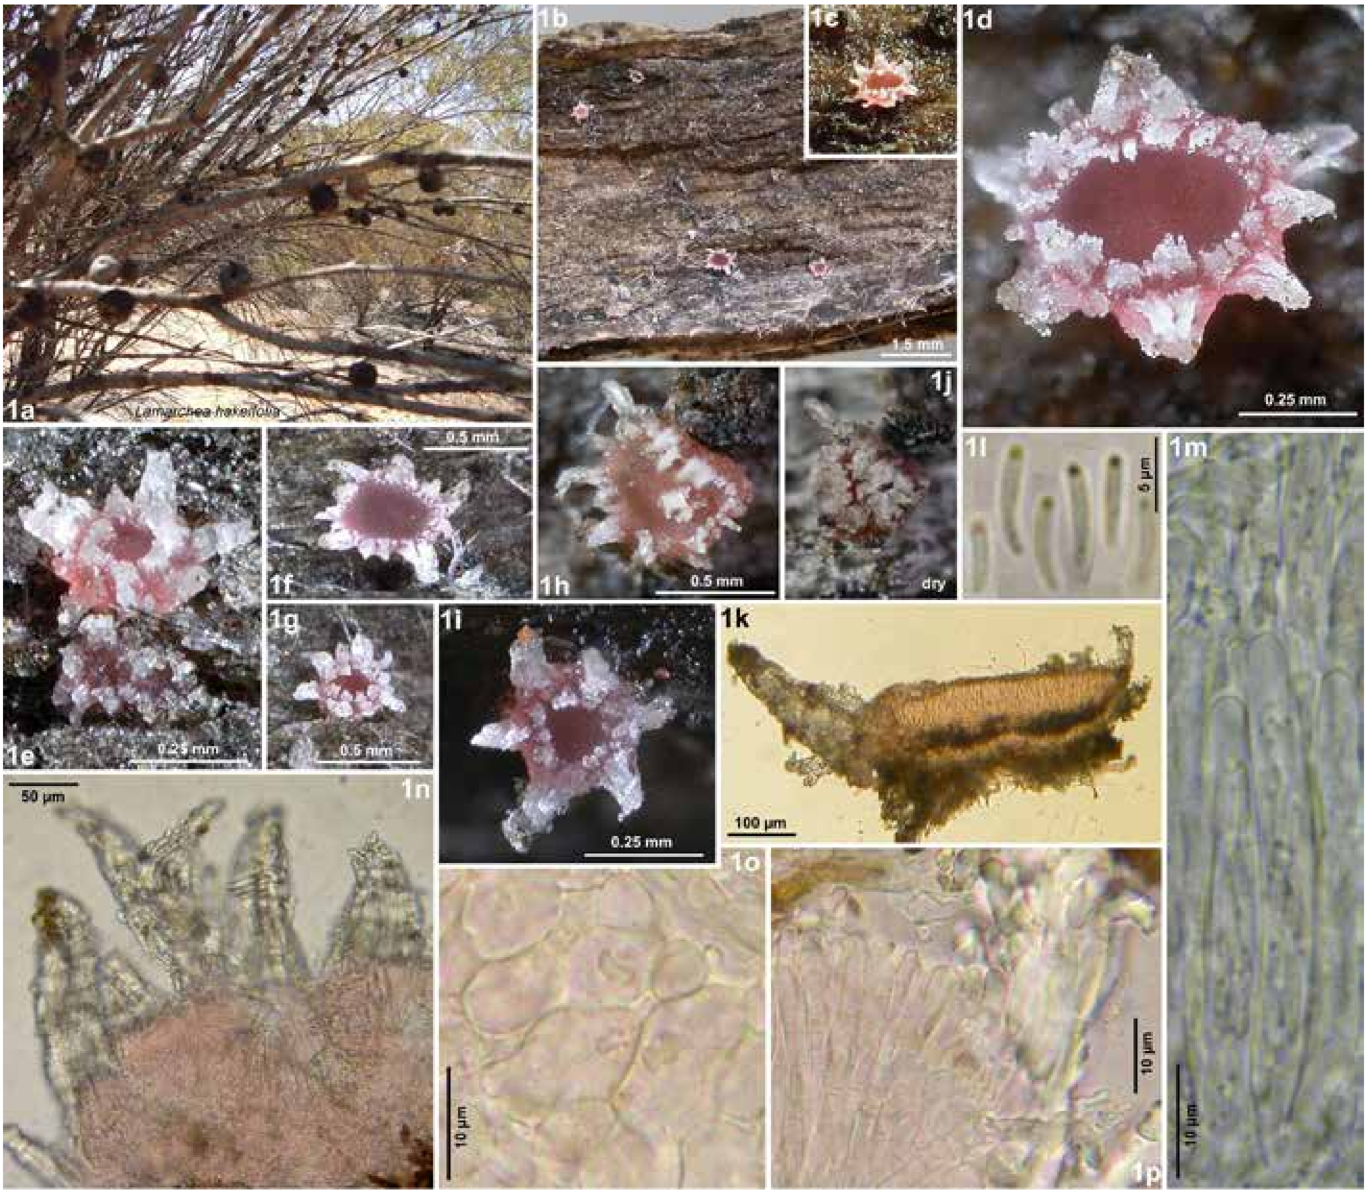


Plate 511. **1**: *Orbilia gemma*. – **1a**. semiarid acacia shrubland with *Lamarchea hakeifolia* in foreground; **1b**. xeric bark of *Lamarchea* detached from living trunk; **1b–i**. rehydrated apothecia; **1j**. dry apothecium; **1k**. apothecium in median section; **1p**. id., marginal ectal excipulum with glassy processes; **1n**. dentate margin of glassy processes in squash mount; **1o**. crystalloid SCBs in ectal excipular cells at lower flanks; **1m**. mature asci (and paraphyses); **1l**. ascospores. – Living state. — **1a–p**. H.B. 9020a (holotype): Western Australia, Yalgoo.

of series *Microsomates* (section *Orbilia*), which differ in orange apothecia: *O. mirabilis* and *O. myriopseudoregalis* further deviate in outwards curved teeth, the former also in much larger, more curved spores; *O. multinanosoma* and *O. myrionanosoma* differ in spores with smaller, more rod-shaped SBs, also in predominantly non-lageniform paraphyses and in short or even absent teeth. In ascospore morphology *O. gemma* further resembles species of section *Orbilia*, such as *O. pleioaustrocylindrica* and *O. multiaustrocylindrica*, or the rose-lilaceous *O. myriolilacina* of section *Ovoideae*. Yet, none of these have spathulate-lageniform paraphyses, glassy processes, or crystalloid SCBs.

Phylogeny. A sequence from apothecia of the holotype comprises SSU (S1506 intron absent), ITS, and LSU. *O. gemma* formed an unsupported clade with an environmental sequence from arctic Canada (Northwest Territories, Banks Island, ~50 m, arctic soil, 103_NA8_P31_K7, KC965955), with very high distance (20% in ITS, 4.7% in LSU D1–D2). The clade clustered unsupported sister to the remaining members of series *Albovinosae* when analysing ITS (S15) or ITS+LSU (Phyl. 13), to which *O. gemma* shows a similarly high ITS distance of 17–20.5%, the lowest to *O. pseudoaristata*. Also when comparing only the 5.8S region, *O. pseudoaristata* was the closest species. In our combined analysis of the entire genus *Orbilia* (Phyl. 7), however, *O. gemma* clustered weakly supported with series *Vibrioides* of section *Hemiorbilia*, a rather unexpected placement from a morphological point of view. This placement is supported by a rare deviation at pos. 70 of LSU (CAAC**C**GGGA) which *O. gemma* shares with some members of section *Hemiorbilia*, including series *Vibrioides*, and which so far does not occur in any other section of *Orbiliomycetes* (see under section *Hemiorbilia*, p. 544).

Ecology. *O. gemma* was found on strongly detaching xeric bark of a twig and a living trunk of *Lamarchea hakeifolia* (*Myrtaceae*) in a subtropical semiarid acacia open shrubland with *Callitris* and *Lamarchea* in the Yalgoo ecoregion of western Australia (see also under the associated *O. lamarcheae*, p. 1486, Pl. 929: 1k–l).

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, twig & trunk of *Lamarchea hakeifolia*, on bark, 8.XI.2007, G. Marson (ex H.B. 9020a, MEL 2389273, **holotype**; **isotype** MEL 2389275B; sq.: KT222350, MH221052).

Orbilia navicularis S. Tello, Baral & E. Weber, **sp. nov.**, MB 825637 — Pls 512–513

Etymology: referring to the naviculate (boat-shaped) ascospores.

Typification: Spain, Andalucía, Jaén, Sierra de Ventisqueros, El Parrizoso, branch of *Pistacia terebinthus*, 18.IV.2017, S. Tello (ex S.T. 18041702 & ex H.B. 10113a, AH 52847, holotype; sq.: MK473416).

Latin diagnosis: *Similis* Orbiliae pubescenti *sed apothecia margine denticulata, processis vitreis agglutinatis, deorsum curvatis, ascosporae latiores. Habitat ad corticem leniter putridum rami sicci* Pistaciae terebinthi *in supramediterranea semihumida Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.5–)0.7–1.3 mm diam., 0.13–0.23 mm high (receptacle 0.1–0.13 mm), pale to bright (ochraceous-)orange-rose, round, undulating when large, scattered to gregarious in small groups; disc ± concave, margin and exterior densely covered by crystal-like tufts of white hairs, 36–100 µm projecting including hairs; sessile on a broad or narrow, conical base. **Asci** *45–55 × 5.7–6.5 µm, †40–46 × 5.2–5.7 µm, 8-spored, spores (*/†) 2-seriate, ((1–))(2–)4(–6) lower spores inverted (sometimes mixed, rarely upper spore inverted), pars sporifera *30–36 µm long; **apex** (†) medium to strongly truncate (not or very slightly indented and/or laterally inflated); **base** with short stalk, L- to Y-shaped. **Ascospores** *(8.5–)9–12(–13) × (2.3–)2.5–3((–3.2)) µm, †8–9.5 × 1.8–2.5 µm, fusiform-naviculate, apex subacute, medium to strongly attenuated towards straight to sometimes slightly curved base; **SBs** *2.7–3.3 × 1.3–1.6 µm, with inflated, globose basal part and 0.8–0.9 µm wide, cylindric-subulate upper part. **Paraphyses** apically not or slightly inflated, cylindrical to sublageniform, terminal cells *13–22 × 2–3 µm, †1.3–2.3 µm wide, 3–6 µm longer than dead asci, lower cells *(3–)7–9.5 × 1.8–2.5 µm; unbranched at upper septum. **Medullary excipulum** 20–60 µm thick, of dense, small-celled textura angularis with some inflated catenate cells. **Ectal excipulum** of vertically oriented t. globulosa-angularis from base to margin, 50–140 µm thick at base, cells *(6–)8–20(–27) × (5–)7–15(–20) µm, (†) slightly gelatinized, 25–40 µm thick at lower flanks, 15–25(–35) µm at mid flanks and margin, externally covered by a layer of t. porrecta passing into ~50–100 µm long **hairs** composed of a 2–3-celled, 35–45 µm long, thin-walled basal part (terminal cell *13–25 × 3.3–4 µm) tipped by **glassy processes** (8–)20–55(–70) × 3–3.5(–4.5) µm, high-refractive, appearing stratified only in KOH, curved outwards, agglutinated to form teeth-like tufts. **Anchoring hyphae** abundant, */†1.5–3 µm wide, walls 0.2–0.5 µm thick, forming a very dense t. intricata 10–60 µm thick. **SCBs** in paraphyses absent or present, faintly refractive, hyaline, globose, 1.5–2 µm diam., also rhomboid (crystalloid); none seen in ectal excipulum. **Exudate** on paraphyses and hairs sparse, finely granular, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 1.8 m above the ground, corticated, 16–20 mm thick branch of *Pistacia terebinthus*, on little to medium decayed bark (outer surface of bast or on periderm amidst lichens), algae not observed. **Associated**: *Lecanora* sp., *Lecidella elaeochroma*, *Melanohalea exasperata*, *Orbilia xanthoguttulata*, *Physcia* sp. etc. **Desiccation tolerance**: many mature asci, paraphyses, and excipular cells viable after 2.5 months. **Altitude**: 1130 m a.s.l. **Geology**: Tertiary calcareous sandstone and breccia with red matrix below dolomite (close to Jurassic and Cretaceous sediments). **Phenology**: IV (but long-lived).

Taxonomic remarks. *Orbilia navicularis* resembles the Australian *O. albidorosea*, from which it differs in an orange hymenium, glassy processes being curved outwards, sublageniform paraphyses, and distinctly wider and slightly longer ascospores. The mediterranean *O. albovinosa* differs in much longer spores. *O. navicularis* is doubtfully distinct from the American *O. pubescens* nom. prov. on *Ribes* (Pl. 514: 1), from which it differs in glassy processes being curved outwards and agglutinated to form teeth, and distinctly wider ascospores. Another American collection, which was also from the Southern Rocky Mountains but ~90 km away and on *Acer* (Pls 514: 2; 515: 1), was only studied in the dead state; it even concurs with *O. navicularis* in spore size (when compared in the dead state) and in having outwards curved glassy processes being agglutinated to form teeth.

Phylogeny. A sequence from apothecia gained from the holotype comprises SSU (without S1506 intron), ITS, and LSU. In our combined analysis (Phyl. 13) it clustered strongly supported with *O. albidorosea* and particularly *O. pleioalbidorosea*, to which it shows a 7% and 2.5% ITS distance (2.5% and 0.5% in LSU D1–D2), respectively, whereas to *O. albovinosa* the distance is 11% (4.5% in LSU).

Ecology. *O. navicularis* grew amidst a large number of lichen species on slightly to moderately rotten bark (bast and periderm) of a xeric branch of *Pistacia terebinthus*, residing in a row of trees and shrubs across a dry pasture land grazed by goat and sheep. The nearby vegetation is a supramediterranean semihumid, north-exposed open woodland with *Quercus rotundifolia*, *Q. faginea*, *Crataegus monogyna*, *Acer monspessulanum*, and *Juniperus oxycedrus*.

Specimens included. **SPAIN**: **Andalucía**, **Jaén**, Sierra de Ventisqueros, 7 km ENE of Valdepeñas de Jaén, 1.9 km S of El Parrizoso, 1130 m, branch of *Pistacia terebinthus*, on bark, 18.IV.2017, S. Tello (ex S.T. 18041702, ex H.B. 10113a, AH 52847, **holotype**; sq.: MK473416).

Orbilia pubescens Baral & G. Marson, **nom. prov.**, MB 813779 — Pls 514–515

Etymology: referring to the hairy apothecia.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.45 mm diam., 0.13 mm high, bright orange-red, round to broadly elliptical, scattered; disc flat, margin pubescent with whitish hairs, 80 µm projecting including hairs; subsessile. **Asci** *40 × 5–5.6 µm, †33–40 × 4.2–4.6 µm, 8-spored, spores (†) ~3-seriate, 3–5 lower spores inverted; **apex** (†) medium to strongly truncate (not indented, laterally not widened); **base** with short stalk, bifurcate. **Ascospores** *8.5–11 × 2–2.2 µm, fusiform to fusiform-clavate, apex subacute to acute, towards base medium to strongly attenuated, here straight to slightly curved; **SBs** *2–3 × 1.1–1.4 µm, tear-shaped. **Paraphyses** apically slightly to medium inflated, sublageniform, terminal cells *12–22 × 2.5–3.5 µm, †1.7–2.8 µm wide, lower cells *(3–)6–10 × 1.5–2.3 µm; unbranched at upper septum. **Medullary excipulum** 30 µm thick, not further examined. **Ectal excipulum** of vertically oriented textura angularis from base to margin, 40–60 µm thick near base, cells *10–20 × 10–14 µm, (†) slightly gelatinized, 30–40 µm thick at lower flanks, 20 µm at mid flanks and margin, oriented at 40–80°, externally covered by a layer of t. porrecta passing into 35–55 µm long **hairs** composed of a 1–2-celled basal part (terminal cell *21–24 × 3.5–4.5 µm) tipped by **glassy processes** 10–35 × 3–5 µm, high-refractive, appearing stratified only in KOH, curved inwards, not agglutinated. **Anchoring hyphae** abundant, */†2–3 µm wide, walls 0.2–0.3 µm thick, forming a very dense t. intricata up to 100 µm thick. **SCBs** in paraphyses globose. **Exudate** on paraphyses and hairs very sparse, finely granular, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 0.1–0.8 m above the ground, decorticated, 12 mm thick branch of *Ribes cereum*, on slightly decayed wood, ungreyed, algae not observed. **Associated**: *Durella* sp., *Hysteropatella* sp., *Melaspilea ermergens*, *Orbilia delphinus*, *O. lentiformis*, *O. maeandrina*, *Ostropales*, *Patellaria* sp. **Desiccation tolerance**: a few mature asci still viable after 7.5 months. **Altitude**: 2615 m a.s.l. **Geology**: granite & gneiss. **Phenology**: VI (but long-lived).

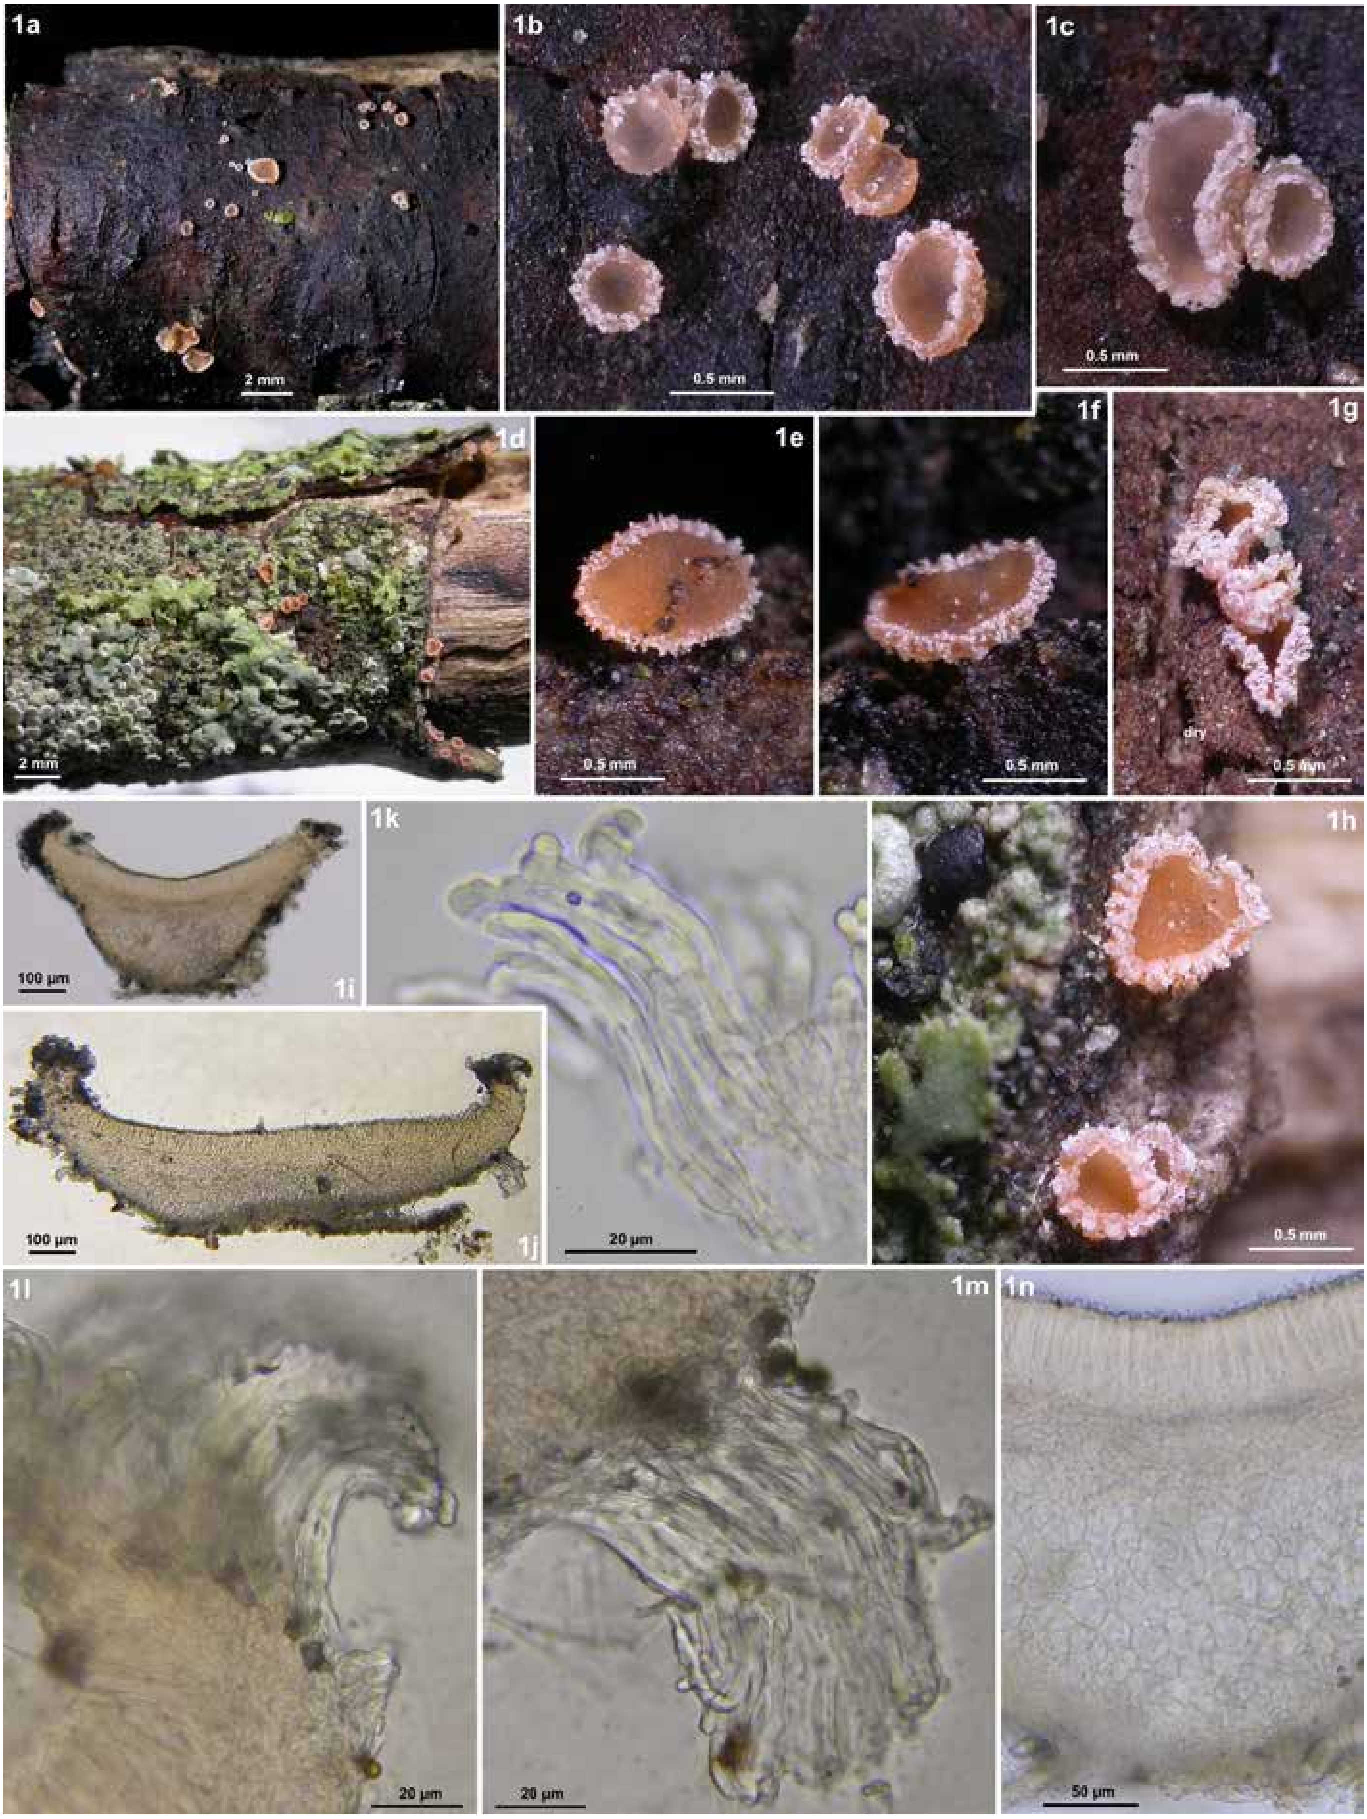

Plate 512. **1**: *Orbilia navicularis*. – **1a–f**, **h**. rehydrated apothecia; **1g**. dry apothecia; **1i–j**. apothecia in median section; **1n**. id., central part; **1k–m**. id., agglutinated glassy processes at margin and flanks. – Living state. – **1i**, **n**: phot. S. Tello. — **1a–n**. H.B. 10113a: Spain, Andalucía, Jaén, on *Pistacia*.

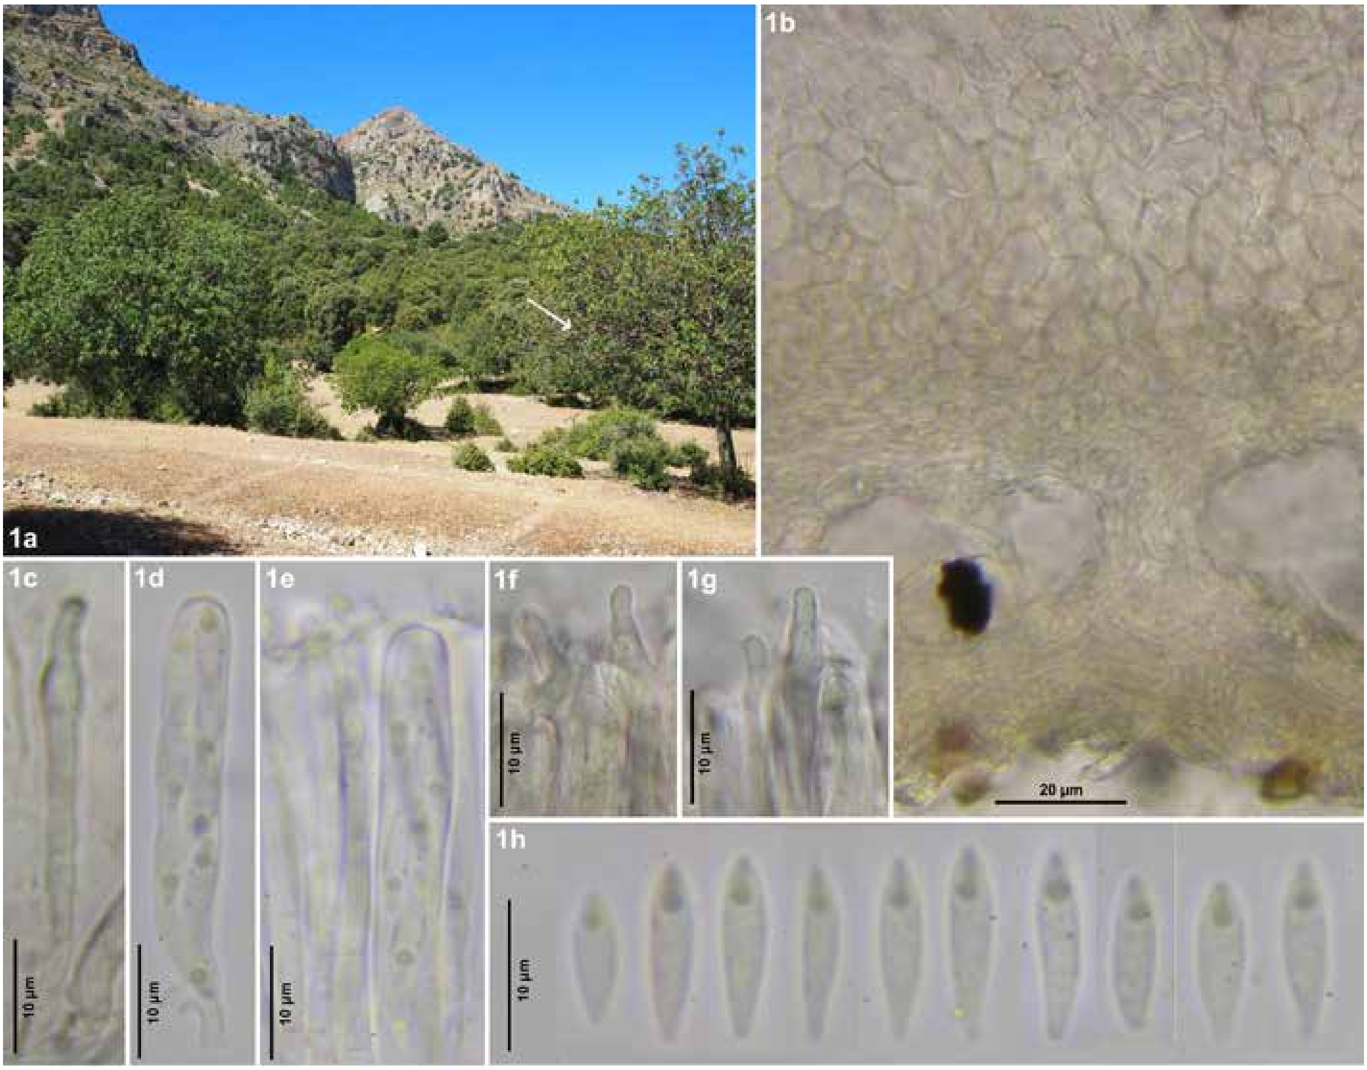

Plate 513. **1**: *Orbilia navicularis*. – **1a**. dry pasture land with *Pistacia terebinthus* tree in front of *Quercus rotundifolia* woodland; **1b**. basal ectal excipulum with abundant anchoring hyphae, in median section; **1c–g**. asci and paraphyses; **1h**. ascospores. – Living state, except for ascus in **1d**. – **1a**, **d–e**, **h**: phot. S. Tello. — **1a–g**. H.B. 10113a: Spain, Andalucía, Jaén, on *Pistacia*.

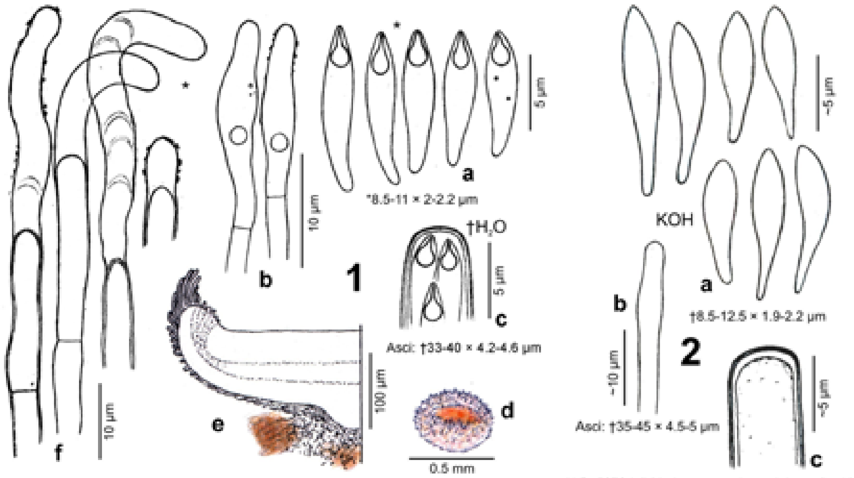
Taxonomic remarks. *Orbilia pubescens* differs from *O. navicularis* in narrower ascospores and in glassy processes being curved inwards and not agglutinated to form teeth. *O. albidorosea* differs from *O. pubescens* in an (orange-)rose to rose hymenium, longer glassy processes which are agglutinated to form teeth, spathulate-lanceolate paraphyses, and slightly narrower ascospores, and in the presence of crystalloid SCBs (but their absence in *O. pubescens* could not be assessed with certainty).

The collection of *O. pubescens* nom. prov. consists of a single apothecium, of which only a fragment and a slide remained.



H.B. 5705g (holotype): USA, Colorado, Shawnee, on *Ribes cereum* (wood)

H.B. 5672d: ibid., Lyons, on *Acer glabrum* (bark)

Plate 514. **1**: *Orbilia pubescens* nom. prov.; **2**: *O.* cf. *pubescens*. – **a**. ascospores; **b**. paraphysis apices; **c**. ascus apices; **d**. apothecium with fimbriate margin; **e**. apothecium in median section; **f**. marginal cortical cells with glassy processes.

Not included collections. A sparse sample on bark of *Acer glabrum* (Pls 514: 2; 515: 1) was only studied in the dead state and differs in more clavate, basally more strongly attenuated spores (†8.5–12.5 × 1.9–2.2 µm) and in somewhat shorter glassy processes (18–27 µm) which are curved outwards and more agglutinated to form teeth.

Two bark-inhabiting Australian records resemble *O. pubescens* and *O. navicularis* in various respects, but seem to belong to two different species. Both are merely known from a single unpreserved apothecium and were only briefly studied, mainly in the dead state. The two were collected at a single site though on different hosts. One (on trunk bark of *Dodonaea*, Pl. 515: 2) differs from the above in distinctly shorter and wider spores (†7–8 × 3–3.3 µm). The 30–70 µm long

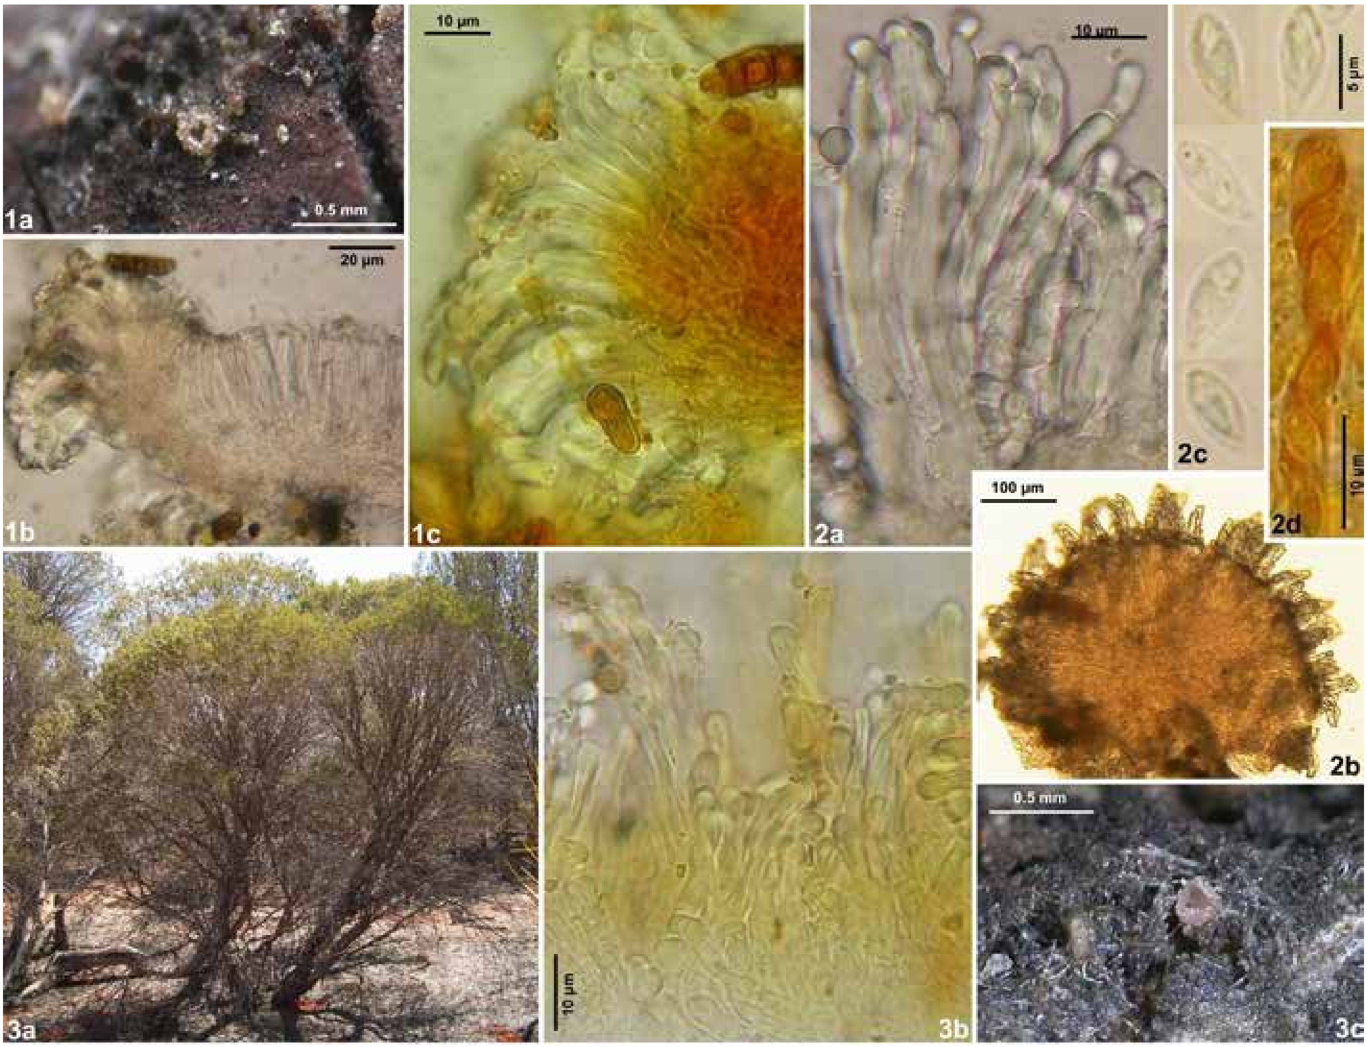


Plate 515. **1**: *Orbilia* cf. *pubescens*; **2–3**: *O.* aff. *pubescens*. – **3a**. *Lamarchea hakeifolia* in semiarid acacia shrubland; **1a**, **3c**. rehydrated apothecia; **1b**. apothecium in median section; **1c**. id., marginal ectal excipulum; **2a**. long glassy processes; **3b**: hairs with thin glassy caps; **2b**. apothecium in top view; **2c**. ascospores; **2d**. mature ascus. – Dead state (in water, **2d** in IKI, **1c**, **3b** in KOH+IKI). — **1a–c**. H.B. 5672d: USA, Colorado, on *Acer*; **2a–c**. H.B. 8838c: Western Australia, Nerren Nerren, on *Dodonaea*; **3a–c**. H.B. 9020n: ibid., on *Lamarchea*.

glassy processes are curved inwards. The other grew on bark of a *Lamarchea hakeifolia* twig (Pl. 515: 3), with spores †8–9 × 2.2–2.4 µm and ~35–65 µm long hairs which have thickened lateral walls and a lumen almost up to the apex, being terminated by 3–15 µm long glassy processes. The spores appear to have a short tail, but were not seen outside the asci.

Ecology. *O. pubescens* was found on slightly rotten wood of a xeric branch of *Ribes cereum* (wax currant) in a boreal humid Engelmann spruce forest of the Southern Rocky Mountains in western North America. The not included collection on bark of *Acer glabrum* (Rocky Mountain maple) was made in a similar region and forest but at lower altitude in a cold-temperate humid Douglas fir forest. The two samples from western Australia derive from a subtropical semiarid acacia open shrubland in the Yalgoo ecoregion.

Specimens included. **USA**: **Colorado**, Southern Rocky Mountains, 65 km SW of Denver, 7.5 km WNW of Shawnee, Santa Maria, north slope of mountain, 2615 m, branch of *Ribes cereum*, on wood, 14.VI.1996, G. Marson (ex H.B. 5705g, **holotype**, M-0276572).

Not included. **USA**: **Colorado**, Southern Rocky Mountains, ~26 km NNW of Boulder, ~6 km WNW of Lyons, ~1885 m, branch of *Acer glabrum*, on bark, 13.VI.1996, G. Marson (H.B. 5672d). — **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, trunk of *Dodonaea viscosa* subsp. *angustissima*, on bark, 8.XI.2007, G. Marson (H.B. 8838c ø). – ibid., twig of *Lamarchea hakeifolia*, on bark, 8.XI.2007, G. Marson (H.B. 9020n ø).

Orbilia albidorosea Baral & G. Marson, **sp. nov.**, MB 813780 — Pls 516–517, Map 86

Etymology: referring to the rose apothecia with white marginal teeth.

Typification: Australia, Queensland, Karoon Station, branches of *Acacia georginae*, 16.X.1998, G. Marson (ex H.B. 6615a, BRI AQ799188, holotype; ex-type culture: CBS 140818; sq.: KT215254, MH878188).

Latin diagnosis: *Apothecia rehydratata 0.2–1 mm diam., rosea, sessilia, margine longe albido-denticulato. Asci 8-spori. Ascosporae *5.5–11 × 1.3–2 µm, fusoideae vel fusiformes, (sub)acutae, basi leniter vel valde attenuatae, rectae vel leniter curvatae, in statu vivo corpusculum refringens lacrimiformem continentes. Paraphyses ad apicem subtiliter vel modice inflatae, spathulatae ad obtuse lanceolatae. Margo excipuli processis vitreis longis agglutinatis praedito. Cellulae vivae excipuli et paraphysium corpuscula globosa et crystalloidea continentes. Habitat ad corticem putridum, etiam lignum, ramorum siccorum* Acaciae, Eucalypti *et* Jacksoniae *in zona tropica ad submediterranea semiarida ad semi- vel subhumida Australiae occidentalis et orientalis et Europae meridionalis.*

µm long; **apex** (†) medium to strongly truncate (not or sometimes slightly indented, laterally not or scarcely widened); **base** with short to medium long, ± thick, flexuous stalk, L-, Y- to h-shaped. **Ascospores** *(5.5–)6–10(–11) × (1.3–)1.4–1.8(–2) µm {6}, †7–8 × 1.5–1.7 µm {1}, fusoid to fusiform, sometimes fusoid- to fusiform-clavate, apex subacute to acute, rarely obtuse or acuminate, not or sometimes slightly to strongly attenuated towards base (partly tail-like), here straight or slightly curved; **SBs** *(1.5–)1.8–2.5(–3) × (0.7–)0.9–1.2(–1.4) µm {4}, tear-shaped, sometimes pear-shaped to ampulliform. **Paraphyses** apically (uninflated to) very slightly or medium spathulate to obtusely lanceolate, terminal cells *(9–)12–18 × (2–)2.3–3.2 µm {4}, protruding *1–5 µm beyond asci (†5–7 µm), lower cells *4–9.5 × 1.6–2.3 µm {4}; unbranched at upper septum. **Medullary excipulum** 30–45 µm thick, of ± dense textura intricata-globulosa with many inflated cells, (medium) sharply delimited only at flanks. **Ectal excipulum** pale rose-pink, of (†) not or slightly gelatinized, vertically oriented t. (globulosa-) angularis(-prismatica) from base to margin, 30–70 µm thick near base, cells *10–25 × 8–17 µm {3}; 15–30 µm thick at lower flanks, 10–20 µm at mid flanks and margin, inner layer of t. prismatica-angularis oriented at a 40–70° angle, cells of *5–9 × 6–9 µm, cortical layer of t. porrecta oriented at 10–50°, partly as free, 2–3-celled **hairs** 18–45 µm long, terminal cells longest, *7–20 × 2.5–3.5 µm {4}; hairs at margin tipped by **glassy processes** 30–100 × (2.3–)2.7–3.5(–5) µm {5} (at upper margin only 3–20 long), high-refractive, not stratified or sometimes near insertion or overall, terminally slightly to strongly curved inwards {5}, sometimes outer processes outwards curved, agglutinated to form teeth, at flanks absent or 40–60 µm long. **Anchoring hyphae** abundant, */†1.7–3.5 µm wide, walls 0.2–0.5(–1) µm thick {4}. **SCBs** in paraphyses and hair bases globose to ellipsoid {4} and crystalloid {4}; in angular excipular cells from base to margin absent {1} or crystalloid {4}, (sub)hyaline, 3–5 × 2–3.5 µm. **Exudate** absent or scattered, finely granular, on hairs absent. — **ANAMORPH**: dwayaangam-like (from ascospore isolate {1}). **Conidiophores** not observed. **Conidia** with a central stipe and 4 straight or only slightly diverging arms, two arms pointing upwards, 2 downwards, total size *40–48 × 13–16 µm, stipe *19–**20** × 3–3.5 µm, 3-septate, arms *15–23 × 2.5–3.5 µm, 1–4-septate, not or slightly tapering {1}.

Habitat: collected 0.5–5 m above the ground, corticated or decorticated, 8–25 mm thick branches or ~20 cm thick logs of *Acacia* sp. {1}, *A. georginae* {1}, *Eucalyptus* sp. {2}, *E. camaldulensis* {1}, *E. globulus* {1}, *Jacksonia* sp. {1}, on 0.1–1 mm deep medium to strongly decayed inner and outer surface of bark (bast) {6}, rarely wood {1}, slightly to strongly greyed, green algae absent or sparse to abundant. **Associated**: *Calycellina* sp. {1}, *Claussenomyces* sp. {1}, *Durella* sp. {1}, *D.* aff. *connivens* {1}, *Gloniopsis praelonga* {1}, *Orbilia acaciae* {1}, *O. arachnopus* {1}, *O. australiensis* {1}, *O. austroocculta* {1}, *O. austroregalis* {1}, *O. curvativitalbae* {1}, *O. eucalypti* {2}, *O. gambelii* {1}, *O. kingsiana* {1}, *O. macrotrapeziformis* {1}, *O. microserpens* {1}, *O. multinanosoma* {1}, *O. myriofusiclava* {1}, *O. myrioobliqua* {1}, *O. nothovinosa* {1}, *O. pleiocrescens* {1}, *Psiloglonium lineare* {1}. **Desiccation tolerance**: fully viable for at least 7.5 months, some mature asci still alive after 14.5 months, many immature asci after 20 months. **Altitude**: 37–514 m a.s.l. **Geology**: Spain: Triassic & Tertiary dolomite, sandstone & gypsum; granite & granodiorite, migmatite & gneiss; Australia: Jurassic & Cretaceous sedimentary rock, Cenozoic regolith; granulite with granitic gneiss. **Phenology**: probably all year round (long-lived).

Taxonomic remarks. *Orbilia albidorosea* is characterized by apothecia with a rosaceous-pinkish hymenium and prominent white marginal teeth composed of long glassy processes, also by rather small, fusoid ascospores, spathulate-lanceolate paraphyses, and the presence of crystalloid SCBs. In all four Australian specimens and that from Asturias the glassy processes attained a maximum length of ~100 µm, while in the other Spanish ones they ranged more at a maximum of 60 µm. The European *O. pleioalbidorosea* differs in 16-spored asci, the mediterranean *O. albovinosa* in much longer spores, absence of crystalloid SCBs, and a different anamorph. For the similar North American *O. pubescens* see p. 936.

Variation. The two collections from eastern Australia (Pl. 516: 1–2) deviate from most of the others in larger asci and spores (ascus size and spore width do not overlap when compared in the living state), but in the sample from Cataluña the spores had an intermediate size (*6.2–8.5 × 1.5–2 µm, IVV: 24.X.2015). The collection in Pl. 516: 1 deviates also in the absence of crystalloid SCBs in the paraphyses though present in the excipular cells. The other features of all these specimens are so similar that we consider them to belong in the scope of a single species. The specimen from Asturias had whitish to very pale rosaceous-lilaceous apothecia apparently due to growing on the moist ground (Pl. 517: 4a), but the other two from Spain had light to bright rose apothecia and were also at rather moist places and partly hidden behind bark. In that from Asturias crystalloid SCBs were only found in the paraphyses, but in that from Cataluña also throughout the ectal excipulum.

Anamorph. The conidia of *O. albidorosea* resemble *Dwayaangam yakuensis* but have distinctly longer arms and stipes, both with more septa. The lower arms are close and parallel to the stipe in their proximal part, which is only exceptionally the case in *D. yakuensis*, e.g., in the Australian strain (Matsushima 1989). However, only very few conidia developed in our culture when flooded by water, and only two could be documented.

Phylogeny. A sequence taken from the ex-type culture comprises SSU, S1506 intron, ITS, and LSU. The entire ITS region shows a distance of 12.5 % to *O. albovinosa* and 15 % to *O. pseudoaristata*. In the LSU D1–D2 the closest species is *O. poitevinica* (series *Poitevinicae*, 2.5 %) which, however, shows a 16.5 % ITS distance, while the LSU distance to *O. pseudoaristata* is 3.5 % and to *O. albovinosa* 4.5 %. *O. albidorosea* formed with *O. pleioalbidorosea* and *O. navicularis* a strongly supported clade in analyses of ITS+LSU or ITS (Phyl. 13, S15). When analysing the intron, *O. albidorosea* clustered unsupported sister to the rest of the section (Phyl. S14), to which it shows a distance of ~ 17–22 %.

Ecology. *O. albidorosea* was found on ± strongly rotten bark (rarely wood) of xeric branches of trees and shrubs of different *Fabales* in a tropical semiarid eucalypt open woodland in northeastern Australia (west of Great Dividing Range), in a subtropical subhumid eucalypt woodland with *Acacia* and *Callitris glaucophylla* in southeastern Australia (west of Great Dividing Range), and in a subtropical semihumid banksia-eucalypt woodlands with *Macrozamia* in southwestern Australia (Darling Range). The three collections from southwestern Europe were on ± hygric bark of *Eucalyptus* logs in mesosub- to mesomediterranean semihumid eucalypt plantations in northern, western, and eastern Spain.

Specimens included. **AUSTRALIA**: **Western Australia**, Jarrah Forest, 25 km NNE of Bindoon, 12 km ESE of Wannamal, 272 m, branch of *Acacia*, on bark, 4.IX.2006, G. Marson (H.B. 8582d). – Swan Coastal Plain, 30 km NE of Perth, 4 km N of Upper Swan, W of Walyunga, 37 m, branch of *Jacksonia*, on bark, 23.XI.2001, G. Marson (H.B. 7284h). – **Queensland**, Desert Uplands, 57 km E of Hughenden, 3 km WSW of Karoon Station, 437 m, branches of *Acacia georginae*, on wood, 16.X.1998, G. Marson (ex H.B. 6615a, BRI AQ799188, **holotype**, anam. cult., CBS 140818; sq.: KT215254, MH878188). – **New South Wales**, Brigalow Belt South, 16 km S of Coonabarabran, Mendooran Rd, 514 m, branches of *Eucalyptus*, on bark, 25.X.1998, G. Marson (H.B. 6387c). — **SPAIN**: **Asturias**, 6 km SE of Avilés, SE of Núñez, 200 m, log of *E. globulus*, on bark, 14.III.2009, A. Suárez (E.R.D. 4716, H.B. 9031). – **Extremadura**, **Cáceres**, 9.3 km SE of Jarandilla de la Vera, 8.5 km NNE of Talayuela, Cuestas de Torresca, 363 m, bark of *E. camaldulensis*, 28.II.2016, E. Rubio (E.R.D. 6658, doc. vid.). – **Cataluña**, **Girona**, 10 km SW of Girona, 2 km NNW of Sant Dalmai, 180 m, log of *Eucalyptus*, on bark, 24.X.2015, M.À. Pérez-de-Gregorio & J. Carbó, vid. J. Bometón (J.B. 621/15, doc. vid.).

Orbilia pleioalbidorosea Baral, **sp. nov.**, MB 813781 — Pls 518–519

Etymology: similar to *O. albidorosea*, but with 16-spored asci.

Typification: Spain, Teruel, Guadalaviar, branch of *Amelanchier ovalis*, 26.IX.1999, G. Marson (ex H.B. 6486a, M-0276556, holotype).

Latin diagnosis: *Differt ab* O. albidorosea *ascis 16-sporis, ascosporis magis fusiformibus, processis vitreis excipuli marginalis brevioribus. Habitat ad corticem putridum rami sicci* Amelanchieris *et* Pistaciae *in zona supra(sub) mediterranea humida ad semihumida Europae meridionalis.*

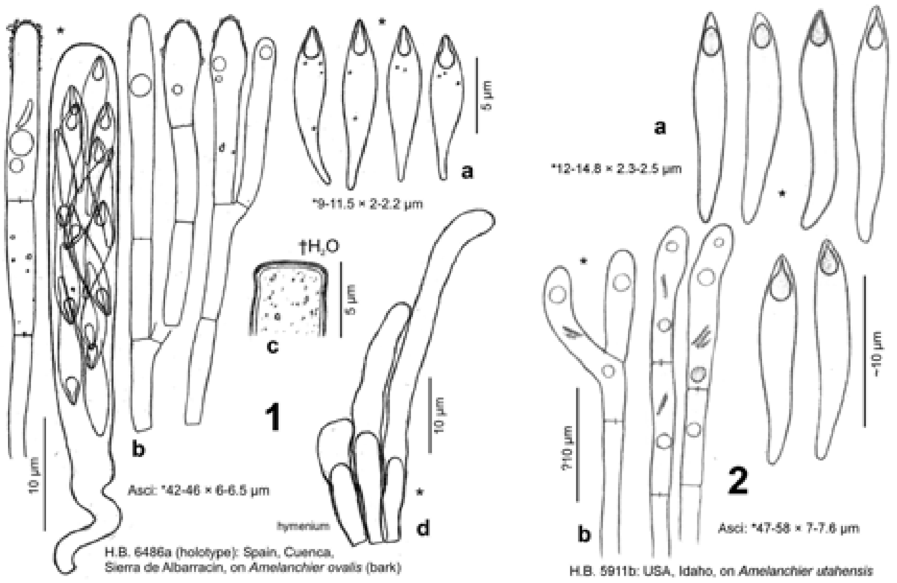

Plate 518. **1**: *Orbilia pleioalbidorosea*; **2**: *O.* cf. *pleioalbidorosea*. – **a**. ascospores; **b**. ascus and paraphyses (with globose and crystalloid SCBs); **c**. ascus apex; **d**. marginal cortical cells with glassy processes, in median section.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.7(–0.85) mm diam., 0.1–0.17 mm high, ± round, solitary or gregarious in small groups; disc medium concave to flat, bright orange-rose(-ochraceous), margin with prominent, whitish, hairy teeth; broadly sessile, superficial. **Asci** *42–46 × 6–6.5 µm {T} or *45–69 × 7–7.5 µm {2}, †39–45 × 5–5.5 {T} or †41–58 × 4.7–6.5 µm {2}, 16-spored, spores *~4-seriate, lower ~8 spores inverted (± mixed), pars sporifera *34 {T} or *43 {1} µm long; **apex** (†) strongly truncate (not indented, laterally not or slightly widened); **base** with short, ± thick, flexuous, L- to Y- or h-shaped stalk. **Ascospores** *9–11.5 × 2–2.2 µm {T} or *(8.5–)10–13(–14.5) × (2–)2.2–2.6(–2.8) µm {2}, †8–10 × 1.8–2 µm {T} or †9–12 × 1.8–2.2 µm {1}, fusiform, apex acute, base strongly attenuated (often tail-like), straight to slightly curved near base; **SBs** 1.9–2.6 × 1–1.3(–1.5) {T} or 2.7–3.2 × 1–1.4 → 2.5 × 1.4–1.6 µm {2}, tear-shaped (to ampulliform). **Paraphyses** apically uninflated to slightly or medium obtusely lanceolate to spathulate or lageniform, terminal cells *(9.5–)13–20(–22) × (1.8–)2.3–3.3(–3.7) µm {3}, lower cells *8–13 × 1.8–2.5 µm {2}; rarely branched at upper septum. **Medullary excipulum** 20–70 µm thick, of dense textura intricata-angularis, indistinctly delimited. **Ectal excipulum** pale rose, of thin-walled, irregularly oriented small-celled t. angularis from base to mid flanks; 30–40 µm thick at base, cells *9–22 × 6–13 µm {1}; ~15 µm thick at margin, of t. porrecta oriented at a ~20–30° angle to the surface, marginal cortical cells */†10–16 × 2–4 µm (at submargin 4–5 µm wide) {2}; **glassy processes** at margin 20–50 × 3–4 µm {2}, high-refractive, stratified or not, outwards curved, loosely agglutinated to form teeth, from lower flanks to submargin forming glassy caps 3–6 × 3.5–5 µm {T} or also up to 50 µm long glassy processes {1}. **Anchoring hyphae** sparse, †2–3 µm wide, walls 0.2 µm thick {T}. **SCBs** in paraphyses globose, rarely with rod-shaped SCBs {2}; in excipulum forming large, thin, rod- to ring-shaped structures {2}. **Exudate** over paraphyses thin, granular, firmly attached. **— ANAMORPH**: unknown.

Habitat: collected 0.3–0.8 m above the ground, corticated to partially decorticated, 10–30 mm thick branches of *Amelanchier ovalis* {T}, *Pistacia terebinthus* {1}, *Rosa sicula* {1}, on medium to strongly decayed bark {2}, on periderm or bast (periderm rolled aside), bark partially detaching, also on inner surface of bark or at edge, strongly greyed or blackened when exposed, with some or many green algae. **Associated**: *Lecidea ?leprarioides* {1}, *Melanohalea exasperata* {1}, *Orbilia ovalis* {1}, *O. xanthoguttulata* {1}, *Physcia stellaris* {1}. **Desiccation tolerance**: fully tolerant for at least 2.5 months. **Altitude**: 1130–1818 m a.s.l. **Geology**: Jurassic dolomite and Cretaceous marly limestone & clay. **Phenology**: III, IX–X (but long-lived).

Taxonomic remarks. *Orbilia pleioalbidorosea* differs from *O. albidorosea* in 16-spored asci, ascospores with or without a short tail-like base, and outwards curved glassy processes.

Variation. The collections on *Pistacia* (Pl. 519: 3) and *Rosa* (Pl. 519: 2) deviate from the holotype in larger, especially longer asci, spores, and SBs, nevertheless we consider them as conspecific. The paraphyses in the *Pistacia* sample were apically almost uninflated, while in that on *Rosa* they were spathulate as in the holotype, though distinctly wider.

Not included collections. Two very sparse, unpreserved North American collections are not included in the description of *O. pleioalbidorosea*. That from Idaho on *Amelanchier utahensis* (Pl. 518: 2) differs from the holotype in distinctly longer spores but falls in the scope of the two paratypes. Another from Arizona on *Pinus ponderosa* differs in much wider spores (*8.5–11.5 × 3–3.5 µm) with wider SBs (1.8–2.4 × 1.3–1.6 µm) and probably belongs to a separate species. Only a few microphotos of the hymenium exist (IVV: 17.VI.2003). Whether the apothecia possessed glassy processes was not documented in both.

Phylogeny. A sequence from one of the Andalusian strains comprises ITS (without S1506 intron) and LSU (D1–D2). In our combined analysis (Phyl. 13) it clustered strongly supported with *O. navicularis* (distance in ITS 2.5%, LSU 0.5%), and *O. albidorosea* sister to them (distance in ITS 6.5%, LSU 2.6%).

Ecology. *O. pleioalbidorosea* occurred on rotten bark of xeric branches of angiosperm shrubs in mountainous calcareous sites of different regions of Spain. The holotype of *O. pleioalbidorosea*, which consisted of only three apothecia, was collected on *Amelanchier ovalis* in a suprasubmediterranean semihumid, south-exposed pine-juniper woodland in the Sierra de Albarracín in eastern Spain. The two paratypes derive from the supramediterranean (semi)humid Sierra Sur de Jáen in southern Spain, that on *Pistacia* from a *Quercus rotundifolia-Q. faginea* open forest with *Juniperus oxycedrus* and *Crataegus monogyna*, and that on *Rosa* from a shrubland with *Amelanchier ovalis*, *Berberis hispanica*, *Crataegus monogyna*, *Prunus mahaleb*, *Rhamnus saxatilis*, *Sorbus aria* etc.

The two not included collections from western North America were on *Amelanchier* from Idaho in a cold-temperate subhumid sagebrush desert scrub at the foot of the Middle Rocky Mountains bordering the Great Basin, and on *Pinus* from Arizona in a cold-temperate humid ponderosa pine forest in the Mogollon Rim.

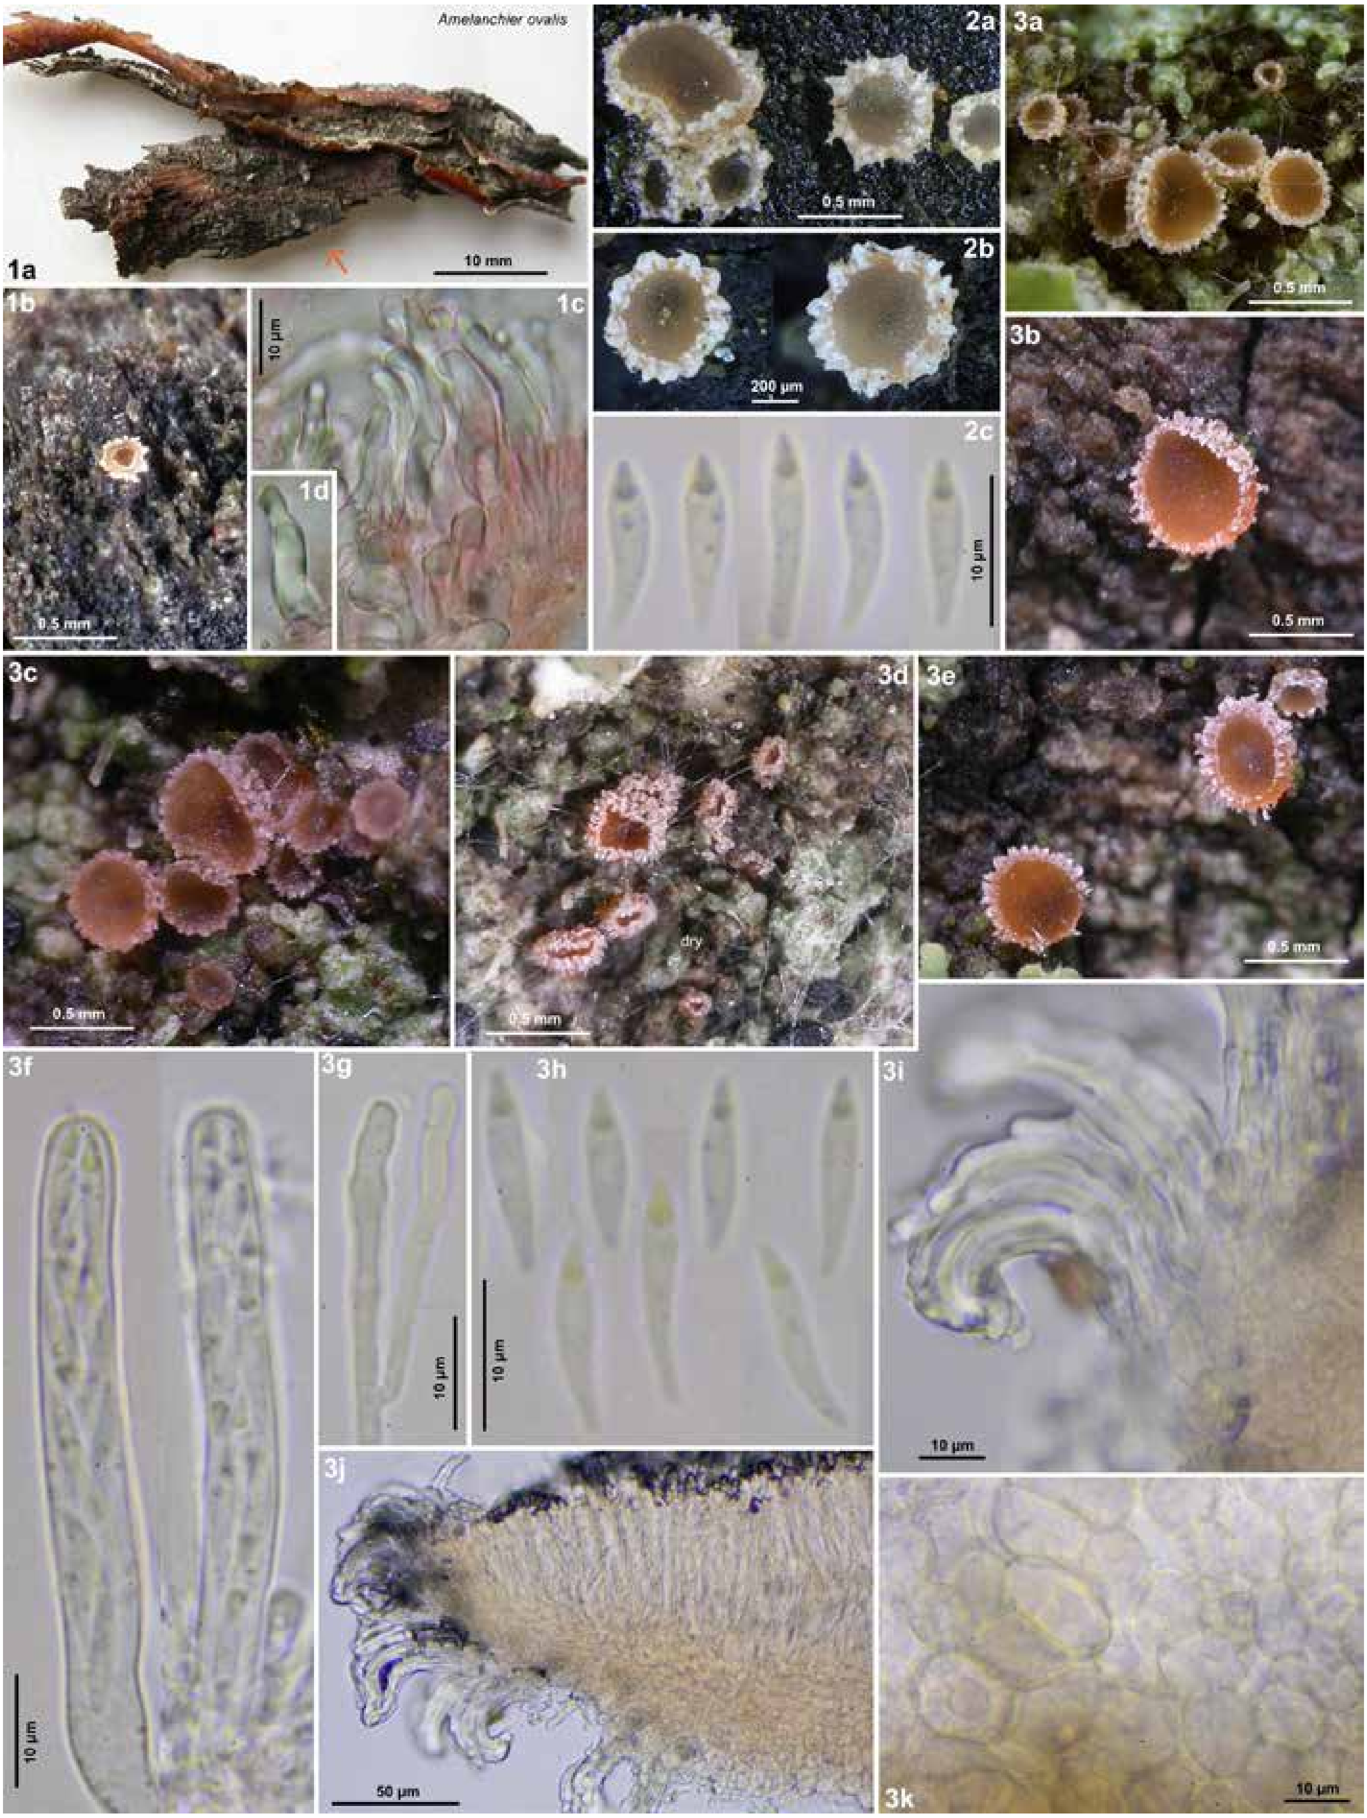

Plate 519. **1–3**: *Orbilia pleioalbidorosea*. – **1a**. xeric bark of a corticated branch of *Amelanchier ovalis*; **1b**, **2a–b**, **3a–c**, **e**. rehydrated apothecia; **3d**. dry apothecia; **3j**. apothecium in median section; **1c–d**, **3i**. marginal glassy processes; **3k**. indistinct crystalloid SCBs in cells of ectal excipulum at lower flanks; **3f–g**. asci and paraphyses; **2c**, **3h**. ascospores. – Living state, except for **1c–d** (in KOH+CR), right ascus in **3f** (in H_2O). – **2a–c**, **3a**, **f–k**: phot. S.T. 05031721: id., Sierra Sur de Jáen, on *Pistacia*.

Specimens included. **SPAIN**: **Castilla-La Mancha**, **Cuenca**, Sierra de Albarracín, 43 km NE of Cuenca, 8 km SW of Guadalaviar, S of Mt. Mogorrit, E of Peñu la Varga, 1600 m, branch of *Amelanchier ovalis*, on bark, 26.IX.1999, G. Marson (ex H.B. 6486a, M-0276556, **holotype**). – **Andalucía**, **Jaén**, Sierra Sur de Jáen, 21 km SSE of Jaén, 9.5 km E of Valdepeñas de Jaén, El Moralejo, 1218 m, branch of *Pistacia terebinthus*, on bark, 5.III.2017, S. Tello (S.T. 05031721, H.B. 10080a; sq.: MK493146). – Sierra de La Pandera, 15.5 km S of Jaén, 3 km W of El Parrizoso, Pico de la Pandera, 1818 m, branch of *Rosa sicula*, on bark, 1.X.2017, S. Tello (S.T. 01101702, doc. vid.).

Not included. **USA**: **Idaho**, Great Basin, Malad City, ~1435 m, branch of *Amelanchier utahensis*, 3.VI.1996, G. Marson (H.B. 5911b ø). – **Arizona**, Mogollon Rim, 16 km NW of Flagstaff, San Francisco Peaks, 6 km WSW of Humphreys Peak, 2550 m, branch of *Pinus ponderosa*, 17.VI.2003, G. Marson (ø).

Orbilia albovinosa Baral, **sp. nov.**, MB 813782 — Pl. 520

≡ *Hyaloscypha albovinosa* Maire in sched., nom. inval., ICN Art. 30.6

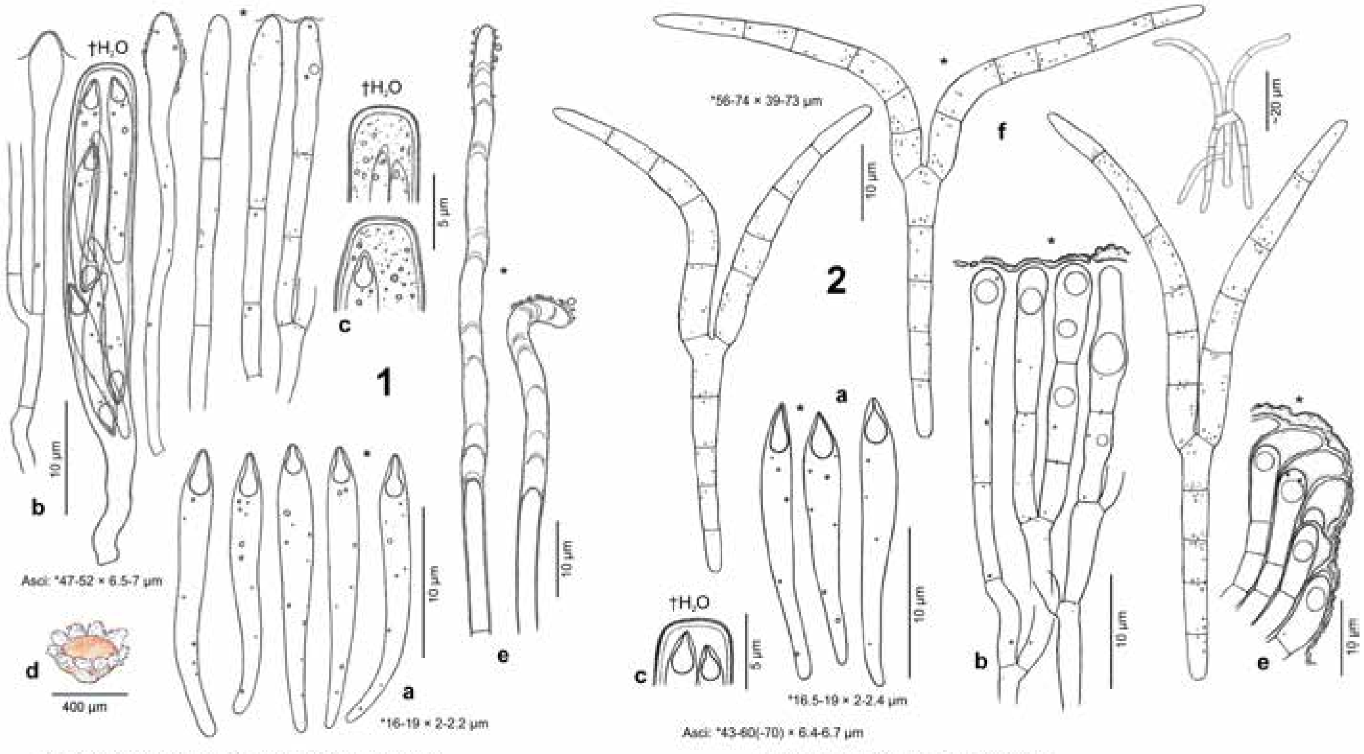
Etymology: referring to the colour of the apothecia with a reddish disc and whitish marginal teeth.

Typification: Croatia, Korčula island, branch of *Lonicera* (?)*implexa*, 4.VI.2000, H.O. Baral (ex H.B. 6683, M-0276431, holotype).

Latin diagnosis: *Differt ab* O. albidorosea *ascosporis multo longioribus*, *cellulis vivis excipuli et paraphysium corpusculis crystalloideis carentibus. Habitat ad corticem putridum ramorum siccorum* Lonicerae *et in lignum* Fici *in zona (sub) mediterranea semihumida Europae meridionalis et Africae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.6(–0.8) mm diam. (incl. teeth), 0.9–1.1 mm high, pale to light (orange-) rose, semitranslucent, round, scattered or in small groups; disc flat, margin thin and smooth {1} or with prominent whitish, rounded, hairy teeth {2}; sessile to substipitate, superficial. **Asci** *(43–)47–60(–70) × 6.4–7 µm {2}, †(38–)43–55 × 5–6(–6.5) µm {3}, 8-spored, spores *4-seriate, 3–5 lower spores inverted {2}; **apex** (†) (slightly to) medium to strongly truncate (not or slightly indented, laterally not widened); **base** with short to medium long stalk, simple or L- to h-shaped. **Ascospores** *16–19 × 2–2.4 µm {2}, †~13–18.5 × 1.5–2 µm {1}, narrowly fusiform(-clavate) with a short to long cylindrical middle part, apex subacute to acute, base gradually attenuated in a thick tail-like end, ± straight but slightly to medium curved or geniculate near base; **SBs** (2–)2.5–3(–3.5) × 1.1–1.4 µm {2}, tear-shaped (to ampulliform). **Paraphyses** apically uninflated to slightly or medium spathulate to obtusely lanceolate {2}, or cylindrical to very slightly capitate {1}, terminal cells *8.5–18 × (1.8–)2.5–3.3 µm {2}, †2–3(–3.5) µm wide {1}, lower cells *(4.5–)6.5–10(–15) × 1.5–2.6 µm {2}; unbranched at upper septum. **Medullary excipulum** hyaline, 20–25 µm thick, rather sharply delimited. **Ectal excipulum** very pale rose, of thin-walled, irregularly oriented textura angularis(-prismatica) from base to mid flanks, 25 µm thick near base, cells *6–11 × 4–9 µm {1}; 20 µm thick near margin, of t. prismatica-porrecta oriented at a 20–30° angle to the surface (inner layer at 45°), marginal cortical cells *8–20 × 2.7–4 µm {3}; **glassy processes** 1–7 {1} or 20–80 µm {2} × (2.5–)3–4(–5) µm, medium to high-refractive, stratified, straight, some apically hooked, when long loosely coherent to form large teeth. **SCBs** in paraphyses absent or mostly present, globose. **Exudate** over paraphyses absent {2} or 0.3–2 µm thick {1}, continuous-cloddy, loosely attached; over margin and flanks sparse to abundant, granular to cloddy. **Anchoring hyphae** medium abundant, *2–3 µm wide, walls 0.2–0.5 µm thick {1}. — **ANAMORPH**: dicranidion/trinacrium-, rarely dwayaangam-like (from ascospore isolate {1}). **Conidiophores** not observed. **Conidia** Y- to T-shaped with the two arms slightly to strongly curved outwards, total size *56–74 × 39–73 µm, stipe *28–33 × 3–4 µm, 4-septate, arms slightly tapering, *33–47 × 3.5–4 µm (in situ, actual length ~38–50 µm), 5–7-septate {1}; rarely 4-armed conidia seen (dwayaangam-like).

Habitat: collected 1–3 m above the ground, corticated, 8–40 mm thick branches of *Ficus carica* {1}, *Lonicera etrusca* {1}, *L.* (?)*implexa* {T}, partly still-living (*L. implexa*), on medium to strongly decayed wood {1} or loosely attached bark (periderm) {T}, strongly greyed or not, no green algae. **Associated**: ?*Nectria* sp. {1}, *Orbilia caulicola* {1}, *O. cylindrosoma* {1}, *O. flavida* {1}, *O. pleiolentiformis* {1}, *O. ungulata* {1}, *O. vitalbae* {1}, *Patellaria atrata* {1}, *Peroneutypa* ?*scoparia* {1}, *Trichopeziza* ?*perrotioides* (immature) {1}. **Desiccation tolerance**: fully viable for at least 3 weeks. **Altitude**: 120–1000 m a.s.l. **Geology**: Croatia: Cretaceous limestone, France: Miocene calcareous sandstone (molasse). **Phenology**: I, VI, X (probably long-lived and throughout the year).



H.B. 6683 (holotype): Croatia, Korčula, on *Lonicera implexa* (bark)

H.B. 7231f: France, Drôme, on *Ficus carica* (wood)

Plate 520. **1–2**: *Orbilia albovinosa*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. rehydrated apothecium with hairy-dentate margin; **e**. marginal ectal excipulum (**2e** in median section), cortical cells with glassy processes; **f**. conidia from culture.

Taxonomic remarks. Typical *O. albovinosa* (on *Lonicera*) is macroscopically characterized by apothecia with a rose hymenium and prominent white teeth at the margin which are composed of long glassy processes, while a sample on *Ficus* had a smooth margin. The species differs from *O. albidorosea* in much longer ascospores, also in lacking crystalloid SCBs. For the similar Australian *O. subalbovinosa* see p. 946. A North American collection differs in 16-spored asci and the presence of crystalloid SCBs (see below).

Variation. *O. albovinosa* was available for study only from very sparse material. The collection on wood of *Ficus* deviates from those on bark of *Lonicera* in having only very short glassy processes, also in a much thicker exudate and in non-spathulate paraphyses. Together with the deviating substrate it possibly represents a different species. It is included in the description since the other features closely concur with the two specimens on *Lonicera*.

Not included collection. A sample on *Euphorbia* from Montenegro (IVV: 21.VI.2019) is not included because of its much shorter spores (*12–16 × 1.9–2.3 µm), but it concurs with that on *Ficus* in the short glassy processes (5–15 × 2.5–3 µm), thick exudate, and non-spathulate paraphyses

Nomenclature and type studies. The north-African specimen of *O. albovinosa*, which bears R. Maire's handwritten diagnosis, was labelled '*Hyaloscypha albo-vinosa* n. sp.' by him. It appears to fit very well the specimen from Croatia. Duplicates of it do not appear to have been distributed in other herbaria. Since the name could not be traced in Maire's publications, his epithet is apparently an invalid herbarium name that appears only in this single specimen. His drawing (Fig. 170: a) shows living paraphyses which he described as apically slightly inflated [narrowly clavate to somewhat (obtusely) lanceolate], with mostly 1 guttule [SCB] below their inflated upper part, and the partly hooked glassy processes with a distinct stratification. Asci ('40–55 × 5.5–6.5 µm, 4–8-spored') and spores ('14–15 × 2 µm') were drawn by him in the dead state, therefore, no SBs are reported. During his monograph of *Hyaloscypha* and a study on glassy-haired taxa of *Hyaloscyphaceae*, Huhtinen (1987a: 281) examined also Maire's specimen, which he considered at that time to belong to *Hyalopeziza*. Huhtinen's unpublished drawing (IVV: H.B. 6707) shows glassy processes 20–80 µm long. In the present study, Maire's collection was only examined from a permanent slide kindly sent by S. Huhtinen.

Anamorph. The peculiar conidia of *O. albovinosa* show similarities to species of both *Dicranidion* and *Trinacrium*. Among the described species, *Trinacrium gracile* comes closest but has much smaller conidia with straight arms. Rarely 4-armed, dwayaangam-like conidia were observed. Révay & Gönczöl (2010: fig. 19–20) illustrated conidia as 'unknown sp. 8' from rainwater on living *Vaccinium myrtillus* in Sweden which are very similar to the 2-armed ones observed in *O. albovinosa*.

Phylogeny. A sequence taken from the ex-type culture (SSU without S1506 intron, ITS, LSU) shows in the entire ITS region a distance of 12.5% to *O. albidorosea* and 16% to *O. pseudoaristata*. The lowest distance in the LSU D1–D2 is 3.5% to *O. pseudoaristata* and 4.5% to *O. albidorosea*. *O. albovinosa* formed in the analysis of LSU a weakly supported clade with *O. pseudoaristata* (Phyl. S16), whereas in the combined analysis it clustered closer to the clade with *O. albidorosea* (Phyl. 13).

Ecology. *O. albovinosa* was found on medium rotten bark of xeric branches of *Lonicera*, but also on xeric wood of *Ficus*, in mesosub- to mesomediterranean semihumid southern Europe and northern Africa. The holotype locality is a shady maquis with *Quercus ilex* and *Arbutus unedo* around a cave in the Dinaric karst. Also the not included sample from Montenegro was from a mesosubmediterranean area.

Specimens included. **ALGERIA**: **Algiers**, Atlas Mts., ~60 km SSW of Algiers, Ben-Chicao, ~1000 m, branch of *Lonicera etrusca*, 3.I.1920, collector unknown (MPU C04768, R. Maire, Champ. de l'Afrique du Nord 6775, as *Hyaloscypha albovinosa*, H.B. 6707 ø). — **CROATIA**: **Dubrovnik-Neretva**, **Korčula**, 11.5 km W of Korčula, 2 km W of Račišće, Samograd cave, 120 m, branch of *Lonicera* (?)*implexa*, on bark, 4.VI.2000, H.O. Baral (ex H.B. 6683, M-0276431, **holotype**). — **FRANCE**: **Rhône-Alpes**, **Drôme**, Préalpes du Dauphiné, 1 km N of Nyons, W of Col du Pontias, S of Forêt Domaniale de Vaux, 415 m, branch of *Ficus carica*, on wood, 11.X.2002, G. Marson (H.B. 7231f, anam. cult., CBS 140882; sq.: KT215255).

Not included. **MONTENEGRO**: 1.5 km NW of Herceg Novi, SW of Trebesinj, 185 m, stem of *Euphorbia*, 21.VI.2019, D. Savić (FG-1090, doc. vid.).

Orbilia subalbovinosa Baral & G. Marson, **sp. nov.**, MB 813783 — Pls 521–522

Etymology: named after the similarity to *O. albovinosa*.
Typification: Western Australia, Nornalup, branches of *Eucalyptus*, 15.XII.2001, G. Marson (ex H.B. 7202, MEL 2389221, holotype).

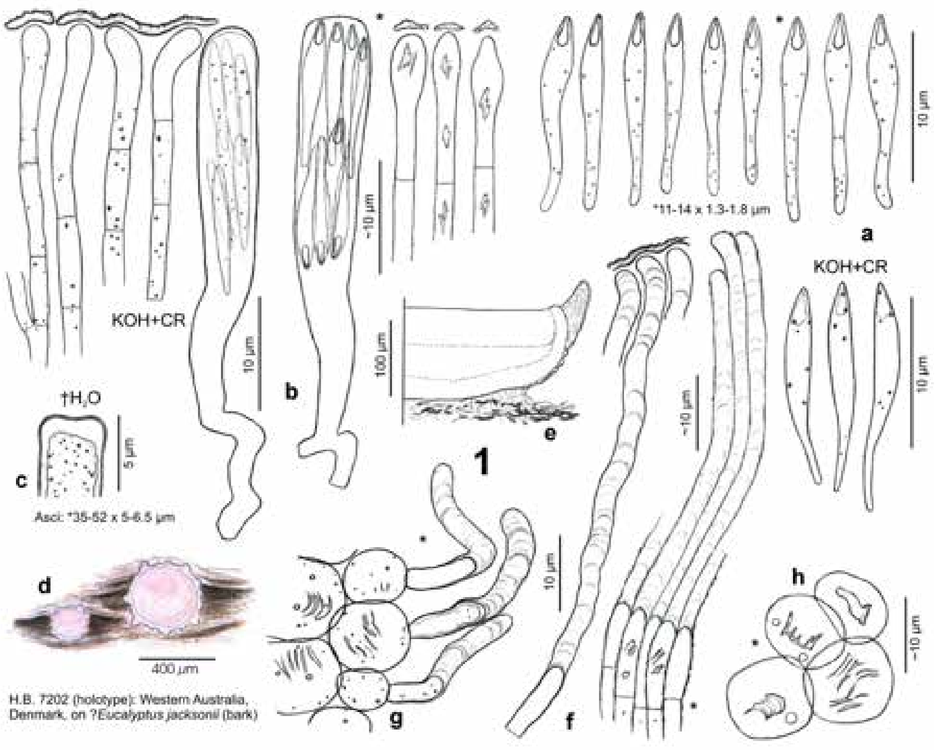


Plate 521. **1**: *Orbilia subalbovinosa*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex; **d**. apothecia with dentate margin (rehydrated); **e**. apothecium in median section; **f**. id., marginal cortical cells tipped by long glassy processes; **g**. id., at mid flanks, hairs here not agglutinated; **g–h**. ectal excipular cells with crystalloid SCBs.

Latin diagnosis: *Differt ab* O. albovinosa *ascosporis et corpusculis refringentibus multo angustioribus, hymenio exsudato distincte tecto. Habitat ad corticem putridum ramorum siccorum* Eucalypti *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.4 mm diam., 0.08–0.12 mm high, (very) pale rose, translucent, round, very scattered; disc flat, margin distinct, with prominent whitish teeth protruding 45 µm beyond disc; broadly sessile, superficial to slightly erumpent; dry disc half closed by the incurved teeth. **Asci** *35–52 × 5–6.5 µm, †38–46 × 4.7–5.3 µm, 8-spored, spores *4-seriate, 3 lower spores inverted; **apex** (†) strongly truncate (distinctly indented, laterally slightly widened); **base** with short to medium long, thick, flexuous stalk, L- to h-shaped. **Ascospores** *11–14 × 1.3–1.8 µm, †13–15 × 1.6–1.7 µm, narrowly fusiform-clavate, apex acute, base always attenuated in a distinct *0.5–1 µm thick tail, straight to slightly curved in lower part; **SBs** *1.8–2.5 × 0.5–0.8 µm, narrowly tear-shaped. **Paraphyses** apically uninflated to medium clavate, sometimes spathulate-lanceolate, terminal cells *~9.5–17 × 2.8–3.5, †8.5–17 × 1.5–2.5 µm, not exceeding the living or dead asci, lower cells †6–8.5 × 1.5–2 µm; unbranched at upper septum. **Medullary excipulum** 20–50 µm thick, of medium dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** of thin-walled († slightly gelatinized) t. globulosa-angularis-prismatica from base to submargin, 20–30 µm thick near base, cells *8–27 × 7–12 µm, guttulate; 15 µm thick near margin, of t. prismatica-porrecta oriented at a 50–70° angle to the surface, marginal cortical cells †7–9 × 2.5–3.5 µm; **glassy processes** 10–70 × 2.5–4 µm, high-refractive, strongly stratified in KOH, inwards curved, coherent to form distinct teeth. **Anchoring hyphae** medium abundant, †1.5–2.7 µm wide, walls 0.2–0.3(–0.4) µm thick. **SCBs** in paraphyses and ectal excipulum crystalloid, in excipulum also small globose SCBs. **Exudate** over paraphyses 0.3–2 µm thick, rough-continuous, hyaline, loosely attached; over margin and flanks 1–2 µm thick, cloddy-continuous. **ANAMORPH**: unknown.

Habitat: collected 1–2 m above the ground, 7–8(–?20) mm thick corticated branches of *Eucalyptus* sp., on bark (periderm & bast), partly on detached bark (on both sides), medium decayed, medium greyed, no algae. **Associated**: *Peniophora* sp., *Sclerococcum* sp. **Desiccation tolerance**: fully viable for at least a few months, after 9 months only ectal excipulum and a few immature asci still alive. **Altitude**: 60 m a.s.l. **Geology**: granulite with granitic gneiss. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia subalbovinosa* resembles *O. albovinosa* and *O. pseudoaristata* in the ascospores and the rose-coloured apothecia with large whitish marginal teeth. It differs in narrower spores and SBs, paraphyses being covered by a distinct exudate, and the presence of crystalloid SCBs (but the *Ficus* collection included in *O. albovinosa* also shows a distinct exudate). *O. albidorosea* differs in much shorter spores and a very sparse exudate.

Ecology. *O. subalbovinosa* was collected on medium decayed bark of xeric branches of *Eucalyptus* sp. in a subtropical semihumid eucalypt (karri-tingle) open forest in a hilly sandy area in the Warren ecoregion of southwestern Australia. The identity of the host genus is not fully certain. It was thought to be *Eucalyptus jacksonii* (Red Tingle), but the wood anatomy of that species shows the largest vessel diameters in the genus in contrast to the present substrate which has very small vessels.

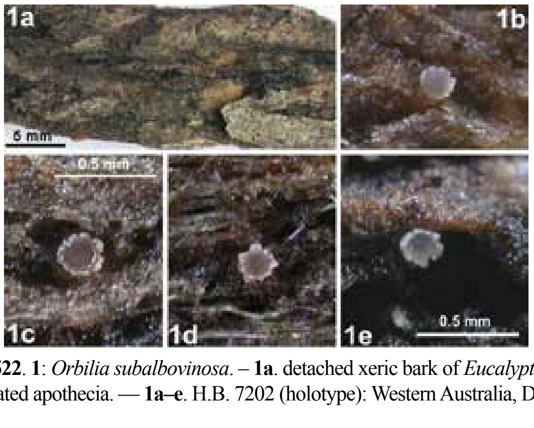

Plate 522. **1**: *Orbilia subalbovinosa*. – **1a**. detached xeric bark of *Eucalyptus*; **1b–e**. rehydrated apothecia. — **1a–e**. H.B. 7202 (holotype): Western Australia, Denmark.

Specimens included. **AUSTRALIA**: **Western Australia**, Warren, 40 km W of Denmark, 8.5 km E of Nornalup, SE of Valley of the Giants, 60 m, branches of *Eucalyptus*, on bark, 15.XII.2001, G. Marson (ex H.B. 7202, MEL 2389221, **holotype**).

Orbilia pseudoaristata Baral & G. Marson, **sp. nov.**, MB 813784 — Pls 523–525, Map 87

Etymology: referring to the similarity in spore shape with *Orbilia aristata* and *O. clavuliaristata.*

Typification: Germany, Baden-Württemberg, Tübingen, branch of *Salix alba*, 19.III.2003, H.O. Baral (ex H.B. 7313, M-0276570, holotype).

Latin diagnosis: *Differt ab* O. albovinosa *ascosporis abrupte caudatis*, *ab* O. subalbovinosa *ascosporis latioribus*, *cellulis vivis excipuli et paraphysium corpusculis crystalloideis carentibus*, *ab* O. aristata *et* O. clavuliaristata *ascis in statu emortuo truncatis*, *tenuitunicatis. Habitat ad corticem putridum ramorum siccorum* Salicis *et* Corni *etc. in zona temperata ad subtropica humida ad semihumida Europae et Australiae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.6(–0.9) mm diam. (excl. teeth), 0.09–0.2 mm high (receptacle 0.08–0.12 mm), pale to light rose to greyish rose(-orange), semitranslucent, round, scattered to subgregarious; disc slightly to medium concave, margin with prominent whitish hairy teeth 40–100 × 40–100 µm, protruding 30–60 µm beyond disc; sessile or with an ill-defined stipe 0.04–0.05 × 0.15–0.17 mm, superficial, somewhat immersed in detritus; dry nearly closed, disc light to bright rose-red. **Asci** *(38–)42–60(–70) × 6–6.7 µm {4} → 6–7.5 µm, †(37–)40–50(–57) × (4.8–)5–5.7(–6) µm {3}, 8-spored, spores (*) biseriate, 0–4(–5) lower spores inverted {8} (not mixed), pars sporifera *28–40 → 17–23 µm long; **apex** (†) (slightly to) medium (to strongly) truncate (not indented, laterally not widened) {5}; **base** with short to very long, thin, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(13–)14–18(–19)(–24.7) × (2.3–)2.4–2.7(–2.8) µm {6} or 16.7–24.5 × 2.2–3 µm {2}, †13–16(–18.7) × 2.3–2.8 µm {1} or 25–26.5 × 2.3–2.5 µm {1}, with fusiform head and medium sharply differentiated tail of about equal length or slightly longer, apex subacute to acute, tail base not or sometimes very slightly inflated, *0.5–1 µm wide, tail straight to slightly (rarely medium) curved; **SBs** *(2–)2.3–3 {7} × (1.1–)1.2–1.4(–1.5) {6} or 1.6–2 µm {1}, broadly tear-shaped to pyriform. **Paraphyses** apically uninflated to very slightly clavate(-capitate) or subspathulate, terminal cells *(7–)9–15(–19) × 2–2.5(–3) µm {4}, †10–15 × 1.5–2.3 µm {1}, sometimes ± flexuous, protruding 5–10 µm beyond dead asci, lower cells *(5–)7–11(–14) × 1.5–2.5(–3) µm {5}; rarely branched at upper septum. **Medullary excipulum** hyaline to pale rose, 20–70 µm thick, of dense textura intricata with many inflated cells, indistinctly to sharply delimited. **Ectal excipulum** hyaline to pale rose, of (†) thin-walled, vertically oriented t. globulosa-angularis-prismatica from base to mid flanks or submargin, 25–80 µm thick near base, cells *(6–)8–16(–22) × (5–)7–10(–13) µm {3}, †7–10 × 5–9 µm {1}; 20 µm thick at flanks, 15–30 µm near margin, oriented at a 45–80° angle to the surface, externally or at upper margin of t. prismatica-porrecta oriented at (10–)30–45°, cortical cells bearing ± free, 17–30 µm long, 3–4-celled hairs with terminal cells *5–15 × 3–4 µm {2}, †7–10 × 2.8–3 µm {1}; tipped by **glassy processes** (13–)20–70(–120) × (2.5–)3–4(–5) µm {5}, low- to high-refractive, ± stratified only in KOH, very strongly outwards curved, coherent to form distinct hairy teeth (sometimes also in centre of disc with fascicles of proliferating glassy processes). **Anchoring hyphae** abundant, */†1.5–3 µm wide, walls 0.2–0.4(–0.5) µm thick {4}. **SCBs** globose, in paraphyses 0.8–1.3 µm diam.; in ectal excipulum (at flanks and margin) 1.2–2.8 µm, rarely with very low-refractive, very pale reddish, angular SCBs 2–3 µm diam. {H.B. 8456b}. **Exudate** over

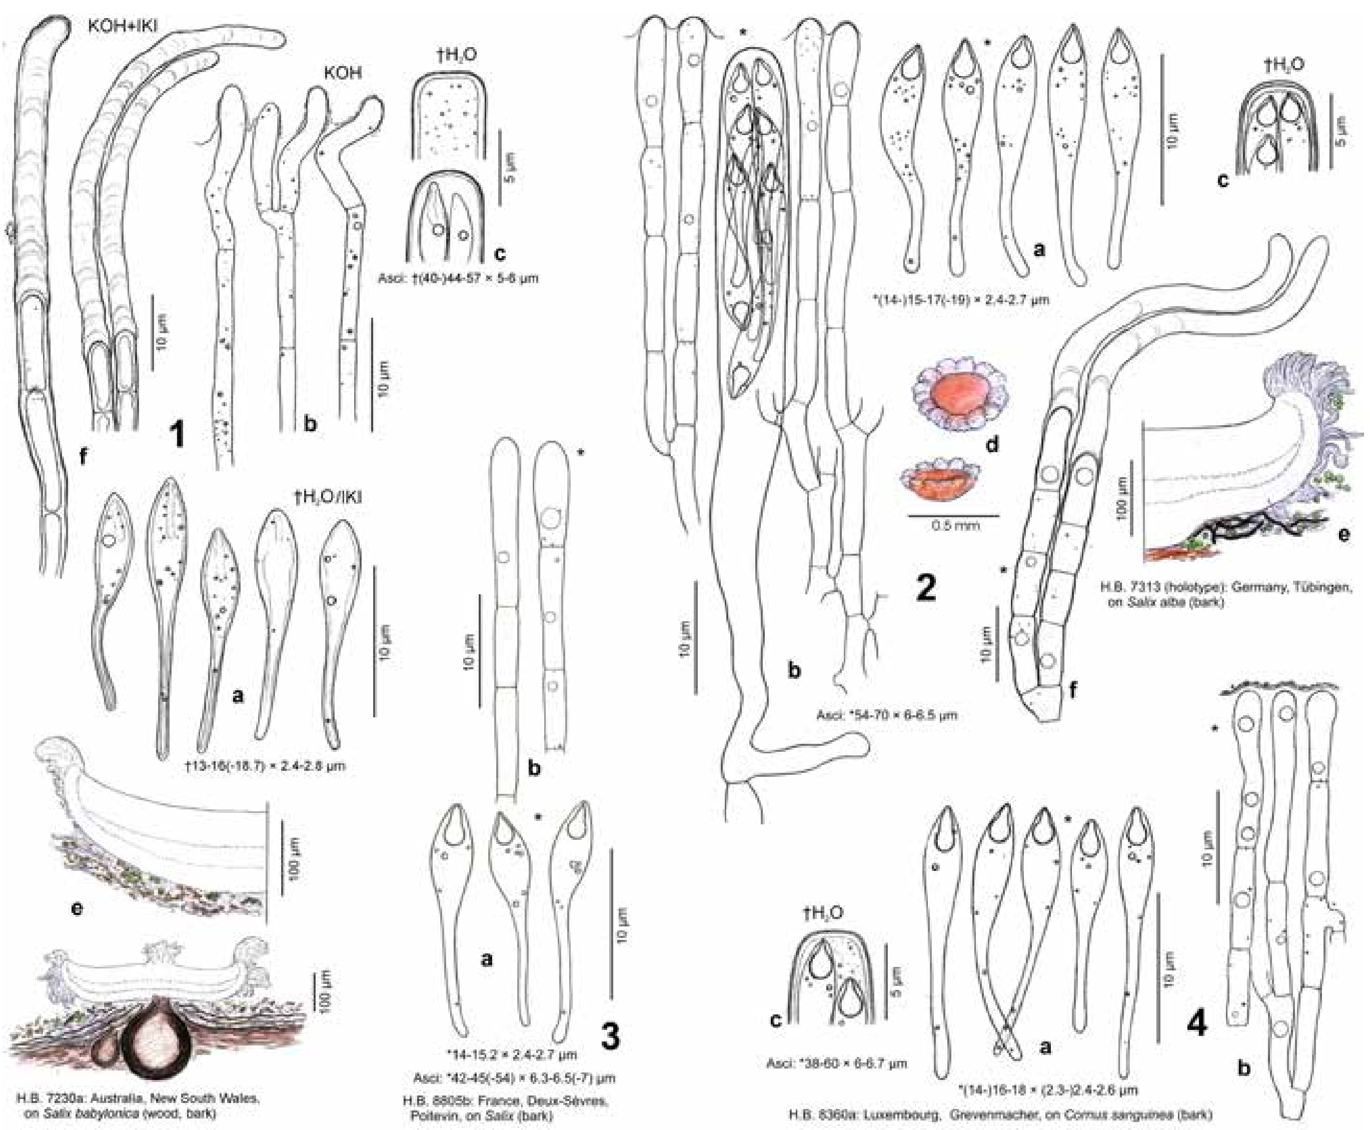

Plate 523. **1–4**: *Orbilia pseudoaristata*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecia with hairy-dentate margin; **e**. apothecia in median section (**1**: on old pyrenomycete); **f**. id., marginal hair-like cells with long glassy processes.

paraphyses and hairs absent or 0.2 µm thick, sparse, minutely granular. **— ANAMORPH**: trinacrium-like (presumed, from natural substrate {3}). **Conidiophores** not seen. **Conidia** T-shaped with the two arms curved downwards, total size *35–46 × 39–52 µm, stipe *28–38 × 2.7–3 µm, 5–6-septate, arms slightly tapering, *17–31 × 2.7–3.5 µm in situ (actual length ~24–32 µm), 4–6(–7)-septate {2}.

Habitat: collected 1–3 m above the ground, ± corticated, 6–40 mm thick branches or > 10 cm thick trunks of *Cornus* sp. {1}, *C. sanguinea* {5}, *Fraxinus excelsior* {1}, *Malus domestica* {1}, *Pistacia lentiscus* {1}, *Prunus padus* {1}, *Salix* sp. {1}, *S. alba* {1}, *S. babylonica* {1}, *Sorbus aucuparia* {1}, *Ulmus glabra* {1}, ?*U. minor* {1}, on medium to strongly decayed bark {12} (bast {6} and periderm {2}) or wood {4}, stem of *Rubus ?armeniacus* {1}, partly beneath periderm rolling aside, also on small cracks in periderm or on peeling bark, sometimes directly over ostioles of an old pyrenomycete, entire bark partially detaching, some apothecia on inner surface of bark, somewhat greyed, mostly covered by many green algae. **Associated**: *Caloplaca ?cerinella* {1}, *Craterocolla cerasi* {1}, *Cryptodiaporthe rostellata* {1}, *Dacrymyces* sp. {1}, *Eutypa* sp. {1}, *Flagelloscypha* sp. {1}, *Gloniella* sp. {1}, *Hyalorbilia fusispora* {1}, *Karstenia rhopaloides* {2}, *Lasiosphaeria* sp. {1}, *Lophiostoma* sp. {1}, *Octospora affinis* {1}, *Orbilia aristata* {2}, *O. aurantiorubra* {1}, *O. clavuliformis* {1}, *O. eucalypti* {1}, *O. ?hesperidea* {1}, *O. xanthoguttulata* {1}, *Orthotrichum ?affinis* {1}, *Parmelia sulcata* {1}, *Patellaria atrata* {2}, *Peniophora lycii* {1}, *Physcia tenella* {3}, *Pyrenopeziza rubi* {1}, *Sclerencoelia fraxinicola* {1}, ?*Synaptospora* sp. {1}, *Thyronectria aurigera* {1}, *Unguiculariopsis* sp. {2}, *Xanthoria parietina* {3}. **Desiccation tolerance**: fully viable for at least 3 months, many cells of paraphyses and excipulum, but also a few spores and immature asci still alive after 15 months. **Altitude**: 3–430 m a.s.l. (temperate Europe), 740 m (southern Europe), 537 m (Australia). **Geology**: Silurian shale, lime- & sandstone, Devonian & Lower Carboniferous greywacke & shale, Buntsandstein, Keuper (Lettenkohle), Lower & Upper Jurassic & Cretaceous shale, sand- & limestone, Pleistocene loess, peat, Holocene alluvial deposits; Australia: Cenozoic regolith (sand). **Phenology**: II–VII, XII (N-hemisphere, probably throughout the year, long-lived).

Taxonomic remarks. *Orbilia pseudoaristata* is characterized by ascospores with very distinct, long tails. Together with the rather long glassy hairs forming whitish teeth at the margin, the species can easily be confused with members of section *Hemiorbilia*, such as *O. aristata*, *O. clavuliformis*, or *O. clavuliaristata*. However, these species differ in asci with a thick-walled, hemispherical apex when viewed in the dead state, partly also in narrower SBs. *O. subalbovinosa* differs in narrower spores and in the presence of crystalloid SCBs, *O. albovinosa* in lacking distinct spore tails.

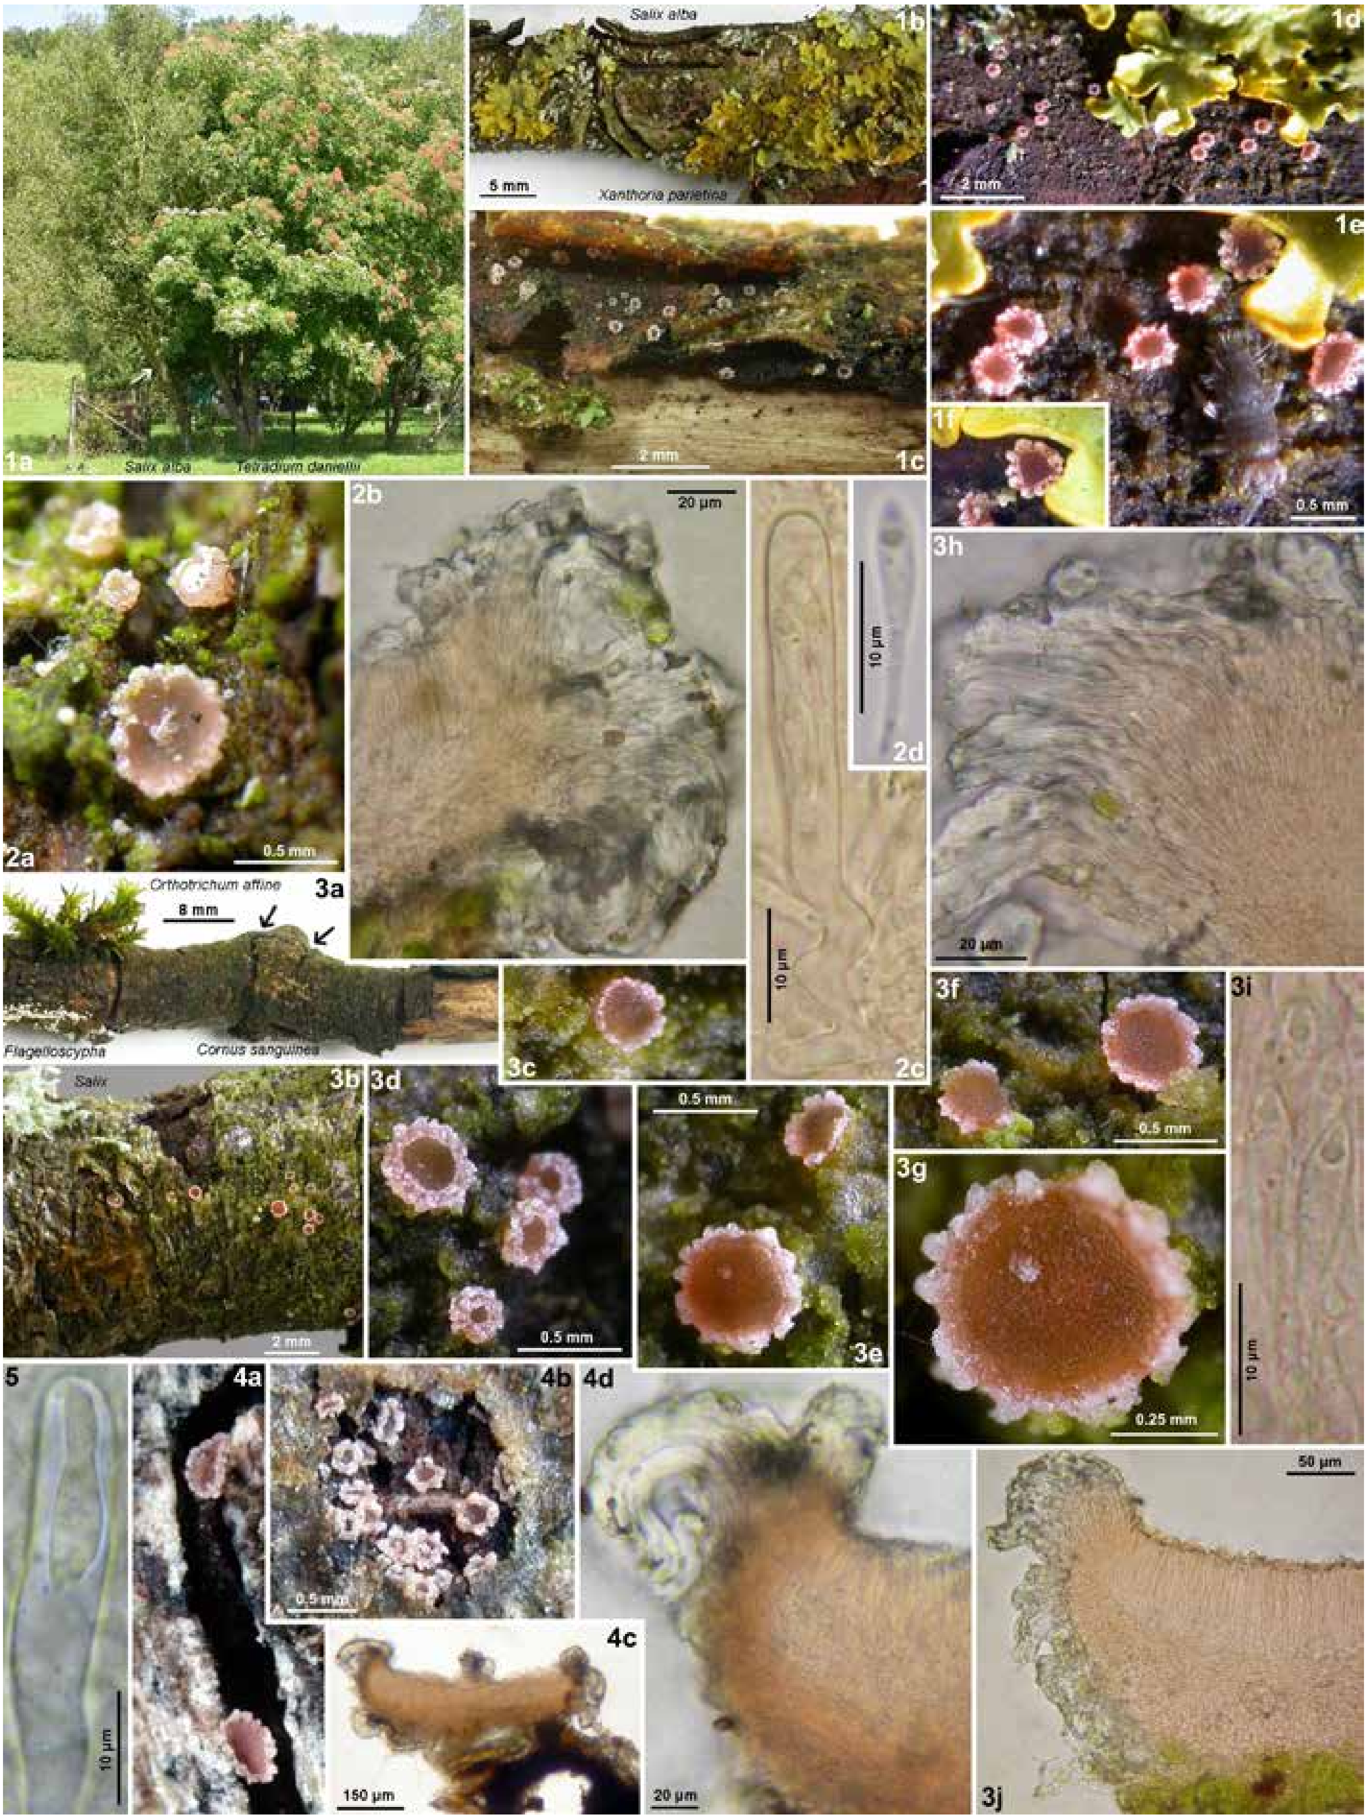

Plate 524. **1–5**: *Orbilia pseudoaristata*. – **1a**. garden estate near Neckar river, with *Salix* and *Tetradium*; **1b**, **3a**. dead xeric corticated branches; **1c–f**, **2a**, **3b–g**, **4a–b**. rehydrated apothecia; **3j**, **4c–d**. apothecia in median section; **2b**, **3h**. id., marginal region with glassy processes; **2c–d**, **3i**, **5**. asci and ascospores. – Living state (**5**: fully turgescent), except for **3l** (living spores in a dead ascus), **4c–d** (in H_2O). — **1a–f**. Plate 525. **1–4**: *Orbilia pseudoaristata*. – **1–3**. conidia from substrate (living state), **4a**. apothecia, 4b. ascus and paraphyses, **4c**. ascus apex, **4d**. ascospores. – Living state, except for ascus in **4c**. – **4a–d**: phot. S. Tello. — **1**. H.B. 8360a: Luxembourg, Wasserbillig, on *Cornus*; **2**. 9.XI.2006: ibid., Differdange, on *Cornus*; **3**. H.B. 8436a: ibid., Dudelange, on *Rubus*; **4**. 5.IV.2014: Spain, Andalucía, on *Pistacia*.

Variation. Within Europe, *O. pseudoaristata* varies only slightly in spore size and shape. However, two recent samples (on *Pistacia* from Spain, Pl. 525: 4; on *Malus* from Austria, IVV: 3.II.2019) have distinctly longer spores compared to the other records due to much longer tails, and the latter also extraordinarily broad SBs (1.6–2 µm). The rich Australian collection was examined only 4 years after being harvested, therefore, the drawing shows only dead elements (Pl. 523: 1). Judging from its persistent characters, it concurs in most respects with the typical European samples. Yet, the very faintly perceptible SBs might differ, looking more filiform (perhaps 3–4 × 0.5 µm) rather than tear-shaped, and the paraphyses are apically flexuous, a feature also seen in the Spanish sample (Pl. 525: 4b). For the time being all these specimens are considered to be conspecific with the typical European samples.

Anamorph. Although *O. pseudoaristata* is phylogenetically distant from series *Hemiorbilia*, its conidia resemble those of *Trinacrium subtile*, a type of anamorph found in several taxa of series *Hemiorbilia*, except that they differ in downwards curved arms.

Phylogeny. Sequences were taken from two samples from Luxembourg, comprising ITS and LSU D1–D3 (G.M. 2013-06-25.2, ascospore isolate; G.M. 2014-12-07.1, from apothecia). Both are without S1506 intron and the latter includes a short part of SSU (V9). Only 1 nt near the 5'-end of ITS1 differs between them. An environmental sequence obtained by Menkis et al. (2016) from elm bark beetles in Gotland (Sweden) comprises 5.8S+ITS2 and differs by 1 nt in the ITS2 and 1 nt in the 5.8S, the latter being a rare deviation.

O. pseudoaristata shows in the entire ITS region a distance of 15% to *O. albidorosea* and 16% to *O. albovinosa*. In the LSU D1–D2 the distance is 3.5% to both but also to *O. jugulospora* and *Orbilia* sp. B.L. 4099 (as *O. decipiens*).

When analysing LSU (Phyl. S16), *O. pseudoaristata* clustered weakly supported with *O. albovinosa*, whereas in the combined analysis (Phyl. 13) sister to the majority of series *Albovinosae*.

Ecology. *O. pseudoaristata* was collected on ± rotten bark of xeric branches of *Salix* and *Cornus* and other angiosperms at ± thermophilous sites, often in floodplains, in atlantic to subcontinental cold- to warm-temperate humid western and central Europe, but also in mesomediterranean semihumid southern Europe. The environmental sample from cold-temperate humid southern Sweden (Gotland) was isolated from elm bark beetles, and the fungus probably originated from *Ulmus* bark. A single collection was made in a subtropical humid eucalypt woodland with *Casuarina cunninghamiana* in the Great Dividing Range of southeastern Australia.

Specimens included. **SWEDEN**: **Gotland**, 12.5 km S of Visby, 1.8 km NNE of Hogräns kyrka, 45 m, from trapped adults of *Scolytus multistriatus* (pheromone trap, probably emerging from *Ulmus minor*), VII–VIII.2013 (Menkis et al. 2016, clone 2170_622, mol. extr.; sq.: KP891509). — **FRANCE**: **Centre**, **Indre-et-Loire**, 3 km SW of Bourgueil, 1 km NE of Le Plessis, 28 m, branch of *Ulmus glabra*, on wood, 10.V.2010, J.P. Plate 526. **1**: *Orbilia pseudoflagellispora*; **2**: *O.* cf. *pseudoflagellispora*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex; **d**. SCBs in cells of basal ectal excipulum.

Orbilia pseudoflagellispora Baral & G. Marson, **sp. nov.**, MB 813785 — Pls 526–527

Etymology: named after the similarity of the ascospores with *O. flagellispora*. **Typification**: Western Australia, Moora, trunks of *Melaleuca rhaphiophylla*, 11.XI.2007, G. Marson (ex H.B. 8973, MEL 2389268, holotype).

Latin diagnosis: *Differt ab* O. flagellispora *ascis in statu emortuo truncatis, tenuitunicatis, corpusculis refringentibus ascosporarum latioribus. Habitat ad corticem putridum siccum in trunco vivo* Melaleucae *et* Lamarcheae *in zona subtropica semihumida ad semiarida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.4 mm diam., 0.1–0.16 mm high, round, very scattered; disc flat, pale to light pure or dirty (brick-)rose to rose-orange, medium translucent; margin distinct, 0–15 µm protruding (incl. teeth), finely crenulate to denticulate, whitish to pale rose; broadly sessile or with a narrowed stipe-like base, superficial but often in cracks of periderm; dry with thick protruding margin, disc bright brick-red. **Asci** †(35–)38–50(–54) × 5.3–6(–6.5) µm {2}, 8-spored, spores (†) biseriate, 0–1 lower spores inverted {2} (not mixed); **apex** (†) medium to strongly truncate (not indented, laterally not or hardly inflated) {2}; **base** with or without short, slightly flexuous stalk, L-, Y- or h-shaped. **Ascospores** *20–25 × 2.7–2.9 µm {1}, †19.5–25 × 2.4–2.8 µm {2}, with fusiform 8–11 µm long head and sharply differentiated narrow tail */†10–14 × 0.2–0.4 µm, apex subacute to acute, tail always with a bulbous base */†0.8–1.4 µm wide {2}, straight to slightly curved in the tail region; **SBs** *2.8–3.5 × 1.4–1.8(–2) µm {T}, tear- to pear-shaped. **Paraphyses** apically uninflated to indistinctly clavate-spathulate, terminal cells †12–18 × 1.6–2.5 µm {T}, lower cells †7.5–9 × 1.2–1.8 µm {T}; never branched at upper septum, hymenium pale rose. **Medullary excipulum** hyaline to pale rose, 20–30 µm thick, of dense textura intricata with many inflated cells, ± sharply delimited. **Ectal excipulum** hyaline, of (†) thin-walled t. globulosa-angularis from base to mid flanks, 40–60 µm thick near base, cells */†9–18 × 8–14(–17) µm {T}; 20–25 µm thick near margin, inner part of t. prismatica-angularis oriented at a 30–50° angle to the surface, outer part of t. porrecta oriented at 10–30°, marginal cortical cells †8–15 × 2–3(–3.5) µm {2}; **glassy processes** 10–30 × 2.5–4 µm {2}, medium refractive, faintly stratified, ± straight or outwards curved, at upper margin also curved inwards, coherent to form ± distinct teeth. **Anchoring hyphae** abundant, */†1.8–3 µm wide, walls 0.2 µm thick {T}, forming a loose hyaline t. intricata 20–30 µm thick. **SCBs** in paraphyses unknown, in ectal excipulum (from base to margin) crystalloid, 2–4 × 1–2 µm {T}, hyaline, at margin mixed with globose ones. **Exudate** over paraphyses and marginal teeth 1–3 µm thick, cloddy, pale yellowish, loosely attached. **— ANAMORPH**: unknown.

Habitat: collected 0.2–2 m above the ground, corticated, ~8–16 cm thick living trunks of *Lamarchea hakeifolia* {1}, *Melaleuca rhaphiophylla* {1}, on medium to strongly decayed, paper-like bark {2}, on outer but apparently also inner surface, slightly to medium greyed, with a few to rather many green algae. **Associated**: *Capronia* sp. {2}, *Claussenomyces* sp. {1}, *Hyalorbilia pleioerythrostigma* {1}, *Orbilia austroobtusispora* {1}, *O. gemma* {1}, *O. kingsiana* {1}, *O. lamarcheae* {1}, *O. myriolilacina* {1}, *O. ?pubescens* {1}, *Ostropales* {1}, *Symbiotaphrina desertorum* {1}, ?*Xerotrema* sp. {1}. **Desiccation tolerance**: ectal and medullary excipular cells, some ascospores, exceptionally also some submature asci still viable after 13 months. **Altitude**: 83–190 m a.s.l. **Geology**: Cretaceous sedimentary rock (whitish or red-brown sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pseudoflagellispora* is readily recognized by its rather long ascospores with fusiform heads and long thin tails with a striking bulbous basal inflation. Apart from their wide SBs, the spores strongly resemble those of *O. flagellispora* (section *Hemiorbilia*) known from Europe and North America. However, *O. pseudoflagellispora* is believed to belong to series *Albovinosae* because of its truncate thin-walled ascus apices (dead state) and the similarity to *O. pseudoaristata*.

Not included collection. A very sparse, unpreserved sample from *Eucalyptus jacksonii* bark (Pl. 526: 2) differs in slightly narrower spores (*19–22 × 2.2–2.6 µm) which were frequently 1-septate, though apparently because of overmaturity. Whether the ascus apex was devoid of an apical thickening was not verified.

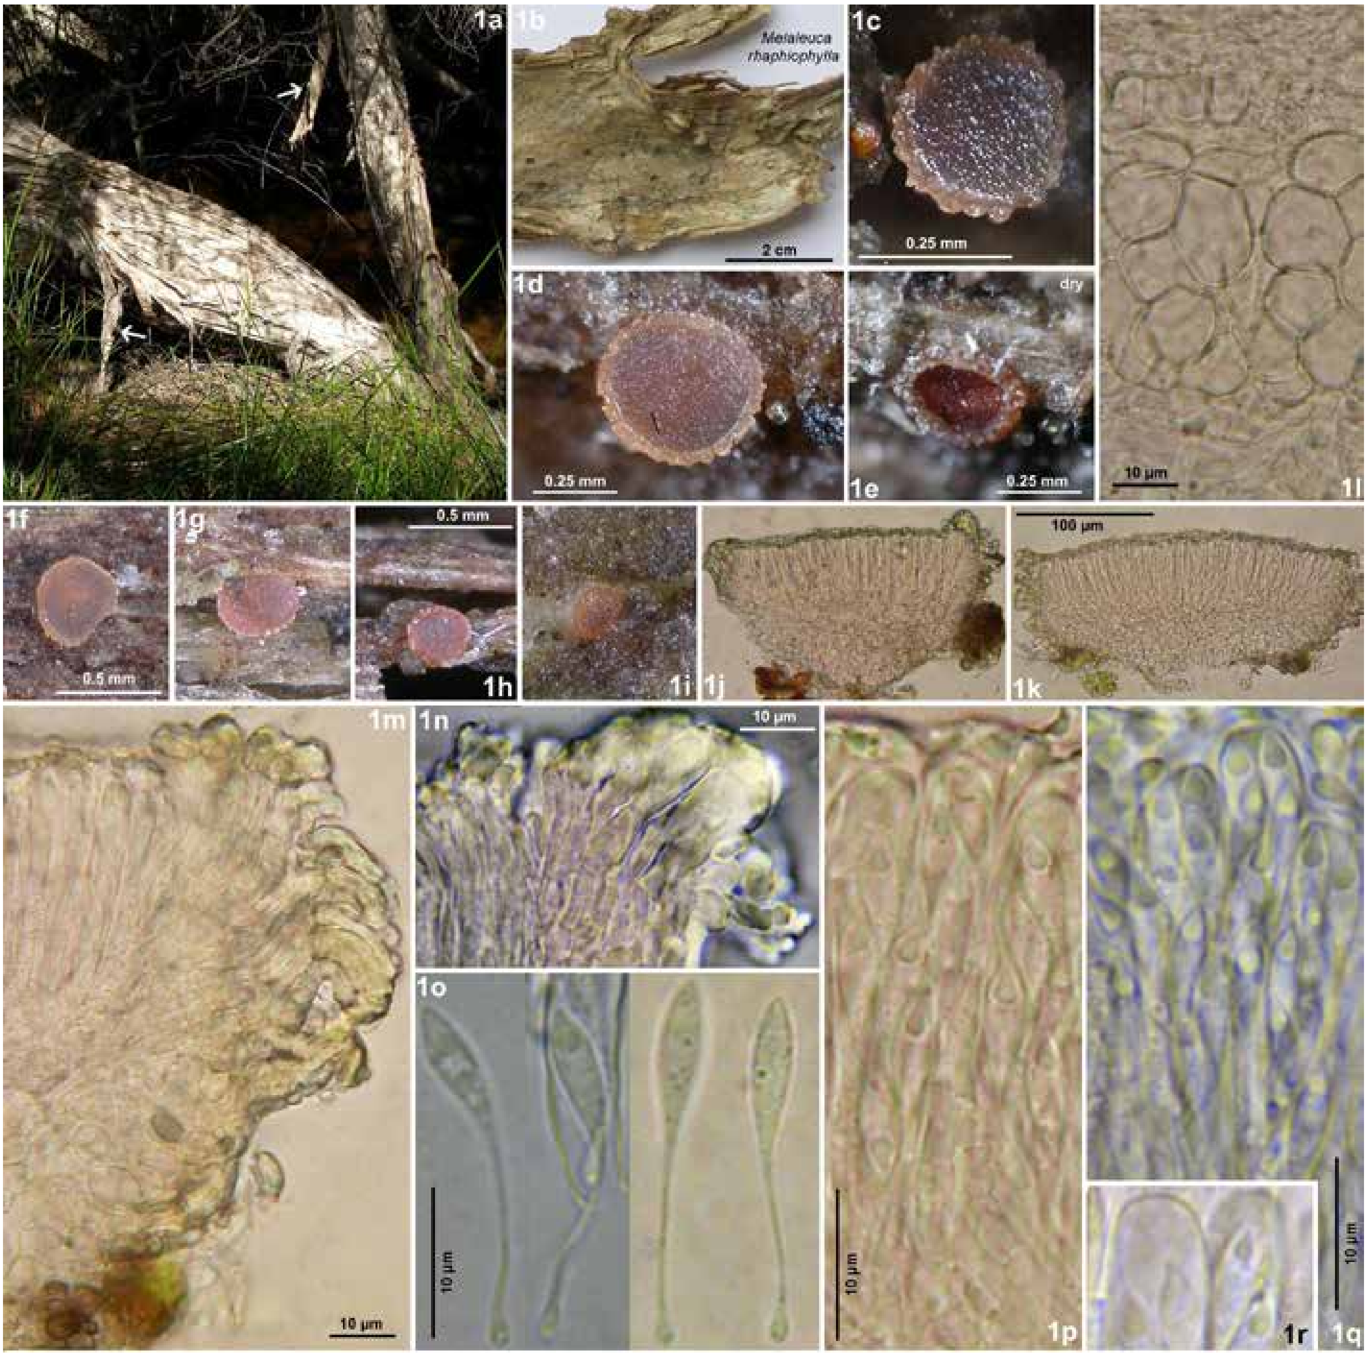

Plate 527. **1**: *Orbilia pseudoflagellispora*. – **1a**. semihumid banksia-eucalypt woodland, living trunk of *Melaleuca rhaphiophylla* at rivulet; **1b**. detaching xeric bark; **1c–d**, **f–i**. rehydrated apothecia; **1e**. dry apothecium; **1j–k**. apothecia in median section; **1m**. id., marginal ectal excipulum; **1n**. id., marginal cortical cells with glassy processes; **1l**. id., basal ectal excipulum; **1o**. ascospores; **1p–r**. upper part of asci, ascospores. – Living state, except for **1o** (3 dead spores, in H_2O), asci in **1p–r**. — **1a–r**. H.B. 8973 (holotype): Western Australia, Moora, on *Melaleuca*.

Ecology. *O. pseudoflagellispora* was found on rotten, xeric, detaching bark of living trunks of two different *Myrtaceae* in subtropical (south)western Australia. The paratype was from a semiarid acacia open shrubland with *Callitris* and *Lamarchea* in the Yalgoo ecoregion, the holotype from a semihumid banksia-eucalypt woodland with *Melaleuca*, *Eremaea* and *Adenanthos* in a marshy area very close to a rivulet in the Swan Coastal Plain. The not included collection was on detached fallen bark of *Eucalyptus* in a subtropical semihumid eucalypt (karri-tingle) open forest on granite in the coastal area south of Darling Range.

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, twig & trunk of *Lamarchea hakeifolia*, on bark, 8.XI.2007, G. Marson (H.B. 9020m ø). – Swan Coastal Plain, 55 km SSW of Moora, 30 km NNE of Gin Gin, Moore River, 83 m, trunks of *Melaleuca rhaphiophylla*, on bark, 11.XI.2007, G. Marson (ex H.B. 8973, MEL 2389268, **holotype**).

Not included. **AUSTRALIA**: **Western Australia**, Warren, 30 km SE of Pemberton, 14 km ENE of Northcliffe, 195 m, branch of *Eucalyptus jacksonii*, on bark, 16.XII.2001, G. Marson (H.B. 7201d ø).
