Hennebert & L.M.Kohn (CUP-MM 1537, as *O. epipora*, in Korf 1992 erroneously as MM 1145). – 2.8 km WSW of Seixal, Fanal, 1190 m, branch of *Ocotea foetens*, on wood, 24.IX.2015 (J.P.P. 15167, doc. vid.). – **Canary Islands**, **Tenerife**, Santa Cruz de Tenerife, Anaga, 2.3 km SW of Taganana, NE of Casa Forestal, 825 m, branch of indet. angiosperm, on bark, 18.IV.1989, E. Weber (REG 291). — **UKRAINE**: **Ivano-Frankivsk**, Nadvirna, 55 km W of Kolomyya, 5 km SE of Maksymets, Gorgany forestry, 1020 m, branch of *Fagus sylvatica*, on bark, 18.VII.2012, A.Y. Akulov (ex CWU Myc 4907, H.B. 9719). – 51 km WSW of Kolomyya, 9.5 km NW of Palyanytsya, Chernigivske forestry, southwest-flank of Dovbushanka Mt., 1350 m, log of *Acer*, on wood, 22.VII.2012, A.Y. Akulov (ex CWU Myc 4908, H.B. 9732). — **RUSSIA (West)**: **Adygea**, Caucasus Mts., ~62 km NE of Sochi, NNE of Guzeripl, Kisha river, ~600 m, branch of *Fagus orientalis*, on bark, 10.IX.1975, M. Pallo (TAAM 63888, H.B. 7996 ø). — **RUSSIA (East)**: **Altay**, **Turochak**, near Kamga cordon, ~8.5 km ENE of Yaylyu, mouth of Malyj Miokok river N of Lake Telezkoje, 450 m, on *Daldinia*, 17.VIII.2008, E.S. Popov (LE 294843, doc. vid.). — **CHINA**: **Xinjiang**, **Xinyuan**, Tian Shan Mts., Nalati grasslands, 1600 m, on wood of *Betula* sp., 15.VIII.2003, B. Liu & X.Z. Liu (B.L. 6564, HMAS 139536; sq.: DQ656660, doc. vid.). – **Tibet**, **Nyingchi** (Linzhi), 36 km ESE of Bomê (Bomi), 1.3 km ENE of Songzong, 3100 m, indet. tree, on wood, B. Liu & X.Z. Liu, 16.VII.2004 (B.L. X034, HMAS 96789; sq.: DQ656661, doc. vid.). – ~90 km W of Bomê, Lulangzhen, 3200 m, on indet. bark, 17.VII.2004, B. Liu & X.Z. Liu (B.L. X076, HMAS 96788; sq.: DQ656659, non vid.). – For further 110 collections across China see Liu (2006). — **AUSTRALIA**: **Queensland**, Wet Tropics, 43 km N of Port Douglas, S of Cape Tribulation, Myall Beach Walk, 5 m, leaflets of *Licuala ramsayi*, 30.VIII.2006, G. Marson (nar, H.B. 8496a). – 7 km S of Port Douglas, SSE of Craiglie, 10 m, branch of *Acacia*, on wood, 31. VIII.2006, G. Marson (nar, H.B. 8406). – **Victoria**, South Eastern Highlands, 160 km SW of Melbourne, 9 km WNW of Marengo, Maits Rest, 270 m, on indet. tree, 28.XII.1963, G. Beaton (Beaton 176, Spooner 1987: 177 fig. 23, doc. vid.). — **PUERTO RICO**, El Yunque, ~6 km SW of Luquillo, El Verde, along Rte. 988, ~150 m, branch of indet. angiosperm, on bark, 17.I.1996, D.H. Pfister & F.A. Harrington (nar, PR 23, FH 00458176, H.B. 5967 ø). – ibid., ~7 km S of Rio Grande, Guzman Obajo, Camino Los Tapia, ~450 m, branch of indet. angiosperm, on bark, 23.I.1996, D.H. Pfister, F.A. Harrington, M. Liftik, S. Hundorf & D.J. Lodge (nar, PR 103, FH 00458346, H.B. 5956). — **UNLOCALIZED**: on ?bark of indet. tree, undated, C.H. Persoon (H.B. 8840, L 910.261-266, as *Peziza aurea*).

Not included. **FRANCE**: **Aquitaine**, **Gironde**, Bordeaux, unlocalized, ?30 m, branch of indet. angiosperm, on bark, 25.VI.1884, L. Forquignon (UPS:BOT:F-015651, authentic material of *Cistella succinea*, H.B. 7335 ø). — **LUXEMBOURG**: **Gutland**, **Luxembourg**, 4.5 km SW of Luxembourg, 1.5 km SW of Cessange, Bois de Cessange, 305 m, branch of *Quercus*, on wood, 5.XI.2000, G. Marson (H.B. 6819, anam. substr.). — **GERMANY**: **Sachsen**, 6 km NW of Leipzig, 1 km SW of Wahren, Burgaue, 120 m, branch of *Quercus robur*, on bark, 22.IV.2003, M. Unterseher (nar, grown in moist chamber, LZ, H.B. 7408). – Brandenburg, Tamsel, Berganlagen, on rotten wood, VIII.1904, P. Vogel (n. 1712; **holotype** of *O. breviasca*). — **CZECHIA**: **Central Bohemia**, 27 km SE of Praha, Mnichovice, ~370 m, branch of *Betula*, on wood, IV.1928, J. Velenovský (PRM 152443, **lectotype** of *O. linata*, H.B. 6190 ø). — **CANADA**: **Ontario**, Ottawa, on indet. angiosperm wood, 23.VI.2018, J. Mack (anam. substr., doc. vid., with *Niesslia* parasite). — **USA**: **Maryland**, near Beltsville, indet. plant material, undated, C. Drechsler (**holotype** of *Dactylella passalopaga*, doc. vid.). – **South Carolina**, Santee River (possibly around Columbia), ~40 m, on pores of *Polyporus*, undated, H.W. Ravenel (wide, herb. Ravenel 1571, K(M) 126131, **lectotype** of *Peziza vulgaris* var. *myceticola*, H.B. 7608 ø). — **VENEZUELA**: **Anzoátegui**, ~135 km WSW of Ciudad Bolivar, Mapire, Orinoco river, ~50 m, branch of indet. ?angiosperm, on bark, V.1887, A. Gaillard (PC, herb. Gaillard No. 5, as *Orbilia* (?)*lancicula*, H.B. 7727 ø). — **INDONESIA**: **Java**, **West Java**, 43 km S of Jakarta, centre of Bogor (Buitenzorg), Botanical Gardens, 260 m, branch of indet. angiosperm, on wood, 2.I.1897, A.J.O. Penzig (W 6467, **lectotype** of *Orbilia sinuosa*, H.B. 7730 ø). — **AUSTRALIA**: **Queensland**, South Eastern Queensland, ~11 km WSW of Brisbane, Brookfield, ~80 m, on wood of indet. tree, 28.VIII.1981, B.C. Sutton & J.L. Alcorn (IMI 263330, Spooner 1987: 178, non vid.).

Hyalorbilia japonica Baral, M.L. Wu & Y.C. Su, **sp. nov.**, MB813470 — Pls 83–85, Map 8

?= *Orbilia epipora* subsp. *major* Speg., An. Soc. Cient. Argent. 12: 223, n. 225 (1881)

≡ *Orbilia major* (Speg.) Mussat, in Sacc., Syll. fung. 15: 233 (1901), nom. inval., ICN Art. 36.1a, b (cited as synonym of *O. epipora*)

Etymology: *japonica*: named after the origin of the holotype specimen, Japan; *major*: based on the rather large apothecia.

Typification: Japan, Suzaka, branch of indet. angiosperm, 24.VIII.1997, W. Gams (ex H.B. 5906, M-0276412, holotype of ***Hyalorbilia japonica***). — Argentina, Buenos Aires, San Benito de Palermo, IV.1880, log of *Populus nigra* '*italica*', C.L. Spegazzini (holotype of ***Orbilia epipora* subsp. *major***, unlocated).

Misapplied name: Liu (2006: 35 p.p.), as *H. inflatula*.

Latin diagnosis: *Differt ab* Hyalorbilia inflatula *ascis et ascosporis minoribus, ab* H. oreadum *sporis angustioribus.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–2.5 mm diam., 0.1–0.22(–0.3) mm high (receptacle 0.06–0.11 → 0.04–0.05 mm), whitish or (very) pale to light chlorinaceous to yellowish or cream(-ochraceous), ± strongly translucent (hygrophanous), round, margin smooth to finely rough, sometimes strongly undulating to lobate with age, slightly gelatinous, scattered to ± gregarious; disc medium concave (cyathiform) to flat, sometimes slightly convex, margin thin, not or slightly protruding, smooth; broadly appressed to substrate or with obconical to abrupt stipe 0.05–0.18 × 0.1–0.18 mm, superficial; dry with inrolled margin, light yellow-ochraceous to buff, old light fox-brown, without or with a distinct white subiculum. **Asci** *(15–)17.5–24(–27) × (3–)3.5–4.5(–5) µm {3}, †(11–)14–20(–22) × (2.8–)3–3.5(–3.8) µm {14}, 8-spored, spores *4-seriate in two superimposed bundles, (†) often irregularly arranged, pars sporifera *10–12 µm long, †9–12 µm; **apex** (†) hemispherical (to slightly truncate); **base** ± unstalked, arising from croziers {9}. **Ascospores** *(3.5–)4.5–6(–6.5) × 0.8–1.1(–1.2) µm {3}, †(3.5–)3.8–5.7(–6) × (0.6–)0.7–0.9(–1) µm {14}, cylindric or sometimes slightly fusoid, sometimes very slightly heteropolar, rounded to obtuse, straight to (very) slightly curved (never distinctly helicoid); **SBs** 0.2–0.5 µm diam. {4}, globose, 1–2 at each end; with 1–3 minute LBs. **Paraphyses** apically uninflated or slightly (rarely medium) capitate, terminal cells *2–3.5 µm wide {1}, †12–16(–23) × (1.5–)1.8–3(–4.2) µm {4}, lower cells †3.3–5 × 1.6–2.3 µm wide. **Medullary excipulum** overall 5–15(–30) µm thick, scarcely to often strongly gelatinized, sharply delimited at least at flanks. **Ectal excipulum** at base of not or slightly (rarely medium) gelatinized, 60–100(–200) µm thick textura angularis-prismatica, cells at base †(10–)15–30(–45) × (5–)10–20(–35) µm {3}, common walls 0.3–0.4 or 0.5–2 µm thick, at lower flanks 50–80 µm thick, of t. prismatica(-porrecta), cells *23–42 × 8–18.5 µm {2}, †7–22 × 5–18 {2} or 20–37(–45) × (6–)10–19(–25) {3} µm, rarely up to †62 µm long {1}; 7–12 µm thick near margin, marginal cortical cells *8–11 × 6–8.5 µm {1}, †(4–)6–12(–15) × (2–)3–6.5 {8} or × 5–10.5 {3} µm, not or slightly gelatinized (wall 0.2–1 µm thick). **Anchoring hyphae** abundant, †(2–)3–6 µm wide, at insertion 5.5–7.5 µm, walls (0.2–)0.3–0.8(–1)((–1.5)) µm thick {9}. **VBs** in terminal cells of paraphyses pale yellowish, elongate. **Exudate** 0.2–0.3 µm thick, continuous, finely rough to granular, pale yellowish. — **ANAMORPH**: brachyphoris-like (presumed, from natural substrate {3}). **Conidiophores** not observed. **Conidia** fusoid to fusiform, straight, *36–41 × 5.5–6 µm {1}, †48–51 × 3.5–4.8 µm {2}, 5–7-septate.

Habitat: collected on moist or wet ground, rarely 0.5 m above the ground, ± corticated or decorticated, 20–50 mm thick branches of *Alnus* sp. {3}, *Bambusoideae* {1}, *Fagus crenata* {1}, *Pinus* sp. {1}, *Quercus* sp. {1}, indet. angiosperm trees {12}, on up to 0.5 mm deep medium to strongly decayed wood {5} or mostly bark (periderm and bast) {14}; slightly greyed, with a few green algae. **Associated**: *Hyalorbilia arcuata* {1}, *H. multiguttulata* {1}, *H. tortuosa* {1}, *Orbilia binchuanensis* {1}, *O. renispora* {1}, *O. xanthostigma* {1}. **Desiccation tolerance**: dead in all parts when examined after 1 month, perhaps slightly desiccation-tolerant. **Altitude**: ~300–1325 m a.s.l. (Japan), 520–2700 m (southern China), 200–385 m (Caribbean belt). **Geology**: Asia: Paleozoic, Devonian-Carboniferous & Tertiary sedimentary and felsic plutonic & volcanic mafic rock; USA: granite. **Phenology**: I, IV, VI–X (N-hemisphere, at present with maxima in I and VIII–IX).

Taxonomic remarks. With its rather large apothecia and narrowly cylindrical, straight to slightly curved ascospores *H. japonica* closely resembles *H. inflatula*. It differs in distinctly smaller asci and ascospores, with a distinctly shorter pars sporifera. However, the limit between these two species is not very sharp, and also *H. oreadum* deviates from *H. japonica* only gradually in wider spores. Five Chinese collections assigned to *H. oreadum* by Guo et al. (2014a) appear to be intermediate to *H. japonica* (for details see under *H. oreadum*, Pl. 74: 3–4). Delimitation from *H. citrina* with helicoid spores is also not sharp due to collections in which spore curvature (compare Pl. 83: 7 and Pl. 87: 9) and the texture of the marginal excipulum are intermediate. *H. japonica* was only available to us from dead herbarium material. However, several fresh specimens from Taiwan were investigated by Y. C. Su and M. L. Wu, and some of their illustrations are reproduced here (Pl. 83: 9; 84: 6–7).

Some of the Chinese collections reported by Liu (2006) under the name *H. inflatula* belong to *H. japonica*. Two were reexamined: B.L. 6446 (HMAS 138524, Guangxi) has straight spores †4–4.5 × 0.8–1 µm, asci †(13–)15–17 × 3 µm, and gelatinized marginal cells 4–7 µm wide, which well fits *H. japonica*; in B.L. 6418 (HMAS 139580, Fujian) the asci measured †15–21(–23) × 3.3–3.6 µm and spores could not be found, nevertheless we have included it here in the scope of *H. japonica*.

Variation. The present concept of *H. japonica* is only tentative due to pronounced variation, especially in excipular characters and apothecial colour, also in molecular data. Highly variable is the excipular cell length at the lower flanks, being quite long in some specimens from eastern Asia (†30–62 × 10–25 µm, H.B. 7461a; †20–45 × 6–11 µm, holotype; †20–37 × 6–15 µm, Pl. 84: 4a) and North America (*23–42 × 8–18.5 µm), but rather short in others (Pl. 84: 3c, 7a, 8h), e. g., in material from Puerto Rico (8–22 × 6–18 µm). Also the marginal cortical cells are in a majority of samples rather narrow and slightly to medium gelatinized (e. g., Pl. 84: 2c, 8g; IVV: H.B. 5906 holotype), but in collections from Puerto Rico (Pl. 83: 7f), Japan (Pls 83: 5f; 84: 4b), and North America (IVV: X.2017) they are ± distinctly wider and partly non-gelatinized. The degree of gelatinization at the flanks also varies from rather low, with common walls 0.3–0.4 µm thick (e. g., Pl. 84: 4a), to distinctly gelatinized, with 0.5–2 µm thick common walls (Pl. 83: 7g, in the holotype 0.5–1 µm). The apothecial colour varies from whitish or pale chlorinaceous (eastern Asia, South Africa, North America) to more light to bright yellow (Puerto Rico).

Type studies. No material of *Orbilia epipora* subsp. *major* from Argentina (on rotten log of *Populus nigra* '*italica*' in a

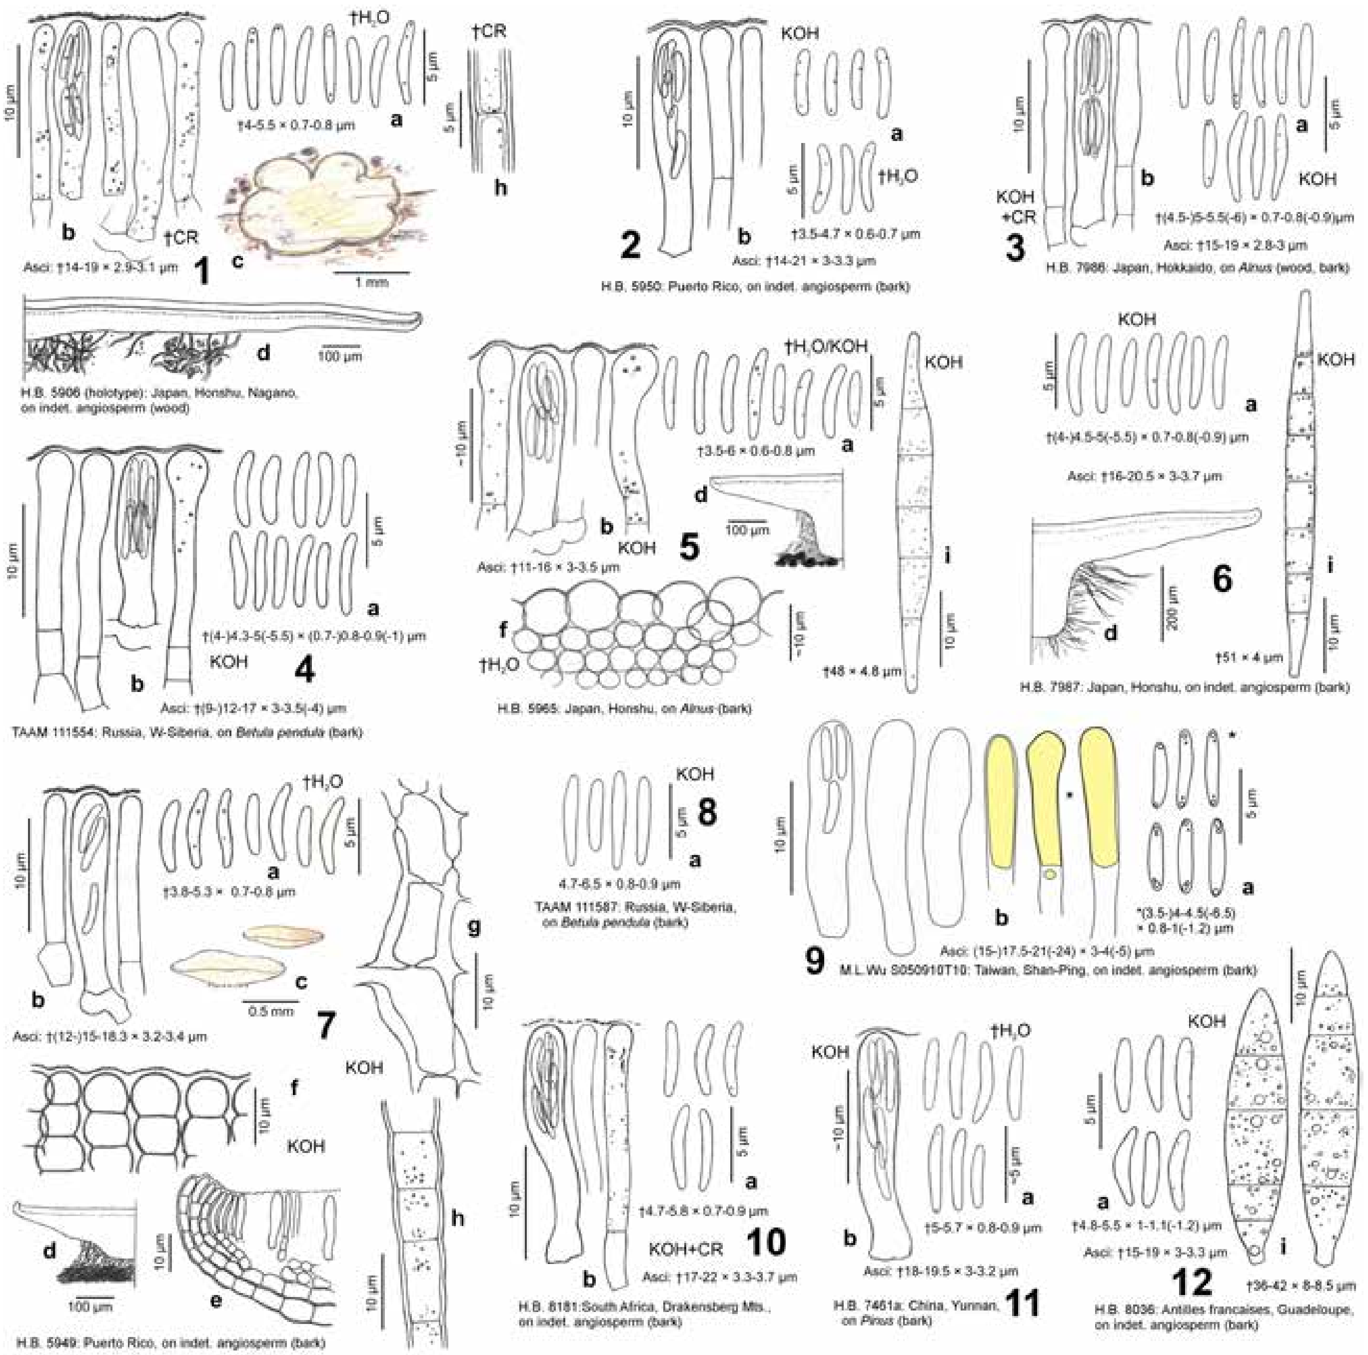

Plate 83. **1–3**, **5–7**, **9–11**: *Hyalorbilia japonica*; **4**, **8**, **12**: *H.* cf. *japonica*. – **a**. ascospores; **b**. asci (with croziers) and paraphyses; **c**. rehydrated apothecia; **d**. apothecia in median section; **e**. id., ectal excipulum at margin and flanks; **f**. marginal cells (**5f**: top view, **7f**: external view); **g**. cortical layer of ectal excipulum at lower flanks in external view; **h**. anchoring hyphae; **i**. conidia from substrate.

marsh) could be located in BAB and PAD. According to the original description by Spegazzini (1881), copied by Saccardo (1889: 626), the nearly unstalked asci (20–25 × 5 µm), uninflated paraphyses, and very large excipular cells (50–60 × 20 µm) point to a *Hyalorbilia*. The rather large apothecia (0.8–1.5 mm) together with small, cylindrical, curved spores (4–5 × 0.5–0.8 µm) are reminiscent of *H. japonica* or *H. arcuata*. Spegazzini considered the collection to be intermediate between *O. epipora* and *O. inflatula* (= *H. inflatula*).

Other not included collections. A collection from the Antilles (Pls 83: 12; 85: 2) is somewhat intermediate between *H. japonica* and *H. oreadum*. The often slightly curved spores are wider than in typical *H. japonica*, and the excipular cells a bit too thick-walled to be included in *H. oreadum*. Comparable is a collection from the Comoros with very similar, more straight spores (IVV: J.P.P. 14035). A very sparse collection from Azerbaijan (Pl. 84: 9, spores †5–6 × 0.9–1 µm) is more probably *H. japonica* than *H. inflatula* because of slightly (to medium) curved spores, but the presumed anamorph deviates (see below). An abundant sample from western Siberia (Tyumen, Pls 83: 4; 84: 10) differs in remarkably cyathiform, stipitate, yellow apothecia. The very short asci and the short, slightly curved spores would fit well *H. japonica*. A separate population in this collection (Pls 83: 8; 85: 1) has slightly longer spores and smaller, less stipitate apothecia, and is difficult to delimit from *H. inflatula*. The marginal cortical cells in the Siberian specimens are rather wide and thin-walled, with only sparse gel between. All these doubtful specimens differ from *H. fagi* in narrower, less curved spores.

Anamorph. Narrowly fusiform brachyphoris-like conidia were observed in three collections on the natural substrate (Pl. 83: 5–6; IVV: H.B. 8717). In a not included collection from Guadeloupe distinctly wider conidia were detected (Pl. 83: 12i), and a much shorter conidium occurred in the sample from Azerbaijan (IVV: TAAM 68123/H.B. 8725b). Conidiophores were not observed in any of these cases. The more slender conidia of *H. japonica* fit quite well those of *H. lignatilis*. However, conidia with this shape do not markedly differ from those known for *H. brevistipitata*, *H. oviparasitica*, and *H. inflatula* (?= '*Dactylella*' *passalopaga*).

Phylogeny. ITS sequences from apothecia of the two here reexamined Chinese specimens, which Liu (2006) included in *H. inflatula*, were available: B.L. 6446 from Guangxi and B.L. 6418 from Fujian. However, no sequence from the type of *H. japonica* from Japan was gained. The two Chinese strains clustered in a clade in the analysis of Liu et al. (2006a). It seems that at least B.L. 6446 represents typical *H. japonica* (see above). In the ITS the two differ by 6.5 % and in our analysis they clustered in an unsupported (ML, strongly supported under NJ) subclade within the strongly supported *citrina-fagi* clade (Phyl. 5). Also for one of the samples from Massachusetts (bhi-F1000.1a) a sequence (S1506 intron, ITS) was available which clustered in our ITS analysis unresolved in the *citrina-fagi* clade (not shown), with a minimum distance of 5.5 % to *H.* cf. *fagi* from Massachusetts (bhi-F041), with which it also clustered when analysing the intron.

Other strains identified by Liu (2006) as *H. inflatula* clustered in our analyses with *H. arcuata* and *H. inflatula* (see under these species). The type of *H. lignatilis* differs by 22–23 % in the ITS region from the two Chinese *H. japonica* specimens.

Ecology. *Hyalorbilia japonica* was found on ± rotten bark and wood of hygric branches of angiosperm (rarely gymnosperm) trees, but also on a stem of bamboo. The collection with large thin-walled excipular cells (H.B. 5965) was from an air-protruding branch ~0.5 m above the ground, whereas all other samples appear to have grown on the moist or wet ground.

The collections are from eastern and southeastern Asia, southeastern Africa, and Middle America, with a cold-temperate to tropical humid (winter-dry), monsoon-influenced climate (in South Africa it was a savannah-like shrubland). According to M.L. Wu (pers. comm.) the species is frequent in southern Taiwan, being collected about 30 times throughout the year. The not included samples are, e. g., from oroboreal and suprasubmediterranean western Asia and cold-temperate central Europe.

Specimens included. **JAPAN**: **Hokkaido**, ~20 km NW of Tomakomai, Shikotsu lake, ~300 m, branch of *Alnus*, on wood & bark, 28.VII.1990, T. Hyalorbilia lignatilis (M.H. Mo & K.Q. Zhang) E. Weber & Baral, **comb. nov.**, MB 829069 — Pl. 86

Basionym: *Dactylella lignatilis* M.H. Mo & K.Q. Zhang, Mycotaxon 91: 186 (2005)

Etymology: named after the growth on bark of a twig of *Pinus*.

Typification: China, Yunnan, Kunming, Xiaobailong Mt., twig of *Pinus*, 10.IX.2003, M.H. Mo (HT1.00596, holotype; YMF 1.00596, ex-type culture; sq.: KT215222).

Description: — **TELEOMORPH**: uncertain. – **ANAMORPH** (from Mo et al. 2005b, modified, see also Pl. 3: a): brachyphoris-like (from ascospore isolate {1}). **Conidiophores** 60–180(–270) µm long, 3.5–5 µm wide at base, 1.5–2.5 µm at the tip, strongly branched, side branches 7–35 µm long, conidiogenesis terminal, singly. **Conidia** unbranched, */†(25–)30–43(–51) × 3.5–5.2 µm, narrowly fusoid to fusiform, rounded at tip, truncate at base, straight, (1–)3–4(–6)-septate, (*) containing groups of refractive, globose to subangular droplets 0.7–1 µm diam. in centre of each cell. **Trapping organs** not observed.

Habitat: twig of *Pinus* lying on moist soil, on bark. **Associated**: *Hyalorbilia arcuata*, *H. japonica*. **Desiccation tolerance**: unknown. **Altitude**: 1580 m a.s.l. **Geology**: Paleozoic sedimentary rock.

Taxonomic remarks. Mo et al. (2005b) described the new species *Dactylella lignatilis* based on the anamorph which they obtained from an ascospore isolate of its teleomorph from *Pinus* bark collected in China. Under the name *Hyalorbilia* sp. they provided a description of the teleomorph. Our restudy

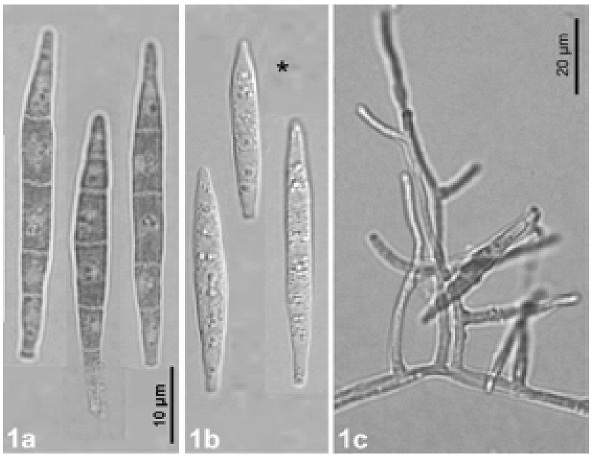

Plate 86. **1**: *Hyalorbilia lignatilis* (holotype). – **1a–b**. conidia from pure culture; **1c**. conidiophores. – Dead state, except for **1b**. — **1a–c**. from Mo et al. (2005b), YMF 1.00596: China, Yunnan, Kunming, on *Pinus*.

of a fragment of this collection revealed, however, a mixed population of at least two different *Hyalorbilia* species: whereas Mo et al. (l.c.: fig. 3) reported apothecia with consistently strongly curved, falcate ascospores and angular to prismatic cells of mostly 10–20 × 6.5–12 µm, which we here refer to *H. arcuata* (H.B. 7461b, Pl. 101: 2), our fragment surprisingly contained only apothecia with almost straight spores and ectal excipular cells at the flanks of 30–62 × 10–25 µm, which fit our concept of *H. japonica* (H.B. 7461a, Pl. 83: 11). Mo et al. appear to have overlooked this mixture of different species, and it might well be that their culture, which represents the type of *D. lignatilis*, derived from the straight-spored population, if not from a third taxon.

Chen et al. (2007b) examined an ex-type culture of *D. lignatilis* but could not observe any conidia. They obtained an ITS sequence from it, which 'showed a far distance from any species of *Dactylella*' (s.l., including *Brachyphoris*), but did not deposit it in GenBank. When we had the opportunity to study an ex-type culture of *H. lignatilis* in 2005, we observed a few of the characteristic brachyphoris-like conidia. Regrettably we did not document them. Molecular data gained by G. Hagedorn from this culture confirmed a relationship with *Hyalorbilia*, and we conclude that Chen et al.'s ex-type culture was contaminated.

Because of its high molecular distance to *H. arcuata* and *H. japonica* (see below), we here propose the new combination *H. lignatilis*, for which only the anamorph is known with certainty. The conidia of *H. lignatilis* hardly differ from other species of *Hyalorbilia*, such as *H. citrina*, *H. fagi*, *H. inflatula* etc. Mo et al. (2005b) gave a very wide range of conidial width (2.5–6.3 µm, mean value 4.8 µm), but from their scale we obtained 3.5–5.2 µm. The refractive droplets in the living conidia (Pl. 86: 1b) are suggestive of SCBs (cubical bodies), but in the dead conidia they are still visible (Pl. 86: 1a) which would, instead, point to lipid bodies.

Phylogeny. When analysing ITS (Phyl. 5), our sequence of the ex-type culture of *H. lignatilis* clustered in *Hyalorbilia* and here with strong support and a 6 % distance with a sample from Nanning under the name *H. inflatula* (B.L. 6193, Liu 2006). An illustration of B.L. 6193 was not available, and we can only assume from Liu's identification and from his general description of *H. inflatula* that it had ± straight ascospores. This might make it more probable that the type culture of *H. lignatilis* was obtained from a teleomorph with straight ascospores.

This is supported by the finding that our Australian collection of *H. arcuata* did not cluster with *H. lignatilis* but with another sample with arcuate spores identified by Liu (2006) as *H. andina* (B.L. 6408). However, an unillustrated sample identified by Liu as *H. inflatula* (B.L. 6426) clustered in the same clade, and another *H. andina* sample (B.L. 6184) clustered with one of '*H. juliae*, B.L. 6449' in a clade of its own (see Phyl. 5). The clade with *H. lignatilis* is also distant from *H. japonica* (B.L. 6446). Given that the ex-type culture of *H. lignatilis* derived from straight-spored apothecia, our description of *H. japonica* would be heterogeneous as it includes the straight-spored part of Mo et al.'s sample (H.B. 7461a). The same applies to the description of *H. arcuata* in which the curved-spored H.B. 7461b is incorporated, in case the apothecia from which *H. lignatilis* derived had curved spores. Because of this uncertainty and the very high ITS distance of 22–23 % between *H. lignatilis* and *H. japonica* (H.B. 9109, H.B. 9110), we here prefer for the time being to consider *H. lignatilis* as a species of its own.

G. Hagedorn's sequence of *H. lignatilis* comprises also SSU (S1506 intron absent) and LSU. When analysing ITS+LSU, *H. lignatilis* formed a medium supported subclade with *H. polypori* (Phyl. 6). When analysing LSU, (Phyl. S5), *H. lignatilis* clustered strongly supported with an environmental clone from Taiwan isolated from the rhizome of the orchid *Gastrodia*. This clone was identified by the authors as *Dactylella lignatilis* based on its short sequence of merely 201 nt of the D1 domain which, however, deviates from the type by 4 nt. Also an unidentified isolate from Michigan (LSU not shown in phylotree) deviates from *H. lignatilis* and from the Taiwan clone by only 4 nt in these 201 nt of LSU.

Ecology. The apothecia from which *Hyalorbilia lignatilis* was isolated grew on bark of a decayed twig of *Pinus*, being with one end submerged in the moist soil. The collection was made in a subtropical humid (winter-dry) mountain forest in southern China. The not included collection from Nanning was on unidentified bark in a lowland forest with a similar climate. This might also apply to the Taiwan clone, whereas the Michigan clone came from a cold-temperate humid climate.

Specimens included. **CHINA**: **Yunnan**, **Kunming**, ~35 km W of Kunming, ~8 km WNW of Jiliang, Xiaobailong Mt., 1580 m, twig of *Pinus*, on bark, 10.IX.2003, M.H. Mo (M.M.H. 005 p.p., HT 1.00596, H.B. 7461c ø, presumed mixture with *H. arcuata* & *H. japonica*; HT1.00596, **holotype**; YMF 1.00596, ex-type culture; doc. vid.; sq.: KT215222).

Not included. **CHINA**: **Guangxi**, **Nanning**, ~3 km SE of Nanning, Qingxiushan, 180 m, on indet. bark, 2.VII.2002, B. Liu (B.L. 6193, HMAS 138509, as *H. inflatula*, non vid.; sq.: DQ656655). – **Taiwan**, unlocalized, *Gastrodia* rhizome (G-jav2-LSU1_OTU-0-064_3, sq.: MF338616). — **USA**: **Michigan**, Pellston, forest soil (clone OTU512, sq.: MG927852).

Hyalorbilia citrina (A.L. Smith) Baral, **comb. nov.**, MB 813471 — Pls 87–88, Map 9

Basionym: *Calloria citrina* A.L. Smith, J. Linn. Soc., Bot. 35: 15 (1901)
= *Orbilia crenulatolobata* Höhnel, Denkschr. Kaiserl. Akad. Wiss. Wien, Math.-Naturw. Kl. 83: 31 (1907)
= *Orbilia andina* var. *lateritia* Pat., Bull. Soc. Mycol. Fr. 11: 218 (1895)

Etymology: *citrina*: named after the bright yellow colour of the apothecia; *crenulatolobata*: according to the roundish lobate protrusions of the apothecial margin; *lateritia*: named after the brick-red apothecia.

Typification: Dominica, Couliabon Mt., branch of indet. angiosperm, on bark, 1.III.1896, W.R. Elliott (K(M) 31762, lectotype of ***Calloria citrina***, designated here, MBT202652); Martinique, La Sérénité, Le St.-Esprit, log of *Swietenia macrophylla*, on *Ganoderma*, 29.VIII.2005, C. Lechat (ex C.L. 5247 & ex H.B. 8012, M-0291768, epitype, designated here, MBT385110; sq.: KT222377). — Brazil, São Paulo, branch of indet. tree, VII.1901, R. von Wettstein (FH, holotype of ***Orbilia crenulatolobata***). — Ecuador, Pululahua Mt., branch of indet. angiosperm, II.1892, collector unknown, (FH, herb. Patouillard, holotype of ***O. andina* var**. ***lateritia***).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.6–1.2 or 1–3.5(–4.5) mm diam., 0.1–0.25 mm high (receptacle 0.07–0.12 → 0.04–0.06 mm), pale or light chlorinaceous-yellow to bright yellow-ochraceous, also white, ± translucent, round, margin somewhat undulating when large, moderately gelatinous, scattered to subgregarious; disc shallowly cyathiform, finally flat, margin even {10} or crenulate-lobate to dentate {18}, lobes or teeth 6–30 up to 50–90 µm long, 30–100 µm wide; sessile on an obconical base or ill-defined stipe ~0.04–0.1 × 0.25–0.4 mm, superficial; dry cupulate to cyathiform, with strongly inrolled margin, pale to light cream or yellow-ochre(-orange), sometimes turning red-brown with age, very fragile. **Asci** *20–28 × 3.5–4 µm {1}, †(14–)15–22(–25) × (2.6–)2.8–3.6(–3.8) ((–4.5)) µm {17}, 8-spored, spores *~4-seriate, ± intertwined but often in two superimposed bundles, pars sporifera †10–15 µm long; **apex** (†) hemispherical to slightly subconical or subtruncate; **base** with or without short, thick stalk arising from croziers {9}. **Ascospores** *(5–)5.5–6(–6.5) × 0.8(–0.9) µm {1}, †(4–)4.5–6(–7) × (0.6–)0.7–0.8(–0.9) µm

{26}, (sub)cylindrical to sometimes slightly fusoid, slightly to medium helicoid (either stair-shaped or allantoid depending on the viewing direction), rarely some spores only very slightly curved; 1 **SB** at ?each end, ~0.4–0.6 × 0.4 µm {1}; often with 1–2 minute LBs. **Paraphyses** apically mostly cylindrical, rarely very slightly capitate or spathulate, terminal cells †(12–)14–20(–25) × (1.2–)1.7–2.5(–3.5) µm {6}, lower cells †3–7 × (1.2–)1.7–2.5(–3) µm {5}, a few paraphyses with rather long terminal cells, these appearing more firm-walled (possibly only by deposition of remnants of VBs) and arising deeply in the medullary excipulum {3}. **Medullary excipulum** hyaline to very pale yellowish, 10–20(–45) µm thick, of medium to very strongly gelatinized prismatic to angular cells, intercellular gel 1–3 µm thick, (very) sharply delimited. **Ectal excipulum** hyaline, of horizontal textura prismatica(-porrecta) from base to mid flanks, 40–130 µm thick near base, cells at lower flanks †(13–)20–60(–70)((–92)) × (6–)10–20(–25)((–32)) µm {12}, slightly to often strongly gelatinized: common walls 0.4–1.2 {6} or (0.7–)1–3(–5) {15} µm thick; 20–30 µm thick at mid flanks, towards margin of t. prismatica-angularis, upper margin or marginal teeth or lobes abruptly of t. globulosa of thick-walled cells, 25–30 µm thick in section, marginal cortical cells †(5–)7–17(–20) × (3–)6–12(–14) µm {6}, external wall 0.4–1 {8} or 1–3(–4) {14} µm thick, typically with a ± pronounced furrow between hymenium and margin. **Anchoring hyphae** sparse to abundant, long, radiating, †(2–)3–7(–10) µm wide (varying from 3–4 to rarely 7–9 µm), walls 0.3–1.2(–2) µm thick {11}. **Exudate** over paraphyses 0.2–0.8 µm thick, continuous, finely to strongly granular; over lower and upper surface of marginal teeth smooth or with scattered to dense fine warts, pale yellowish. — **ANAMORPH**: brachyphoris-like (presumed, from natural substrate {3}). **Conidiophores** not observed. **Conidia** narrowly fusoid to fusiform, straight, */†(36.5–)40–55(–61) × (3–)4–5(–5.5) µm {3}, 3–6-septate, containing some globose **SCBs** 0.9–1.2 µm diam. in centre of cells {2}.

Habitat: lying on the moist ground (rarely min. 0.5 m above the ground), on 1.3–5 or ~8–10 cm thick, corticated, rarely decorticated branches of *Cordia borinquensis* {1}, *Fraxinus* (*?mandshurica*) {1}, *Inga laurina* {1}, *Ormosia krugii* {1}, *Swietenia macrophylla* {1}, indet. angiosperm trees {20}, especially on the underside, on superficially or deeply (slightly to) medium (to strongly) decayed bark (partially detaching, usually on periderm) {21}, or wood {7}; on stem of *Bambusa* sp. {1}, petioles of *Oenocarpus* sp. {1}, fruit of *Hymenaea* sp. {1}; on hymeniophore (pores) of *Ganoderma* sp. {1}, *Phellinus* sp. {1}, *Trametes hydnoides* {1}, often on or close to old black pyrenomycetes {8}; no algae. **Further associated**: *Ascocoryne sarcoides* {Dennis 1954}, *Catinella olivacea* {1}, *Monodictys* sp. {1}, *Nectriaceae* {1}, *Ombrophila pura* {Dennis 1954, as '*O. microspora*'}, *Orbilia bambusina* {1}, *O. ?tremulae* {1}, *O. subuliformis* {1}, ?*Parmelia* sp. {1}. **Desiccation tolerance**: presumably desiccation-sensitive (dead in all parts when examined after 3 months), but in 2 collections apparently slightly desiccation-tolerant; conidia survived for 6.5 months in the herbarium. **Altitude**: 3–1165 or up to min. 1600 m a.s.l. (Middle & South America), 20–210 m (Japan). **Geology**: Japan: marine Tertiary sedimentary & volcanic pyroclastic rock. **Phenology**: in tropical belt almost throughout the year, in Japan in spring and summer.

Taxonomic remarks. *Hyalorbilia citrina* is characterized by subcylindrical, narrow ascospores which typically show a distinct helicoid curvature (appearing somewhat stair-shaped in profile view), and by a gelatinized medullary and ectal excipulum. *H. citrina* could only be studied in the dead state, therefore, no data on the SBs are available, except for a single observation by J.P. Priou (pers. comm.). Similar helicoid spores occur in the temperate taxa *H. helicospora*, *H. tortuosa* and *H. fagi*. These differ either in much smaller, more whitish apothecia, or in the constant absence of a gelatinized ectal excipulum and a dentate margin, or slightly longer or wider spores with more tapered ends. The more tropical *H. japonica* differs in shorter, never helicoid spores and a usually less gelatinized excipulum which never forms teeth at the margin.

Variation. The rehydrated apothecia vary in colour between pale and (e. g., in the lectotype of *H. citrina*) bright yellow-chlorinaceous. Typically, the margin is distinctly crenulate or dentate. The teeth consist of globose cells with often extraordinarily thick walls, and have a rounded to obtuse rather than acute shape. However, in 9 out of 30 collections the margin was smooth or only very slightly and irregularly crenulate (e. g., in the type of *O. andina* var. *lateritia*). 15 collections from Puerto Rico were examined, but only nine of them showed a ± toothed margin. All four specimens from Brazil were toothed, whereas all three Japanese collections showed smooth margins, and only one of them [from (sub)tropical Ogasawara islands, H.B. 7983a, Pl. 88: 5c] very thick-walled excipular cells. The degree of gelatinization, i. e., the thickness of the common walls, actually varies considerably among the collections. The collection from Hokkaido (on *Fraxinus*, H.B. 7984) is the only specimen from a temperate climate here referred to *H. citrina*. It differs from *H. tortuosa* only tentatively in a stronger gelatinization of the ectal excipulum, and resembles closely a collection from more southern Japan (H.B. 7985).

More constant proved ascus and spore size, and spore shape. Yet, in some specimens included here the characteristic helicoid shape of the spores is less pronounced (e. g., Pl. 87: 9a). This causes problems in separating *H. citrina* from species with straight or only slightly curved but never distinctly helicoid spores. Collections with such spores and with the marginal ectal excipulum medium gelatinized are tentatively assigned here to *H. japonica* (e. g., Pl. 83: 7) and *H.* cf. *inflatula* (Pl. 79: 1, 3–5), and a sharp limit to *H. citrina* is difficult to draw. Moreover, some collections here included in *H. citrina* with distinctly helicoid spores show an only very slightly gelatinized margin (IVV: e. g. D.H.P. PR 120 & PR 134), thus causing problems in delimitation from *H. tortuosa* or *H. fagi*. Furthermore, the flanks may sometimes be only slightly gelatinized though the margin is strongly gelatinized, and vice versa, which was the case in, e. g., a sample on fruit of *Hymenaea* (Pl. 87: 9). Here the margin shows deep incisions typical of *H. citrina*, yet the spores were often only very slightly curved. In this collection some of the paraphyses have extraordinarily long and firm-walled terminal cells, a character also noted in the type of *H. citrina*, but not seen in most other collections examined and referred to *H. citrina*.

Not included collection. A sample from Puerto Rico (IVV: D.H.P. PR 134) deviates by the excipulum being rather thin-walled at flanks and margin, although the spores fit *H. citrina*.

Type studies. The brief protologue of ***Calloria citrina*** in Smith (1901) and Saccardo & Saccardo (1906: 143) includes lemon-yellow apothecia up to 4 mm diam., turning fuscous with age, externally with enlarged angular cells. The spores are described as ellipsoid, eventually 1-septate (no size indicated), the asci cylindrical, 50 × 6 µm, spores obliquely uniseriate, and the paraphyses as filiform. The species was based on two collections from Dominica (Elliott No. 1476: on wood, head of Castle Bruce River, II.1896; Elliott No. 1581: Morne Couliabon, III.1896). No. 1581 exists in K and bears W.R. Elliott's handwriting, but No. 1476 could not be located there. Dennis (1954: 297) apparently reexamined authentic material when stating that 'the name *Calloria citrina* A.L. Smith appears to have originated in confusion from a mixture of a bright yellow *Orbilia* with *Coryne sarcoides* [≡ *Ascocoryne sarcoides*] and *Ombrophila microspora* [= *Ombrophila pura*]'.

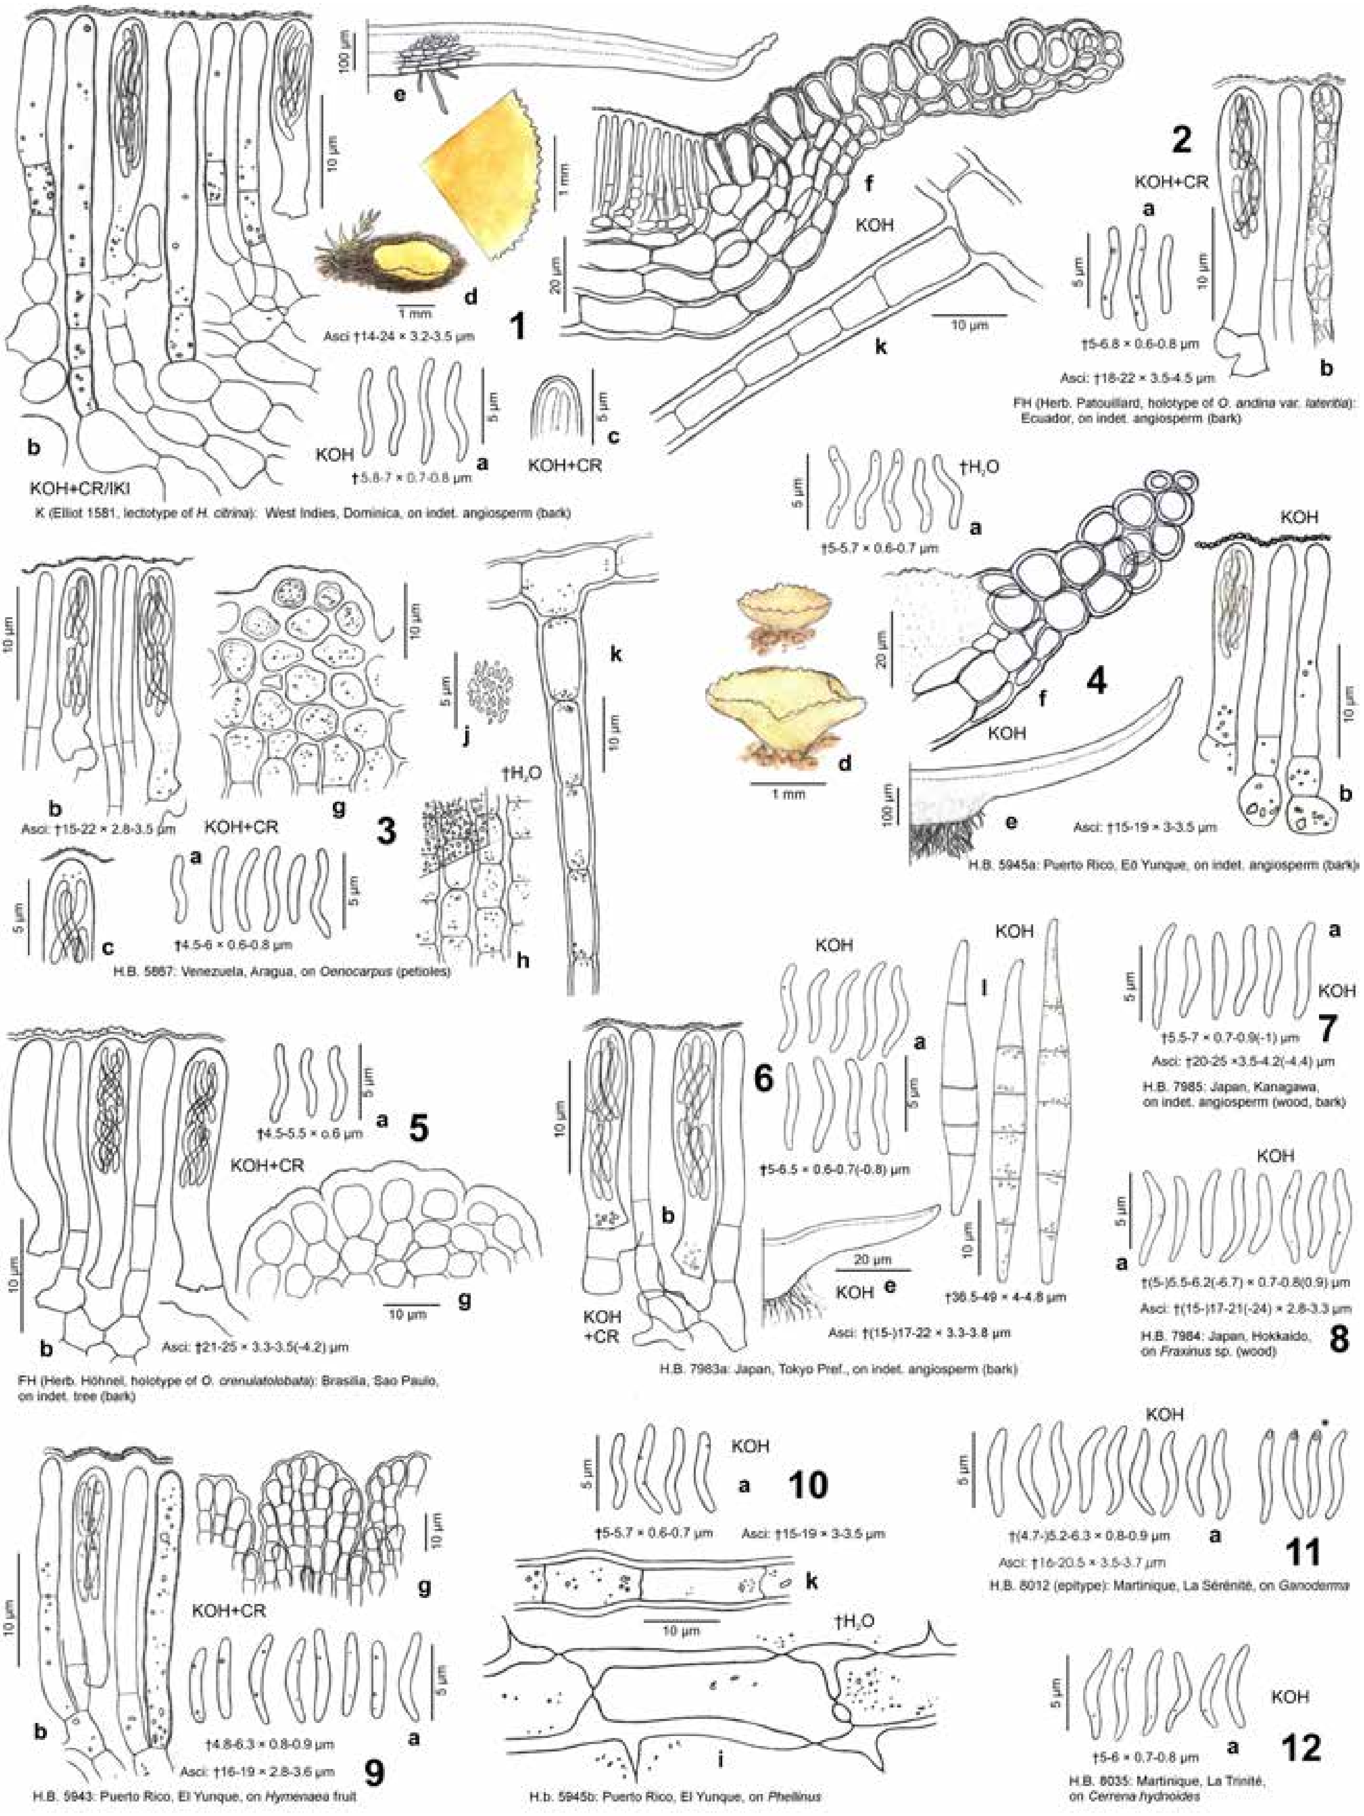

Plate 87. **1–12**: *Hyalorbilia citrina*. – **a**. ascospores; **b**. asci (with croziers) and paraphyses; **c**. ascus apices; **d**. apothecia with dentate margin; **e**. apothecia in median section; **f**. id., ectal excipulum at margin and mid flanks; **g**. marginal ectal excipulum in external view; **h**. id., at flanks, with warted exudate; **i**. lower flanks in median section, ectal excipular cells with thick gelatinized walls and thin septa; **j**. warted-cloddy exudate on ectal excipulum; **k**. anchoring hyphae; **l**. conidia from substrate.

H.B. 9671: Brazil, Itatiai, on indet. angiosperm.

No. 1581 contains fragments of bark and wood. The bark fragments bear yellow apothecia of the *Hyalorbilia* redescribed here (Pl. 87: 1). The wood fragments bear dark apothecia which were not examined in the present study and which probably represent the *Ombrophila* mentioned by Dennis. The microscopic data as well as the fuscous colour mentioned in the protologue appear to be based on the dark apothecia. Apparently, Smith did not find any spores in the yellow apothecia. Because the specific epithet clearly refers to the *Hyalorbilia*, we here designate the yellow apothecia in Elliott No. 1581 (K) as **lectotype** of *Calloria citrina*. A specimen from Martinique (on *Ganoderma*, ex H.B. 8012, Pls 87: 11; 88: 2), for which a sequence was gained, is designated here as **epitype** of *H. citrina*.

Examination of the holotype of ***O. crenulatolobata*** (Pl. 71: 5) revealed conspecificity with *H. citrina*. The taxon was described by Höhnel (1907b) as having 'white' apothecia, but now they are light yellowish-ochraceous when dry. Höhnel based his new taxon on the deeply notched margin of roundish lobes composed of cartilaginous, thick-walled cells. He considered the hymenia to be immature and described the spores as 'probably sausage-like curved, very small'. No doubt, Höhnel's statement it due to the frequent difficulty to find free spores in *Hyalorbilia*. In fact, mature asci occur abundantly in the holotype, but the spores could only be seen inside the asci. Höhnel compared his taxon with *O. sinuosa* Penz. & Sacc. [?= *H. inflatula*], apparently because of the undulating margin reported for that species. He found the ectal excipulum to be composed of radially (horizontally) arranged cells measuring 60–100 × 25–35 µm, an extraordinary size which was approximately observed in the present study in the type of *O. andina* var. *lateritia* (40–92 × 10–23 µm).

The very brief protologue of ***Orbilia andina*** **var.** ***lateritia*** in Patouillard (1895) simply reads 'brick-red, spores 5 × 1 µm', and 'close to *Orbilia lancicula*'. Revision of the holotype at FH revealed helicoid spores of about that size, an ectal excipulum of very thick-walled cells (common walls 1–3 µm), and a smooth gelatinized margin (Pl. 87: 2). Contrary to the protologue, the colour of the dry apothecia was light ochre-yellowish-amber. The label bears Patouillard's handwritten notes and sketches that show, e.g., the margin made up of thick-walled cells, and asci 20–22 × 4 µm. Dennis (1954: 294) assumed *O. andina* var. *lateritia* to be a possible synonym of *O. juruensis* Henn. However, the latter is not a *Hyalorbilia* but belongs to *Orbilia* section *Helicoon.*

Anamorph. The fusoid conidia observed in *H. citrina* on the natural substrate (Pls 87: 6l; 88: 6d, 9) resemble those of *H. arcuata*, *H. japonica*, *H. fagi*, and others.

Phylogeny. Sequences taken from apothecia of two samples of *H. citrina* were available, one comprising the ITS region (Martinique, H.B. 8012), the other SSU, half of 5.8S, ITS2, and LSU (Rio de Janeiro, H.B. 9661). The S1506 intron is absent in H.B. 9661 (unclear in H.B. 8012). A high distance of 16% is observed when comparing the two sequences in the available ITS2 region. Nevertheless, a large gappy region is characteristic for *H. citrina* in the alignment of ITS2, where the other sequences of the *citrina-fagi* clade have about 20–25 nt more.

S1506 intron, ITS1, and LSU D1–D2 exists for a sample from Florida in GenBank (not shown in phylograms). In the ITS1 5 nt & 1 gap differ from H.B. 8012, suggesting conspecificity, while in the LSU it clustered supported with H.B. 9661, with a likewise 5 nt & 1 gap difference. The intron region is closest to *H. fagi* but differs here in over 40 nt.

When analysing the entire ITS region (Phyl. 5), the two sequences formed a weakly supported subclade within the strongly supported *citrina-fagi* clade, which is part of the large *inflatula-polypori* clade. The complete ITS sequence of the Martinique strain shows in an alignment of all members of the *citrina-fagi* clade an 8–11% distance to *H. japonica*, *H. lunata*, *H. fagi*, and *H.* '*polypori*' (B.L. 288), while in the ITS2 alone the distance lies for *H. citrina* in the range of 15–20% (13% between the two *H. citrina* strains). Also when analysing LSU (Phyl. S5), *H. citrina* clustered with medium support in the *citrina-fagi* clade. In our combined analysis (Phyl. 6), *H. citrina* clustered with strong support with B.L. 288 and *H. fagi*, with a 2.5% and 2% LSU distance, respectively (1.5% between B.L. 288 and *H. fagi*).

Ecology. *Hyalorbilia citrina* is a plurivorous species and appears to occur widespread in the Neotropis in tropical humid rain or cloud forests in the Caribbean belt and in tropical northeastern parts of South America. It also occurs in subtropical humid eastern (Serra da Mantiqueira and Sao Paolo) and western parts of South America (Ecuadorian Andes), in (sub)tropical to cold-temperate humid, continental to oceanic eastern Asia (Japan), in the tropical wet & dry rainforest of the Comoros, and in tropical humid northeastern Australia. *H. citrina* inhabits a wide range of substrates of angiosperm trees, predominantly periderm of rotten bark and less often wood of hygric branches and logs, sometimes also petioles and fruits, xeric stems of *Bambusa*, or polypores. Judging from the associated discomycetes, the species appears to be desiccation-sensitive. However, the presence of a foliose lichen in one of the Japanese collections (H.B. 7983a) and the occurrence on standing stems of *Bambusa* in Australia seem to indicate a certain desiccation tolerance. Florida wetland in a *Quercus-Acer-Liquidambar* dominated forest.

Specimens included. **USA**: **Florida**, 6.3 km E of Melrose, E of Ashley Lake, 33 m, indet. tree, 8.VIII.2017, B. Kaminsky & M.E. Smith (FLAS-F-60759, as *Orbilia* sp., non vid.; sq.: MH281853, MH620243). — **PUERTO RICO**: 10.5 km SE of Isabela, 1.7 km S of Pueblito de Ponce, Reserva Forestal Guajataca, 200 m, branch of indet. angiosperm, on bark & wood, 23.I.1996, D.H. Pfister, F.A. Harrington, M. Liftik, S. Hundorf & D.J. Lodge (D.H.P. PR 118, FH 00304917; PR 120, FH 00304911). – El Yunque, ~9.5 km SW of Luquillo, trail to falls of Rio de la Mina, 500 m, branch of *Inga laurina*, on bark, 5.VI.1970, R.P. Korf, J.B. Benson, J.B. Dixon etc. (CUP-PR 3841). – trail to El Toro, 750 m, on wood of *Cordia borinquensis*, 5.VI.1970, R.P. Korf, J.B. Benson, J.B. Dixon etc. (CUP-PR 3835). – 30 km ESE of St. Juan, Rio Grande, El Verde Field Station, 15 m, on *Phellinus*, 20.I.1996, D.H. Pfister, F.A. Harrington & M. Liftik (D.H.P. Hyalorbilia tortuosa Baral, E. Weber, Y.C. Su & M.L. Wu, **sp. nov**., MB 813472 — Pls 89–90, Map 10

Etymology: named after the helicoid (tortuous) ascospores.

Typification: France, Reims, on *Fuscoporia* (?)*ferruginosa* on branch of *Fraxinus excelsior*, 11.IX.2004, F. Valade (ex H.B. 7576, M-0276420, holotype).

Latin diagnosis: *Ab* Hyalorbilia fagi *ascosporis paulo longioribus et angustioribus*, *magis helicoideis*, *conidiis cylindrico-ellipsoideis*, *brevioribus et latioribus differt*, *ab* H. helicospora *ascosporis angustioribus*, *habitat in ramis et truncis uvidis differt.*

Description: — **TELEOMORPH**: **Apothecia** fresh (0.09–)0.15–0.42(–0.47) {7} or (0.2–)0.5–1.5(–2.2) {5} mm diam., 0.07–0.25 mm high (receptacle 0.06–0.07 → 0.03–0.055 mm), whitish to pale cream-chlorinaceous or light yellowish-ochraceous, translucent, round, ± lobate when large, scarcely to medium gelatinous, gregarious; disc slightly concave to flat, finally medium convex, margin thin, smooth to finely rough, not or only slightly raised; with indistinct obconical or often distinct cylindrical stipe 0.03–0.1 × 0.05–0.2 mm, superficial; turning reddish-ochraceous when senescent, dry cupulate when large, with inrolled margin. **Asci** *(15–)18–28(–31) {10} × 3–3.8 {1} or (3.7–)4–5(–6) {9} µm, †(13–)16–23(–25) × (3–)3.2–4.2(–4.5) µm {6}, 8-spored, spores *4-seriate, intertwined, often in two superimposed bundles but also in one bundle, (†) arrangement more irregular, pars sporifera *(9–)11–14(–15) µm long; **apex** (†) hemispherical; **base** with or without short, thick stalk, with croziers {8}. **Ascospores** *((4–))(5–)6–7.5(–8)((–8.5)) × (0.7–)0.8–1.2 µm {13}, †(4.5–)5–7(–7.5) × 0.7–0.9(–1.1) µm {7}, subcylindric to mostly narrowly fusoid, ± homopolar, both ends rounded to obtuse (rarely subacute), (slightly to) medium to rather strongly helicoid (looking S- or C-shaped depending on the viewing direction); **SBs** *0.2–0.3(–0.5) µm {5}, ± globose, 1–2(–4) near each end. **Paraphyses** apically uninflated to slightly, rarely medium clavate-capitate, terminal cells *12–24 × 2.5–5.5 µm {2}, †12–22 × 2–5 µm {3}, lower cells *5–12 × 2–3 µm {1}, †5–6 × 1.7–2.5 µm {2}. **Medullary excipulum** 5–20 µm thick, of textura prismatica-globulosa-intricata, not or only slightly, also strongly gelatinized, scarcely to sharply delimited. **Ectal excipulum** of thin-walled to slightly gelatinized, horizontally oriented t. prismatica(-globulosa) from lower flanks up to margin, 50–210 µm thick near base, of t. globulosa-angularis, cells at lower flanks */†(10–)20–45(–60)((–83)) × (5–)10–25(–30)((–40)) µm {5}, common walls 0.4–1(–1.3) µm thick {3}; 5–15 µm thick near margin, marginal cortical cells *8–17(–23) × (4–)5–12(–15) µm {4}, †5–11 × 2.5–4.5 {2}, × 6–7.5 {1} or × 7–10 µm {1}, wall */†0.2–0.3 µm thick. **Anchoring hyphae** sparse to medium abundant, radiating, †(1.5–)2.5–5(–6) µm wide, at insertion 4–11 µm, walls 0.2–0.6(–0.9) µm thick {8}. **VBs** in terminal cells of paraphyses globose to elongate, hyaline to very pale yellowish, slightly refractive. **Exudate** over paraphyses and excipulum 0.2–0.4(–1) µm thick, granular-cloddy to rough or even smooth, continuous. **— ANAMORPH**: brachyphoris-like (from ascocarp in Petri dish {1} and natural substrate {4}). **Conidiophores** ~150–200 µm long, frequently branched, side branches ~18–45 µm long, conidia formed terminally or on short lateral denticles (sympodial). **Conidia** cylindric-ellipsoidal, straight, from pure culture *22–35.3 × 6–7.3 µm {1}, 3-septate; from natural substrate *15.5–19 × (4–)4.7–5.2(–5.8) {1} or *18.5–21.5 × 5.8–6.5 µm {2}, †15.5–22(–25) × 4.3–5.3 µm {Japan}, 1–3(–4)-septate, with small peripheral LBs (KOH-resistant) and several large SCBs 1–1.7 µm diam. (KOH-sensitive).

Habitat: collected on or close to moist ground, corticated or decorticated, 2–20 cm thick branches and logs of *Alnus* sp. {1}, *Carpinus betulus* {1}, *Castanea sativa* {1}, *Erica arborea* {1}, *Fagus sylvatica* {2}, *Myrica faya* {2}, *Quercus* sp. {3/2}, *Salix* sp. {1}, indet. angiosperm {4}, stem of *Bambusa* sp. {1}, on 2–10 mm deep strongly decayed wood {10} or bark {5} (periderm), on upper or lower side, with or without algae; on pores of slightly to strongly rotten *Fuscoporia*

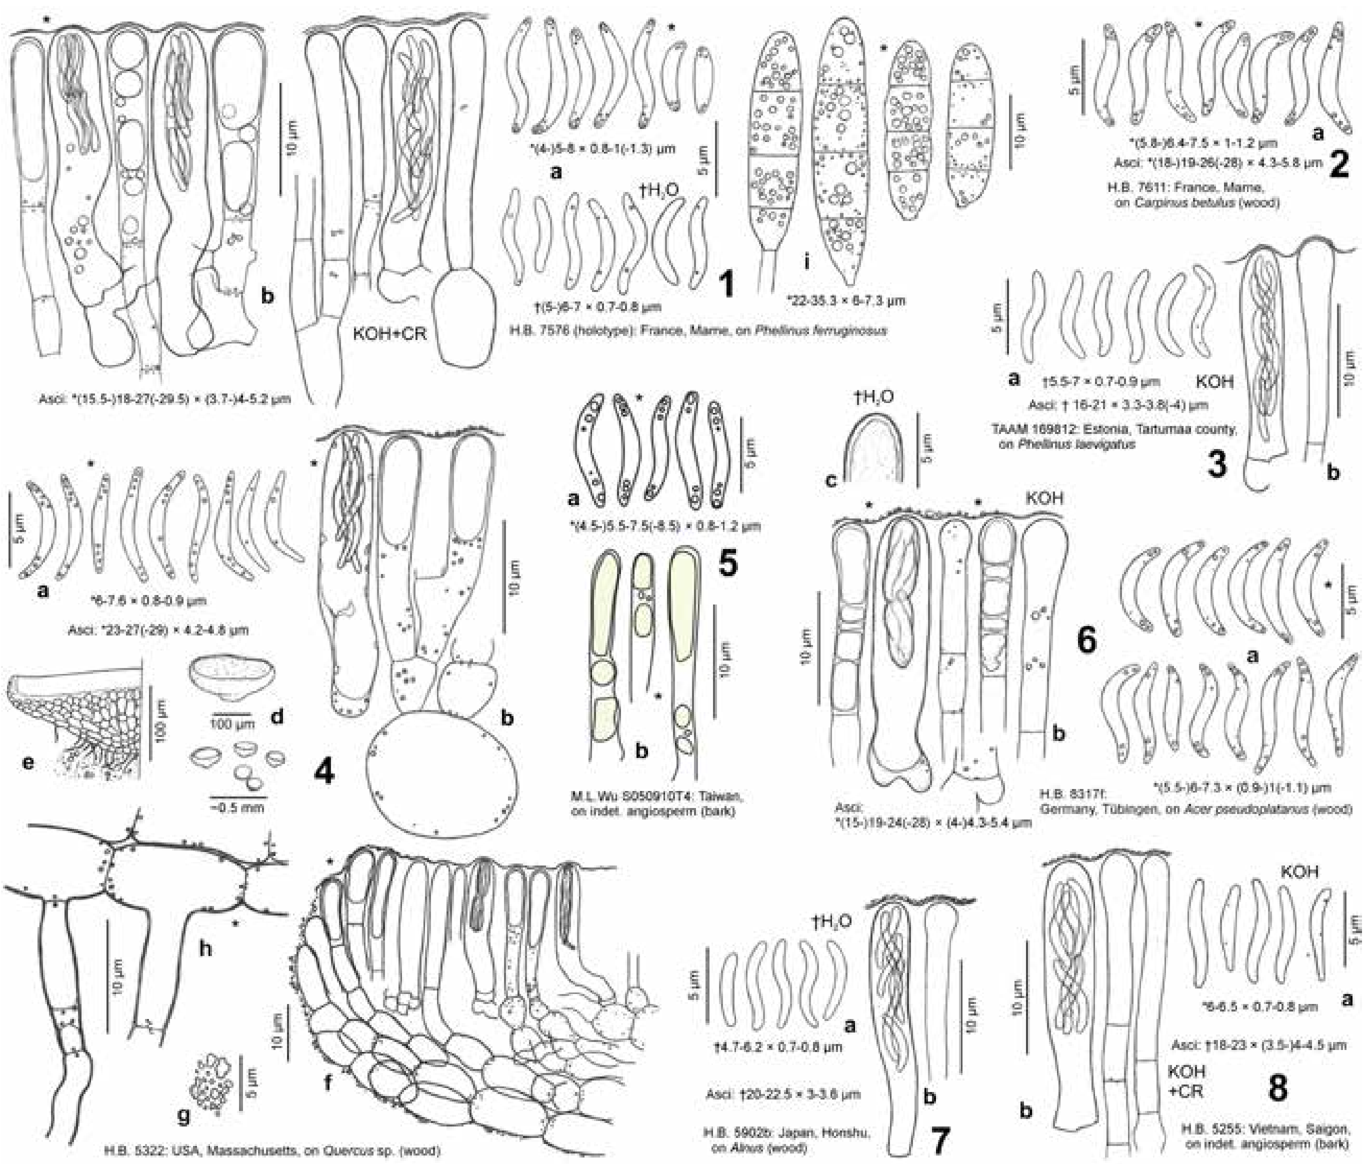

Plate 89. **1–7**: *Hyalorbilia tortuosa*. – **a**. ascospores; **b**. asci and paraphyses (bases with croziers); **c**. ascus apex; **d**. fresh apothecia; **e**. apothecium in median section; **f**. id., ectal excipulum and hymenium near margin; **g**. warted-cloddy exudate on ectal excipulum; **h**. anchoring hyphae; **i**. conidia. – **5**: del. Y.C. Su.

?*ferruginosa* {1}, *P. laevigatus* {1}, *Trametes gibbosa* {1}, rarely jumping on living *Hypnum cupressiforme* or *Lasiosphaeria hirsuta* {H.B. 8317f}. **Further associated**: *Brachysporium* sp. {1}, *Calycina citrina* {1}, *Cirrenalia lignicola* {1}, *Dematioscypha olivacea* {1}, *Hyalorbilia japonica* {1}, *Lasiosphaeria hirsuta* {1}, *Leptodontidium trabinellum* {1}, *Mollisia* ?*oblonga* {2}, *Orbilia leucostigma* {1}, *O. orientalis* {1}, *O. polybrocha* {1}, *O. xanthostigma* {1}, *Tubeufia* sp. {1}. **Desiccation tolerance**: dead in all parts when examined after 1 hour dry on slide. **Altitude**: 0–485 m a.s.l. (Europe), 665–895 m (Macaronesia), 40–2000 m (southeastern Asia). **Geology**: Ordovician & Devonian clay & sandstone, Lower & Upper Jurassic and Tertiary clay, sand- & limestone, Pleistocene loess & silt; volcanic sedimentary deposits, tephritic & phonolitic mafic flows, basalt. **Phenology**: I, IV, VI, VIII–XI (throughout the year?).

Taxonomic remarks. *Hyalorbilia tortuosa* is very similar to the tropical *H. citrina* in its helicoid ascospores, but differs in somewhat longer spores, a thin-walled ectal excipulum (especially at the always ± smooth margin), and in usually lacking any chlorinaceous colour typical of *H. citrina*. *H. helicospora* closely resembles *H. tortuosa* in the spores which are, however, slightly wider and contain more SBs. Contrary to *H. tortuosa* the apothecia of *H. helicospora* usually grow on xeric branches. The also similar *H. fagi* deviates from *H. tortuosa* in slightly shorter and wider, less curved spores, but a remarkable difference is found in the anamorph (see below).

Variation. Among the European collections, the two on *Phellinus* formed much larger apothecia (0.6–1.6 mm) than those on rotten wood and bark (0.15–0.4 mm). Apothecia from Macaronesia on wood were also small (0.2–0.5 mm), whereas southeastern Asian samples from wood and bark had quite a large size (0.5–1.5 mm). All of them were mature, and the microscopic features very similar. The medullary excipulum was usually slightly gelatinized, but in some of the eastern Asian collections it was strongly gelatinized. The excipular cells at the margin varied in size among the collections from Europe as well as eastern Asia, also apothecia colour varied between whitish and distinctly yellowish. Ascospores varied especially in width from *0.8–1 up to *1.1–1.2 µm. The collection from cold-temperate North America (Pl. 89: 4) deviates from European specimens in apparently 2–4 rather small instead of 1–2 SBs near each spore end, though the other characters fit well (apothecial size was here 0.2–0.35 mm). In

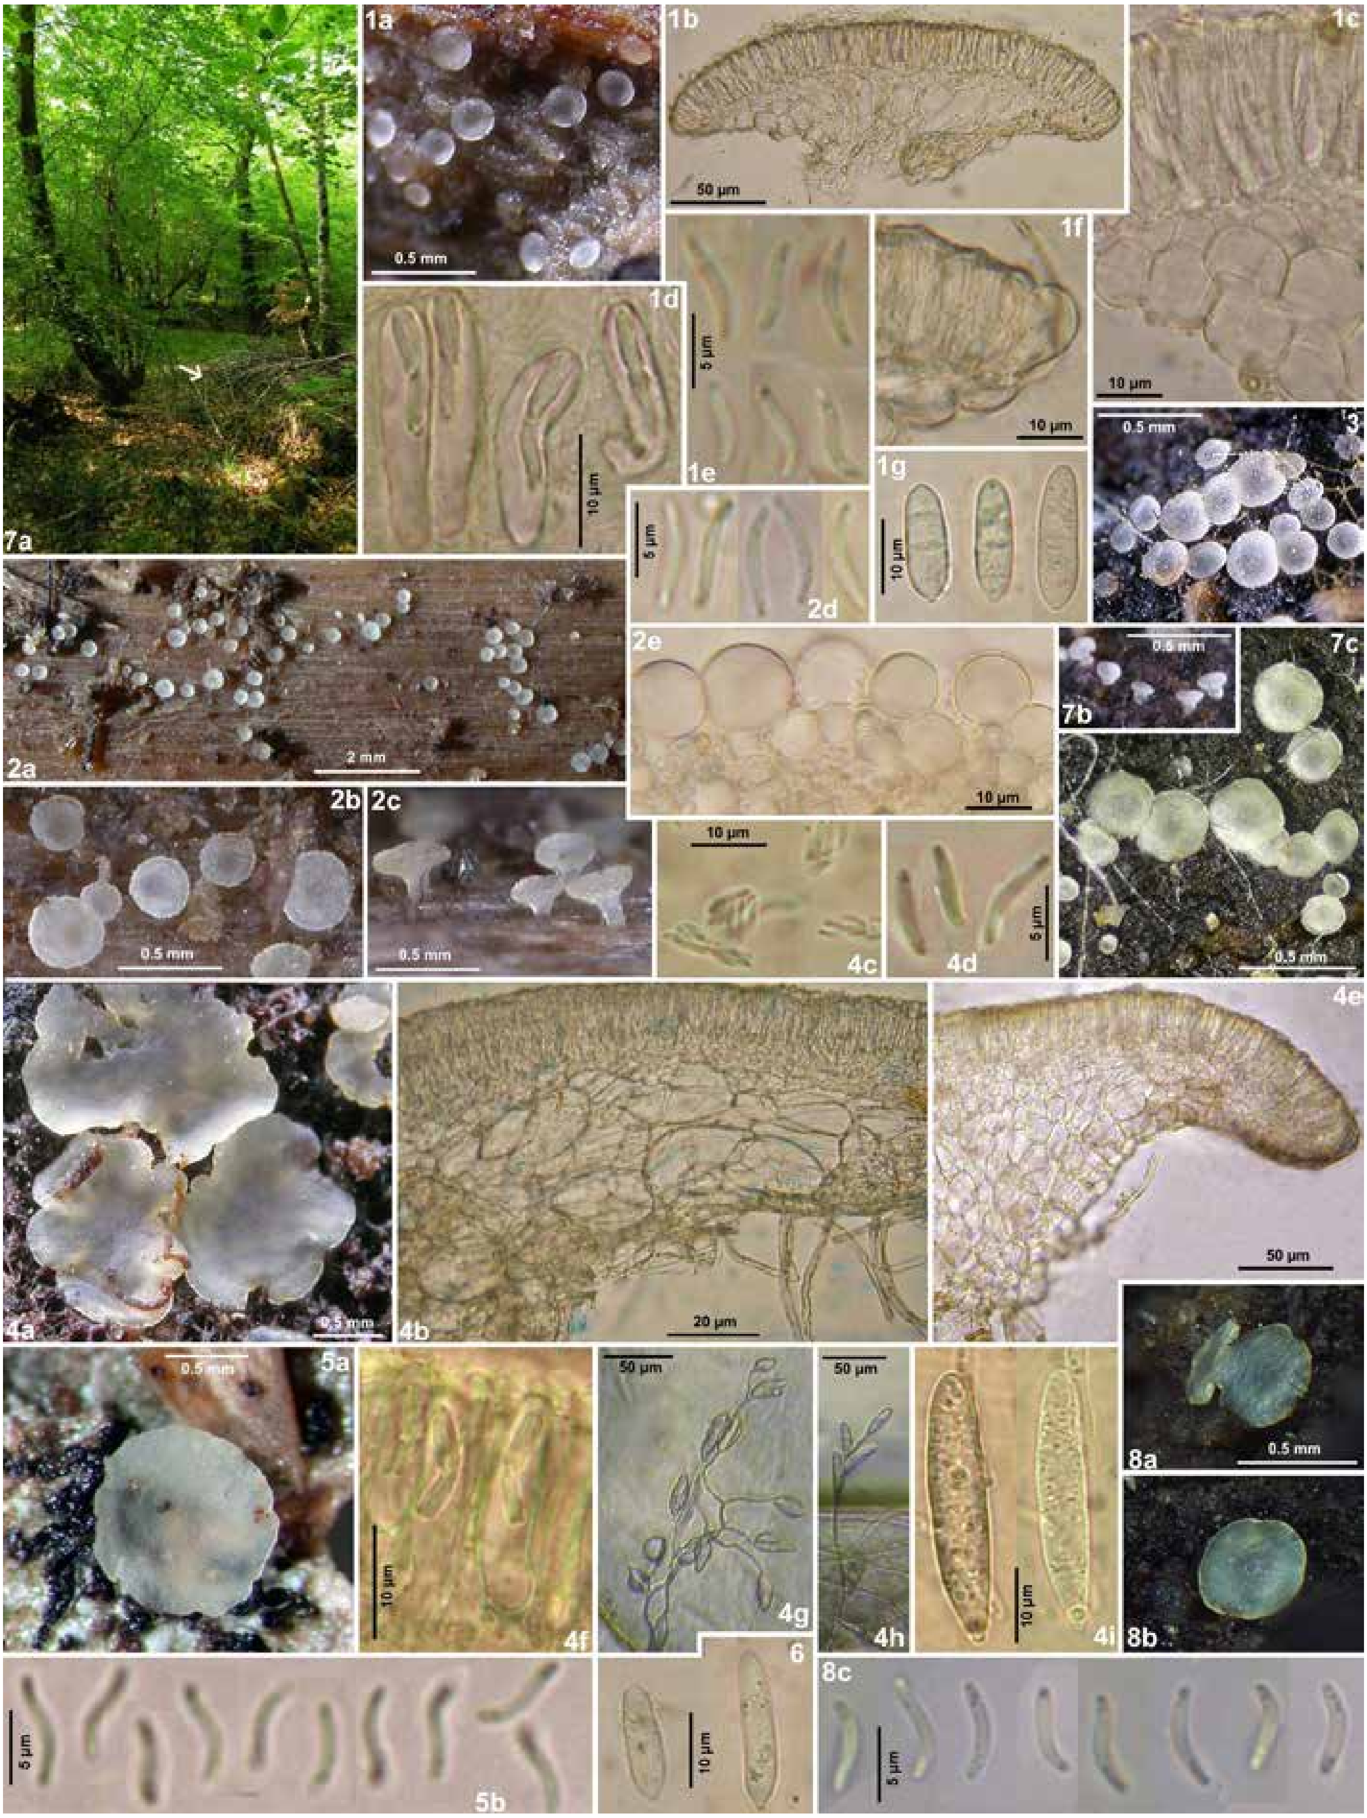

Plate 90. **1–8**: *Hyalorbilia tortuosa*. – **7a**. mixed mesosubmediterranean (mesotemperate?) *Fagus* forest; **1a**, **2a–c**, **3**, **5a**, **7b–c**, **8a–b**. fresh apothecia; **4a**. rehydrated apothecia; **1b**, **4e**. apothecia in median section; **1c**, **g**. marginal part of apothecium in median section; **2e**. margin in top view; **4b**. apothecium at lower flanks (median section); **1d**, **4f**. asci and paraphyses; **1e**, **2d**, **4c–d**, **5b**, **8c**. ascospores; **4g–h**. conidiophores; **1g**, **6**. conidia from substrate; **4i**. conidia from culture. – Living state, except for **4i** right & **6** (in KOH, **4i** right: same conidium as left, SCBs disappeared). – **5a–b**: phot. TMUE S050910T4: Taiwan, on indet. angiosperm; **6**. H.B. 5902b: Japan, Honshu, on *Alnus*; **7a–c**. H.B. 9485: France, Deux-Sèvres, on *Fagus*; **8a–c**. TFC Mic. 23527: Tenerife, on *Myrica faya*.

subtropical specimens studied in the living state, the spores contained 2–3 not or slightly larger SBs near each end (Pls 89: 5; 90: 5b, 8c).

A sample from Germany on *Populus* wood (IVV: H.B. 10202) is not included because of rather short and only sometimes helicoid spores of *4.7–6.2 × (0.8–)0.9 µm and rather short asci of *16–23 × 4–5 µm. *H. oreadum* and *H. japonica* differ from it in never helicoid spores, *H. oreadum* also in much wider spores and narrower marginal cortical cells.

Anamorph. The conidia are cylindric-ellipsoid, with obtuse ends and (1–)3(–4) septa, whereas those of the similar *H. citrina*, *H. fagi*, and *H. helicospora* are distinctly longer and narrower, fusoid to fusiform, with tapered ends and 3–5 or more septa. The observed conidiophores of *H. tortuosa* grew out of the ascocarps placed at the lid of a Petri dish. Conidia from natural substrate (wood and *Trametes*, Pl. 90: 1g, 6) showed a similar shape and number of septa as those from culture (holotype on *Phellinus*, Pls 89: 1i; 90: 4i), but were distinctly smaller. However, a single conidium found in the holotype near apothecia had the large size seen in the culture. No anamorph was so far observed in specimens from subtropical to tropical evergreen forests in southeastern Asia and from the laurel forest in Macaronesia.

Dactylella zhongdianensis resembles the anamorph of *H. tortuosa* quite well with its 17.5–35 × 5–10 µm large, mainly 3-septate conidia borne on branched conidiophores. Yet, a molecular analysis placed this species in *Dactylella*, distant from *Brachyphoris* (Chen et al 2007a/b, see also under *Orbilia zhongdianensis*, p. 1472). *H. polypori* has a very similar anamorph which differs from that of *H. tortuosa* in larger, especially wider conidia.

Phylogeny. A sequence was gained from apothecia of a sample from the Netherlands (on *Quercus* bark, IVV: S.H. 868, apothecia small, spores *6.5–7.5 × 1.1–1.2 µm), comprising SSU (without S1506 intron), ITS, and LSU. The strain clustered in our combined analysis (Phyl. 6) weakly supported with *H. berberidis*. It shows a minimum ITS distance of 15% to *H. berberidis* (8.3% in LSU D1–D2) and ~20% to *H. helicospora* and *H. inflatula* (8–9% in LSU). Various environmental strains clustered in the ITS analysis unsupported and with high distance with *H. tortuosa* (H6–H12), the closest being that from Minnesota (H7, ITS distance 18.5%).

In the SSU V7–V9 *H. tortuosa* fully concurs with *H. berberidis*, while other available *Hyalorbilia* sequences differ in the V8–V9 region by 1–5 nt, the closest being *H. inflatula* (H.B. 9080 & 9915). *H. tortuosa* is unique within *Hyalorbilia* in the Orb5.8s3F primer region, but concurs here with some groups of *Orbilia* (Tab. 18). Also in the first 4 nt of ITS2 (ATTA) it is unique within *Hyalorbilia* but concurs with *Lilapila* and various *Orbilia* species (Tab. 20).

Ecology. *Hyalorbilia tortuosa* was found on rotten wood and bark of hygric branches of angiosperm trees but also on perennial polypores. Collection sites are scattered in atlantic to subcontinental, hemiboreal to mesotemperate or mesosubmediterranean humid, planar to colline central Europe, cold-temperate humid lowlands of eastern North America, cold-temperate humid continental highland of Japan (central island), and thermo- to lower mesomediterranean subhumid to humid laurel forests (*Lauro novocanariensis-Perseetum indicae*) of Macaronesia. The collection on *Castanea* was in a degraded woodland with *Erica arborea* in the lower laurel forest zone (Monte de la Esperanza). Collections from southeastern Asia are from subtropical to tropical humid (winter-dry) evergreen forests (China) and tropical rainforests in northern Thailand and southern Vietnam.

Specimens included. **NETHERLANDS**: **Utrecht**, 6 km SSE of Utrecht, 2 km N of Houten, Nieuw Wulven, 0 m, branch of *Quercus*, on bark, 28.VI.2016, E. Osieck, vid. S. Helleman (S.H. 868, doc. vid., sq.: KY419192). —**FRANCE**: **Champagne-Ardenne**, **Marne**, 8 km E of Reims, 1 km SW of Berru, Bois de Berru, 220 m, on *Fuscoporia* (?)*ferruginosa* on branch of *Fraxinus excelsior*, 11.IX.2004, F. Hyalorbilia fagi E. Weber, Baral & J.W. Guo, **sp. nov.**, MB 813473 — Pls 91–93, Map 11

?= *Calloria chrysocoma* var. *microspora* Sacc., Michelia 2 (8): 571 (1882)
  ≡ *Orbilia chrysocoma* var. *microspora* (Sacc.) Sacc., Syll. Fung. 8: 624 (1889)
?= *Hyalinia inflatula* var. *lonicerae* Rehm in Straßer [as '*inflata*'], Verh. K. K. Zool.-Bot. Ges. Wien 60: 472 (1910)
  ≡ *Orbilia inflatula* var. *lonicerae* (Rehm in Straßer) Sacc. & Trotter, Syll. Fung. 22: 723 (1913)

Etymology: *fagi*, *lonicerae*: named after the substrate of the type; *microspora*: small spored.

Typification: Germany, Tübingen, branch of *Fagus sylvatica*, 23.VII.2005, E. Weber & H.O. Baral (ex H.B. 7847a, M-0276407, holotype of ***Hyalorbilia fagi***). — USA, New Jersey, Newfield, on wood and bark, undated, J.B. Ellis (Ellis n. 64 et 3547, type of ***Calloria chrysocoma* var. *microspora***, not located). — Austria, Ybbsitz, on decorticated branch of *Lonicera*, undated, P. Lambert (type of ***Hyalinia inflatula* var. *lonicerae***, not located).

Latin diagnosis: Hyalorbiliae inflatulae *similis sed ascosporae distincte curvatae, plerumque helicoideae.*

Description: — **TELEOMORPH**: **Apothecia** fresh (0.15–)0.3–0.8(–1) {5} or (0.5–)1–2.5(–4) {16} mm diam., 0.12–0.25(–0.32) mm high [receptacle 0.07–0.15 → 0.03–0.06(–0.1) mm], whitish or pale to light cream-chlorinaceous-yellowish, ± translucent, round, slightly to strongly lobate when large, somewhat gelatinous, scattered to sub- or densely gregarious; disc young cupulate, remaining slightly to medium concave or often becoming flat, margin thin, smooth; with ± distinct obconical stipe 0.05–0.17 × 0.1–0.5 mm, superficial; dry light to bright yellow-chlorinaceous-ochraceous, sometimes turning sulphur-yellow or red-brown. **Asci** *18–29(–36) × (3.8–)4–4.8(–5) µm {8}, †(13–)15–22(–26) × (2.8–)3.2–4(–4.7) µm {15}, 8-spored, spores mostly *4-seriate in two superimposed bundles, pars sporifera *10–13 µm long; **apex** (†) hemispherical; **base** unstalked, with croziers {11}. **Ascospores** *((3.5–))(4.3–)4.7–6.5(–7)((–8)) × (0.8–)1–1.2((–1.5)) µm {12}, †((4–))4.5–6.5(–7.5) × (0.7–)0.8–1.1(–1.2) µm {12}, (sub)cylindric to narrowly fusoid, sometimes fusoid-clavate, slightly to medium helicoid, sometimes only slightly inequilateral, rarely sickle-shaped; **SBs** *0.2–0.3(–0.4) µm {4}, globose, 1(–2) at each end. **Paraphyses** apically uninflated, rarely slightly capitate, terminal cells *14.5–24 × (2–)2.5–3.5(–4.3) µm {5}, lower cells *(3–)4–7(–9) × 2–3.5(–4) µm {5}. **Medullary excipulum** 15–30 µm thick, of medium dense to dense textura globulosa-angularis-prismatica, not or usually slightly to medium, sometimes strongly gelatinized, ± sharply delimited. **Ectal excipulum** of thin-walled to slightly gelatinized [common walls †1–1.5(–2) µm], horizontally oriented t. prismatica or t. globulosa-angularis from base to margin, 30–60 or up to 150–250 µm thick near base, cells */†(15–)25–60(–80) × (8–)15–30(–40) µm {4}; 25–40 µm thick at flanks, 10–20 µm near margin, marginal cortical cells */†(5–)7–15(–23) × (2.5–)4–8 µm {11}, in surface view (2.5–)4–10(–12) {11} or 10–18 µm wide {2}, ± thin-walled (†0.2–0.5 µm). **Anchoring hyphae** ± abundant, long radiating, */†3–6 µm wide (up to 6–8.5 µm at insertion), walls 0.3–1(–2) µm thick {13}. **SCBs** rarely present in ectal excipular cells from lower flanks up to margin (Pl. 76: 1d), strongly refractive, ring-shaped, ~1.5–2 µm diam.; **VBs** in paraphyses subhyaline to chlorinaceous, low- to rather high-refractive, globose to elongate. **Exudate** over paraphyses and excipulum 0.2–0.4(–1) µm thick, finely granular-cloddy, also nearly smooth. — **ANAMORPH**: brachyphoris-like (from ascocarp in Petri dish {2} and from natural substrate {8}). **Conidiophores** *13–50 × 3.3–3.7 µm when unbranched, 1–2-septate in lower part, up to ~110 µm long when repeatedly branched, *(1–)1.3–1.7 µm wide at the tip, conidia formed terminally. **Conidia** fusoid to fusiform, *((24–))(30–)35–55(–67) × (4–)4.5–5.5(–6) µm {6}, †(32–)37–54(–58) × 4–5.3(–5.7) µm {4}, (1–)3–6(–8)((–10))-septate {9}, with many small peripheral LBs, in centre often with groups of 0.4–1.4(–1.7) µm large, globose, strongly refractive **SCBs** {7} (living state); also a few small 1-septate conidia seen (*13–17 × 3–3.5 µm {2}).

Habitat: collected on the moist ground, mostly decorticated, 1.5–15 cm thick branches and logs of *Aesculus hippocastanum* {1}, *Alnus incana* {1}, *Betula* sp. {1}, *B. pubescens* {1}, *Carpinus* sp. {1}, *Fagus sylvatica* {9}, *Fraxinus* sp. {1}, *Picea abies* {1/1}, *Populus* sp. {1}, *Quercus cerris* {1}, *Robinia pseudoacacia* {2}, *Rosa canina* {1}, *Sorbus domestica* {1}, ?*Ulmus* sp. {1}, indet. resupinate basidiomycete {2}, *Ischnoderma benzoinum* {1}, *Jackrogersella* ?*multiformis* {1}, old pyrenomycete {2}, on 0.5 mm or much deeper medium to usually strongly decayed wood {17} or bark (periderm and bast) {8}, on underside and laterally. **Associated**: *Calycina citrina* {1}, *Ceriporia* sp. {2}, *Chaetosphaeria* sp. {1}, *Hyaloscypha leucostigma* {1}, *Lasiosphaeria hirsuta* {2}, *L. ovina* {1}, *Mollisia rosae* {1}, *Nectria* sp. {1}, *Nemania chestersii* {1}, *Orbilia dryadum* {1}, *O. eucalypti* {1}, *O. nemaspora* {1}, *O. oxyspora* {1}, *Psilocistella quercina* {1}, *Rhizodiscina lignyota* {1}, *Scutellinia* sp. {1}, *Tubeufia cerea* {2}, *Trichoderma* ?*sinuosum* {1}, *Trichosphaeria notabilis* {1}. **Desiccation tolerance**: only excipular cells viable after 12 days. **Altitude**: 50–1350 m a.s.l. (Europe), 5–900 m (Caucasus). **Geology**: Keuper (marl and sandstone), Jurassic-Cretaceous sandstone and dolomite, Tertiary molasse, Miocene lime- and marlstone, Pleistocene calcareous till. **Phenology**: (II–)VI–X.

Phenology of *H. fagi*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
0	1	0	1	0	2	9	6	1	4	0	0

Taxonomic remarks. *Hyalorbilia fagi* resembles the variant of *H. inflatula* with flatter apothecia in macroscopical appearance, but is rather easily recognized in most cases, at least within Europe, by its distinctly curved, somewhat helicoid ascospores. The similar *H. tortuosa* differs in slightly longer and narrower, more distinctly helicoid spores and particularly in ellipsoid-oblong conidia, often also in much smaller apothecia. *H. helicospora* differs in longer spores containing 2–4 SBs in each half, and smaller, desiccation-tolerant apothecia. The tropical *H. citrina* differs in thick-walled excipular cells forming often teeth or lobes at the margin, and in narrower asci and spores, and *H. arcuata* in sickle-shaped, only exceptionally slightly helicoid spores.

Variation. Considerable variation among the collections of *H. fagi* was noted in width of the marginal cortical cells. Most included collections had a medium width of about 4–8 µm, but in two samples the cells were extraordinarily inflated (10–18 µm wide in surface view, Pls 92: 6b; 93: 3d, f–g). As an exception, one of these samples (Pl. 93: 3) showed truncate teeth-like protrusions at the margin of some apothecia, formed by rather large cells similar as in *H. citrina* but thin-walled. The medullary excipulum was usually not or only slightly to medium gelatinized in the collections from central Europe, but strongly so in that from Italy (Pl. 92: 7) and in one from Caucasus (TAAM 109518).

A collection on wood of *Fagus* from Tübingen (Pl. 92: 8) deviates by more concave apothecia with an incurved margin composed of a textura porrecta of very narrow cells (†2.5–4 µm, surface view 2.5–5 µm), in combination with rather long asci (*25–36 × 4.2–4.8 µm) and spores (*6–8 × 1–1.1 µm). It resembles the cupulate variant of *H. inflatula* with narrow marginal cells, from which it deviates in its distinctly helicoid spores. It is included in the description because a sequence of it falls to a typical collection of *H. fagi* from the same area and substrate (Pl. 92: 3). Cupulate apothecia occurred also in specimens from Bretagne and Canada, but the marginal cells seem to be broader here. The spores were sometimes only slightly curved in the latter two samples. Nevertheless, we have also included the Bretagne sample in the scope of *H. fagi*.

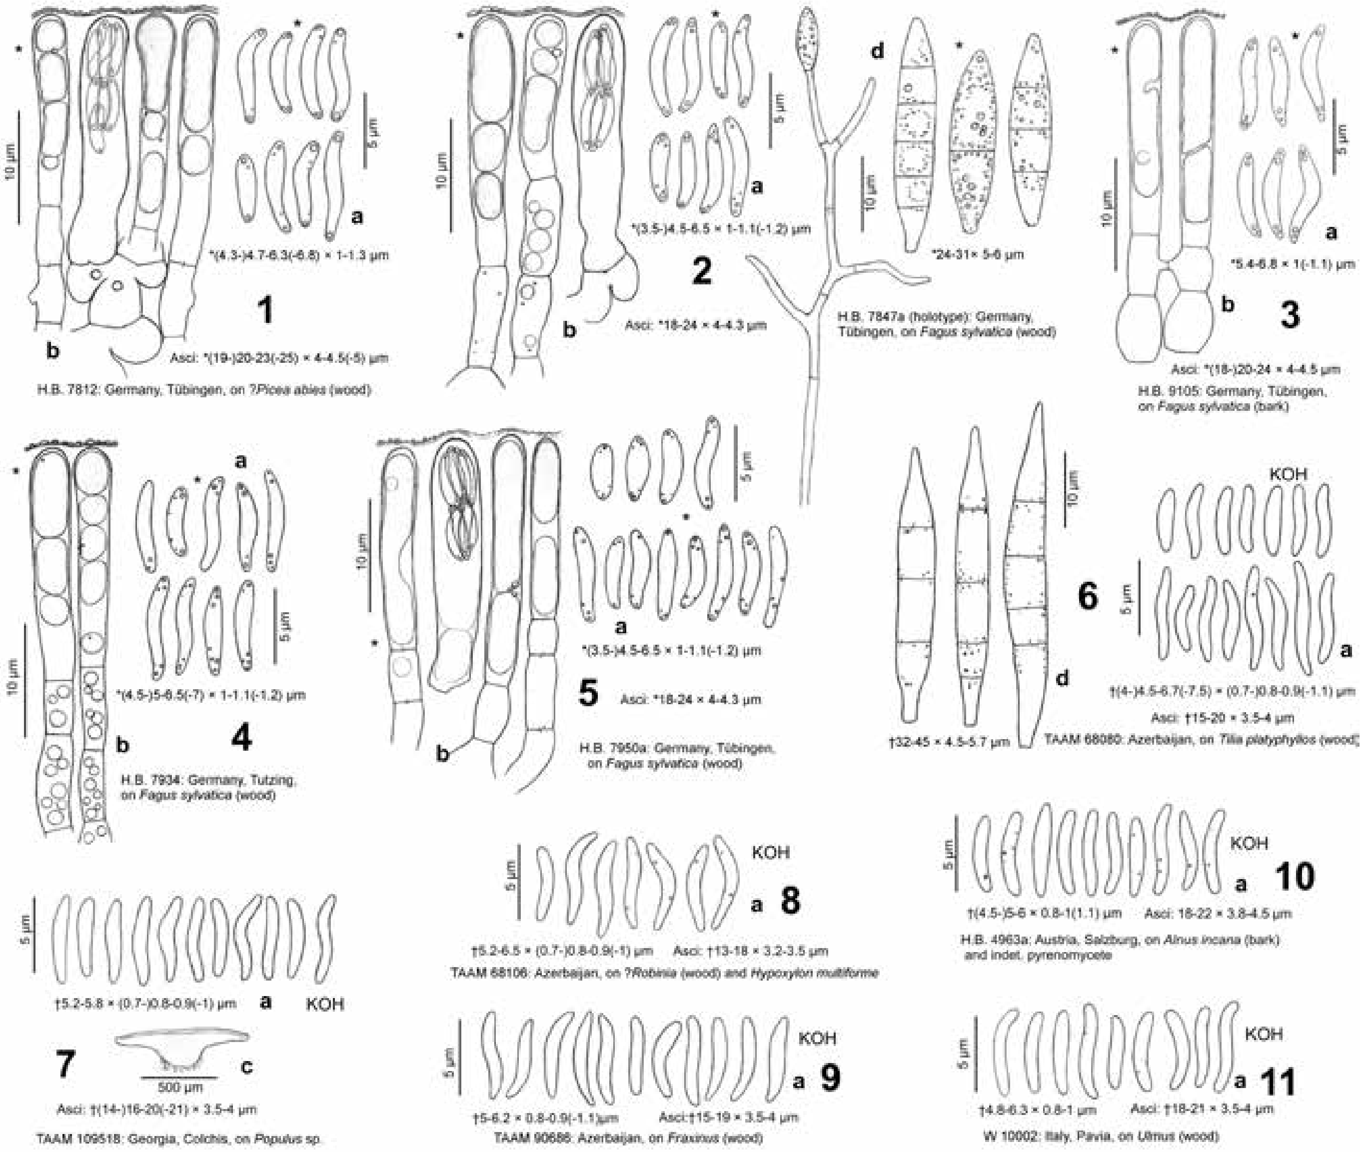

Plate 91. **1–11**: *Hyalorbilia fagi*. – **a**. ascospores; **b**. asci (with croziers) and paraphyses; **c**. apothecium in median section; **2d**. conidiophore and conidia from culture, **6d**. conidia from substrate.

Not included collections. The four North American samples closely concur with European *H. fagi*, based on the available morphology. However, because of strongly deviating molecular data in two of them (see below) we have excluded also those from eastern Asia and restricted the above description on samples from Europe. Yet, also a Slovakian sample (IVV: A.P. 19/27) is genetically very distant, although its ± strongly helicoid spores of *5.8–7(–7.7) × 1–1.1 µm resemble those of *H. fagi* or *H. tortuosa*, while the associated conidia exclude the latter and resemble with its 6–10 septa more those of *H. inflatula*.

In China, J.W. Guo (pers. comm.) often found the ectal excipulum at the flanks to be composed of rather globose cells. He believed this to be a character separating *H. fagi* from *H. tortuosa* (for photos of his sections showing globose excipular cells see IVV: th4b-28 & zcw-j-3). We have actually also sometimes seen European *H. fagi* with quite isodiametric excipular cells at the flanks (Pl. 92: 1c, 2b), but our specimens of *H. tortuosa* had likewise rather broad, sometimes almost isodiametric cells. One of these Chinese collections of *H.* cf. *fagi* (zcw-j-3, Pl. 93: 4) seems to concur well with European *H. fagi* and was even said to grow on a branch of *Fagus*. Two others for which J.W. Guo provided us photos deviate in wider spores with a falcate instead of helicoid shape (*5–6.5 × 1.1–1.5 µm, Pl. 93: 5–6). Although a few falcate spores were seen in European samples (see Pl. 91), these refer at least in part to helicoid spores seen in profile view. Predominantly falcate but narrower spores were noted in some other south Chinese samples which are, therefore, tentatively assigned to *H. arcuata* (Pl. 101: 7–8).

Type studies. Type material of ***O. chrysocoma* var. *microspora*** (USA, New Jersey, Newfield, on wood and bark, J.B. Ellis n. 64 & 3547) could not be located in PAD, PAL, W (no response from TO). The yellow, membranaceous apothecia and the nearly unstalked asci (20–26 × 5 µm) with cylindrical, curved spores of 5–6 × 0.5 µm point to a *Hyalorbilia*. A specimen in W under that name ([Italy, Pavia,] in horto botanico ticinensi, on ring-pored wood, F. Cavara, possibly authentic) was studied and found to be conspecific with *H. fagi* (Pls 91: 11; 92: 7). Rehm (1891: 456) referred a specimen with much shorter spores (3–3.5 × 0.5 µm) to this variety (Ostpreußen, Cladow, log of *Fagus*, H. Sydow). '*O. chrysocoma* var. *macrospora*' in McNabb (1973: 501) is a misspelling for *microspora*.

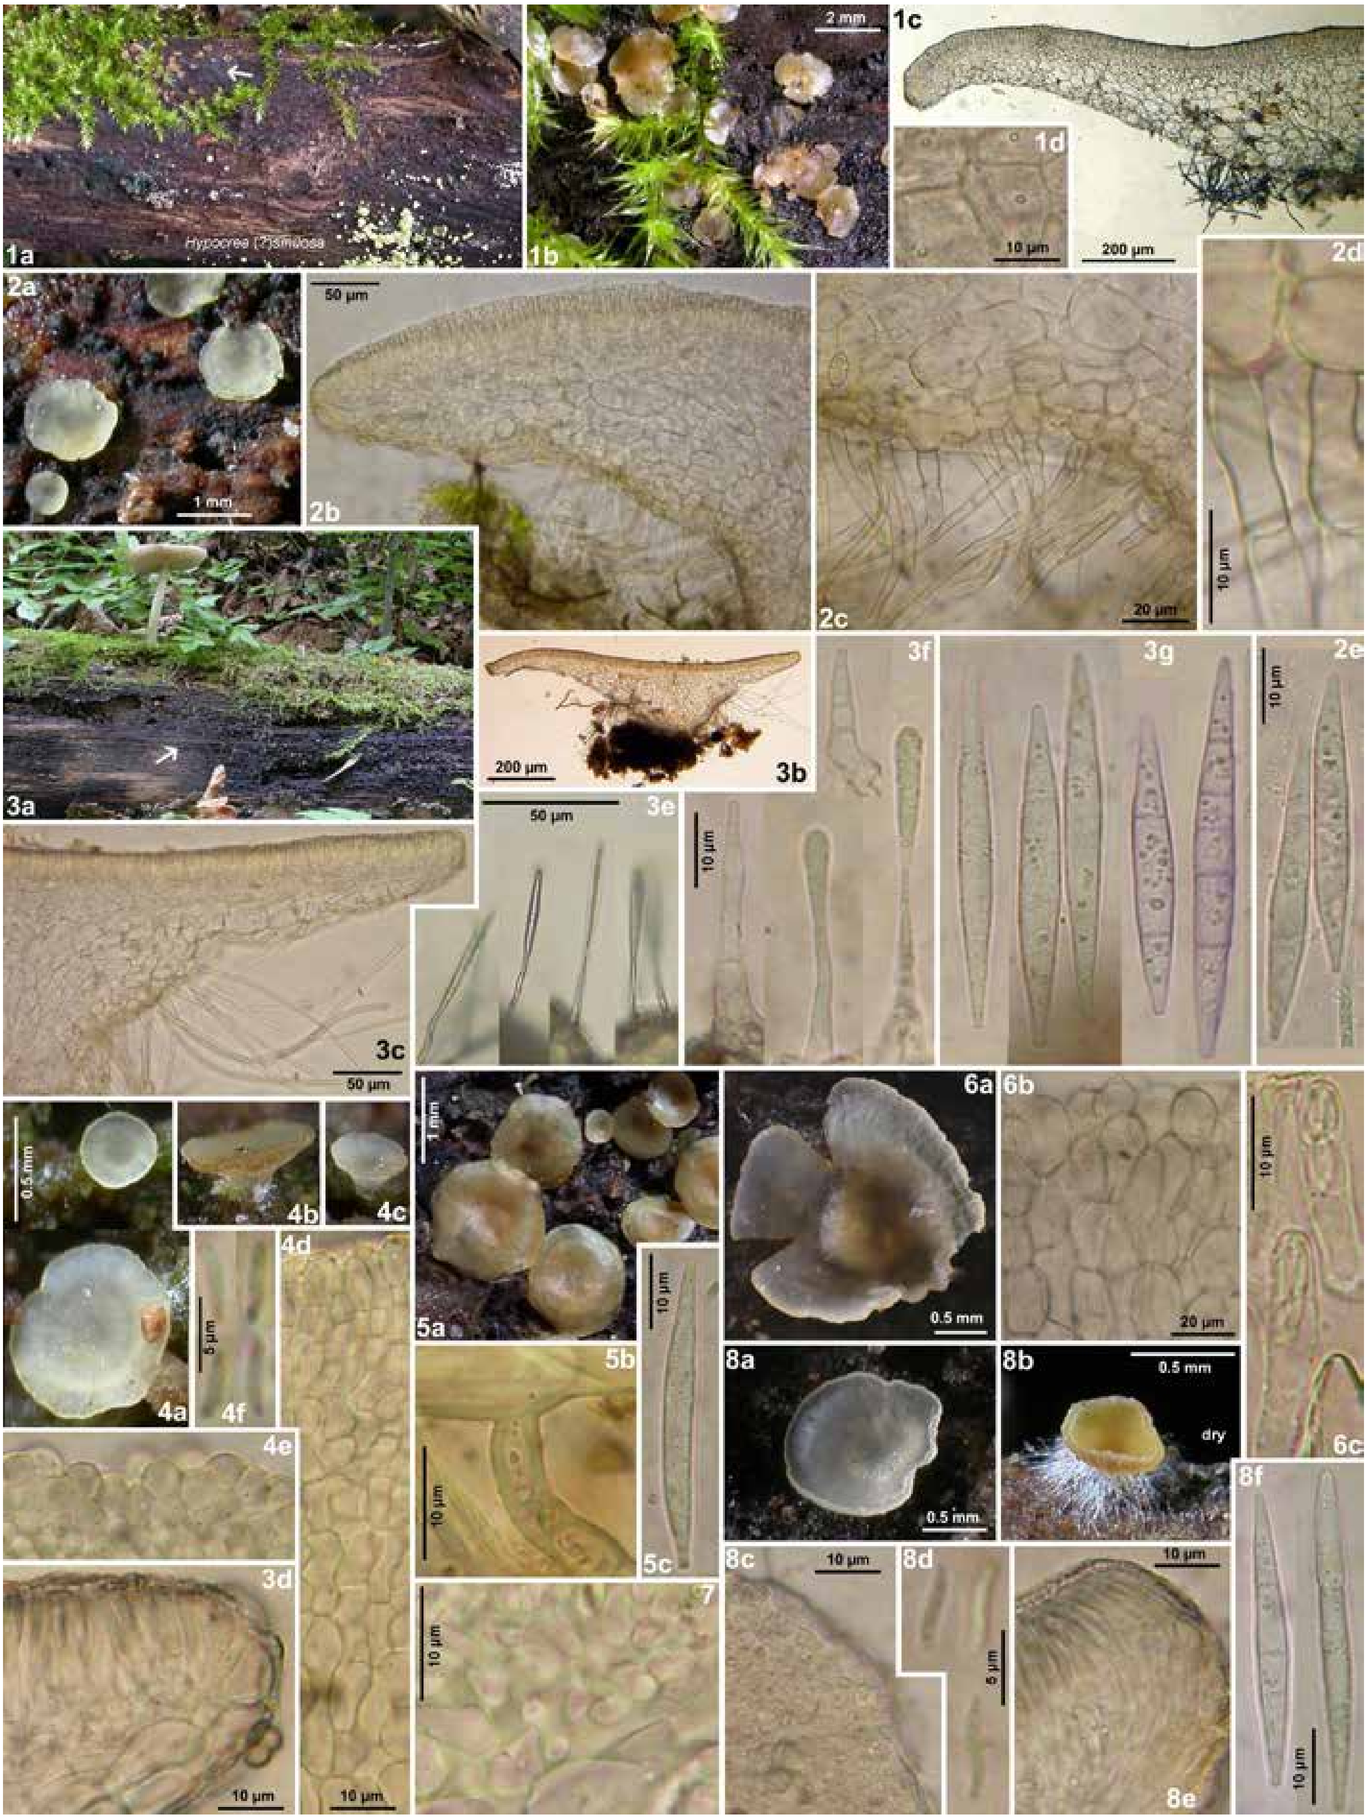

Plate 92. **1–8**: *Hyalorbilia fagi*. – **1a**, **3a**. decorticated branch/log of *Fagus sylvatica*; **1a–b**, **2a**, **4a–c**, **6a**, **8a**. fresh apothecia; **5a**. rehydrated apothecia; **8b**. dry apothecium; **1c**, **2b**, **3b–c**. apothecia in median section; **3d**, **8e**. id., marginal ectal excipulum; **4d–e**, **6b**, **8c**. id., in external or top view; **2c**. median section of basal ectal excipulum, with anchoring hyphae; **7**. gelatinized medullary excipulum; **1d**. ring-shaped SCBs in excipular cells; **2d**, **5b**. anchoring hyphae; **6c**. asci; **4f**, **8d**. ascospores; **3e–f**. conidiophores with mature/young conidia; **2e**, **3g**, **5c**, **8f**. mature conidia. – Living state, except for **8d** (in H_2O), **5b–c**, **7**, **8c** (in KOH). — **1a–d**. H.B. 7847a (holotype): Germany, Tübingen, on *Fagus*; **2a–e**. H.B. 7934: Germany, Tutzing, on *Fagus*; **3a–g**. H.B. 9105a: Germany, Tübingen, on *Fagus*; **4a–f**. H.B. 8224b (topotype): Germany, Tübingen, on *Fagus*.

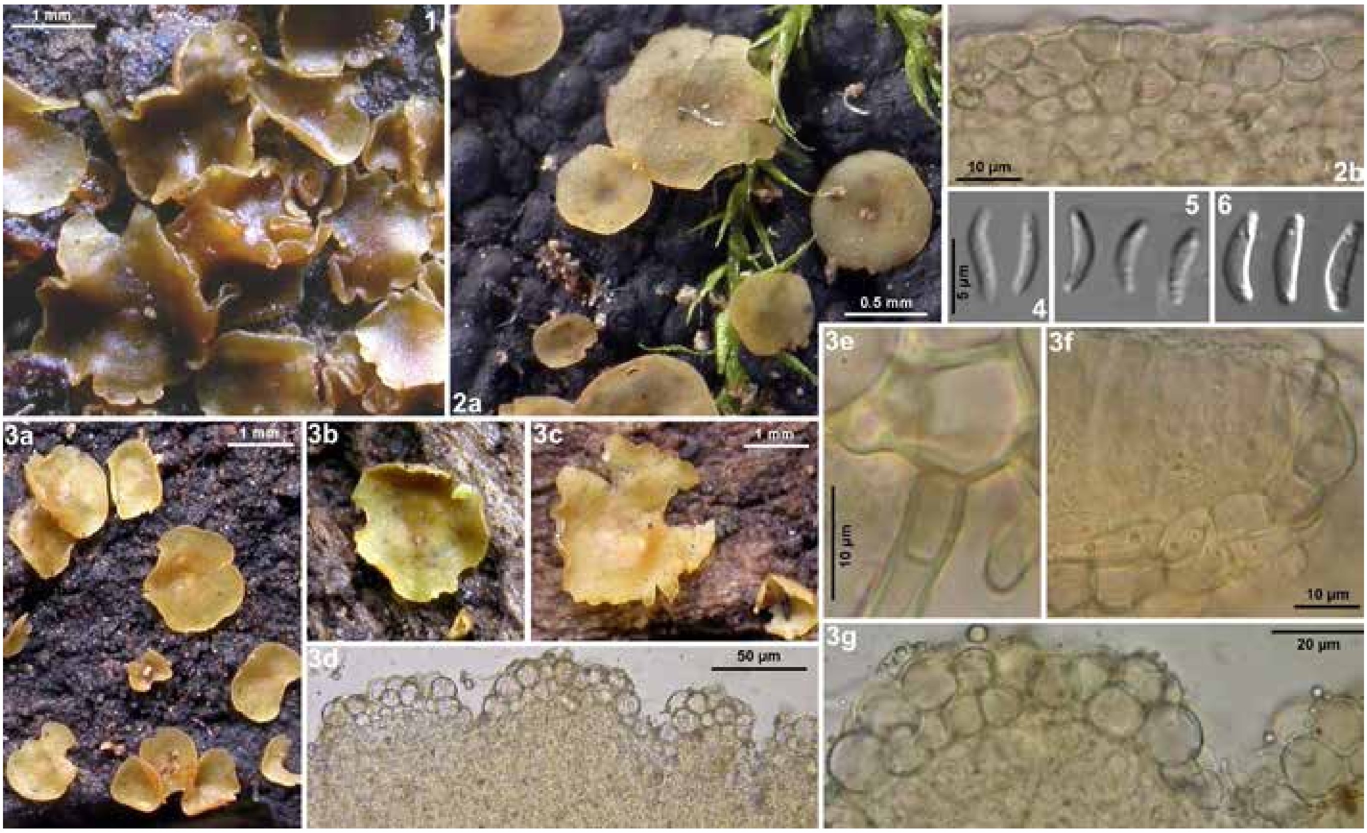

Plate 93. **1–4**: *Hyalorbilia fagi*; **4–6**: *H.* cf. *fagi*. – **1**, **2a**, **3a–c**. rehydrated apothecia; **3f**. marginal part of apothecium (median section); **2b**, **3d**, **g**. margin in top view; **3e**. anchoring hypha; **4–6**. ascospores. – Dead state (in KOH, **4** in H_2O) except for **5–6**; **3b** illuminated with Luxeon-LED. – **4–6**: phot. J.W. Guo (DIC). — **1**. TAAM 68080: Azerbaijan, on *Tilia*; **2a–b**. TAAM 68106: ibid., on *Hypoxylon*; **3a–g**. TAAM 90686: ibid., on *Fraxinus*; **4**. J.W.G. zcw-j-3: China, Sichuan, on *Fagus*; **5**. J.W.G. jzh-2: ibid., on indet. angiosperm; **6**. J.W.G. th4b–28: China, Yunnan, on indet. angiosperm.

Type material could also not be located for ***Hyalinia inflatula* var. *lonicerae*** in PAD and S (on decorticated branch of *Lonicera*, Ybbsitz, Niederösterreich, leg. P. Lambert). The original description obviously refers to a *Hyalorbilia*, perhaps *H. fagi*: apothecia yellowish-hyaline, with thin acute margin, ectal excipulum prosoplectenchymatous, subgelatinous, asci 20–25 × 4 µm, with rounded apex, spores 5–7 × 1–1.2 µm, subcurvate, 1-guttulate at each end, paraphyses scarcely inflated.

Anamorph. In H.B. 7847a and H.B. 9105 we obtained unbranched or branched conidiophores forming conidia, growing out of the ascocarps that hung at the lid of a Petri dish, and in a total of seven further collections fusoid conidia occurred on the natural substrate. The anamorph closely resembles that observed in *H. inflatula*, but the conidia tend to be shorter and to have fewer septa, although the values strongly overlap. This appears to exclude conspecificity with '*Dactylella*' *passalopaga*. In *H. lignatilis* the conidia are a bit shorter and narrower than in *H. fagi*. However, conidial size varied rather strongly among the collections of *H. fagi*, being shortest in H.B. 7847a (holotype, Pl. 91: 2d), longest in H.B. 9105a (Pl. 92: 3g), and rather narrow in H.B. 8224b (topotype, Pl. 92: 8f) (all from Tübingen).

Phylogeny. Three sequences gained from apothecia of central European *H. fagi* were available: H.B. 9105a (SSU, ITS, LSU), H.B. 8224b (ITS), and H.B. 9724 (ITS+LSU). In the ITS region they differ by only 1 nt in H.B. 8224b (but the ITS of H.B. 9105a lacks over 200 nt, especially in ITS1), while a collection from Boston (North America, H.B. 9995) differs by 7–7.5% from them, suggesting a different species. A recent sample under the name *H. lunata* from Florida in GenBank (MH211887, ITS) coincides with *H. fagi* from Boston with a 0.5% distance (not shown in phylograms), but both differ from *H. lunata* H.B. 9113 from China by 5.2–5.5%. H.B. 9724 and the Boston sample include the S1506 intron, in which the distance is even 14.3% in the overlapping ~280 of 339 nt (the other two sequences do not cover the intron region). In the LSU the two central European samples differ in the overlapping 403 nt of the D1 domain by 1 nt, but also *H. citrina* (H.B. 9661) and *H.* '*polypori*' (B.L. 288) differ from them by only 1–2 nt in that region. In the entire LSU (D1–D2) the distance between these three taxa is around 1.5% (4 nt, the formation of two subclades for the two *H. fagi* samples in Phyl. S5 is due to incomplete D2 in H.B. 9105a).

When analysing ITS (Phyl. 5) or ITS+LSU (Phyl. 6), *H. fagi* clustered with *H. citrina*, *H. japonica* and *H. lunata* (B.L. 6416) in a strongly supported clade, which is referred here to as *citrina-fagi* clade and forms a subclade within the *inflatula-polypori* clade. The distances within the *citrina-fagi* clade range at 4.5–10.5%, whereas the distance to *H. inflatula* is much higher. The not included *H.* aff. *fagi* from Slovakia (S1506 intron, ITS) shows a high ITS distance of 22% to *H. fagi*. When analysing ITS or the intron (both not shown) it clustered with a 16–20% ITS distance more near *H. inflatula* s.l.

Ecology. *Hyalorbilia fagi* was found on rotten wood (rarely bark) of hygric branches and logs of angio-, rarely gymnosperm trees, often on *Fagus*, exceptionally on perennial basidiomycetes or pyrenomycetes. The species was mainly found from June to October, but sometimes in spring. European collections derive from atlantic to subcontinental, warm- to cold-temperate and hemiboreal humid regions, but also from mesotemperate to suprasubmediterranean humid Caucasus at border to Asia. The not included eastern Asian samples were on branches of mostly unidentified trees in orotemperate to subtropical humid (winter-dry) broad-leaved, mainly evergreen forests of southern China (J.W. Guo pers. comm., once on a deciduous Asian species of *Fagus*), that from central Asia (Irkutsk) in a continental, boreal humid forest, and those from northeastern North America in continental, hemiboreal to cold-temperate humid forests.

Specimens included. **POLAND**: **Greater Poland**, 9 km WSW of Śrem, 2 km ENE of Rąbiń, Uroszysko Rąbiń, 100 m, stump of *Betula*, on wood, 25.VIII.2007, A. Kujawa & P. Hyalorbilia helicospora Baral & G. Marson, **sp. nov.**, MB 813474 — Pls 94–95, Map 12

Etymology: named according to the helicoid shape of ascospores.

Typification: Luxembourg, Alzingen, branch of *Quercus*, 22.VII.1993, G. Marson (ex H.B. 4923a, M-0276409, holotype).

Latin diagnosis: *Differt ab* Hyalorbilia fagi *ascosporis longioribus*, *ab* H. tortuosa *ascosporis latioribus*; *habitat in ramis siccis in aere prominentibus differt.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.12–0.8(–1.4) mm diam., in total 0.06–0.17 mm high (receptacle 0.05–0.09 → 0.03–0.05 mm), whitish-greyish to pale (or light) cream-chlorinaceous, turning light reddish-brown with age, translucent, round, slightly gelatinous, subgregarious to gregarious in swarms; disc slightly concave to flat, finally slightly convex, margin thin, scarcely protruding, smooth to finely rough, exterior glabrous; subsessile or with distinct, glassy stipe 0.03–0.1 × 0.08–0.15 mm, superficial; dry light ochre-amber. **Asci** *(16–)20–30(–33) × (4–)4.2–5.2(–6) µm {7}, †(16–)18–24(–26) × 3.4–4.3(–4.7) µm {6}, 8-spored, spores *±4-seriate, sometimes forming two superimposed bundles, pars sporifera *(11–)13–15 µm long, **apex** (†) hemispherical; **base** unstalked, with croziers {5} with or without small to large perforation. **Ascospores** *(5.5–)6–7.5(–8) × 1–1.3(–1.4) µm {12}, †5.3–7.3(–7.8) × (0.8–)0.9–1.2(–1.3) µm {7}, subcylindrical to narrowly fusoid, rarely slightly fusoid-clavate, both ends obtuse (sometimes subacute), slightly to medium helicoid (looking very slightly S-shaped or falcate depending on the viewing direction), with 2–4 globose **SBs** 0.3–0.5(–0.6) µm diam. {8} and 1–2 minute LBs in each spore half. **Paraphyses** apically uninflated to slightly (rarely medium) clavate-capitate, terminal cells *17–27 × (2.5–)3–4(–5.5) µm {2}, †13–20 {2} × 2–3.7 {4} µm, lower cells †4–6 × 1.4–2 µm {1}. **Medullary excipulum** 10–30 µm thick, of medium dense textura intricata-angularis, (very) slightly gelatinized, rather sharply delimited. **Ectal excipulum** of thin-walled, horizontally oriented t. prismatica-angularis from base to margin, 25–70(–120) µm thick near base, cells */†(8–)10–40(–55) × (4–)8–22(–26) µm {4}, common walls †0.3–1.2 µm thick, at flanks 10–25 µm thick, at margin 8–15 µm, marginal cortical cells */†7–20 × (4–)5–9(–11) µm {7}, external wall †0.2–0.3 µm thick. **Anchoring hyphae** sparse to abundant, */†(1.5–)2.5–4.5(–6.5) µm wide, wall *0.2–0.3 µm thick

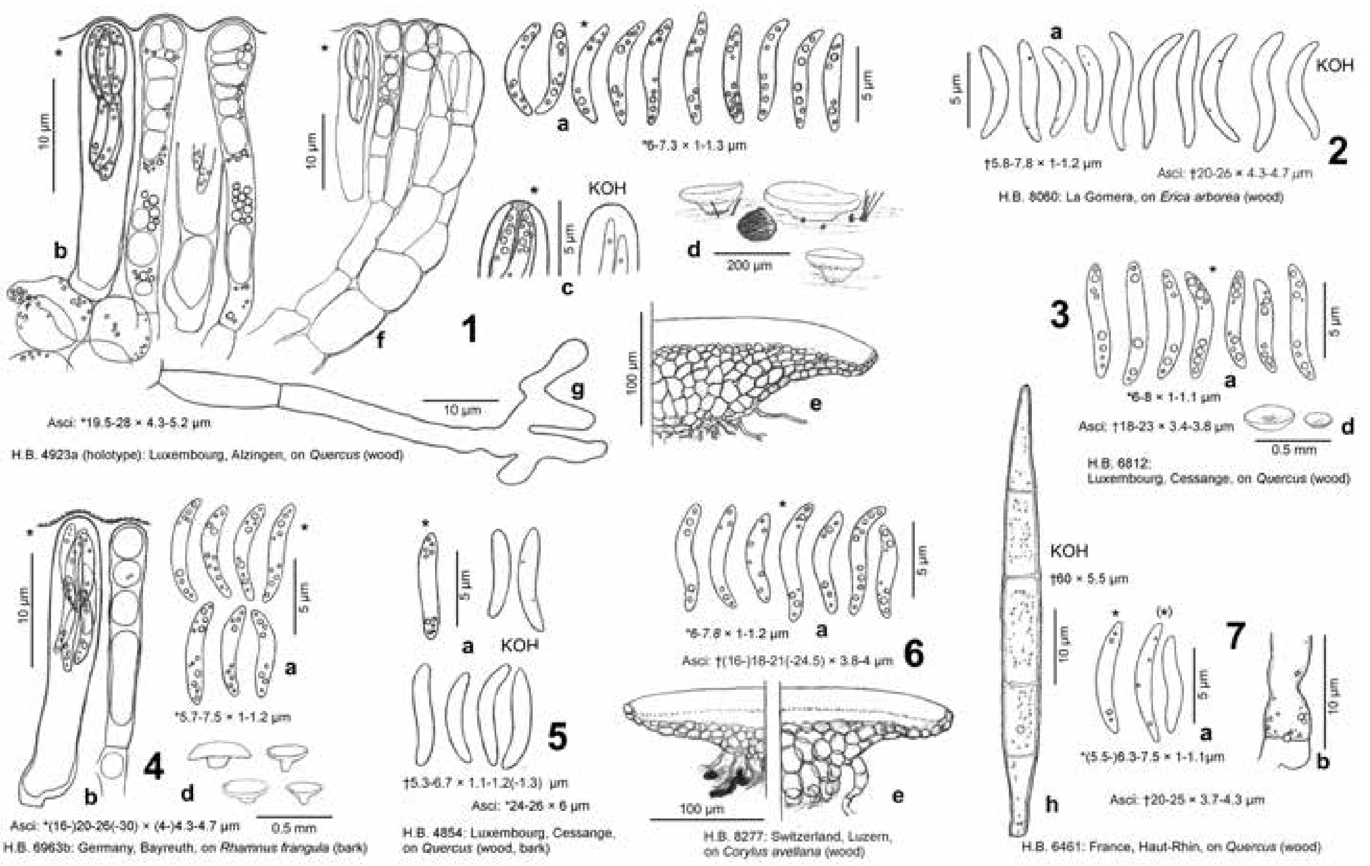

Plate 94. **1–7**: *Hyalorbilia helicospora*. – **a**. ascospores; **b**. asci and paraphyses (**7b**: ascus base with croziers); **c**. ascus apices; **d**. apothecia (moist or rehydrated); **e**. apothecia in median section; **f**. ectal excipulum in median section (margin and mid flanks); **g**. terminally branched anchoring hypha; **h**. conidium from substrate.

{6}. **VBs** in terminal cells of paraphyses slightly to strongly refractive, large, subhyaline to pale chlorinaceous. **Exudate** over paraphyses and excipulum 0.2(–0.3) µm thick, smooth to finely warted or granular. — **ANAMORPH**: brachyphoris-like (presumed, from natural substrate {1}). **Conidiophores** not observed. A single observed **conidium** fusiform, straight, †60 × 5.5 µm, 4-septate.

Habitat: 1–4 m above the ground, also on moist ground (on underside with close contact to soil), corticated or ± decorticated, 15–50 mm thick branches of *Corylus avellana* {2}, *Erica arborea* {1}, *Fagus sylvatica* {1}, *Frangula alnus* {1}, *Ilex aquifolium* {1}, *Quercus* sp. {11}, *Sorbus aucuparia* {2}, on partly very deeply medium to usually strongly decayed wood {17} and bark {4} (periderm {1} & bast {2}), on senescent resupinate basidiomycete {1}, often greyed and with abundant green algae. **Associated**: *Calocera cornea* {1}, ?*Chaetosphaerella* sp. {1}, *Colpoma quercinum* {1}, *Dothiorina tulasnei* {1}, *Mollisia* ?*oblonga* {2}, *M. albogrisea* {1}, *Orbilia arachnovinosa* {1}, *O. cejpii* {1}, *O. eucalypti* {1}, *O. pleistoeuonymi* {1}, *O. tremulae* {1}, *O. vinosa* {1}, *Proliferodiscus pulveraceus* {1}, *Propolis farinosa* {1}, *Resupinatus* sp. {1}, *Rutstroemia firma* {1}. **Desiccation tolerance**: mature asci tolerate desiccation for min. 1 week. **Altitude**: 75–1145 m a.s.l. (temperate Europe). **Geology**: Lower Carboniferous sediment, Buntsandstein, Keuper (Knollenmergel), Lower Jurassic sandstone, Pleistocene calcareous till & loess; granite, gneiss. mica schist, volcanic rock. **Phenology**: III–IV, VII–XII (apparenty throughout the year).

Taxonomic remarks. *Hyalorbilia helicospora* is characterized by more or less distinctly helicoid ascospores with 2–4 SBs near each end, and comparatively small, ± desiccation-tolerant apothecia. *H. sibirica* is only tentatively separated (see p. 375). Four species with more desiccation-sensitive apothecia resemble *H. helicospora* in spore shape: *H. tortuosa* and *H. citrina* differ in narrower spores (*H. citrina* also in shorter spores), *H. fagi* in larger apothecia and shorter spores with only 1(–2) SBs at each end, and *H. arcuata* in falcate spores. *H. juliae* occurs in similar habitats as *H. helicospora* but differs in longer, straight spores. However, the limits between all these species are not always clear.

Variation. The collection from Macaronesia (Pls 94: 2; 95: 4, on *Erica arborea*, with *Proliferodiscus pulveraceus*) deviates from the European samples in larger (0.4–0.8 mm), more intensely pigmented apothecia. It was only studied in the dead state, therefore, no information on the SBs in the spores is available.

Anamorph. A single brachyphoris-like fusoid conidium was observed (Pl. 94: 7h), which concurs with anamorphs of similar *Hyalorbilia* species with curved ascospores, except for *H. tortuosa* which has cylindric-ellipsoid conidia.

Phylogeny. Sequences of *H. helicospora* were taken from apothecia of two samples from Sonneberg (Germany), one from Berchem (Luxembourg), and one from Ardèche (France), all on wood of *Quercus*, comprising S1506 intron, ITS, and LSU (one also S943-intron and SSU V6–V9). In the ITS and LSU (D1–D6), the four strains are identical, and also in the intron only 1 nt deviates in H.B. 9897 (one of the Sonneberg samples) from the other three.

In analyses of ITS, ITS+LSU, and LSU, *H. helicospora* clustered in a strongly (Phyls 5, 6) or weakly (S5) supported clade with the *H. lunata* strain from England, with a distance of 2.1 % in the ITS and 2 nt difference in the D2 domain of LSU. Moreover, the S1506 intron is absent in *H. lunata*, while both possess the S943 intron (for differences see p. 382). A minimum distance of ~14–16 % is observed in the ITS region to any other sequence of a *Hyalorbilia*. In the ITS

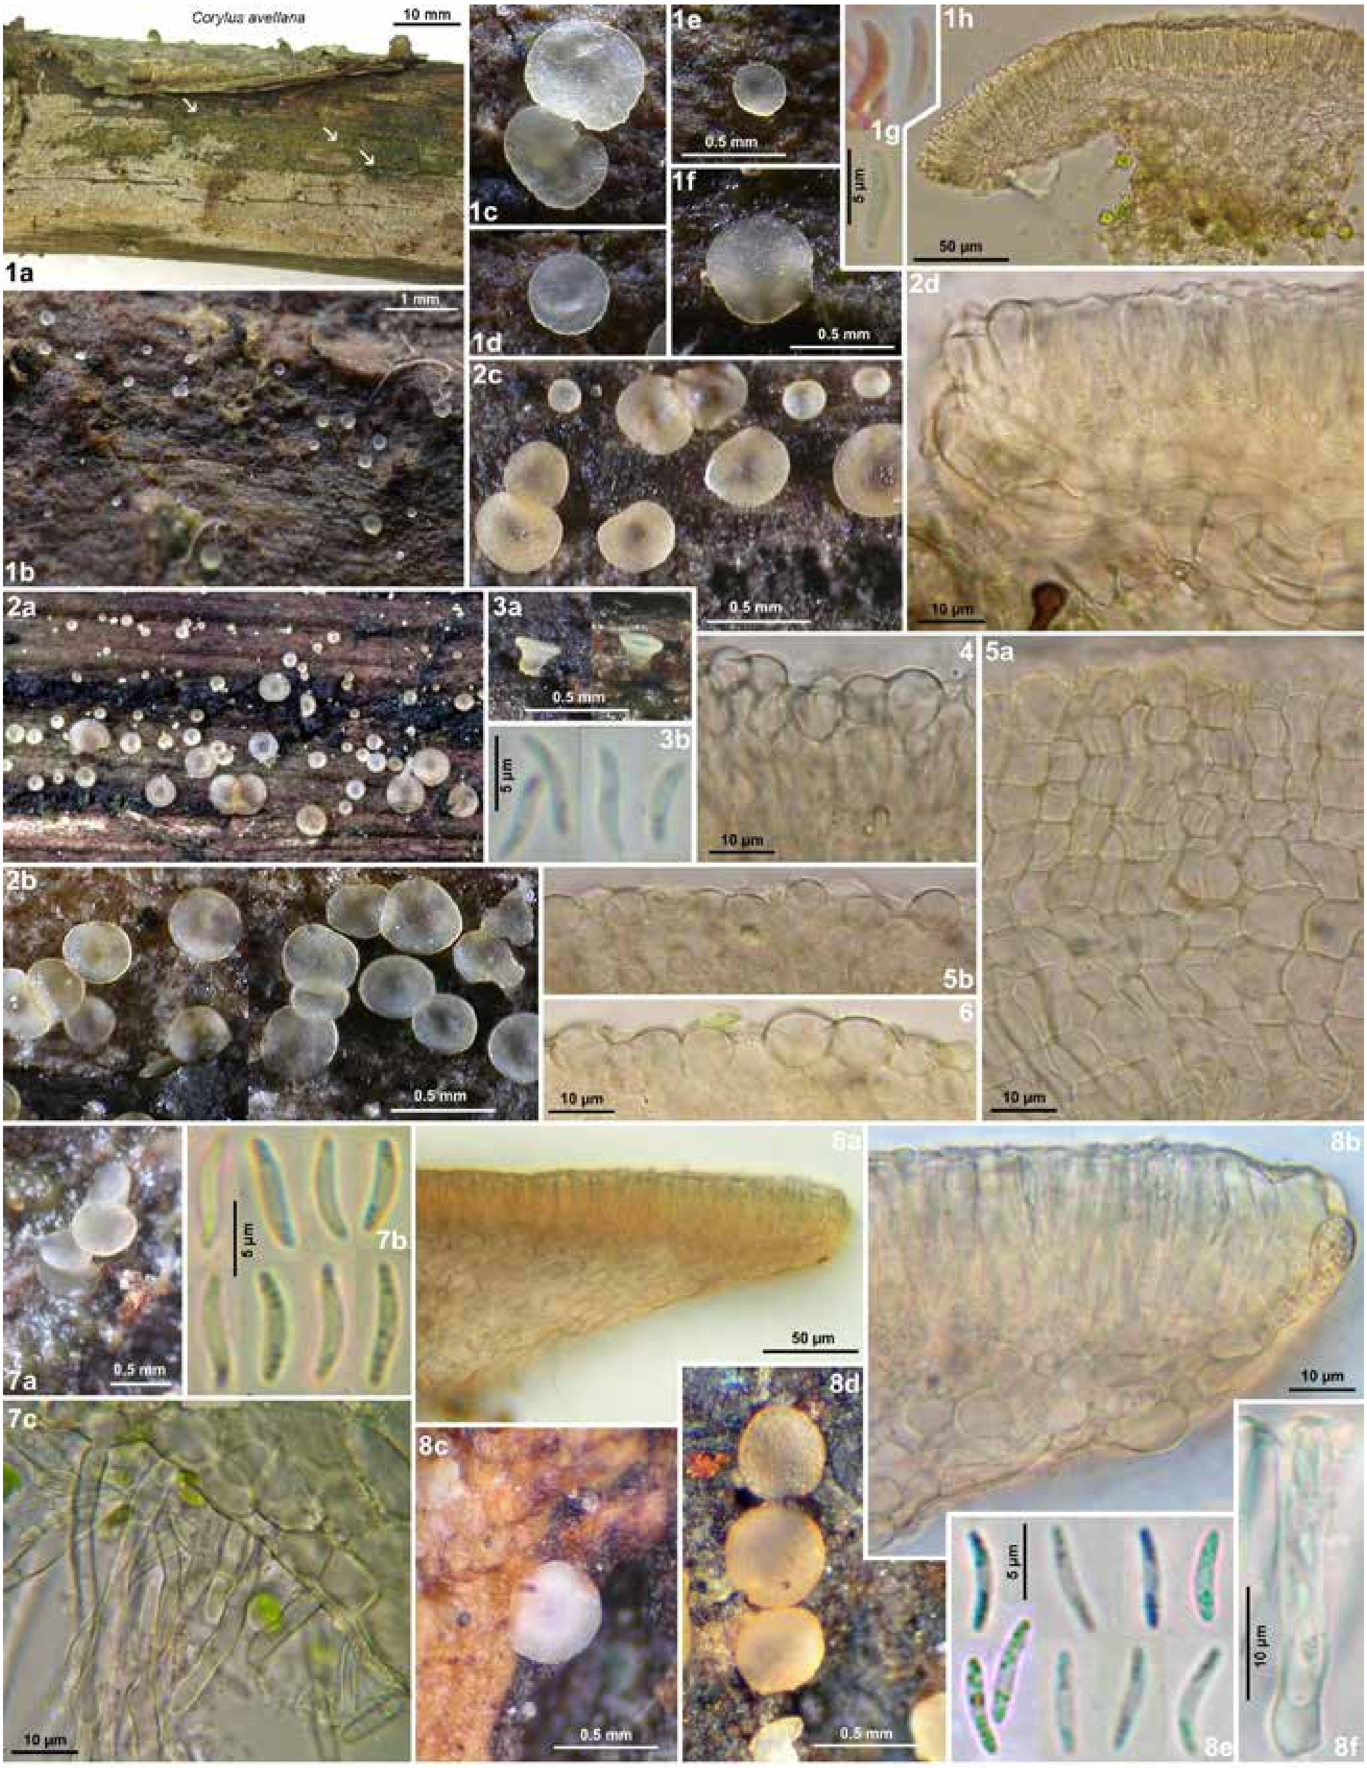

Plate 95. **1–8**: *Hyalorbilia helicospora*. – **1a**. decorticated xeric branch with remnants of bark; **1b–f**, **2a–c**. rehydrated apothecia; **3a**, **7a**, **8c–d**. fresh apothecia; **1h**, **8a**. apothecium in median section; **2d**, **8b**. id., near margin; **5a**. marginal ectal excipulum in surface view; **4**, **5b**, **6**. id., in top view; **1g**, **3b**, **7b**, **8e**. ascospores; **8f**. ascus; **7c**. anchoring hyphae. – Living state (**8e** partly in CRB) except for **2d**, **4**, **5a–b**, **6** (in KOH), **1g** (in KOH+CR). – **3a** right, **3b**: phot. I. Wagner; **7a–c**: phot. P. Perz; **8a–f**: phot. M. Bemmann. — **1a–h**. H.B. 8277: Switzerland, Luzern, on *Corylus*; **2a–d**. H.B. 6812: Luxembourg, Cessange, on *Quercus*; **3a–b**. H.B. 9897: Germany, Sonneberg, on *Quercus*; **4**. H.B. 8060: La Gomera, on *Erica*; **5a–b**. H.B. 6816: Luxembourg, Cessange, on *Quercus*; **6**. H.B. 4854: ibid.; **7a–c**. P.P. 20080713: Poland, substrate unknown; **8a–f**. 17.10.2010: Germany, Heidelberg, on *Fagus*.

analysis, the two species clustered strongly supported with two environmental strains from the Netherlands (H3). This clade falls unsupported in the *inflatula-polypori* clade, whereas in the LSU analysis they fall with strong support in this clade, and in the combined analysis in a strongly supported subclade with *H. citrina* and *H. inflatula.*

Ecology. *Hyalorbilia helicospora* was found on ± rotten wood and bark of both xeric and hygric branches of various angiosperm trees and shrubs, predominantly *Quercus*. The species does not appear to be rare. It was so far recorded from cold-temperate humid atlantic western and subcontinental central Europe. Vegetation types include rather moist (*Fagus*-) *Quercus* forests. The Macaronesian collection was from thermomediterranean semihumid fayal-brezal ridge crest forest (*Myrico fayae-Ericetum arboreae* or *Ilici canariensis-Ericetum platycodonis*).

Specimens included. **FRANCE**: **Bretagne**, **Morbihan**, Bretagne, 3 km S of Baud, 1.2 km W of Camors, Etang du Petit Bois, 75 m, branch of *Ilex aquifolium*, on wood, 23.X.2004, J.P. Map 12. Known distribution of *H. helicospora* in Europe and Macaronesia.

Hyalorbilia sibirica E. Weber & Baral, **sp. nov.**,
MB 813475 — Pls 96–97

Etymology: from the type locality (Tuva, Siberia).

Typification: Russia (East), Tuva, Tannu-Ola Mts., log of *Larix*, 19.VII.1972, A. Raitviir (TAAM 62289, holotype).

Latin diagnosis: Hyalorbiliae helicosporae *similis sed ascosporae paulo latiores*, *apothecia majora*, *asci majores*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.4–1 mm diam., 0.13–0.15 mm high (receptacle 0.1 → 0.065 mm), light chlorinaceous-cream, medium translucent, round, slightly gelatinous, scattered to gregarious in small groups; disc flat, margin thin, not protruding, smooth; sessile on a narrow obconical base, superficial; dry light honey-brown, ± cupulate. **Asci** †(22–)24–30(–33) × 4–4.7 µm, 8-spored, spores 3–4-seriate, intertwined; **apex** (†) hemispherical; **base** unstalked, with croziers. **Ascospores** †(5.5–)6–7(–7.7) × (1.1–)1.2–1.3(–1.4) µm, subcylindrical, homopolar, both ends obtuse, consistently rather strongly helicoid; **SBs** not seen in dead state. **Paraphyses** apically uninflated to slightly capitate, terminal cells †12–17 × 2–2.5(–3) µm, lower cells †6–8 × 2–2.5 µm wide. **Medullary excipulum** 10–20 µm thick, slightly gelatinous, of medium dense textura prismatica-globulosa, rather sharply delimited. **Ectal excipulum** of slightly gelatinized, horizontally oriented t. prismatica-globulosa from base to margin, 90–100 µm thick near base, cells †(10–)15–25(–30) × (7–)10–13(–20) µm, at flanks 10–20 × 6–20 µm, common walls 0.8–1.7 µm thick, cortical wall 1–2 µm; 15 µm thick near margin, marginal cortical cells †9.5–16 × 3.7–7 µm, external wall 0.2–0.4 µm thick. **Anchoring hyphae** medium abundant, †2–5 µm wide (at insertion sometimes up to 7 µm), walls (0.2–)0.3–0.5(–0.7) µm thick. **Exudate** over paraphyses and margin yellowish-ochraceous, 0.2–0.3 µm thick, smooth to finely warted. **— ANAMORPH**: unknown.

Habitat: decorticated surface of over 10 cm thick log of *Larix* sp., on 0.1 mm deep medium decayed wood, strongly greyed, with some green algae, with old black fructifications of ?pyrenomycete below apothecia **Associated**: *Coccocarpia* sp. (or *Pannariaceae*?), indet. foliose lichen. **Desiccation tolerance**: unknown, probably somewhat desiccation-tolerant because of the associated lichens. **Altitude**: ~1000 m a.s.l. **Phenology**: VII.

Taxonomic remarks. *Hyalorbilia sibirica* is very similar to *H. helicospora* from which it is tentatively separated by larger apothecia, slightly wider ascospores, larger asci, and more thick-walled anchoring hyphae, also by substrate and geographical origin. *H. tortuosa* and *H. fagi* likewise differ from *H. sibirica*

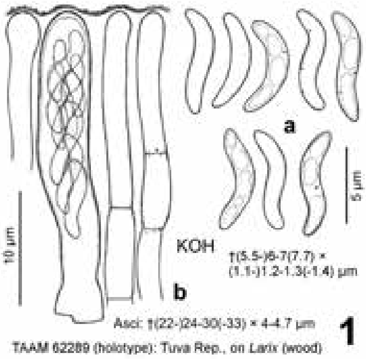

Plate 96. **1**: *Hyalorbilia sibirica*. – **a**. ascospores; **b**. ascus and paraphyses.

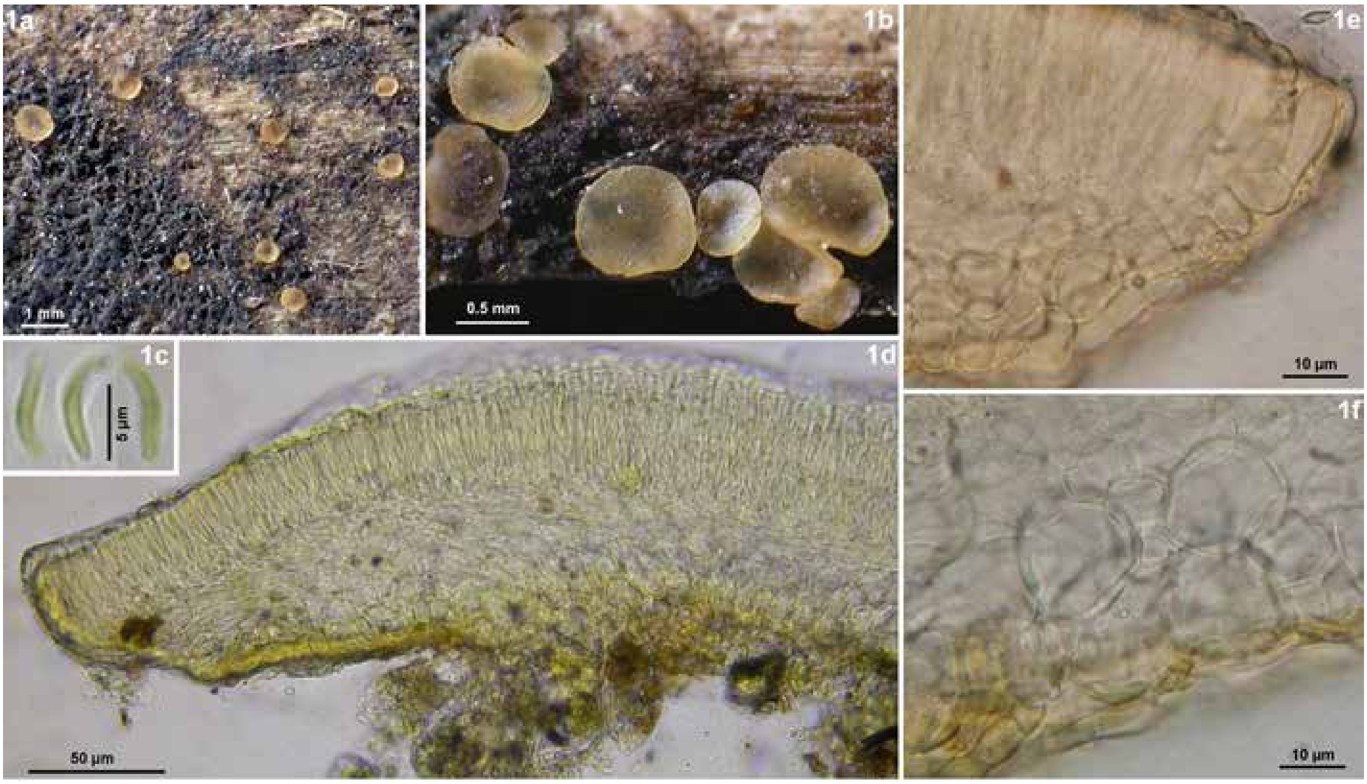

Plate 97. **1**: *Hyalorbilia sibirica*. – **1a–b**. rehydrated apothecia; **1c**. ascospores; **1d**. median section of apothecium; **1e**. id., marginal ectal excipulum; **1f**. id., basal ectal excipulum in median section. – Dead state (in KOH, **1c** KOH+IKI). — **1a–f**. TAAM 62289 (holotype): Russia, Tuva, on *Larix*.

in narrower spores, smaller asci, and perhaps in their more desiccation-sensitive apothecia.

Ecology. *H. sibirica* was found on medium rotten wood of a log of *Larix* in the continental, cold-temperate humid Sayan Mountains of central Asia.

Specimens included. **RUSSIA (East)**: **Tuva**, Sayan Mts., Tannu-Ola Mts., ~70 km S of Kycyl, Durgenj river, ~1000 m, log of *Larix*, on wood, 19.VII.1972, A. Raitviir (TAAM 62289, **holotype**, as *Orbilia oreadum*, H.B. 7993a ø)

Hyalorbilia macrohelicospora Baral & Hong Y. Su, **sp. nov.**, MB 813476 — Pls 98–99

Etymology: named after the comparatively large, strongly helicoid ascospores.
Typification: China, Yunnan, Jizushan, log of indet. angiosperm, 20.X.2008, X.M. Gao, H.Y. Su & X.J. Su (ex H.B. 8956, M-0276414, holotype).

Latin diagnosis: Hyalorbiliae helicosporae *et* H. sibiricae *similis sed ascosporae multo majores, valde helicoideae, asci latiores, paraphyses ad apicem magis inflatae.*

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated 0.22–0.45 mm diam., 0.11 mm high (receptacle 0.06 → 0.04 mm), whitish-cream to pale chlorinaceous, translucent, round, non-gelatinous, scattered; disc flat to medium convex, margin finely rough, not protruding; with a hidden 0.05 mm high stipe, superficial. **Asci** *22–28 × 6.2–6.7 µm, †20–25 × 5–6 µm, 8-spored, spores *3–4-seriate, strongly intertwined, pars sporifera *14–19 µm long; **apex** (†) hemispherical to slightly conical; **base** sessile or with short, thick stalk, arising from croziers (with or without slit). **Ascospores** *9.5–12 × 1.4–1.7 µm, †9.5–11(–13) × 1.3–1.5 µm, cylindrical, ends very slightly tapered, rounded to obtuse, consistently very strongly helicoid (like a right-hand thread); **SBs** *0.7–1.1 µm diam., globose, about 3–4 in each spore half together with a few small LBs. **Paraphyses** apically (slightly to) medium to strongly clavate-capitate, terminal cells †19–23 × 4–5.5 µm, lower cells †4–7 × 1.5–2 µm. **Medullary excipulum** non-gelatinized. **Ectal excipulum** of ± thin-walled, horizontally oriented textura prismatica from base to margin, cells at flanks †15–23 × 7–12 µm (up to 18 µm wide near base); marginal cortical cells †17–23 × 5–9 µm, clavate, thin-walled. **Anchoring hyphae** sparse, †2–3(–3.5) µm wide, walls 0.2 µm thick. **VBs** in living paraphyses low-refractive, elongate. **Exudate** over paraphyses and marginal excipulum absent or as scattered, 0.1–0.2 µm thick, granular. **— ANAMORPH**: unknown.

Habitat: 15 cm thick log of unidentified angiosperm tree lying on moist ground, decorticated, on eroded, deeply medium decayed wood, ± strongly blackened, no algae. **Associated**: closely associated with an old black pyrenomycete and a yellow ?*Orbilia* (later not rediscovered). **Desiccation tolerance**: apparently intolerant (dead in all parts when examined after 1 month). **Altitude**: 2700 m a.s.l. **Geology**: mafic volcanic rock. **Phenology**: X.

Taxonomic remarks. *Hyalorbilia macrohelicospora* resembles *H. helicospora* and *H. sibirica* in the helicoid shape of its ascospores, but differs from these species in much larger and much more strongly curved spores, wider asci, and more inflated apices of paraphyses.

Ecology. The sparse collection was made on rotten wood of a hygric log of an unidentified angiosperm tree in a subtropical humid, winter-dry evergreen broad-leaved forest in southeastern Asia.

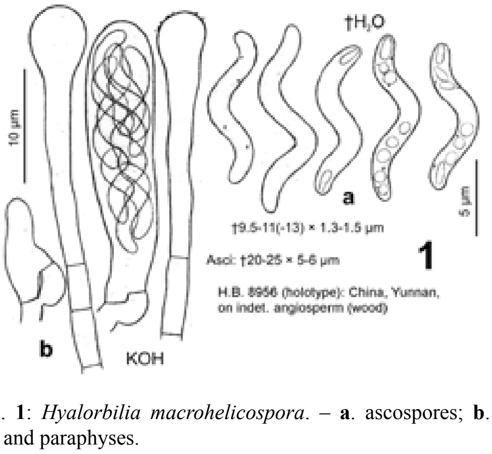

Plate 98. **1**: *Hyalorbilia macrohelicospora*. – **a**. ascospores; **b**. asci (with croziers) and paraphyses.

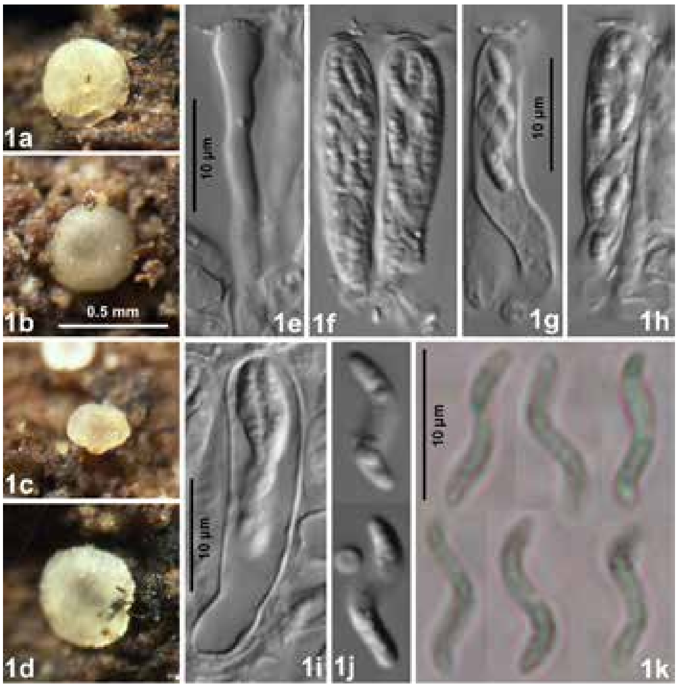

Plate 99. **1**: *Hyalorbilia macrohelicospora*. – **1a–d**. fresh apothecia; **1e**. paraphysis; **1f–i**. asci; **1j–k**. ascospores. – Living state, except for **1k** (in H_2O), asci in **1f–h**. – **1a–j**: phot. Specimens included. **CHINA**: **Yunnan**, **Dali**, Binchuan, 42 km NNE of Dali, Jizushan, 2700 m, log of indet. angiosperm, on wood, 20.X.2008, X.M. Gao, H.Y. Su & X.J. Su (ex H.B. 8956, M-0276414, **holotype**; H.Y.S. jz-7, CBCD, **isotype**).

Hyalorbilia arcuata Baral, M.L. Wu & Y.C. Su, in Wu et al., Fungal Diversity 25: 235, figs 5–15 (2007) — Pls 100–101, Map 13

Etymology: named according to the strongly curved, bow-shaped ascospores.
Typification: Taiwan, Tengjhih, indet. angiosperm, 30.X.2005, Y.C. Su (TNM F20072, holotype).
Misapplied name: Liu (2006: 26), as *H. andina* (HMAS 139538); Liu (2006: 36), as *H. inflatula* (HMAS 139537); Ekanayaka et al. (2018: 160), as *H.* cf. *inflatula*.

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated (0.2–)0.4–1.8 mm diam., 0.09–0.19 mm high (receptacle 0.075–0.12 → 0.04–0.06 mm), watery-whitish to pale or light yellowish-chlorinaceous(-orange), translucent, round to somewhat undulating, membranaceous, slightly gelatinous, scattered to gregarious; disc slightly concave to flat, margin thin, not protruding, smooth; sessile on a broad base, sometimes with a stipe 0.06 × 0.15 mm, superficial; dry light yellowish-buff, with distinct whitish subiculum. **Asci** *20–27(–32.5) × 4–4.8 µm {1}, †18–26(–29) × 3.2–4.3(–4.8) µm {4}, 8-spored spores *3–4-seriate, pars sporifera *13–16 µm long; **apex** (†) hemispherical to slightly conical; **base** unstalked or only slightly narrowed, with croziers {5}. **Ascospores** *5.8–7(–8) × (0.8–)0.9–1.2(–1.4) µm {1}, †5–7 {4} × 0.8–1 {3} or 1.1–1.2 {1} µm, (sub)cylindrical, sometimes narrowly fusoid when dead (then sometimes distinctly heteropolar), both ends obtuse (also subacute or rounded), (slightly to) medium to (very) strongly curved (falcate), not or sometimes very slightly helicoid, in dead state less curved; **SBs** *0.2–0.4(–0.5) µm diam. {1}, globose, (1–)2–3(–4) near each end. **Paraphyses** apically uninflated or slightly capitate, terminal cells *2–3.5 µm wide {1}, †13–20 × 1.8–2.5 µm {2}, lower cells †4–5 × 1.6–1.8 µm {1}, strongly agglutinated with asci. **Medullary excipulum** 10–30 µm thick, of slightly to strongly gelatinized textura angularis-prismatica-intricata, medium to very sharply delimited. **Ectal excipulum** thin-walled, in cortex slightly to rather strongly gelatinized (common walls †0.3–1 µm thick), at base of t. angularis to t. prismatica, 25–60 µm thick, cells *20–28 × 13–17 µm {1}; at lower flanks of horizontally oriented t. prismatica, 15–25 µm thick, cells †(10–)15–40(–48) {4} × 5–7 {1} or (6–)8–15(–22) {3} µm; 5–20 µm thick at margin, of t. prismatica to t. porrecta, marginal cortical cells †6–11 {2} or 11–15 {T} × 2.5–4 {2} or 7–10 {T} µm, thin-walled to slightly gelatinized. **Anchoring hyphae** abundant, radiating, */†(2.5–)3–5(–6) µm wide, at insertion also *7–10 µm, walls (0.2–)0.3–0.5(–1) µm thick {3}. **Exudate** over paraphyses and marginal excipulum 0.2–0.5 µm thick, rough-warted to granular. **VBs** in terminal cells of paraphyses and marginal cortical cells globose to elongate, hyaline or pale yellow, slightly to medium refractive. — **ANAMORPH**: unknown (but see below).

Habitat: collected on moist ground, also 0.5–1.5 m above the ground, on corticated (to almost decorticated), 7–28 mm thick twigs and branches of *Barringtonia racemosa* {1}, *Pinus* sp. {1}, *Prunus persica* {1}, indet. angiosperm {4}, indet. tree {6}, on slightly to strongly decayed bark (outer surface of periderm, sometimes bast) {9} or wood {4}, ± greyed, no algae, also on stroma of immature ?*Hypoxylon* {1}. **Associated**: *Hyalorbilia japonica* {1}, *Orbilia cejpii* {1}, *O.* ?*fusiformis* {1}. **Desiccation tolerance**: immature asci and excipular cells still viable after 11 months (Australia). **Altitude**: 460–?2000 m a.s.l. (Asia), 5 m (northeastern Australia). **Geology**: Australia: Devonian sedimentary rock; Asia: Paleozoic & Tertiary sedimentary and felsic plutonic rock. **Phenology**: I, III, V–VII, IX–X (Asia).

Taxonomic remarks. *Hyalorbilia arcuata* is characterized by falcate ascospores with mostly 2–3 spore bodies near each end. It herein resembles *H. berberidis*, from which it differs in much shorter but also narower spores and in fewer and smaller SBs. For the similar *H. nodulosa* see below. *H. fagi*, *H. helicospora* and *H. tortuosa* mainly differ in their helicoid spores.

Variation (***H. arcuata*** s.l.). *H. arcuata* varies in the strength of spore curvature, often even within a collection. Typically, the spores are moderately to strongly curved (Pls 100: 1–3; 101: 1d). In the dead state the strength of curvature slightly decreases (Pl. 100: 1a, 2a). A slightly helicoid curvature is sometimes seen in dorsal view (Pl. 100: 2a upper right spore). Such spores resemble those of the temperate species *H. fagi*.

The spores are usually homopolar, but some slightly heteropolar spores were observed (particularly in the dead state) in those specimens with strongly curved spores (Pl. 100: $1a_2$, 3a). The spores in the Australian specimen contain a fewer number of SBs Pl. 100: 2a compared to the holotype, and the asci and spores are wider. This specimen is also extraordinary in growing on xeric substrate. Great variation was noted in the marginal cortical cells, which are very narrow in the specimens from Australia (Pl. 101: 4l) and in one of the not included Chinese samples (H.B. 8716), and widest in the holotype of *H. arcuata* (Pl. 101: 1f). Further collections are needed to clarify the taxonomic value of these morphological traits. The falcate ascospores illustrated as the teleomorph of *Dactylella lignatilis* by Mo et al. (2005b, Pl. 101: 2) fit rather well the holotype of *H. arcuata* (Pl. 100: $1a_2$) when compared in the dead state, also the large (2–3 mm diam.), pale orange apothecia concur (the size of the marginal cortical cells was not stated). In the type of *H. arcuata* the apothecia were described as 0.8–1.8 mm diam. and whitish to pale chlorinaceous.

Literature reports and misapplications. Liu (2006: 25, fig. 2) reported six south Chinese collections under the name *H. andina*, with apothecia 0.5–3 mm diam. and medium curved spores 5.4–7.2 × 0.8–1.3 µm (figured in the dead state). The illustrated collection (HMAS 139533, Pl. 101: 5a–c) and another which was reexamined here (HMAS 139632, Pls 100: 3; 101: 3)

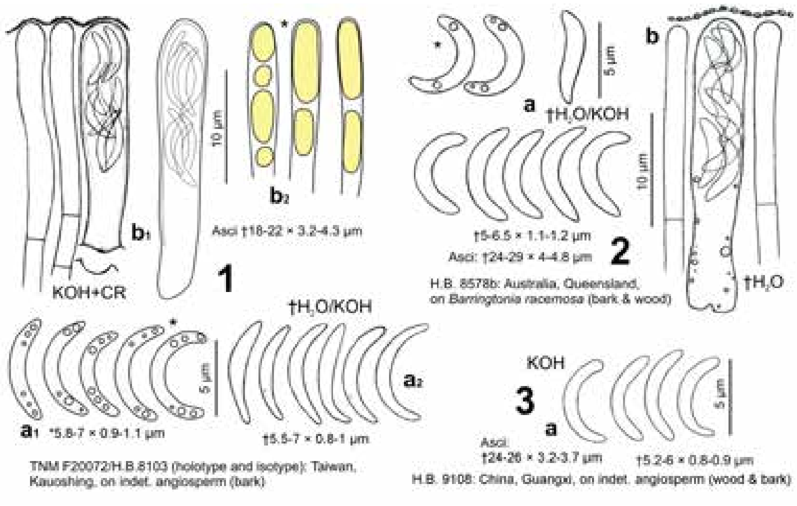

Plate 100. **1–3**: *Hyalorbilia arcuata*. – **a**. ascospores; **b**. asci and paraphyses. – **1a**$_1$ and **1b**$_2$: from Wu et al. (2007).

appear to fit well *H. arcuata*. Guo et al. (2014b) reported 11 south Chinese collections under the name *H. arcuata*, one of which was illustrated on their fig. 5 (details in Pl. 101: 6). Guo et al. did not specify which collection was illustrated, but when J.W. Guo (pers. comm.) earlier sent us the plate he referred it to th-j-21, a code which does not appear in his publication. The given spore size lies with (4.6–)5.8–7.4(–9) × 0.8–1.3 µm at the upper range regarding the length, while the illustrated spores measure only about †4.5–5 × 1 µm. A sample from Northern Thailand on indet. wood was reported by Ekanayaka et al. (2018) as *H.* cf. *inflatula*. It has slightly to medium, sometimes strongly curved spores of †4.5–5.5 × 0.5–1.3 µm (average 5.2 × 1.1 µm, but ~0.6–0.8 µm wide according to scale). The authors believed that their sample was conspecific with *H. inflatula* as described by Quijada et al. (2014a) although the spores are reported there as straight to very slightly curved.

Not included collections. Three Chinese collections from Guizhou (Pls 101: 7–8) and Yunnan (IVV: H.B. 8718) deviate by somewhat shorter, less curved spores.

Anamorph. The anamorph in the sample on *Pinus* bark from Kunming described from an ascospore isolate as *Dactylella lignatilis* by Mo et al. (2005b) is regarded here to represent a species different from *H. arcuata* (see under *H. lignatilis*, p. 359).

Phylogeny. An ITS sequence was gained from apothecia of the Australian sample (H.B. 8578b), while no sequence was available from the type of *H. arcuata*. Among the six Chinese specimens named *H. andina* by Liu (2006), three were sequenced by him regarding the ITS region: B.L. 6184 and 6185 from Guangxi and B. L. 6408 from Fujian. Another ITS sequence from Fujian (B.L. 6426, without microscopic data, B. Liu pers. comm.) was treated in Liu (2006) as *H. inflatula*, and both Fujian sequences were uploaded as *H. inflatula* in GenBank. Our drawing of B.L. 6185 (Pl. 100: 3) and photos of B.L. 6184 and 6408 kindly provided by B. Liu (pers. comm., see IVV) show the typical spores of *H. arcuata*. For the Thailand sample (as *H.* cf. *inflatula*), sequences of S1506 intron, ITS, and LSU exist.

Our Australian *H. arcuata* clustered highly supported but with a 9% ITS distance in a clade with the two strains from Fujian (Phyl. 5). The latter show a 2.5% distance between each other, so they might be conspecific, whereas the Australian sample appears to belong to a different taxon. A distant, likewise strongly supported clade is formed by the two Guangxi strains and that from Thailand (the latter not shown in phylogram). The Guangxi strains show a 10.5% distance between each other, while that from Thailand differs by 4.5% from B.L. 6184 and 12% from B.L. 6185. The type of *H. lignatilis* differs by 22–23% from all these strains and is, therefore, not conspecific with any sequenced *H. arcuata* strain.

There was some confusion of numbers in Liu's unpublished list of strains regarding B.L. 6185 (HMAS 139632, as *H. andina*) and B.L. 6449 (HMAS 139535, as *H. juliae*), a strain not included in Liu (2006), if not confused with HMAS 139553, listed in Liu (2006) under *H. juliae*. B.L. 6449 appears in GenBank (DQ656650), but this sequence is tentatively assumed here to belong to B.L. 6185, because it was labelled '*H. andina*' in Liu et al.'s (2006a) phylogenetic analysis and Liu's unpublished list of strains. Yet, B. Liu (pers. comm.) expressed some doubts about the correctness of this attribution. Sample B.L. 6449 is morphologically very deviant from *H. arcuata*, in having long straight spores as in the long-spored variant of *H. juliae* in spore shape (see under *H. juliae*, p. 389). It appears unlikely that a species with such long and straight spores clusters in a clade with one with short and curved spores, whereas our sequences of European *H. juliae* clustered very distant from DQ656650.

Because we cannot see morphological differences between Australian and Taiwanese *H. arcuata* in comparison with Liu's concept of *H. andina* based on the samples from Guangxi and Fujian and a photo plate of the unsequenced HMAS 139533, we have included all illustrated *Hyalorbilia* samples from China with similar falcate spores in the description of *H. arcuata*.

Ecology. *Hyalorbilia arcuata* was found on rotten bark and wood of hygric or sometimes xeric (Australia) branches of both angio- and gymnosperm trees and shrubs in evergreen broad-leaved rainforests of subtropical to tropical humid (winter-dry) southeastern Asia and tropical northeastern Australia.

Specimens included. **CHINA**: **Yunnan**, **Kunming**, ~35 km W of Kunming, ~8 km WNW of Jiliang, Xiaobailong Mt., 1580 m, twig of *Pinus*, on bark, 10.IX.2003, M.H. Mo (M.M.H. 005 p.p., H.B. 7461b ø, doc. vid., mixture with *H. japonica*

Hyalorbilia nodulosa Baral, Hong Y. Su & X.J. Su, in Su et al., Mycol. Progress 10: 380, fig. 5 (2011) — Pls 102–103

Etymology: named after the knob-like glassy processes on the marginal cortical cells.

Typification: China, Yunnan, Yongping, branch of indet. angiosperm, 8.XII.2007, R.X. Bi, X.M. Gao & H.Y. Su (ex H.Y.S. jgs-1, CBCD, holotype).

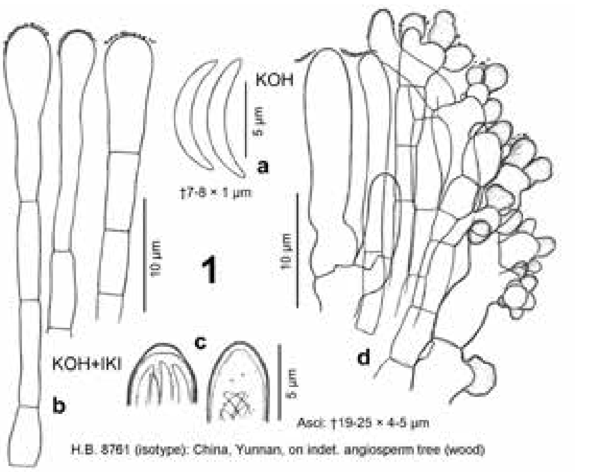

Plate 102. **1**: *Hyalorbilia nodulosa*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices; **d**. ectal excipulum in median section at margin.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.14–0.24 mm diam., 0.08 mm high (receptacle 0.06 → 0.035 mm), whitish when fresh, rehydrated whitish to light brownish, slightly translucent, round, gregarious in small groups; disc flat, margin thin, 5 µm protruding, finely crenulate; with a short stipe 0.02 × 0.05 mm, superficial; dry pale reddish-brownish. **Asci** *20–24 × 5–5.5 µm, †19–25 × 4–5 µm, 8-spored, spores *~4-seriate, pars sporifera *15–16.5 µm long; **apex** (†) obtuse to submammiform; **base** unstalked, arising from croziers (without distinct slit). **Ascospores** *6.8–8 × 1–1.1 µm, †7–8 × 1 µm, fusoid, sometimes slightly heteropolar, ends *obtuse or †subacute to acute, consistently medium curved; **SBs** globose, *0.2–0.5 µm diam., ~3–4 in each half. **Paraphyses** apically uninflated to medium clavate-capitate, terminal cells †10–19 × 2.5–4.2 µm, lower cells †6–9.5(–13) × 1.8–2.5 µm; unbranched at upper septum. **Medullary excipulum** 10–15 µm thick, non-gelatinized, of medium dense textura prismatica-porrecta, upwards oriented in centre, horizontally at flanks, indistinctly delimited. **Ectal excipulum** at lower flanks of thin-walled (to medium gelatinized), irregularly horizontally oriented t. prismatica, 20 µm thick, cells †10–15 × 5–8 µm; 10 µm thick near margin, marginal cortical cells †5–12 × 2–4 µm, thin-walled; cells at mid flanks and margin with short protuberances which bear one or mostly several knob-like, strongly refractive **glassy processes** (1–)1.5–3 × (1.3–)2–2.5 µm, these KOH-

Plate 103. **1**: *Hyalorbilia nodulosa*. – **1b**. fresh apothecia; **1a**, **c**. rehydrated apothecia; **1d**. apothecium in median section; **1h**. id., marginal ectal excipulum, with glassy processes; **1i**. margin in surface view, with glassy processes; **1e**. asci; **1f**. ascospores; **1g**. paraphyses. – Living state: **1e** (four asci with clearly visible spores), **1f** (left spore); dead state: **1f–g** (in H_2O), **1d**, **h–i** (in KOH). – **1b**, **e–g**: phot. H.Y. Su (p.p. from Su et al. 2011c, DIC). — **1a**, **c–d**, **h–i**. H.B. 8761 (isotype), **b**, **e–g** (holotype): China, Yunnan, on indet. angiosperm.

resistant, IKI-. **Anchoring hyphae** sparse at base, †2–3.5 µm wide, walls 0.2–0.4 µm thick. **VBs** in paraphyses: no data available. **Exudate** over paraphyses 0.2–0.5 µm thick, granular to continuous, over margin as sparse minute granules. **— ANAMORPH**: unknown.

Habitat: collected on moist ground, decorticated, ~5–10 cm thick branch of unidentified angiosperm tree, on strongly decayed wood, somewhat blackened, no algae. **Associated**: none observed. **Desiccation tolerance**: unknown (dead in all parts when examined after 2 months). **Altitude**: 2730 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: XII.

Taxonomic remarks. *Hyalorbilia nodulosa* deviates from *H. arcuata* in small, knob-like glassy processes resting in groups on short protuberances of the marginal cortical cells, also in slightly longer ascospores, wider paraphyses with longer lower cells, smaller excipular cells at lower flanks, and in distinctly smaller apothecia. The presence of glassy processes is so far unique within the genus *Hyalorbilia*. Similar protuberances were occasionally seen in *H. juliae* and *H. resinae*, but they never carried glassy caps.

Ecology. *H. nodulosa* was found on rotten wood of an unidentified angiosperm tree lying near a ditch in a subtropical humid (winter-dry) evergreen virgin mountain forest (with *Castanopsis orthacantha*, *Cinnamomum glanduliferum*, *Magnolia campbellii* etc.) in southeastern Asia.

Specimens included. **CHINA**: **Yunnan**, **Dali**, Yongping, 35 km ENE of Baoshan, Jinguangsi virgin forest, 2730 m (as 2850 m), branch of indet. angiosperm, on wood, 8.XII.2007, R.X. Bi, X.M. Gao & H.Y. Su (H.Y.S. jgs-1, CBCD, **holotype**, doc. vid.; H.B. 8761, **isotype**).

Hyalorbilia lunata (Korf) Baral, Micologia 2000: 44 (2001) — Pls 104–105, Map 14

≡ *Orbilia lunata* Korf, Mycotaxon 45: 508 (1992)

Etymology: named according to the spore shape that resembles a half-moon in profile view.

Typification: Macaronesia, Tenerife, Las Mercedes, branch of indet. angiosperm, 7.I.1976, R.P. Korf, W.C. Denison, L.M. Kohn & M.A. Sherwood (CUP-MM 247, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.23–)0.35–1.5(–3) mm diam., (0.08–)0.1–0.17(–0.22) mm high (receptacle 0.05–0.1 → 0.035–0.05 mm), pale to light yellowish-chlorinaceous(-ochraceous), ± translucent with darker centre, round, somewhat lobate when large, not or moderately gelatinous, medium scattered to gegarious; disc slightly concave, soon flat, centre sometimes with a slight depression, margin distinct, 0–8 µm rising above disc, smooth to finely rough or crenulate; broadly sessile or with an obconical to abruptly cylindrical stipe somewhat hidden in biofilm, 0.03–0.13 × 0.1–0.25(–0.4) mm, superficial; dry flat to cupulate, light yellowish-ochre, reddish-brown with age. **Asci** *(23–)27–35(–40) × (4.5–)4.8–5.5(–6) µm {4}, †(21–)24–32(–35) × (3.5–)4–5(–6) µm {4} [Quijada: *(25–)30–34(–41) × (4.8–)5–5.5(–6) µm, †(20–)24–30(–32) × 3.2–4 µm {6}], 8-spored, spores (*) obliquely biseriate, often intertwined, pars sporifera *13–20 µm long → 10.5 µm (†22–25 µm, irregularly arranged; or †14–17 µm long if still intertwined); **apex** (†) hemispherical to slightly truncate; **base** with a very short, thick stalk arising from croziers {6}. **Ascospores** *((4.1–))(4.5–)5–7(–8) × (1.5–)1.6–2(–2.1) ((–2.3)) µm {5}, †(4.3–)5–6.5(–7) × (1.3–)1.5–1.8(–2) µm {4} [L. Quijada: *(4.8–)5–5.5(–6) × 1.7–2.1 µm, †4.3–4.9 × 1.5–1.7 µm {6}], fusoid to fusiform, sometimes fusoid-clavate, both ends obtuse to subacute († subacute to acute), slightly or usually medium to strongly curved, partly or consistently helicoid (like a right-hand thread), in profile view looking like a half-moon; **SBs** globose, *0.4–0.8(–1) ((–1.3)) µm diam. {3}, 1–4 in each half, sometimes laterally attached; LBs absent or sparse, minute. **Paraphyses** apically uninflated to medium clavate-capitate, terminal cells *(16–)19–25(–31) × (2.5–)3–4(–4.5) µm {3}, †(11–)18–24(–27) × (2–)2.3–3.5(–4) µm {4}, lower cells *6–8.5 × 2.7–3.3 µm {1}, †4–8 × 1.4–2 µm {1}; unbranched. **Medullary excipulum** hyaline, 10–30 µm thick, of dense textura intricata-epidermoidea–globulosa, slightly horizontally oriented, cells

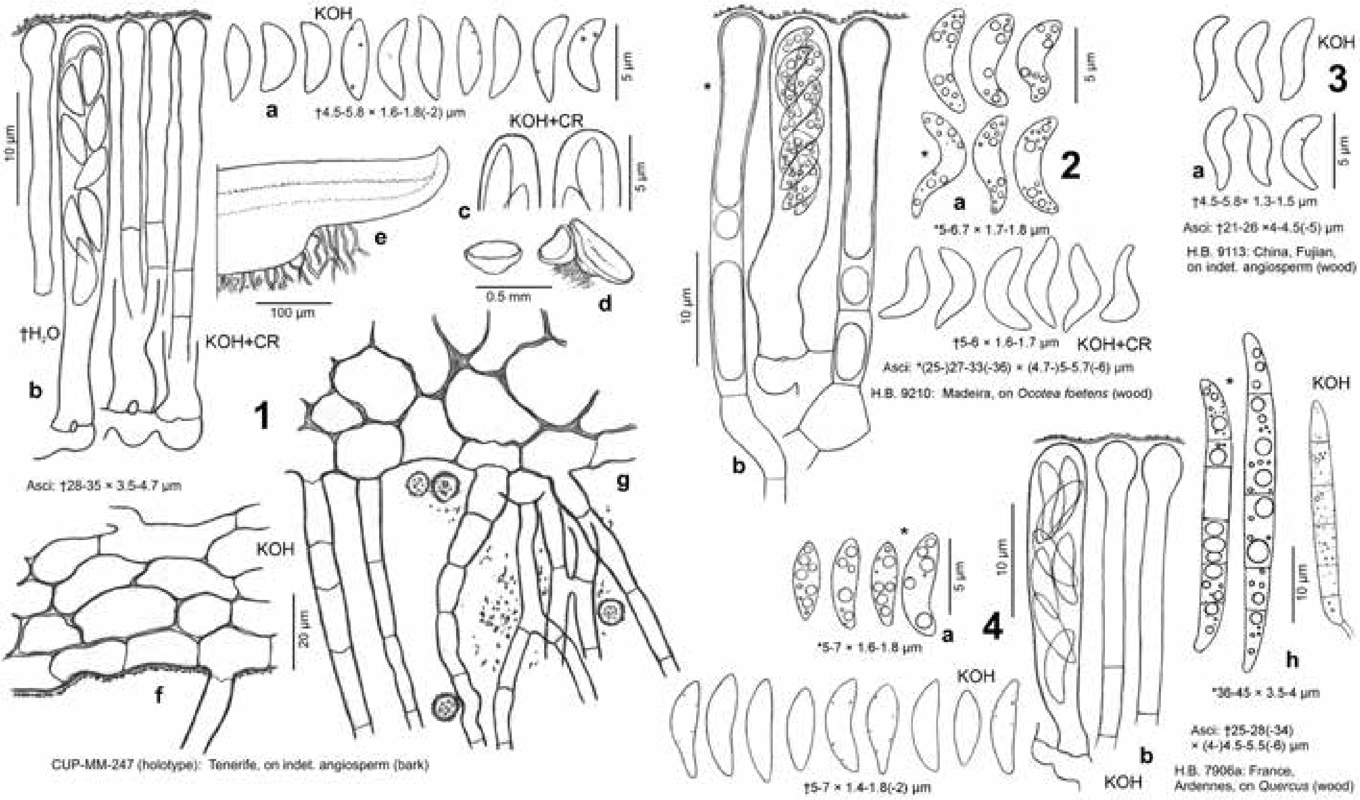

Plate 104. **1–4**: *Hyalorbilia lunata*. – **a**. ascospores; **b**. asci (with croziers) and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., ectal excipulum at lower flanks; **g**. id., basal ectal excipulum and anchoring hyphae; **h**. conidia from substrate.

10–17 × 2–4.2 µm, not or slightly to strongly gelatinized, not or rather sharply delimited. **Ectal excipulum** hyaline, at base of vertically oriented t. angularis-prismatica, (40–)60–120(–180) µm thick, cells *(12–)15–25(–30) × (7–)12–20(–24) µm {2}, †12–25 × 10–20 µm {1} or †7–20 × 5–10 {T+1}, ± gelatinized near exterior [common walls †0.5–1.5(–3) µm], sometimes with a unicellular cortical layer of horizontal prismatic cells; 20–70 µm thick at lower flanks, of horizontal t. prismatica, cells */†(15–)20–35(–42) × 10–17(–23) µm {3} or †8–17 × 5–9 {T+1}, 10–20 µm thick at margin, marginal cortical cells *8–11 × 6–7 µm {1} or *12–16(–20) × 7–11 µm {1}, †8–11 × 5–8(–9) µm {T+1}, in surface view up to 10–12(–15) µm wide. **Anchoring hyphae** medium to very abundant, hyaline, long and straight (radiating) or undulating, */†2–4(–7) µm wide, near insertion 3–6(–8) µm, walls 0.2–0.3 {4} or sometimes 0.5–1 µm thick {2}, anastomoses and branches rare. **Exudate** over paraphyses continuous, 0.2–0.5(–1.2) µm thick, slightly to strongly granular; over margin and flanks a thin layer of fine warts and clods. **VBs** pale chlorinaceous, medium refractive; large **LBs** in ectal excipulum absent. **— ANAMORPH**: brachyphoris-like (presumed, from natural substrate {3}). **Conidiophores** not observed. **Conidia** unbranched, elongate fusoid, slightly curved at both ends, *36–45 × 3.5–4 µm {1}, †29–41 × 3–3.1 µm {1}, ~4–5-septate, with some large LBs and many small ones (both KOH-resistant) {H.B. 7906a}; or ± straight, *50–65 × 4.5–6 µm, 6–11-septate, with some large or many small or only a few minute LBs {N.A. 342}.

Habitat: collected on moist ground, corticated or decorticated, 16–200 mm thick, entirely decayed branches and logs of *Acer campestre* {1}, *Erica arborea* {2}, *Eucalyptus gunnii* {1}, *Ilex canariensis* {1}, *Laurus novocanariensis* {1}, *Myrica faya* {1}, *Ocotea foetens* {3}, *Picconia excelsa* {1}, *Quercus* sp. {1}, ?*Salix* sp. {1}, indet. angiosperm {3}, on lower, lateral or upper side, on 0.3 mm to deeply very rotten wood {8} or bark {8}, partly blackened, sometimes on old pyrenomycete, green algae absent or abundant among anchoring hyphae. **Associated**: *Capronia pilosella* {1}, *Coenogonium pineti* {1}, *Coprinellus* sp. {1}, *Mollisia* ?*cinerea* {1}, *Pluteus salicinus* {1}, *P. umbrosus* {1}, *Rhizodiscina lignyota* {1}, ?*Ruzenia spermoides* {1}, *Simocybe centunculus* {1}, small foliose liverwort. **Desiccation tolerance**: many mature asci and excipular cells survived for about 1 hour dry on slide, after ~½ day in the herbarium only some immature asci viable, after a few days only ascospores survived. **Altitude**: 15–210 m a.s.l. (Europe), 665–1136 m (Macaronesia), ~1400–2500 m (southern China). **Geology**: Macaronesia: volcanic sedimentary deposits, tephritic and phonolitic mafic and basaltic flows; England: Triassic & Lower Cretaceous mud-, silt- & sandstone; Pleistocene loess & silt. China: Jurassic sedimentary rock; felsic plutonic rock. **Phenology**: I–VI, VIII–X (apparently throughout the year).

Taxonomic remarks. Korf (1992) characterized the species by lunate ascospores (looking like a half-moon) which are in fact often slightly to distinctly helicoid. *H. lunata* closely resembles *H. fusispora* and *H. subfusispora*, which mainly differ in wider and predominantly straight spores with a somewhat higher in situ length, also in smaller, more desiccation-tolerant apothecia. Yet, a few slightly curved spores were encountered in a few collections of *H. fusispora* and *H. subfusispora*. A French sample on *Robinia* (J.P.P. 11179) with ± distinctly curved spores mentioned under *H. subfusispora* is not included in *H. lunata* because of smaller apothecia growing on xeric wood.

Variation. Spore shape in *H. lunata* is in fact often helicoid, which is evident when seeing the spores in dorsal view (looking S-shaped), while in profile view such spores look lunate (C-shaped). A few spores look ± straight (Pl. 104: 1a, 4a), but such are probably seen from their dorsal side, and are in fact falcate by lacking the helicoid curvature.

The collection from France referred to *H. lunata* (Pls 104: 4; 105: 1) corresponds rather well to the Macaronesian samples. It differs from the holotype (Pl. 104: 1) in slightly longer, sometimes heteropolar (fusoid-clavate) spores, slightly shorter asci, apically slightly more enlarged paraphyses, larger excipular cells at flanks, and occurrence on wood. That these differences lie in the scope of variation of this species is supported by a collection from Madeira (Pls 104: 2; 105: 2) in which most of these features also occur. However, in this sample the often distinctly heteropolar spores are always medium to strongly helicoid, contrary to the holotype and the French specimen.

In a specimen from Fujian (China) reported under the name *H. lunata* by Liu (2006: 42) the spores are also distinctly helicoid, though slightly smaller (Pls 104: 3; 105: 3). The cortical excipular cells at the flanks are more strongly gelatinized, and the anchoring hyphae thicker-walled. In two further Chinese specimens (from Sichuan and Yunnan) reported by Guo et al. (2014a) the spores are distinctly lunate though not helicoid; they measure *3.2–4.6 × 1.4–1.7 µm (but 4.5–5 × 1.5–1.6 µm according to scale) and contain rather large SBs (Pl. 105: 4). The apothecia are described in Guo et al. as 0.1–0.3 mm, with a 85 µm long stipe and a hairy margin, but in the median section no hair-like projections are seen.

Although the spores of *H. lunata* do not lose their helicoid curvature in the dead state, their intertwined arrangement was often only seen inside the living asci, due to a more condensed arrangement of the spores. In the sample from Fujian, however, the spores were consistently intertwined also in the dead asci.

Type studies. The holotype consists of ~40 well-preserved apothecia and fairly concurs with the protologue, except for the substrate being bark, not wood as originally stated. The anchoring hyphae were found to be narrower than indicated by Korf (1992) who reported them as 3.7–10.2 µm wide and ± moniliform, even in their middle part. The here gained ascus length slightly exceeds that given in the protologue while spore size fits well [data given by Korf: asci 26–30 × 3.7–4.4 µm, spores (4.1–)4.4–5.1(–5.9) × (1.1–)1.5–1.9 µm]. Korf mentions two paratypes from the same laurel forest in Tenerife, which were not examined in the present study.

Anamorph. A few conidia were observed on the substrate in three collections, sometimes emerging from the base or margin of an apothecium. In the French collection the conidia were somewhat curved at both ends (Pl. 104: 4h), but in the sample from southern England they were straight and larger, with more septa (Pl. 105: 5f). Also in the sample from Madeira (H.B. 9210) J.P. Priou (pers. comm.) observed ± straight conidia. In culture no conidia were formed (Liu 2006).

Phylogeny. Sequences of two strains included in *H. lunata* were available which, however, are very distant. An ITS sequence was gained by B. Liu from the Chinese culture (B.L. 6416, HMAS 139531), and a sequence with S943-intron and SSU V6–V9 (without S1506 intron), ITS, and LSU (D1–D5) by us from apothecia of a British sample (N.A. 342). The Chinese strain clustered with *H. citrina*, *H. fagi*, and *H. japonica* in the strongly supported *citrina-fagi* clade (Phyl. 5) which is part of the supported *inflatula-polypori* clade (Phyls 6, S5; see also Liu et al. 2006a). The lowest ITS distance was 7–8 % to *H. fagi*. In the 5.8S region, this sequence fully matches *H. arcuata* (H.B. 8578b), *H. inflatula*, and *H. citrina*. The British strain clustered also in the *inflatula-polypori* clade, but strongly supported with two strains of *H. helicospora*, with a 2.1 % distance in the ITS, 2 nt in the LSU (D2), and 3 nt and 2 gaps in the S943 intron, which is surprising considering the much broader spores. The 100 % identity of the four *H. helicospora* ITS sequences supports the

H.B. 7906a: France, Ardennes, on *Quercus*; **2a–i**. H.B. 9210: Madeira, on *Ocotea*; **3a–c**. H.B. 9113: China, Fujian, on *Salix*; **4a–b**. J.W.G. ch-9: China, Sichuan, on indet. angiosperm; **5a–f**. N.A. 342: Great Britain, West Sussex, Plaistow, on *Acer*.

H. lunata sample being not conspecific. The morphologically similar *H. subfusispora* and *H. fusispora* show to *H. lunata* s.l. an ITS distance of 19–23.5 % and 23–24 %, respectively. More sequences of *H. lunata* from different regions, especially from Macaronesian samples are necessary to elucidate the boundaries of this species.

Ecology. *Hyalorbilia lunata* was found on rotten wood and bark of hygric branches and logs of different trees and shrubs in Madeira and especially in different regions of Tenerife (Teno, Monte de las Mercedes, Anaga). It occurs mainly in the thermo- to meso- or mesosubmediterranean subhumid to humid laurel forest (*Lauro novocanariensis-Perseetum indicae*) and fayal-brezal (*Ilici canariensis-Ericetum platycodonis*), but also in the thermomediterranean semihumid Monteverde seco (*Visneo mocanerae-Arbutetum canariensis*) adjacent to *Sideritido solutae-Pinetum canariensis* in the Valle de Güímar in eastern Tenerife. In the laurel forest *H. lunata* seems to be among the most common species of *Hyalorbilia* (L. Quijada pers. comm.). The French sample grew on *Quercus* in a supratemperate subatlantic *Quercetum* in the region of Argonne Ardennaise (France), and those from England in the supratemperate East Midlands and mesotemperate Southeast. The Chinese collections came from orotemperate to subtropical humid (winter-dry) evergreen broad-leaf forests.

Specimens included. **GREAT BRITAIN**: **East Midlands**, **Nottinghamshire**, 5 km NW of Retford, 2 km NE of Barnby Moor, Daneshill Energy Forest, 15 m, trunk of *Eucalyptus gunnii*, on ?bark, 26.V.2011, C. Hobart (ø, doc. vid.). – **South East England**, **West Sussex**, 9.5 km WNW of Billingshurst, 2 km SSW of Plaistow, 60 m, log of *Acer campestre*, on wood & old pyrenomycete, 2.X.2016, N. Aplin (N.A. 342, anam. substr., doc. vid.; sq.: KY419195). — **FRANCE**: **Champagne-Ardenne**, **Ardennes**, 11 km ESE of Vouziers, 4 km SE of La-Croix-aux-Bois, Forêt Domaniale de la Croix-aux-Bois, 210 m, branch of *Quercus*, on wood, 25.IX.2005, R. Jouan (H.B. 7906a, anam. substr.). — **MACARONESIA**: **Canary Islands**, **Tenerife**, Los Silos, Teno, 6.5 km SSE of Buenavista del Norte, 1.9 km ESE of Las Portelas, La Rife, 1098 m, branch of *Picconia excelsa*, on wood & bark, 4.V.2012, L. */†(6–)9–23(–28) {15} × 2.5–4 {5} or (4–)5–9(–11)((–13)) {17} µm (in section or external view), very rarely with denticulate, ± protruding apical protuberances {1}. **Anchoring hyphae** sparse to abundant, */†2–3.5(–4.5)((–5.5)) µm wide, sometimes moniliform, walls 0.2–0.3(–0.4) µm thick {7}. **SCBs** globose to irregularly shaped, 0.5–2.3 µm diam., medium refractive, in centre of cells of ectal excipulum at flanks or margin {2}, but usually absent; **VBs** in terminal (and lower) cells of paraphyses and in marginal cortical cells large, low to medium refractive, pale chlorinaceous; **LBs** in ectal excipular cells at base and lower flanks usually absent or with some minute ones, rarely with large LBs 1–2 µm diam. {1}. **Exudate** (0.1–)0.2–0.4(–1) µm thick, continuous, pale yellowish-amber, very finely to roughly warted, sometimes with loose granules; margin and flanks densely covered by ± fine, cloddy, pale chlorinaceous warts. — **ANAMORPH**: unknown (but see below).

Habitat: Collected 0.1–5 m above the ground, rarely lying on moist ground, ± corticated (rarely decorticated), often completely rotten, (5–)10–50 mm thick branches, also 10–80 cm thick, sometimes living trunks of *Acer* sp. {1}, *A. campestre* {1}, *A. platanoides* {1}, *Aesculus hippocastanum* {1}, *Alnus alnobetula* {1}, *A. incana* {1}, *Carpinus betulus* {2}, *Clematis vitalba* {3}, *Cornus sanguinea* {1/1}, *Corylus cornuta* {1}, *Crataegus laevigata* {1}, *Eremaea pauciflora* {1}, *Fagus sylvatica* {10}, *Fraxinus excelsior* {2}, *Hedera helix* {1}, *Hippophae rhamnoides* {1}, *Juglans regia* {1}, *Larix decidua* {1}, *Ligustrum vulgare* {1}, *Lonicera tatarica* {1/1}, *L. ?xylosteum* {1}, *Malus domestica* {2}, *Pinus* sp. {1}, *Platanus* × *acerifolia* {3}, *Populus* sp. {1}, *P. ?× canadensis* {1}, *P. tremula* {2}, ?*Prunus* sp. {1}, *P. domestica* {1}, *P. spinosa* {3}, *Pyrus communis* {1}, *Quercus* sp. {1}, *Q. ilex* {1}, *Robinia pseudoacacia* {2}, *Salix* sp. {7}, *S. caprea* {2}, *S. ?cinerea* × *aurita* {1}, *S. ?viminalis* {1}, *Tamarix anglica* {1}, *Tilia* sp. {2}, *T. cordata* {1}, *T. platyphyllos* {2}, *Ulex* sp. {1}, *U. europaeus* {3}, *Ulmus* sp. {5}, *U. laevis* {2}, *U. minor* {1}, on (slightly to) medium to strongly decayed bark {61} (bast and periderm), on inner and outer surface of detached bark, often at edges of bark, sometimes on detritus, less often on wood {28}, 1–2 mm deep medium to often strongly rotten, often on smaller or larger decorticated spots, sometimes below bark, or in larger cavities, sometimes greyed, often with abundant green algae, rarely on blackened resin; on *Fomitiporia hippophaeicola* {1}, hymenophore of *Hymenochaetopsis tabacina* {1}, *Trametes ?hirsuta* {1}, *Xanthoporia radiata* {1}, stromata or perithecia of *Bertia moriformis* {1}, *Diaporthe* sp. {1}, *Hypoxylon* *fragiforme* {1}, indet. {1}. **Further associated**: *Calycina claroflava* {1}, *Capitotricha bicolor* {1}, *Capronia* sp. {2}, *Ciliolarina laricina* {1}, *Coenogonium pineti* {1}, *Corticiaceae* {3}, *Crepidotus cesatii* {1}, *Cryptocoryneum condensatum* {1}, *Cryptodiscus foveolaris* {1}, *Diatrype bullata* {1}, *Durella connivens* {1}, *Entoloma alliodorum* {1}, *Episphaeria fraxinicola* {1}, *Gloniopsis praelonga* {1}, *Glyphium elatum* {1}, '*Helotium*' *uvidulum* {1}, *Hyalorbilia fusispora* {4}, *H. inflatula* {2}, *H. rotifera* {2}, *H. subfusispora* {4}, *H. ulicicola* {1}, *Hyaloscypha minuta* {1}, *Hymenochaete* sp. {1}, *Hysteropatella prostii* {1}, *Karstenia rhopaloides* {6}, *Lachnum virgineum* {1}, *Lasiobelonium corticale* {1}, *L. lonicerae* {1}, *L. variegatum* {1}, *Lasiosphaeria* sp. {1}, *L. hirsuta* {1}, *L. ovina* {1}, *Licea castanea* {1}, *Lophiostoma compressum* {1}, *L. subcorticale* {1}, *Lophium mytilinum* {1}, *Lophocolea* sp. {1}, *Mollisia ?oblonga* {2}, *M. prunicola* {1}, *Mycoceros antennatissimus* {1}, *Nectria pseudopeziza* {1}, *Octospora affinis* {1}, *Olla scrupulosa* {2}, *Orbilia amberina* {1}, *O. aprilis* {2}, *O. arachnovinosa* {1}, *O. aradi* {1}, *O. aristata* {1}, *O. auricolor* {1}, *O. austrocylindrica* {1}, *O. clavispora* {1/1}, *O. curvativitalbae* {1}, *O. eucalypti* {6}, *O. euonymi* {1}, *O. filiformis* {1}, *O. microserpens* {1}, *O. multicurvula* {1}, *O. obtusispora* {1}, *O. orientalis* {1}, *O. pilifera* {1}, *O. pleistovitalbae* {1}, *O. plurililacina* {1}, *O. sarraziniana* {1}, *O. subclavuliformis* {1}, *O. trapeziformis* {1}, *O. tremulae* {1}, *O. vinosa* {2}, *O. vitalbae* {1}, *O. xanthoguttulata* {1}, *Orthotrichum* sp. {1}, *Parmelia* sp. {1}, *Patellaria atrata* {1}, *Physcia* sp. {1}, *Proliferodiscus pulveraceus* {2}, *P. olivaceoviridis* {1}, *Propolis farinosa* {1}, *Pseudohelotium sordidulum* {1}, *Resupinatus* sp. {1}, *Rosellinia aquila* {1}, *R. britannica* {1}, *Stictis* sp. {1}, *Thelonectria discophora* {1}, *Tubeufia cerea* {1}, *Unguiculariopsis* sp. {2}, *Vibrissea filisporia* {1}, *Xanthoria parietina* {2}, crustose lichens, further apo- and pleurocarpous mosses. **Desiccation tolerance**: asci survive for min. 2 days, excipular cells for at least 9 days, ascospores for 13.5 months. **Altitude**: 0–1310 m a.s.l. (Europe), ?2500 m (eastern China). **Geology**: Neoproterozoic, Cambrian & Ordovician shale, silt, greywacke & sandstone, Buntsandstein, Keuper (marl & limestone), Lower & Upper Jurassic and Cretaceous sand-, clay-, marl- & limestone, Tertiary molasse, Pleistocene loess, marl & till, peat; granite, quartz diorite, gneiss, mica schist, phyllite, biotite-amphibolite, serpentinite. **Phenology**: throughout the year (long-lived).

Phenology of *H. juliae* (N-hemisphere)											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
6	5	7	7	8	2	6	9	8	13	8	11

Taxonomic remarks. *Hyalorbilia juliae* is characterized by more or less straight, narrowly subcylindrical to fusoid ascospores containing mostly 3–6 SBs near each end. The species comes close to *H. subfusispora*, but spore width in *H. juliae* is only very exceptionally up to *1.7(–1.9) µm whereas *H. subfusispora* has mostly *1.8–2.4 µm wide spores. Those collections of *H. juliae* with long, sometimes very slightly curved spores resemble *H. berberidis*, a very close taxon which can merely be separated by its consistently more or less distinctly falcate spores. *H. berberidis* shows a tendency to slightly longer spores but the values strongly overlap with those of *H. juliae*. *H. juliae* differs from *H. inflatula* in distinctly larger ascospores containing a higher number of SBs, and in smaller, never cup-shaped, more desiccation-tolerant apothecia. The asci have a similar length as in *H. inflatula* but are wider.

The spores of *H. polypori* are similar as in short-spored specimens of *H. juliae*, but they are slightly wider and contain only 1–2 SBs at each end. The excipular cells of *H. polypori* are much larger, and the apothecia desiccation-sensitive. Although the two species rather sharply differ in spore guttulation and desiccation tolerance, delimitation of their holotypes is less clear, mainly because Velenovský neglected spore guttules in most of his orbiliaceous taxa. The protologue of *H. juliae* says 'on damp bark of *Fagus*' but this does not exclude a desiccation-tolerant fungus. The small excipular cells at the lower flanks in the type of *H. juliae* (10–14 × 6–9 µm) clearly exclude conspecificity with *H. polypori*. A distinction based on the medullary excipulum (strongly gelatinized in the type of *H. polypori*, nearly non-gelatinized in the type of *H. juliae*) seems irrelevant because the degree of gelatinization was found to be variable at the species level: collections here included in *H. juliae* varied from non- to medium gelatinized. The holotype of *Orbilia cryptocarpa* seems to be intermediate between *H. juliae* and *H. polypori*, but fits better *H. polypori* with its large apothecia growing on hygric substrate, and its spores with just one SB at each end.

Variation. In the present circumscription of the species, *H. juliae* is very variable, especially in spore length, but also in spore width and shape, ascus length, and apothecial size, colour, and shape. Although ranges in spore length do not even overlap in many of the ~90 measured samples, trials to split the species based on morphology alone failed because of the frequent occurrence of collections with intermediate spore length.

About 50 samples lie within the range of 10–14(–15) µm, with mean values of 11–12 µm in ~40 of them (including the type of *O. fusispora* var. *microscopica*) and 12.2–13.5 µm in ~13 samples. About 12 collections (including the type of *H. juliae*) show a spore length of only (6.5–)7.5–10(–11) µm, with mean values of 8–9 µm. However, about 26 intermediate samples occur, with spores around 8–11 µm (mean values 9.2–9.8 µm) in six samples (e.g., Pl. 106: 2, 5) and around 9–12 µm (mean values 10–10.8 µm) in the remaining ~20 samples (Pl. 108: 2, 4) (measurements mostly in living state). Also spore width varied somewhat, within the long-spored group between *1.1–1.4 µm (Pl. 108: 2, 4–5) and *1.3–1.5(–1.7) µm (Pl. 108: 3, 6), and to a similar rate in the short-spored group.

Spore shape varied from ± cylindrical (mainly in the long-spored specimens) to distinctly narrowly fusoid or fusiform (more often seen in the short-spored and intermediate collections but also in the long-spored ones). Hence, no clear cut between short- and long-spored collections, or between those with subcylindric and fusoid spores could be established, nor any correlation with other features, besides a tendency of the short-spored specimens to occur at a more montane altitude. The type of *H. juliae* is, therefore, rather marginal in comparison with the majority of collections here assigned to that species.

Spore arrangement within the asci appears to be more or less correlated with spore length. If short-spored, the 8 spores are sometimes found in two superimposed bundles of four spores (Pl. 106: 4b), a feature being very typical of *H. inflatula*, whereas in the long-spored specimens the spores often form a single parallel bundle (Pl. 108: 3b, 5b). However, a less regular arrangement is frequently observed, especially in those specimens with an intermediate spore length, also the arrangement may change to some degree in dead asci. Specimens with short spores tend to have short asci of ca. *(21–)25–30(–35) µm, whereas those with long spores often measured *(25–)30–35(–45) µm in length.

Rather great variability was observed in the width of the marginal cortical cells. They are frequently rather strongly inflated to 4–10 µm [in the type of *H. juliae* (6–)7–10(–12) µm] and show a ± clavate shape. However, in at least four specimens with ± long spores (H.B. 8447a, 8797a, 8894a, 13.X.1983) they were 2.5–4 µm wide, and in only one (H.B. 8067a) they were intermediate: (2–)3–6(–8) µm. This striking difference

represents one of the separating characteristics between *H. subfusispora* and *H. fusispora*, and it may well be that *H. juliae* is heterogeneous in the present circumscription. In any case, a correlation with spore length was not observed: many of the long-spored collections possessed very wide marginal cells, and these were often seen in rather small apothecia. Macroscopically, some of the specimens with narrow marginal cells closely resemble *H. fusispora* in their ochraceous colour (Pl. 109: 3a–c), whereas others are quite hyaline (Pl. 109: 14a–c).

Apothecia varied in diameter between (0.1–)0.15–0.4 and 0.3–0.7(–0.9) mm, and in colour between whitish and light yellowish-amber. In two collections the margin was distinctly crenulate (H.B. 9494, Pl. 109: 17; J.P.P. 13121). In H.B. 9494 the first inspection revealed curved spores reminiscent of *H. berberidis* (T. Læssøe pers. comm.), nevertheless the few documented spores look ± straight (see IVV). In another collection assigned to *H. juliae* the cortical cells formed striking denticulate protuberances (Pls 106: 7; 107: 2a–i). In its other features it concurs with the short-spored samples, therefore this specimen is not believed to represent a separate taxon. The single very sparse Australian collection (on xeric bark of *Eremaea*, Pl. 107: 5) with a medium spore length seems to be conspecific with *H. juliae*. It differs from *H. texensis* from subtropical humid North America in much longer spores.

Richter (in Montag & Richter 2017: 62) described and illustrated the long-spored form of *H. juliae* from a collection on branches of *Ligustrum* from northern Germany, with small apothecia of 0.2–0.4 mm diam. and spores of *(8.5–)10–12.5 × 1.2–1.3 µm.

Type studies. The holotype of ***H. juliae*** now contains three scattered apothecia. Velenovský (1934) gave a spore length of 6–10 µm which is confirmed here, whereas ascus size (25 × 6–8 µm) exceeds our measurements of living asci in width. Yet, on his uncalibrated manuscript sketch the asci are drawn distinctly narrower, which corresponds to the here evaluated width of the dead asci of mainly 4–4.5 µm (Pl. 106: 1). Svrček (1954) found the spores only 6–7 × 1 µm and referred the taxon to synonymy with *O. inflatula*. Spore width as evaluated in the present study corresponds to Velenovský's sketch and clearly segregates *H. juliae* from *H. inflatula*. Velenovský found the apothecia 0.5–1 mm diam. but they are now rehydrated only 0.3–0.5 mm.

Although the holotype of ***O. fusispora* var. *microscopica*** (PRM 152442, a mixture with the holotype of var. *fusispora*) was said to contain no longer any apothecia (Svrček, 1954), a total of nine were detected (see under *H. fusispora*, p. 400). One out of three very small whitish apothecia that grew on a single chip of bark was examined and found to belong to this taxon, whereas two of the six larger ones on separate bark chips represent *H. fusispora*. Velenovský's description is very brief ('apothecia 0.1 mm diam., hyaline, glassy, spores linear-acicular'). The differences to var. *fusispora* were seen by him merely in the spores which he gave on his illustrated manuscript sheet as 12 µm long. Though the spores of var. *fusispora* and var. *microscopica* greatly differ in Velenovský's drawings, the author apparently could not believe that the two closely associated populations belong to two separate species. Besides the very different spores, the type of var. *microscopica* differs from that of var. *fusispora* also in ascus size and in the length

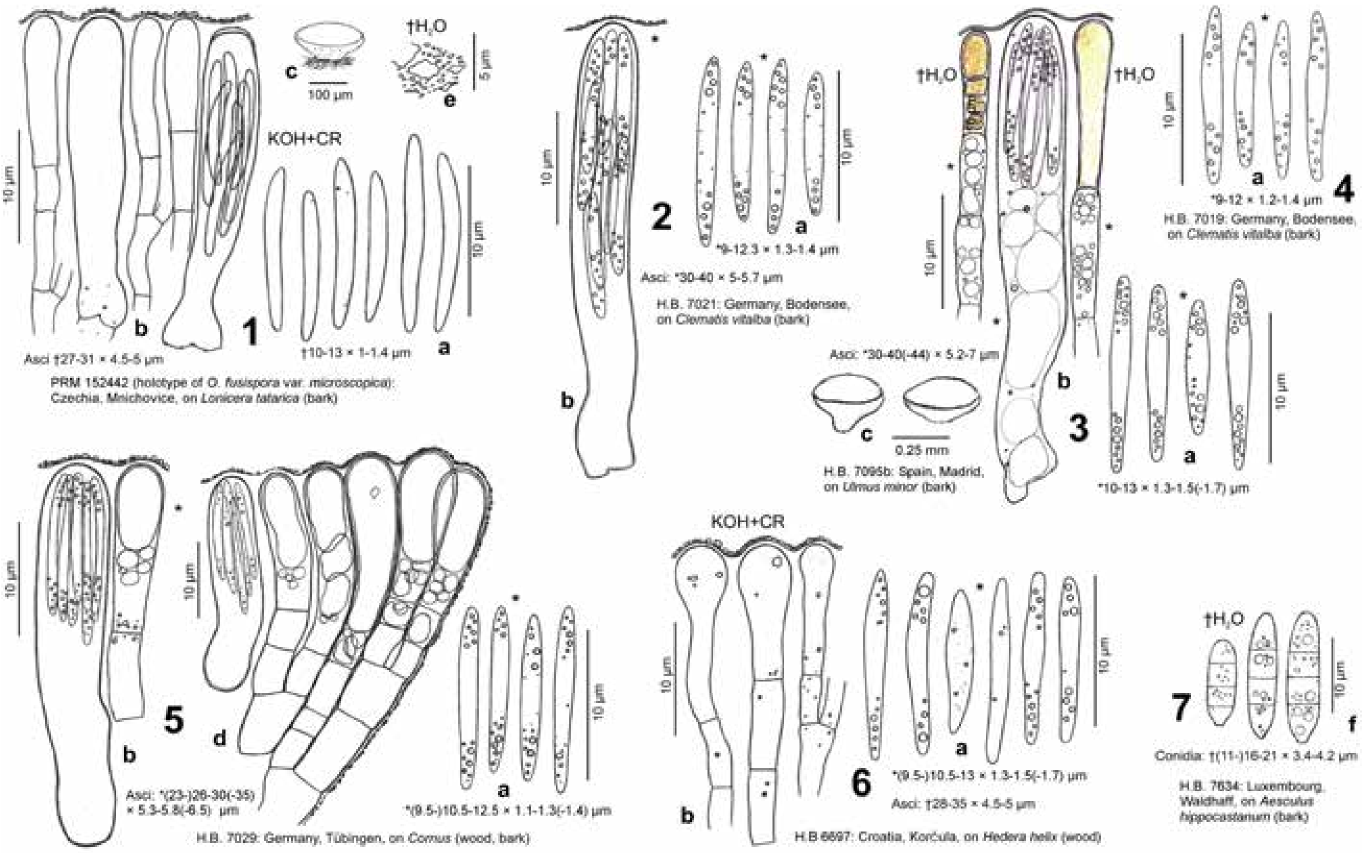

Plate 108. **1–7**: *Hyalorbilia juliae*. – **a**. ascospores; **b**. asci and paraphyses (**3**: VBs in dead cells with secondary pigmentation, **5**: living cells with hyaline VBs); **c**. rehydrated apothecia; **d**. marginal ectal excipulum (median section); **e**. warted-cloddy exudate on ectal excipulum; **f**. conidia from substrate.

of the terminal cells of paraphyses (10–13 vs. 18–27 µm, see Pl. 108: 1 and Pl. 114: 1).

Not included collections: A collection from Poland, on culms of *Phleum pratense* lying on the moist ground (Pls 106: 4; 107: 4a–e), has very small apothecia (0.12–0.2 mm diam.), which are easily overlooked and do not tolerate drying, spores of the short type as in the type of *H. juliae*, but rather short asci. Similarly, a tropical collection from the Comoros was on a hygric log of *Albizia*, with very small apothecia (around 0.12 mm), very short asci (*17–20.5 × 5.3–6.2 µm, †16.5–18 × 4.7–5 µm) but spores as in the type of var. *microscopica*: *11–14(–15) × 1.1–1.3 µm. In the apothecia on *Phleum* the marginal cells were *(4.5–)6–10(–12.5) µm wide and without VBs, while in those on *Albizia* they were *5–6 µm wide and each contained a single globose VB (IVV: J.P.P. 13004). Due to the extraordinary habitat and short asci we refrained from including the two samples in the description.

Among records from China, Liu (2006: 41, pl. 8; 2007b) reported under the name *H. juliae* three and Guo et al. (2014b) five Chinese collections (provinces of Beijing, Zhejiang, Anhui, Yunnan, Sichuan, on wood of *Quercus* etc.). Liu's description of the spores (*7.2–11.8 × 1.2–1.7 µm) with many small SBs would very well fit *H. juliae*, but the larger apothecia (0.5–3 mm) point to a different species. Also Guo et al. gave rather large apothecia (0.6–1 mm) and very similar spores (*7.4–12.8 × 1.2–1.7 µm) with 4–7 large globose SBs of 0.6–0.9 µm diam. in each half. Because of the large apothecia we preferred not to include any eastern Asian records in the description. A unpublished sample from Sichuan (IVV: zcw-j-4, J.W. Guo pers. comm., not mentioned in Guo et al. 2014b, originally referred to *O. fusispora* var. *microscopica*) has small apothecia of 0.5 mm diam., but the straight spores measure only *6–8 × 1–1.2 µm according to the scale and contain, unlike *H. inflatula*, several rather large SBs near each end. A similar collection (IVV: ys-j-8) was included in *H. juliae* by Guo et al.; it has the very same collection data and same spore size of *6–7.5 × 1–1.2 µm (from scale), according to its unpublished plate, but the spores are sometimes curved and with less SBs. Longer spores occurred in four samples which Guo et al. (2014b: fig. 8) referred to *H. inflatula*, with spores of *5.9–10.3 × 0.9–1.2 µm with 3–4 rather large SBs in each half. Apothecial size (0.2–0.55 mm diam. from scale) would fit *H. juliae*, but spores are also too narrow to belong to short-spored *H. juliae*.

Anamorph. In one collection ellipsoid-cylindrical, 3-septate conidia were observed on the natural substrate (Pls 108: 7; 109: 9), which resemble those of the brachyphoris-like anamorphs of *H. polypori* and *H. tortuosa*, but differ in a smaller size: *(11–)16–21 × 3.4–4.2 µm. Their cells contained some large low-refractive guttules and many small LBs. In another sample (IVV: H.B. 8279c) two ± cylindrical, 3-septate conidia of *40–42 × 7.5–8 µm were seen. In addition, in H.B. 5980 (Pl. 106: 2k) and H.B. 8279c (Pl. 107: 2h) narrower conidia (†31–49 × 1.7–2.3 µm) were found similar to those observed near apothecia of *H. rotifera* and *H. subfusispora*. However, it is unclear which of these conidial types represent the anamorph of *H. juliae*.

Phylogeny. Sequences of four long-spored strains of *H. juliae* were available (France: *Ulmus* [from apothecia]; Luxembourg: *Clematis* [from culture], *Populus* and *Fagus* [from apothecia]). Two comprise only ITS, the other two ITS and LSU D1–D3. The S1506 intron is present in three of them (for the *Ulmus* sequence the ITS1 primer was used). Spore size varied among these collections: *(10–)11.5–14.5 × 1.3–1.4 µm on *Ulmus*, *10–

13.5 × (1.2–)1.4–1.6(–1.8) µm on *Clematis*, *9–12.5 × 1–1.2 µm on *Populus*, *(10.5–)12–13 × 1.2 µm on *Fagus*.

The *Fagus* sequence differs from the other three in a 1.5–2.1 % ITS distance (2.5 % in the intron). The other three differ among each other in the ITS at 4 positions and 2 gaps (when neglecting untrustworthy 14 nt at the 5'-end in the *Ulmus* sample), resulting in a 0.4–0.5 % distance between each of them. Also in the intron these differ by only 2 nt and 1 gap in the overlapping 339 nt (0.6 %), while their LSU is identical.

When analysing ITS, *H. juliae* clustered with *H. tenuifusaria* and *H. fusispora* (H.B. 8447b) in an unsupported clade (Phyl. 5) by showing a very high distance of 20 and 25 %, respectively. In the 5.8S region, *H. juliae* fully matches *H. tenuifusaria* and *H. subfusispora* but deviates from *H. fusispora* by 1 nt (pos. 142). When analysing ITS+LSU, *H. juliae* clustered with high support in a clade with *H. tenuifusaria* and various uncultured DNA soil and leaf litter isolates (*juliae-tenuifusaria* clade, Phyl. 6, H18–H19, H21–H23, H26), with a minimum distance of 2 % in the LSU (D1–D2) to EF446004 from California, while the ITS distance to uncultured strains was very high. When analysing the S1506 intron, a high distance is found to all *Hyalorbilia* species that possess the intron (see Phyl. S4).

An ITS sequence in GenBank under the name *H. juliae* (DQ656650, strain [B.L.] 6449) was gained by B. Liu from apothecia of HMAS 139535 (IVV), with spores strongly reminiscent of *H. juliae*, but collection data and spore size were unavailable to him (B. Liu pers. comm.). Surprisingly, the distance of this sequence to European *H. juliae* lies at over 25 %. Instead, it clustered highly supported and with a 10.5 % distance with a strain identified as *H. andina* (B.L. 6184, HMAS 139534, from Guangxi) in the *inflatula-polypori* clade (Phyl. 5). Possibly a confusion is the reason for this mismatch (see under *H. arcuata*, p. 378). Note that the very similar number HMAS 139553 is among the three *H. juliae* samples listed in Liu (2006, see also under *H. arcuata*).

Ecology. *Hyalorbilia juliae* was found on rotten bark (more rarely wood) of xeric branches and trunks of various angiosperm trees, shrubs and climbers. Sometimes it occurred on aphyllophoralean fungi or pyrenomycetes, and a single very sparse collection was on blackened resin (large wound of a *Larix* branch). *H. juliae* is quite a common species, being recorded from various parts of atlantic to subcontinental Europe, including hemi- to mesoboreal, meso- to orotemperate, and suprasub- to thermomediterranean, humid to semihumid regions. The vegetation includes sun-exposed or shady borders of forests, old hedges, also rather moist woodlands, shrubs, ditches such as *Aceri-Fraxinetum*, *Salicetum* or *Alnetum viridis*, and in mediterranean regions (*Quercetum ilicis*). *H. juliae* does not seem to differ markedly in its ecological preferences from *H. subfusispora* (see p. 403). Both occur almost exclusively on xeric branches, nearly always of angiosperm trees, whereas *H. inflatula* is predominantly found on hygric substrate. Also the not included samples from China are from (oro)temperate as well as subtropical humid (winter-dry) regions, and a collection from the island of Mayotte (Comoros) was in a tropical wet & dry rainforest on a log of *Albizia* lying on the moist ground, where the apothecia grew intermingled with the desiccation-sensitive *Orbilia blumenaviensis*.

Hyalorbilia fomentarii Baral, **sp. nov.**, MB 813464 — Pls 110–111

Etymology: named after the substrate, *Fomes fomentarius*.

Typification: Germany, Niederbayern, Zwiesel, on *Fomes fomentarius* on log of *Fraxinus excelsior*, 14.VI.2008, P. Welt (ex H.B. 8876, M-0276408, holotype).

Latin diagnosis: Hyalorbiliae juliae *similis sed ascosporae angustiores.*

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated 0.13–0.28 mm diam., 0.05–0.08 mm high (receptacle 0.04 → 0.03 mm), whitish-greyish to whitish-cream, translucent, ± round, medium gregarious; disc flat, margin thin, not protruding, very finely rough; sessile on an obconical base or with a distinct stipe 0.04 × 0.05–0.06 mm, superficial, dry pale cream. **Asci** *20–30 × 6–7 µm {1}, †19–25(–28.5) × 4–5.3 µm {2}, 8-spored, spores (*) in a parallel bundle, pars sporifera *15–16 µm long; **apex** (†) hemispherical (to very slightly truncate); **base** ± unstalked, arising from croziers {2} (rarely with a slit). **Ascospores** *(11–)12–14.5(–15.5) × 1.1–1.2(–1.3) µm {1}, †11–15 × (0.8–)0.9–1.1(–1.2) µm {2}, subcylindrical to narrowly fusoid, both ends rounded to obtuse, straight to ± inequilateral, exceptionally medium curved; **SBs** *0.3–0.5 µm diam. {1}, ~4–6 in each half, globose, intermingled with a few small LBs. **Paraphyses** apically uninflated to mostly slightly (rarely medium) clavate-capitate, terminal cells †14–20(–25) × (2–)2.5–4.5(–6) µm {2}, lower cells †5–6(–7) × 1.5–1.8 µm {1}; unbranched at upper septum. **Medullary excipulum** 15–30 µm thick in centre, of dense textura angularis(-intricata), non-gelatinized, indistinctly delimited. **Ectal excipulum** at base of 15–20 µm thick, ± vertically oriented t. prismatica-angularis, cells †12–18(–22) × (6–)8–12 µm {1}, thin-walled, at flanks of horizontal t. prismatica, 10 µm thick near margin, marginal cortical cells */†15–20 × 5–7.5 µm {2} (5–10 µm wide in surface view). **Anchoring hyphae** sparse at base, †(1.5–)2–3.5(–5) µm wide, walls 0.2 µm thick {2}. **VBs** unknown (no living paraphyses seen). **Exudate** over paraphyses, margin and flanks 0.2–0.5 µm thick, continuous, finely rough to small-cloddy, hyaline to pale yellow-ochraceous, lying over gel. **— ANAMORPH**: unknown.

Habitat: collected 0.1 m above the ground, on basidiocarps of *Fomes fomentarius* {2}, at border of pileus, mainly on pores, medium decayed, still-attached to strongly decayed logs of *Betula* sp. and *Fraxinus excelsior*, green filamentous algae sometimes abundant around apothecia. **Associated**: *Hypnum cupressiforme* {1}, *Lophocolea* sp. {1}, *Mnium* sp. {1}. **Desiccation tolerance**: after ~2 days dead in all parts. **Altitude**: 5 m a.s.l. (Estonia), 1015 m (Bayern). **Geology**: marine sand & clay over Ordovician rock; gneiss. **Phenology**: VI, IX.

Taxonomic remarks. *Hyalorbilia fomentarii* is characterized by extraordinarily long and narrow, ± straight, rarely distinctly curved ascospores. It is very closely related to H. *juliae* and *H. berberidis*. The former deviates in wider and sometimes also shorter spores, the latter in always distinctly curved spores. Due to infraspecific variation of these two related species, *H.*

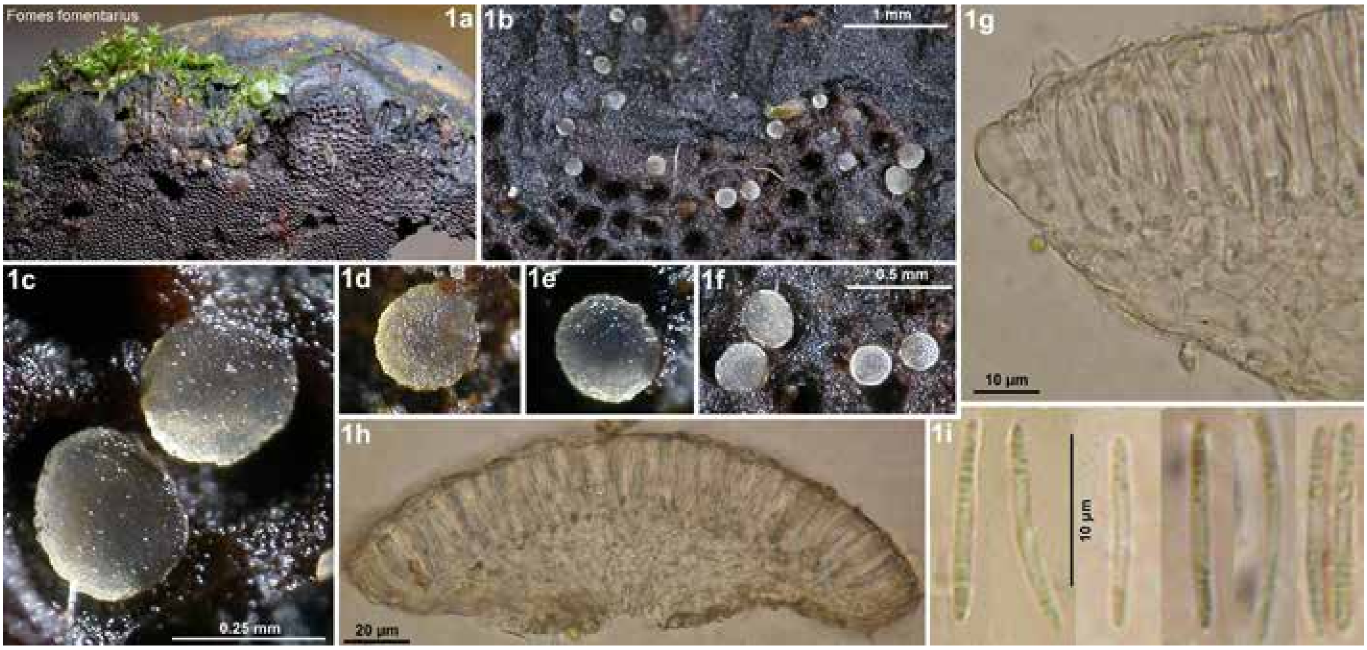

Plate 111. **1**: *Hyalorbilia fomentarii*. – **1a**. old fruitbody of *Fomes fomentarius*; **1b–f**. fresh apothecia; **1h**. apothecium in median section; **1g**. id., marginal region; **1i**. ascospores. – Living state. — **1a–i**. H.B. 8876 (holotype): Germany, Bayerischer Wald, on *Fomes*.

fomentarii is only tentatively separated from these. However, the close morphological resemblance of the two so far known collections, and the very similar ecology at the two rather distant sites support separation at the species level.

Four collections on basidiocarps (*Fomitiporia*, *Hymenochaetopsis*, *Trametes*, *Xanthoporia*) included in *H. juliae* differ from *H. fomentarii* in distinctly shorter and wider spores (*/†9–12(–13) × 1.1–1.5 µm). The description of *Orbilia polyporacea* Velen. (?= *H. berberidis*) on *Phylloporia ribis*, with rather long ('15 µm') and narrow spores, resembles *H. fomentarii*, but the spores are described as consistently slightly curved (the holotype is without apothecia, see under *H. berberidis*).

Not included collections. Two samples on *Hymenochaete* and *Phellinus* (IVV: J.P.P. 24240, 29205) with a spore size of *9–12 × 0.8–1.2 µm resemble *H. juliae* in spore shape. However, spore width excludes this species, whereas spore length is too short to include them in the description of *H. fomentarii*.

Ecology. Apothecia of the two known records of *Hyalorbilia fomentarii* grew on decayed basidiocarps of *Fomes fomentarius* in subcontinental humid forests of orotemperate central and hemiboreal northeastern Europe. The two not included samples on *Hymenochaete* and *Phellinus* are from atlantic and subatlantic western Europe on calcareous Lower Jurassic and Oligocene clay, marl- & limestone.

Specimens included. **ESTONIA**: **Saaremaa**, 12 km S of Kuressaare, island of Abruka, 5 m, on *Fomes fomentarius* on log of *Betula*, 14.IX.1993, K. Põldmaa (TAAM 161039, H.B. 5209 ø). — **GERMANY**: **Bayern**, **Niederbayern**, Bayerischer Wald, 9 km NE of Zwiesel, Höllbachspreng, 1015 m, on *F. fomentarius* on log of *Fraxinus excelsior*, 14.VI.2008, P. Welt (ex H.B. 8876, M-0276408, **holotype**).

Not included. **FRANCE**: **Bretagne**, **Ille-et-Vilaine**, 5.5 km ESE of Guer, NNW of Les Brulais, Rue des Buis, 60 m, on *Hymenochaete rubiginosa*, 19.XI.2004, J.P. Priou (J.P.P. 24240, doc. vid.). – **Bourgogne**, **Côte-d'Or**, 30 km NW of Dijon, 3 km ENE of Salmaise, Eremitage St-Jean-de-Bonnevaux, 432 m, on *Phellinus* (on *Acer*), 26.X.2009, A. Gardiennet, vid. J.P. Priou (J.P.P. 29205, doc. vid.).

Hyalorbilia berberidis (Velen.) Baral, in Baral & G. Marson, Micologia 2000: 44 (2001) — Pls 112–113, Map 16

≡ *Orbilia berberidis* Velen., Monogr. Discom. Bohem.: 99, pl. 11 fig. 27 (1934)

= *Orbilia exigua* Velen., Monogr. Discom. Bohem.: 100, pl. 11 fig. 2 (1934)

Misapplied name: Saccardo (1878: 429), as *O. chrysocoma* (identity uncertain).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.08–)0.12–0.4(–0.6) mm diam., 0.09–0.2 mm high (receptacle 0.06–0.1 → 0.04–0.045 mm), whitish, finally pale to light yellowish-cream, translucent, round to slightly undulating, non-gelatinous, ± scattered or in small groups; disc flat, margin thin, indistinct, smooth; subsessile or often with a distinct, obconical or cylindrical stipe 0.03–0.11 × 0.06–0.15 mm, superficial or very slightly immersed; dry yellowish-ochraceous-amber(-reddish). **Asci** *(25–)30–40(–46) × 5–7.5(–8) µm {9}, †(21–)23–35(–40) × 3.8–5.2 µm {8}, 8-spored, spores *4-seriate in two superimposed bundles, also mixed in one bundle, pars sporifera *(16–)19–26(–31) µm long; **apex** (†) hemispherical to slightly truncate; **base** with very short, thick stalk, arising from croziers {12} without or often with small, round or slit-like perforation; often with a group of medium-sized LBs inside stalk near base {6}. **Ascospores** *(9.5–)11–14(–17.5) × (1.1–)1.2–1.6(–1.8) µm {14}, †(9–)10–13(–15) × (0.9–)1–1.2(–1.3) µm {9}, narrowly fusoid (± cylindrical in middle part), rarely one end less tapered than the other, both ends rounded to subacute (obtuse to acute when dead), consistently slightly to strongly curved (falcate, sometimes slightly helicoid), in dead state very slightly to medium curved; 3–6 **SBs** in each half towards the poles (18), globose (to broadly ellipsoid), 0.3–0.8 × 0.3–0.6 µm {5}; LBs sparse, minute. **Paraphyses** apically uninflated to medium (rarely strongly) clavate-capitate, terminal cells *16–21 × 3–5.5 µm {3}, †11.5–20 × (1.8–)2.6–5(–6) µm {3}, lower cells *5.5–10(–12) × 2–3.5(–4) µm {2}, †4–8 × 1.5–3 µm {3}. **Medullary excipulum** 10–35 µm thick, of dense textura globulosa-angularis or medium dense t. intricata, non-gelatinized, medium sharply delimited. **Ectal excipulum** slightly gelatinized, in stipe of vertical t. prismatica, 20–110 µm thick near base, cells */†(9–)12–30(–40) × 7–16(–19) µm {6}; at flanks of thin-walled, horizontally oriented t. (angularis-)prismatica(-porrecta), cells *7–23 × 5–13 µm {4}, 10–15 µm thick near margin, marginal cortical cells ± strongly clavate, *8–24 × (4–)5–9 µm {3}, †10–19 × 4–9.5 µm {2}. **Anchoring hyphae** sparse, only at base, *2.2–4 µm wide {1}, †1.7–3.7 µm {3}, up to 5 µm at insertion, walls 0.2–0.3(–0.4) µm thick {4}. **VBs** in paraphyses and marginal cortical cells rather low-refractive, either one large elongate or some smaller globose VBs. **Exudate** over paraphyses 0.1–1.2 µm thick, continuous, strongly warted; over margin and flanks finely granular, pale yellowish-amber. — **ANAMORPH**: unknown.

Habitat: usually lying on moist ground or on a pile 0.2–0.5 m above the ground, corticated, 9–40 mm thick branches, also on thick stumps or logs, of *Alnus glutinosa* {1}, *Berberis vulgaris* {2}, *Betula* sp. {2}, *Corylus avellana* {1}, *Cytisus scoparius* {1}, *Fagus sylvatica* {2}, *Ilex canariensis* {1}, *Picea abies* {1}, *Pinus sylvestris* {1}, *Prunus spinosa* {1}, *Pseudotsuga menziesii* {1}, *Quercus* sp. {1}, *Q. robur* {1}, *Rosa* sp. {1}, *Ulex europaeus* {7}, unidentified angiosperm {3}, on 0.5–2 mm deep strongly decayed bark {12} (on periderm or edges of bast), wood {10}, or boring dust {1}; herbaceous stems of *Hydrangea* sp. {1}; on or rarely in pores of *Fomes fomentarius* {1}, *Fomitiporia punctata* {2}, *Fomitopsis pinicola* {1}, *Ganoderma applanatum* {2}, *Phylloporia ribis* {1}, *Physarum* sp. {1}, *Schizopora paradoxa* {1}, *Stereum rugosum* {1}, indet. resupinate polypore {1}, basidiomata sometimes internally with abundant insect galleries, sometimes on old stromata of *Diatrypella favacea* {1}; substrate ungreyed or ± blackened, without or sometimes with abundant green algae. **Associated**: *Ascotremella faginea* {1}, *Bionectria ralfsii* {1}, *Cacumisporium capitulatum* {1}, *Hymenoscyphus phiala* {1}, *Hyalorbilia inflatula* {1}, *H. polypori* {1}, *H. ?subfusispora* {1}, *Hyaloscypha leucostigma* {1}, *Hypomyces albidus* {1}, *Lophocolea* sp. {1}, *L. heterophylla* {1}, *Mollisia* sp. {1}, *Orbilia eucalypti* {1}, *O. vinosa* {1}, *Polydesmia pruinosa* {1}, *Schizophyllum commune* {1}, *Torrubiella* sp. {1}, *Trichaptum biforme* {1}, *Venturiocistella ulicicola* {1}. **Desiccation tolerance**: after 1–6 days in the herbarium only the spores survived. **Altitude**: 12–1050 m a.s.l. (central Europe), ~1800–2730 m (southern China). **Geology**: Europe: Ordovician & Silurian marble, shale, silt- & sandstone, Devonian & Carboniferous sediments, Buntsandstein, Cretaceous flysch, Tertiary calcareous clay- & marlstone, molasse, Pleistocene sand, clay & till; granite, granodiorite, granitoid (syenitoid), basalt, biotite-amphibolite & quartz diorite, mica schist, gneiss, serpentinite; China: Paleozoic & Jurassic rock. **Phenology**: throughout the year.

Phenology of *H. berberidis*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
3	0	1	0	1	4	2	7	6	5	3	3

Taxonomic remarks. *Hyalorbilia berberidis* is characterized by comparatively long, very narrowly fusoid, more or less distinctly curved (falcate) ascospores. Populations with only slightly curved spores approach the straighter-spored *H. fomentarii* or *H. juliae* in which some slightly curved spores sometimes occurred. In contrast to *H. berberidis*, *H. juliae* prefers distinctly more xeric substrate. A somewhat intermediate taxon (*H. fomentarii*) differs from both in narrower spores. *H. arcuata* differs from *H. berberidis* in much shorter and more curved spores. *Orbilia auricolor* and related species may be confused with *H. berberidis* due to their arcuate, similarly sized though heteropolar spores. This superficial similarity was also stated by Svrček (1959: 214, as *O. curvatispora*).

Variation. The examined collections of *H. berberidis* somewhat vary among each other, mainly in spore length (from 9.5–13 to 13–16 µm in situ) and in the strength of spore curvature, also in ascus size. Seemingly straight spores (Pl. 113: 3) probably belong to slightly curved spores seen in dorsal view. Nine out of 33 collections of *H. berberidis* were on basidiomycetes, and they did not differ in their microscopic features from those on bark and wood. Three records from southern China (Pl. 113: 11–13) are obviously conspecific, although the spores are mostly only slightly curved and a few even straight in the dead state, approaching *H. juliae*. In a collection on wood of *Sorbus aucuparia* from central Boehmia, Svrček (1959: 214) measured rather narrow spores (9–12 × 0.5–1 µm), but this might be an error since he measured too narrow spores also in the lectotype (compare measurements here gained from the lectotype, see below). The Belgian specimen (BR5020213021208V, with sequence) had spores of the short range (*9.5–13.5 × 1.2–1.4 µm, medium curved, IVV: 28.IX.2018) and is herewith designated as **epitype** of *H. berberidis*.

Type studies. Velenovský mentioned five substrates in the protologue. The lectotype of ***H. berberidis*** (PRM 152381, on branch of *Rosa*) was reexamined. It contained ~16 mature apothecia (rehydrated 0.15–0.25 mm in diam.) on decayed bark. Svrček (1954: 11) reported them as 0.1–0.5 mm, and the ascospores (11–14 × 0.7–0.8 µm) and paraphysis apices (up to 3 µm) distinctly narrower compared to the present result [Pl. 112: 1b, paraphyses (2–)4–6 µm wide]. Svrček designated the specimen on *Rosa* as lectotype, because he could not find apothecia in three of the remaining four paralectotypes of *H. berberidis*: *Hedera helix* (PRM 147718), *Prunus avium* (PRM

Lieksa, on *Fomes*; **7a–f**. H.B. 8653: Poland, Kłodzko, on *Diatrypella*; **8a–c**. H.B. 7638: Great Britain, Suffolk, on *Ulex*; **9**. TAAM 161311: Finland, Tammela, on *Fomitopsis*; **10a–b** H.B. 7655b: Portugal, Serra da Estrela, on *Cytisus*; **11a–c**. H.B. 8933: China, Yunnan, Dali, on indet. angiosperm; **12a–b**. H.B. 8934: ibid.; **13a–b**. J.W.G. xs-j-23: China, Yunnan, Kunming, on indet. angiosperm.

152396), and *Quercus palustris* (PRM 152414). Also in the present study no apothecia could be found in them. Svrček did not mention the collection on *Berberis vulgaris* (PRM 614783), however, perhaps because it was unavailable to him.

The protologue of *O. berberidis* appears to be derived mainly from the description of the *Berberis* collection, which was the first of Velenovský's five collections recorded on his manuscript sheet, and the measurements in the protologue (asci 30–35 × 5 µm, spores 10–12 µm) are exactly those on the only drawing on this sheet, which obviously concerns the *Berberis* collection. On this drawing the spores are about 0.5–1 µm wide, while on the modified drawing on pl. XI fig. 27 of the protologue they are about 0.3–0.8 µm wide. No apothecia could be found in the present examination of the *Berberis* collection.

Similarly, no apothecia were found in the type convolutes of ***O. emarginata*** (PRM 151746, on wood of *Picea*) and ***O. polyporacea*** (PRM 152458, on *Phylloporia ribis*), neither by Svrček nor in the present study. According to Svrček (1954: 19), a syntype of *O. polyporacea* (PRM 152384, on wood of *Quercus*) contains immature apothecia reminiscent of *O. tremulae* (as *O. xanthostigma*). No type material exists for ***O. exigua*** (on rotten stump of *Cornus sanguinea*, Svrček 1954: 14).

Velenovský (1934) did not explain why he distinguished four different species with so similar arcuate spores. Manuscript sheets with drawings exist for all of them. Spore length in *O. polyporacea* was given as 15 µm, whereas the other three had spores of 10–12 µm (*O. berberidis*, *O. emarginata*) or 12 µm (*O. exigua*). Since Velenovský did not always indicate the spore length range and omitted spore width, the differences remain obscure. The *Berberis* collection is described with the longest asci (30–35 × 5 µm). This length well corresponds to the measurement of dead asci in the lectotype on *Rosa* by Svrček (28–35 × 3.5–4.5 µm) and in the present study (Pl. 112: 1). On his manuscript sheet Velenovský described only the *Berberis* collection, but since he referred different collections to *O. berberidis*, it remains unclear to which of them his drawing belongs. The illustration provided by Velenovský (1934) for *O. berberidis* deviates somewhat from that on his manuscript sheet. In the other three taxa the asci are stated to be shorter (20–25 µm). Nevertheless, Svrček (1954: 14, 18) considered all of them as synonyms of *O. berberidis*, with the consequence that *H. berberidis* attains priority over them (ICN Art. 11.5). We more or less share Svrček's synonymisation here, because ascus length in *H. berberidis* was found to vary to some degree among the material included here, therefore, dead mature asci of 20 µm length might indeed occur in this species.

O. exigua shows rather strongly curved spores in the protologue, and Velenovský's illustration leaves little doubt about the identity with *H. berberidis*. In *O. polyporacea* and *O. emarginata* the spores are described and figured less curved. The figure of *O. emarginata* in Velenovský's manuscript shows somewhat heteropolar spores and an angular excipulum, which recalls a member of *Orbilia* section *Arthrobotrys*. However, the ascus base is illustrated unstalked, with 2 short legs and a deep notch between, suggestive of a perforated crozier, which is typical of *H. berberidis*. Hence *O. emarginata* clearly belongs to *Hyalorbilia*. The 'parenchymatic' excipulum of *O. exigua* was described as 'small-celled' (no cell size stated), and that of *O. polyporacea* as 'large-celled', but the excipulum of the latter is not figured on Velenovský's manuscript sheet.

Velenovský placed these four taxa in his subgroup 'IIa *Spirospora*', characterized by 'filiform, arcuate-curved' spores and unstalked asci, together with a fifth taxon, *O. oreadum*, with much shorter, very strongly curved spores (yet, in the type of *O. oreadum* all five apothecia examined showed almost straight spores, see Pl. 72: 1a). The name *Spirospora* is misleading since the spores do not form clear spirals in either of the included taxa.

Misapplication. *O. chrysocoma* s. Saccardo (1878: 429, Italy, [Venice, Treviso,] Conegliano, on *Morus alba*) might represent *H. berberidis*, judging from the brief description (nearly sessile asci, slightly curved spores 14–15 × 0.75–1 µm). The interpretation of *O. chrysocoma* was, however, highly different among the authors (Rehm 1891: 458), and the taxon is today used for a *Dacrymyces* (see p. 1665).

Phylogeny. A sequence comprising SSU (lacking S1506 intron), ITS, and LSU was gained from apothecia of the Belgian specimen. When analysing ITS or LSU separately (not shown), *H. berberidis* clustered, like *H. tortuosa*, unresolved in the core clade of *Hyalorbilia*, despite its morphological resemblance with *H. juliae*. When analysing ITS+LSU (Phyl. 6), *H. berberidis* clustered weakly supported with *H. tortuosa*, from which it differs in the ITS by 15% (8.3% in LSU D1–D2), which seems to be the lowest distance in comparison to other species (e.g., *H. fusispora* 21.5%). An environmental strain from Minnesota (H7, ITS) that clusters with *H. tortuosa* differs from *H. berberidis* by 15.7%.

In the LSU D1–D2 the lowest distance was 6.2% to *H. juliae* (ITS ~25%), 6.5% to *H. inflatula* (H.B. 9080, ITS 19%), and 7% to *H. helicospora* (ITS 19%). In the SSU V7–V9 *H. berberidis* fully concurs with *H. tortuosa*, while other available *Hyalorbilia* sequences differ in the V8–V9 region by 1–5 nt, the closest being *H. inflatula* (H.B. 9080 & 9915).

H. berberidis is unique within *Hyalorbilia* in the Orb5.8s3F primer region, differing by at least 1 nt from other taxa (*inflatula-polypori* clade, *H. subfusispora*, *H. latispora*) (Tab. 18). In the first 4 nt of ITS2 (AGTG) it concurs with only a few *Hyalorbilia* species, including *H. subfusispora* (Tab. 20). *H. berberidis* is also unique in stem-loop 8 of 5.8S where it concurs only with environmental strains (H7–8), although it did not cluster with them.

Two environmental sequences from Sweden in GenBank (FMOTU 3018, 5464), comprising partial 5.8S and ITS2, are very close to the present sequence of *H. berberidis*. In the entire ITS2 they differ from *H. berberidis* by 0.9% (FMOTU 5464) and 1.7% (FMOTU 3018), although they differ from each other by 2.5%. In stem-loop 8 and Orb5.8s3F of 5.8S and in the first 4 nt of ITS2 they concur with our *H. berberidis* sequence. Together with a high ITS distance to other *Hyalorbilia* spp. this seems to indicate that the Swedish extracts are conspecific with *H. berberidis*.

Ecology. The wide ecological amplitude of *Hyalorbilia berberidis* includes rotten bark and wood of hygric or sometimes mesic branches and stumps of trees and shrubs of angio-, rarely gymnosperms, also perennial basidiocarps, and even herbaceous stems. The species was found in various parts of planar to altimontane, humid or sometimes sub- or semihumid, atlantic to subcontinental Europe, with a meso- to orotemperate but also hemi- to mesoboreal and sometimes supra- to thermomediterranean climate. The vegetation includes gardens and orchards, alder swamps, conifer forests, atlantic *Ulex* and xerothermic *Cytisus* scrubs. The environmental isolates from Sweden (FMOTU 3018) came from *Pinus sylvestris* monocultures of very different age on acidic grass- or later moss-covered soil (Umbric podzol) over sandy, loamy till with many boulders, with increasingly abundant *Picea abies* in understory (A. Rosling & P. Fransson pers. comm., see also Hagenbo et al. 2017). The origin of FMOTU 5464 could not be clarified (A. Rosling & P. Fransson pers. comm.). In Macaronesia it grew in the thermomediterranean subhumid laurel forest zone of Monte de las Mercedes in northeastern Tenerife. Collections from southern China are from subtropical humid (winter-dry) evergreen forests.

H. berberidis was collected on hygric or mesic substrate close to the ground, often on branches lying on a pile, also on the lower side of logs. In a few collections the apothecia grew on more xeric substrate: dry standing *Hydrangea* stem at a shady and moist place, dry *Picea* wood (type of *O. emarginata*), *Cytisus* branch with *O. vinosa*. This indicates a certain desiccation tolerance of the apothecia, though our tests did not reveal such a tolerance so far.

Specimens included. **SWEDEN**: **Uppsala**, 32 km NNE of Uppsala, 8 km SSW of Österbybruk, 71 m, soil isolate from 46 years old *Pinus sylvestris* forest, X.2014, P. Fransson (FMOTU 3018, mol. extr., sq.: KU062739). – ibid., 3 km SW of Österbybruk, 63 m, 12 years old *Pinus sylvestris* forest (FMOTU 3018, mol. extr.). – ibid., 2.8 km SSW of Österbybruk, 54 m, 160 years old *Pinus sylvestris* forest (FMOTU 3018, mol. extr.). – unlocalized (FMOTU 5464, mol. extr., sq.: KU062066). — **FINLAND**: **North Karelia**, 14 km WNW of Outokumpu, Rikkaranta, Pennala farm, ~125 m, on *Fomitiporia punctata* on log of *Salix*, 27.VI.2010, M. Pennanen (ex M.P. 100634, JOE, doc. vid.). – 26 km SSW of Lieksa, 1.5 km SE of Koli, ENE of Forest Research Institute, ~180 m, on *Fomes fomentarius*, 11.VIII.1995, K. Põldmaa (TAAM 161661, H.B. 5361 ø). – **Kanta-Häme**, 18 km SSE of Tammela, 0.4 km N of Korteniemi, Liesjärvi, Ahonnokka spruce forest, 110 m, on *Fomitopsis pinicola* on log of *Betula*, 11.IX.1994, K. Põldmaa (TAAM 161311, H.B. 7978 ø). — **ESTONIA**: **Harjumaa**, 6 km WSW of Aespa, 6 km NE of Kernu, Metsanurga, 55 m, on *Fomitiporia punctata* on log of *Corylus avellana*, 26.IX.1994, K. Põldmaa (TAAM 161475, H.B. 7979 ø). — **POLAND**: **West Pomerania**, 20 km SE of Szczecin, 1.7 km NE of Dobropole Gryfiński, Puszcza Bukowa, 88 m, on *Ganoderma applanatum*, 21.III.2009, P. Perz & G. Domian (H.B. 9160a). **Lower Silesia**, 9 km S of Kłodzko, 2 km S of Żelazno, Bielica Mt., 420 m, on *Diatrypella favacea* and bark of branch of *Betula*, 27.VIII.2007, P. Perz (P.P. 20070827-1, H.B. 8653). – ibid., on stump of *Pinus sylvestris*, on bark, 21.XI.2006, P. Perz (P.P. 20070820-1, H.B. 8605a). – 12.5 km SE of Bystrzyca Kłodzka, 8.5 km NE of Miedzylesie, N of Nowa Wies, 525 m, on *Schizopora paradoxa* var. *paradoxa* on branch of ?*Corylus*, 26.XII.2009, P. Perz (P.P. 20091226-2, doc. vid.). — **GREAT BRITAIN**: **East England**, **Suffolk**, 4 km ESE of Halesworth, 0.4 km NNW of Wenhaston, Bicker's Heath, 15 m, branch of *Ulex europaeus*, on bark, 14.I.2004, S. Francis & E. Batten (E.B. 4472, H.B. 7455). – ibid., NNE of Wenhaston, Blyford Lane, Garden Hill Cottage, 12 m, branch of *U. europaeus*, on bark, 8.XII.2004, E. Batten (E.B. 4573, H.B. 7638 ø). – ibid., branch of *Ulex europaeus*, on bark, 10.I.2005, E. Batten (H.B. 7648b ø). – branch of *U. europaeus*, on bark, 5.VIII.2005, E. Batten (E.B. 4619, H.B. 7866). – ibid., branch of *U. europaeus*, on bark, 19.IX.2005, S.M. Francis (H.B. 7905a). — **NETHERLANDS**: **Noord-Brabant**, 4 km NNW of Boxmeer, 1 km W of Helbroek, De Vilt, 12 m, branch of *Quercus*, on wood, 4.X.2009, S. Helleman (S.H. 641, doc. vid.). — **BELGIUM**: **Vlaanderen**, **Antwerpen**, 13 km SE of Turnhout, 5 km WSW of Dessel, Prinsenpark, 27 m, branch *Fagus sylvatica*, on wood and indet. resupinate polypore, 28.IX.2018, F. Bartholomeeusen (ex F.B. 20180928PP01, BR5020213021208V, doc. vid., **epitype** of *H. berberidis*; sq.: MK473403). — **FRANCE**: **Bretagne**, **Morbihan**, 2 km S of La Gacilly, S of Lestun, Pré Naval, 17 m, branch of *Ulex europaeus*, on wood, 5.XI.2013, J.P. Priou (J.P.P. 13222, doc. vid.). – **Nord-Pas-de-Calais**, **Pas-de-Calais**, 17 km WSW of Calais, 1.4 km SSW of Wissant, la Motte du Bourg, 10 m, branch of *Ulex europaeus*, on bark, 29.X.2016, J.P. Priou (J.P.P. 16279, doc. vid.). – **Champagne-Ardenne**, **Ardennes**, 3 km WSW of Charleville- Mézières, 1 km W of Prix-lès-Mézières, rue de Moulin, 150 m, stem of *Hydrangea*, 18.VIII.2001, R. Collot (ø, doc. vid.). – **Lorraine**, **Vosges**, 4 km SE of Gérardmer, La Ferme de Grouvelin, 1050 m, branch of *Alnus glutinosa*, on bark, 4.IX.1996, H.O. Baral (H.B. 5574). — **GERMANY**: **Sachsen**, 9.5 km SE of Chemnitz, 1.3 km NW of Dittmannsdorf, 375 m, branch of *Quercus robur*, on wood, 4.VIII.2014, B. Mühler (ø, doc. vid.). – **Rheinland-Pfalz**, Pfälzer Wald, 14 km SE of Pirmasens, 0.8 km SE of Dahn, below military cemetery, 250 m, branch of *Prunus spinosa*, on wood, 2.X.1994, H.O. Baral & G. Marson (H.B. 5158a). – **Bayern**, **Niederbayern**, Bayerischer Wald, ~12 km SE of Zwiesel, ~4.5 km NNE of Spiegelau, Lärchenberg (southern slope of Großer Rachel), 890 m, on *Ganoderma applanatum*, 25.V.1990, N. Luschka 1658 (M, H.B. 5210 ø). — **CZECHIA**: **Central Bohemia**, 27 km SE of Praha, Mnichovice, ~370 m, branch of *Rosa*, on bark, VIII.1926, J. Map 16. Known distribution of *H. berberidis* in Europe and Macaronesia.

Hyalorbilia fusispora (Velen.) Baral & G. Marson, Micologia 2000: 44 (2001) — Pls 114–115, Map 17

≡ *Orbilia fusispora* Velen., Monogr. Discom. Bohem.: 96, pl. 11 fig. 38 (1934)

Etymology: referring to the fusiform (rhomboid) shape of the ascospores.
Typification: Czechia, Central Bohemia, Mnichovice, branch of *Lonicera tatarica*, VII.1926, J. Velenovský (PRM 152442, holotype); France, Deux Sèvres, Niort, trunk of *Ulmus*, 2.III.2007, M. Hairaud (ex H.B. 8447b, M-0291770, epitype, designated here, MBT385108; sq.: KT222379).
Misinterpretation of *H. fusispora*: Liu (2006: 33, 2007b), (?)= *H. ulicicola*; Guo et al. (2014b), ?= *H. texensis* or *H. ulicicola.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–1.5(–2.2) mm diam., 0.14–0.25 mm high (receptacle 0.1–0.19 → 0.06–0.09 mm), pale chlorinaceous-olivaceous to mostly light yellowish-cream or ochraceous-orange-amber, bright red-brown with age, semitranslucent, round to slightly undulating, not or only slightly gelatinous, very scattered or subgregarious in small groups; disc slightly to strongly concave, eventually flat, margin thin or thick, 0–15 µm rising

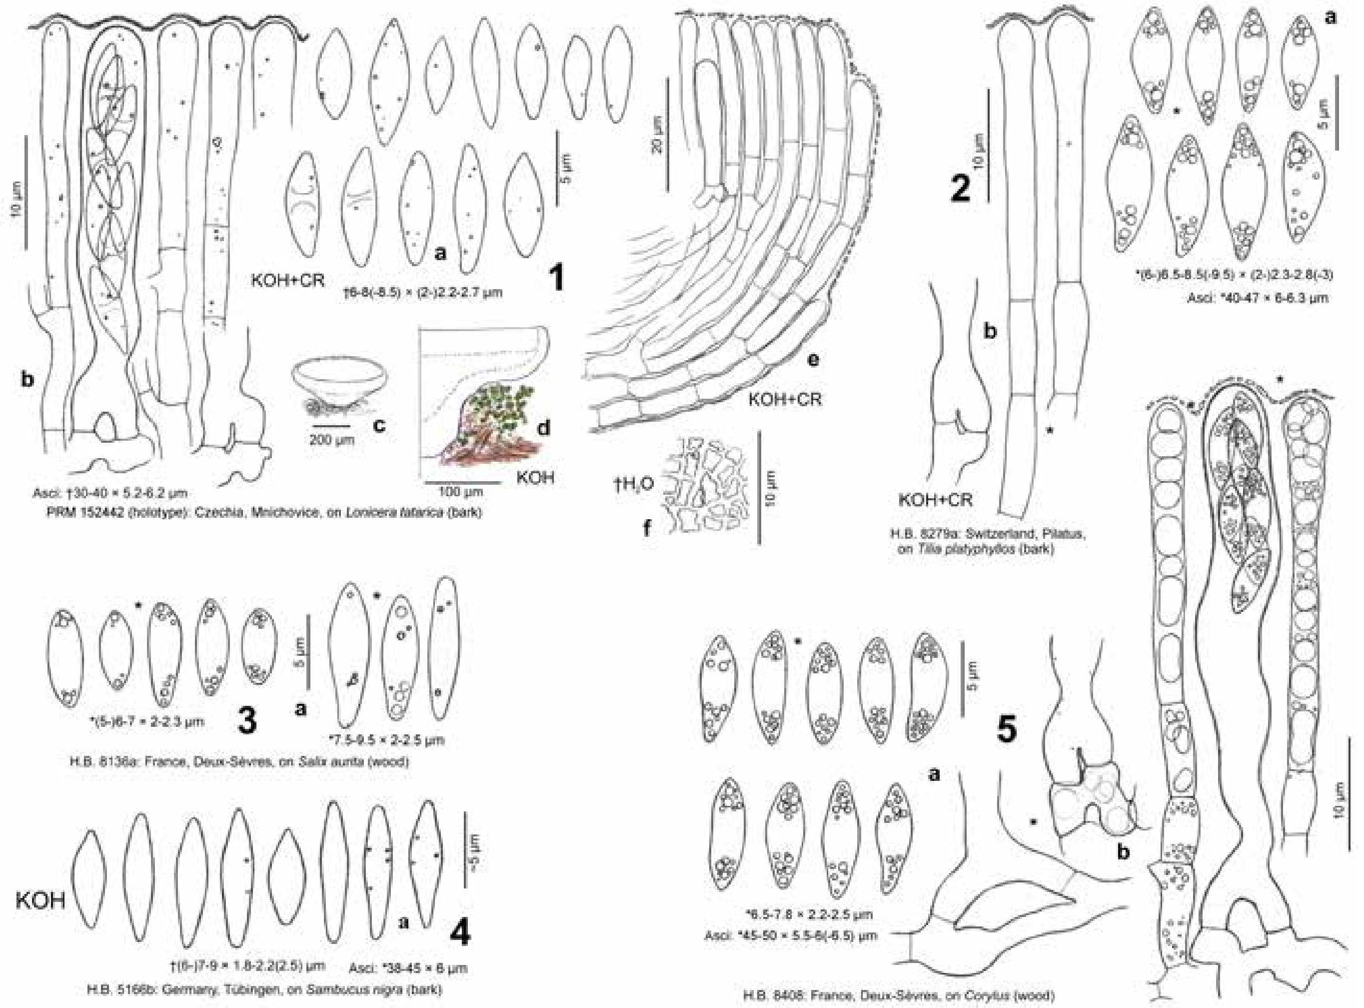

Plate 114: **1–5**: *Hyalorbilia fusispora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. apothecium (rehydrated); **d**. apothecium in median section; **e**. id., ectal excipulum at margin and mid flanks; **f**. cloddy exudate on ectal excipulum in surface view.

above disc, smooth; subsessile or with a distinct, obconical to cylindrical stipe 0.08–0.1 × 0.1–0.22 mm, superficial; dry light yellowish-ochre or bright orange-brown. **Asci** *(30–)35–47(–50) × (5.5–)5.7–6.5(–7) µm {6}, †(26.5–)30–47 × (4.5–)5–5.8(–6.2) µm {5}, 8-spored, spores 2–3-seriate, pars sporifera *15–28 µm long; **apex** (†) hemispherical; **base** with short to medium long, thick, ± flexuous stipe arising from croziers {8} with minute or often pore- to slit-like to very large perforation (base Y- to nearly T-shaped). **Ascospores** *((4.5–))(5–)6–9(–9.7)((–10.3)) × (2–)2.2–2.7(–3) µm {24}, †(4.5–)5.5–8(–9.5) × (1.7–)2–2.4(–2.7) µm {8}, fusoid to fusiform (rhomboid), rarely ellipsoid, ± homopolar, ends obtuse or mostly distinctly subacute to acute, straight to slightly, exceptionally distinctly inequilateral; (1–)2–5 globose **SBs** in each end, *0.3–0.8 µm diam. {6}; with a few minute LBs. **Paraphyses** apically uninflated or only slightly clavate, terminal cells *15.3–21 {1} or *23–33 {2} × 2.5–4.7 µm {3}, †12–19 × 2–3.8 µm {2} or †18–27 × (2–)2.5–3.5(–4) µm {T}, lower cells *6–11 × 2–3(–4) µm {2}, †5.5–11 × 1.7–3 µm {T}. **Medullary excipulum** 20 µm thick, of dense, non-gelatinized textura intricata-angularis, very indistinctly delimited. **Ectal excipulum** of thin-walled, rarely slightly gelatinized, horizontally oriented t. prismatica at base and flanks, at base ~40–120 µm thick, cells *(9–)15–35(–46) × 6–13(–26) µm {6}, †7–17 × 5–9 µm {T}, inner part of t. prismatica-porrecta (cells *20–60 × 8–12 µm), at flanks 10–30 µm thick, cells *7–20 × 4.5–7 µm {2}, †8–13 × 3–4.5 µm (T), at margin of t. porrecta, 10–20 µm thick, marginal cortical cells narrowly clavate, *8–22 × 3–5 µm {4}, †(8–)12–20(–25) {4} × 3–5 µm {7}, in surface view likewise 3–5(–6) µm wide. **Anchoring hyphae** sparse to very abundant, ± vertically radiating, */†2–4(–6), walls 0.2–0.4(–1) µm thick {7}. **VBs** in terminal cells of paraphyses and in marginal cortical cells low- to medium refractive, pale yellowish-chlorinaceous, multiguttulate to elongate; **LBs** in ectal excipular cells minute or absent. **Exudate** over paraphyses and complete ectal excipulum, 0.2–0.4(–1) µm thick, continuous to granular, mostly distinctly warted, light golden yellowish(-orange) mainly over excipulum. **— ANAMORPH**: unknown (but see below).

Habitat: collected 0.7–4 m above the ground, corticated to almost decorticated, 6–45 mm thick branches (and roots), also standing 20–30 cm thick living trunks of *Acer* sp. {1}, *A. pseudoplatanus* {1}, *Aesculus hippocastanum* {1}, *Artemisia thuscula* {1}, *Betula* sp. {1}, *Cornus sanguinea* {1}, *Corylus avellana* {2}, *Euonymus europaeus* {1}, *Ficus carica* {1}, *Frangula alnus* {1}, *Fraxinus excelsior* {3}, *Juniperus* sp. {1}, *Lonicera periclymenum* {1}, *L. tatarica* {1}, *Malus domestica* {1}, *Olea europaea* {1}, *Prunus avium* {1}, *P. ?serotina* {1}, *P. spinosa* {1}, *Quercus* sp. {1}, *Q. pubescens* {2}, *Robinia pseudoacacia* {1}, *Rubus fruticosus* {1}, *Salix* sp. {9}, *S. aurita* {1}, *Sambucus nigra* {2}, *Suaeda vera* {1}, *Tilia platyphyllos* {1}, *Ulmus* sp. {4}, indet. angiosperm {1}, on outer surface of (partially detaching) bark (periderm and bast) {28} or wood {19} (but often close to bark), up to 1 mm deep medium to very strongly decayed, sometimes on edges of bark or hidden in cracks and holes, slightly greyed (sometimes blackened), also on living leaves of *Frullania dilatata* {1}; green algae sparse to very abundant, often among lichens and small bryophytes. **Associated**: *Bryocentria brongniartii* {2}, *B. callicarpa* {1}, *Caloplaca* sp. {1}, *Dacrymyces* sp. {1}, *Decaisnella mesascium* {1}, *Diplolaeviopsis* sp. {1}, *Frullania dilatata* {1/1}, *Helicogermslita gaudefroyi* {1}, *Hyalorbilia inflatula* {1}, *H. juliae* {4}, *H. ulicicola* {1}, *Hysterium angustatum* {2}, *Karstenia idaei*

Phenology of *H. fusispora*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
5	6	6	7	1	3	4	5	0	2	4	3

Map 17. Known distribution of *H. fusispora* in Europe and Macaronesia.

Taxonomic remarks. *Hyalorbilia fusispora* is characterized by broad, straight, fusoid to fusiform ascospores, a textura porrecta of rather narrow cells at the margin, and comparatively large, often distinctly ochraceous, desiccation-tolerant apothecia. For the similar *H. subfusispora* see under that species, p. 401. *H. texensis* and *H. polypori* differ in narrower spores eguttulate or with only a few minute drops at each end, the former also in shorter spores, the latter in more cylindrical spores and desiccation-sensitive apothecia with wider marginal cells. *H. ulicicola* deviates in much smaller spores and desiccation-sensitive apothecia. A collection from France (Niort, on *Ulmus*, ex H.B. 8447b, Pl. 115: 7), from which a sequence was gained and which well corresponds to the holotype, is designated here as **epitype** of *H. fusispora*.

Variation. The species shows some variability in ascus and spore size and in spore shape (between ellipsoid and fusiform), but this variation is often also observed within a collection. In the sample from Austria the spores were extraordinarily small (†5–6.5 × 1.7–2 µm).

Type studies. Svrček (1954) stated that the holotype convolute of *Orbilia fusispora* and *O. fusispora* var. *microscopica* (PRM 152442, a mixture in the same convolute) is empty. Yet, nine apothecia of *Hyalorbilia* (and some of *Karstenia rhopaloides*) were found on the three small fragments of bark. Three apothecia (each from a different bark fragment) were examined. Two were found to have broadly fusiform spores which fit very well Velenovský's protologue of *O. fusispora*. The third showed long and narrow, subcylindrical spores which closely match the protologue of *O. fusispora* var. *microscopica* (Pl. 108 Fig. 1), a taxon which is considered here to be a synonym of *H. juliae*. This was one of three distinctly smaller, more whitish apothecia, which all occur on the same chip of bark and which obviously represent the holotype of var. *microscopica*. The examined apothecia of *H. fusispora* are larger (rehydrated 0.2–0.5 mm) than indicated by Velenovský (0.1–0.3 mm) who seems to have included apothecial size of var. *microscopica* in the protologue of *O. fusispora*. Also the asci are larger (see Pl. 114: 1b) than stated by him (25–30 × 5 µm). The spores fit very well his drawing. Velenovský gave a length of 4–10 µm, although he wrote in his manuscript 4–6 µm. No data of further collections are mentioned. The large range of spore size probably includes var. *microscopica*, though spore length of that taxon in his manuscript is give as 12 µm. That Velenovský separated these two very different taxa only at the variety level is probably due to their mixed growth on the same branch. The extraordinary width of the spores observed in the holotype of *H. fusispora* (Pl. 114: 1a) appears to originate from artificial flattening.

Misapplication. Under the name *H. fusispora*, Liu (2006: 33) and Liu et al. (2007b) reported 13 collections from China which, because of their rather small ascospores, appear to fit better *H. ulicicola* (see p. 325). The same is true for eight Chinese collections reported by Guo et al. (2014b), except that spore shape is more similar to *H. texensis*. The spore bodies described by Guo et al. (one elongate terminal and 3–5 globose peripheral SBs 0.4–0.5 µm diam. in each spore half) recall *H. subfusispora*, but the spores of †4.3–6 × 1.3–1.5 µm are too small.

Anamorph. We observed in H.B. 8033 narrow, flexuous phragmoconidia (*28–30 × 1.5 µm, see IVV) and in H.B. 8136a one small dwayaangam yakuensis-like conidium (*35 × 20 µm, Pl. 115: 10d). Whether one of these conidial types represents the anamorph of *H. fusispora* is unclear.

Phylogeny. An ITS sequence of *H. fusispora* (H.B. 8447b) was gained from apothecia. It clustered unsupported and with a > 20 % distance sister to the *juliae-tenuifusaria* clade (Phyl. 5). When tentatively including it in the combined analysis (Phyl. 6, not shown), *H. fusispora* clustered unresolved, although the *juliae-tenuifusaria* clade received strong support. The morphologically similar *H. subfusispora* shows a 26 % distance and clustered sister to the *oviparasitica-multiguttulata* clade. In the 5.8S region, *H. fusispora* differs from the identical *H. tenuifusaria* and *H. juliae* by 1 nt, from *H. ulicicola* by 2 nt, and from *H. subfusispora* by 3 nt (all deviations in Orb5.8s3F, Tab. 18), whereas *H. lunata* differs by 6 nt (all deviations in Orb5.8s3F and stem-loop B8, Tab. S4).

Ecology. *Hyalorbilia fusispora* was found on ± rotten wood and bark of xeric branches and trunks of various angiosperm (rarely coniferous) trees and shrubs. From its consistent occurrence on exposed substrate, a drought tolerance higher than here observed can be expected. The species was collected in humid (rarely semihumid), atlantic to subcontinental Europe in a meso- to supratemperate but also suprasub- to mesosubmediterranean, rarely orotemperate to orosubmediterranean, or mesomediterranean climate. The vegetation comprises sun-exposed borders of mostly thermophilous forests, hedges, overgrown gardens, also marshland. A single record in Macaronesia (Tenerife) was in the inframediterranean semiarid cardonal xerophytic scrubland (*Periploco laevigatae-Euphorbietum canariensis*).

Specimens included. **GREAT BRITAIN**: **South East England**, **West Sussex**, 3.3 km NE of Crawley, Milton Mt. Lake, 72 m, branches of *Salix*, on bark, 1.I.2016, N. Aplin (N.P. 333, doc. vid.). — **NETHERLANDS**: **Gelderland**, 6 km SW of Nijmegen, W of Aldenhof, Staddijkpark, 12 m, branch of ?*Prunus serotina*, on wood, 17.II.2007, S. Helleman (S.H. 432, doc. vid.). – ibid., branch of *Salix*, on wood, 24.II.2007, S. Helleman (S.H. 434, doc. vid.). – **Noord-Brabant**, 5.5 km NW of Boxmeer, 3 km NW of Beugen, NW of Haart, 10 m, twig of *Prunus avium*, on bark, 22.III.2011, S. Helleman (ø, doc. vid.). – 4 km NNW of Boxmeer, 1 km NNW of Beugen, W of Helbroek, De Vilt, 12 m, branch of *Salix*, on wood & bark, 18.II.2007, S. Helleman (S.H. 433, doc. vid.). – 1 km NW of Boxmeer, Brestbos, 18 m, 9.VI.2015, twig of *Frangula alnus*, on wood, 9.VI.2015, S. Hyalorbilia subfusispora Baral, G. Marson & P. Perz, **sp. nov.**, MB 813461 — Pls 116–118, Map 18

Etymology: named after the spores that resemble those of *H. fusispora*.
Typification: Germany, Baden-Württemberg, Tübingen, branches of *Salix caprea*, 26.III.1996, H.O. Baral (ex H.B. 5432a, M-0276418, holotype).
Misapplied name: Baral in Krieglsteiner (1999: 271), as *Orbilia vitalbae*.

Latin diagnosis: Hyalorbiliae fusisporae *similis sed apothecia minora*, *pallide colorata*, *cellulae marginales multo magis inflatae*, *ascosporae vivae prope polos plerumque duo corpuscula refringentia elongata continentes*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.08–)0.1–0.35(–0.5)((–0.65)) mm diam., (0.06–)0.08–0.15(–0.21) mm high (receptacle 0.05–0.11 mm), whitish-greyish, pale yellowish-cream to chlorinaceous, medium to strongly (glassy-)translucent, ± round, slightly or medium or strongly gelatinous, very scattered to gregarious in usually only small groups; disc slightly concave to flat, rarely slightly convex, margin thin, 0–5(–10) µm rising above disc, even; sessile on an obconical base or often with a ± distinct, obconical to cylindrical stipe 0.03–0.11(–0.18) × 0.04–0.14 mm, superficial; dry pale greyish-cream-chlorinaceous. **Asci** *(22–)25–35(–38) × (5.5–)6–7(–7.5) µm {8}, †19–25 {4} or 24–30(–35) {12} × (4.2–)4.8–6.2(–7) µm {16}, 8-spored, spores 2–4-seriate, rarely a single basal heteropolar spore inversely oriented, pars sporifera *15–20(–24) → 11.5–14 µm long; **apex** (†) hemispherical (to somewhat conico-truncate); **base** with short, thick stipe arising from croziers {9} with or without round to often slit-like perforation. **Ascospores** *(4.5–)5.5–8(–9.5) × (1.7–)1.9–2.3(–2.5) µm {32}, †(5–)6–8(–9.5) × (1.5–)1.7–2(–2.2) µm {7}, fusoid- to fusiform(-clavate), sometimes ellipsoid, ends subacute to acute, sometimes obtuse or acuminate, straight to slightly inequilateral, only a few slightly curved; 1 **SB** in each spore end, *(0.4–)0.6–1.4(–1.8) × (0.4–)0.5–0.8(–1) µm {15}, (sub)globose to ovoid or (elongate) tear-shaped, closely attached or sometimes with an inconspicuous, very short filum (mostly not seen), often 1–5 further, ± laterally arranged, ± globose SBs in each spore half, 0.3–0.6(–1) µm diam., sometimes all SBs globose; with a few minute LBs. **Paraphyses** apically uninflated or slightly (to medium) clavate-capitate, terminal cells *(10–)13–19(–25) × (2.5–)3–5(–5.5) µm {5}, †10–19(–21) × (2–)2.5–4.2(–5) µm {5}, lower cells *(3.5–)5–10 × 1.8–3 µm {2}, †6–10 × 1.3–2 µm {1}. **Medullary excipulum** 10–20(–50) µm thick, of non- or slightly gelatinized textura globulosa-intricata or t. prismatica-porrecta, indistinctly delimited. **Ectal excipulum** of very thin-walled or slightly gelatinized, indistinctly oriented t. globulosa-angularis or horizontal

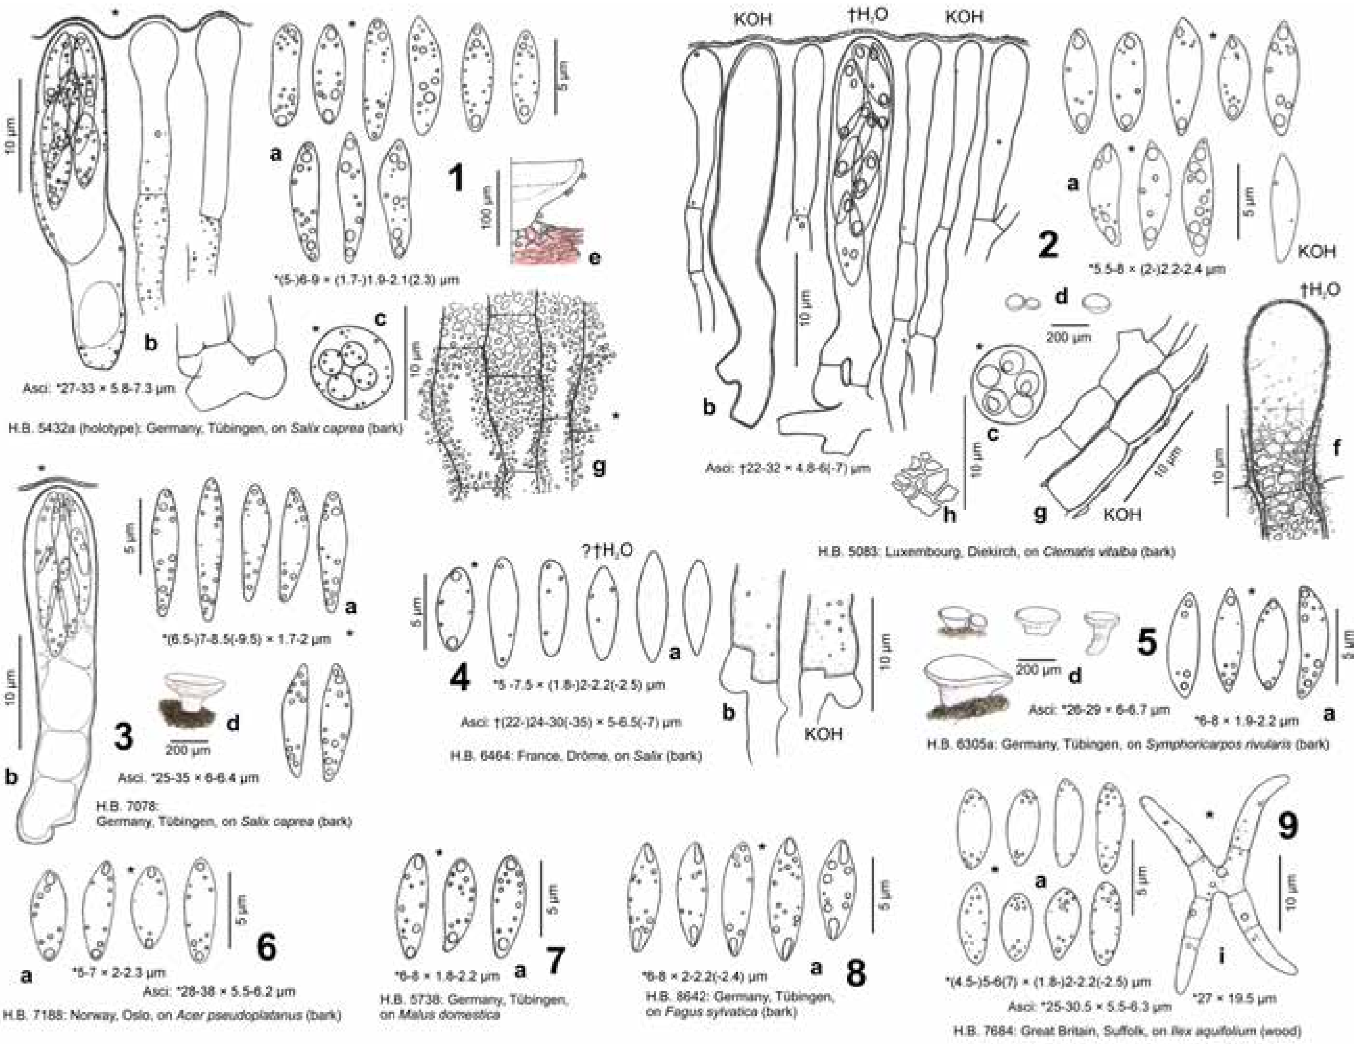

Plate 116. **1–9**: *Hyalorbilia subfusispora*. – **a**. ascospores; **b**. asci and paraphyses (ascus bases with croziers); **c**. asci with spores in optical cross section; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. marginal cortical cell (surface view); **g**. ectal excipulum at flanks (with warted exudate, surface view in **1g**, median section in **2g**); **h**. cloddy exudate on hymenium (top view); **i**. conidium from substrate.

t. angularis-prismatica from base to margin, at base ~40–50 µm thick, cells near stipe *10–27(–35) × 7–15(–23) µm {6}, at flanks 10–20 µm thick, cells */†(3–)5–12(–15)((–18)) × (2.5–)3–8(–11) × 8–11 µm {5}, marginal cortical cells broadly clavate, */†(8–)10–18(–20) × (3.5–)6–7.5 µm {16} [(5–)6–10(–12.5) µm wide in surface view]. **Anchoring hyphae** sparse to medium abundant, vertically radiating, */†(1.5–)2–4 µm wide, near insertion 4–5.5 µm, walls */†0.2(–0.3) µm thick {8}. **VBs** present in terminal cells of paraphyses, very low to medium refractive, very pale chlorinaceous, rarely yellowish, large but also multiguttulate; in marginal cortical cells absent or with 1 large VB; **LBs** in ectal excipulum near base: 1 or several large (1–2.8 µm) and some small ones in each cell {4}, but LBs absent or sparse and minute in a major part of collections. **Exudate** over paraphyses and excipulum 0.2–0.8 µm thick, continuous, nearly smooth or mostly distinctly rough to clod-shaped, pale chlorinaceous. — **ANAMORPH**: curucispora-like (presumed, from natural substrate {5}). **Conidiophores** not observed. **Conidia** mostly K-shaped (under cover slip, but forming a tetragonal structure when floating), with 3 arms and a stipe, rarely 2-armed or more than 4-armed, total size *27–45 × 11–22 µm {4} (K-conidia in side view in a plane), stipe *14–20 × 2.5–4.5 µm, 2–4-septate, arms *(10–)14–22 × 2–4(–4.5) µm, 2–4-septate; containing globose refractive SCBs.

Habitat: collected 0–4 m above the ground, corticated to partially, rarely entirely decorticated, 4–60 mm thick dead twigs and branches, also 10–20 cm thick living trunks of *Acer* sp. {2}, *A. campestre* {1}, *A. pseudoplatanus* {4}, *Aesculus hippocastanum* {1}, *Betula pendula* {1}, *Carpinus betulus* {1}, *Clematis vitalba* {8}, *Cornus* sp. {1}, *C. sanguinea* {5}, *Corylus avellana* {2}, *Cryptomeria japonica* {1}, *Cydonia oblonga* {1}, *Elaeagnus angustifolia* {1}, *Fagus sylvatica* {10}, *Fraxinus excelsior* {1}, *Ilex aquifolium* {3}, *Ligustrum vulgare* {1}, *Malus domestica* {3}, *Picea abies* {1}, *Pinus nigra* {1}, *Populus* sp. {1}, *Populus tremula* {1}, *Prunus avium* {1}, *P. domestica* {1}, *P. spinosa* {4}, *Quercus* sp. {4}, *Q. rubra* {1}, ?*Rhamnus cathartica* {1}, *Robinia pseudoacacia* {2}, *Rubus* (?)*bifrons* {1}, *R. fruticosus* {3}, *Salix* sp. {6/1}, *S.* ?*alba* {1}, *S. caprea* {13}, *S. cinerea* {2/1}, *Symphoricarpos albus* {2}, *Tilia* sp. {2}, *T. cordata* {1}, *Ulex europaeus* {2}, *U. parviflorus* {1}, *Ulmus laevis* {1}, *Vitis* sp. {1}; in gall of *Neonectria ditissima* {1}, on hymenophores or pilei of *Cerrena unicolor* {1}, *Hymenochaetopsis tabacina* {1}, *Trametes hirsuta* {1}; on (partially detaching) bark (periderm and bast) {72}, more rarely on wood {28}, (slightly to) medium or very strongly decayed (wood ~1 mm deep strongly rotten, core often also), in holes or on stub of broken twigs, old wounds, in small decorticated areas, in old beetle galleries, in lenticelles, on both sides of detached bark, often on edges of bark or hidden in cracks, sometimes slightly greyed, not or often medium to strongly covered by green, mainly coccoid algae, sometimes with lichens and small mosses, in black mould of *Sporidesmium* {1}, on stromata of *Diatrype stigma* {2}, *Eutypa spinosa* {1}, indet. pyrenomycetes {2}. **Further associated**: *Allophylaria macrospora* {1}, *Arachnopeziza aurata* {1}, *Bulbillomyces* sp. {1}, *Capronia* sp. {1}, *Crepidotus cesatii* {2}, *Cryptodiscus foveolaris* {2}, *Dacrymyces* sp. {2}, *Durella atrocyanea* {1}, *D. connivens* {2}, *Entoloma jahnii* {1}, *Eutypella* ?*prunastri* {1}, *Hamatocanthoscypha laricionis* {1}, *Hyalorbilia berberidis* {1}, *H. erythrostigma* {4}, *H. juliae* {4}, *H.*

(1035 m in Asturias). **Geology**: Cambrian, Ordovician & Devonian sandstone & shale, Buntsandstein, Muschelkalk, Keuper, Jurassic, Cretaceous & Tertiary sand- marl- & limestone, calcareous clay, molasse, Quaternary loess, till, silt & sand; mica schist, gneiss. **Phenology**: throughout the year (long-lived).

Phenology of *H. subfusispora*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
12	8	8	5	5	7	3	8	4	0	13	8

Taxonomic remarks. *Hyalorbilia subfusispora* is characterized by ± straight, fusoid to fusiform ascospores very similar to *H. fusispora*, from which it differs in smaller, less pigmented apothecia and much more inflated marginal cortical cells, also in the frequent presence of a large, often ± elongate SB at each spore end. Further tentative differences to *H. fusispora* are shorter asci, shorter terminal cells of paraphyses, and slightly narrower spores. However, the two species are morphologically not always easy to distinguish. *H. polypori* and *H. texensis* differ from *H. subfusispora* in almost eguttulate, distinctly narrower spores with rounded ends, the former also in more cylindrical spores. *H. polypori* and *H. ulicicola* differ in much larger, desiccation-sensitive apothecia, the latter species also in shorter spores. See also under the similar *H. rotifera* (with smaller spores), *H. lunata* (with curved spores), and *H. latispora* (with shorter spores without large SBs).

Variation. *H. subfusispora* shows rather strong variability, mainly in ascus and spore size, but also in spore shape and especially in spore content. Two very distinct subglobose to tear-shaped spore bodies, one at each spore end, were seen in many of the collections (e.g., Pl. 116: 1–2, 6–8). They are surrounded by a few often much smaller globose SBs, but sometimes there are several large SBs in each spore half (e.g., Pls 116: 2a; 117: 4d) and then the spore content resembles that of *O. fusispora*. However, SBs in *H. fusispora* were always globose whereas the large SBs of *H. subfusispora* tend to be ellipsoid to tear-shaped and narrowly attached to the spore ends. In some specimens (e.g., Pl. 116: 3, 5, 9) several rather small globose SBs in each spore half similar to *H. fusispora* were seen; these specimens are assigned here to *H. subfusispora* because of wide marginal cortical cells and rather small, pale-coloured apothecia. We have included in *H. subfusispora* also collections with rather short spores (e.g., Pls 116: 4, 6; 117: 10d) which appear to form a transition to *H. latispora*, but differ from that species in containing globose or tear-shaped polar SBs. This was also the case in a photo of H.B. 7684 (Pl. 117: 15), whereas the spores from another apothecium of the same sample (Pl. 116: 9a) were slightly shorter and did not show larger polar SBs. Perhaps this apothecium belonged to *H. latispora*, but the conidium observed nearby (Pl. 116: 9i) resembles those presumed as anamorph of typical *H. subfusispora*.

The spore ends are usually acute or subacute, but in some collections a strong tendency to obtuse was observed (Pl. 116: 9, see also the drawings by E. Batten, IVV). The ectal excipulum at the flanks varies between t. prismatica (Pls 116: 1g, 2g; 117: 8a), and t. globulosa-angularis (Pl. 117: 2f, 3f). The excipular cells at base and flanks contain large oil drops in some collections (e.g., Pl. 117: 2f) but such LBs were not observed in a major part of the specimens. A rich sample from Navarra collected on a branch on the moist ground deviates by extraordinarily large apothecia (0.38–0.65 mm).

Not included collections. A collection from southern France on branch of *Robinia* (IVV: H.B. 9621a, associated with *O. aprilis*) has slightly curved, lunate to helicoid spores which closely resemble those of *H. lunata*. It differs from *H. lunata* in small apothecia (0.15–0.35 mm) growing on xeric substrate. The Canadian record was only very briefly documented and is, therefore, doubtful.

Anamorph. Branched, K-shaped conidia (curucispora-like) with ± globose refractive bodies (SCBs) occurred on the natural substrate in five collections (see Pls 116: 9i; 118), but a proof for their connection to a teleomorph is wanting. In Gönczöl & Révay (2006: figs 7–8) and Révay & Gönczöl (2010: fig. 12) such conidia were figured as 'unknown sp. 1' from rainwater from Germany (Tübingen) on *Fagus* and *Carpinus* and from Hungary (Királyrét, Budapest, Börzsöny Mts.) on *Fagus*, *Taxus*, *Chamaecyparis*, and *Picea*. This anamorph remarkably resembles *Curucispora ponapensis* Matsush. described from Micronesia. In two collections of *H. subfusispora* (H.B. 7693 and H.B. 5387) we detected another type of conidia near the apothecia: slender, vermiform, slightly curved (†40–48 × 2 µm, 4–5-septate), similar to those observed near apothecia of *H. rotifera*. In the sample from Slovakia a vermispora-like, ~6-septate conidium of *48 × 3.7 µm occurred (A. Polhorský, IVV: A.P. 19/16).

Phylogeny. Sequences were gained from apothecia of five samples on *Cornus* and *Salix* from three sites in Luxembourg, comprising ITS, four also LSU D1 (two also D2–D3 or D2–D5). The S1506 intron is present in all of them. The five sequences vary in the ITS by 0–0.7% (0–3 nt) and in the intron by 0–0.6% (0–2 nt), while no variation occurs in the LSU D1–D3. One sample (G.M. 2019-01-28.4) comprised only one apothecium and was identified by its DNA. The other four were also too sparse to be preserved. They were tentatively identified by one of us (G.M.), but not microscopically documented.

In analyses of ITS, LSU, or ITS+LSU, *H. subfusispora* clustered unsupported (ITS) or with weak (LSU) or high support (ITS+LSU) sister to the *oviparasitica-multiguttulata* clade (Phyls 5–6, S5). In the LSU (D1–D2) the distance to most other members of the genus is 8–11% (including *H. juliae* with 9%), but 13% to *H. latispora*, 15–15.3% to *H. rotifera*, and 16–17% to *H. erythrostigma*. In the ITS *H. subfusispora* clustered with some uncultured clones (H13–H14), e.g., a clone from forest soil in Canada (FJ553822) with

a distance of 10 %, while the distance to the morphologically most similar species is much higher (20 % to *H. ulicicola*, 26 % to *H. fusispora*, 33–34 % to *H. rotifera*).

Ecology. *Hyalorbilia subfusispora* was collected on ± rotten bark (and wood) of xeric (rarely hygric) twigs and branches of various angiosperm (rarely coniferous) trees, shrubs, and climbers, also on stems of *Rubus*. It does not seem to differ ecologically from *H. juliae*, with which it was four times found in association. In both species the small and often very scattered, preferably corticolous apothecia are easily overlooked and do not differ by macroscopy.

H. subfusispora is a common species in cold-temperate humid, atlantic to subcontinental central Europe, where it also occurs in hemiboreal and orotemperate or mesotemperate humid, or suprasub- to mesosubmediterranean semihumid regions. The collection sites include sun-exposed borders of mostly thermophilous forests, hedges, old quarries, overgrown gardens, alluvial forests at rivers and lakes, and salt marshes, at planar to colline or montane altitude. The collection site in the southeast of Northern America was a warm-temperate subhumid *Quercus virginiana*/*Juniperus occidentalis* forest, that in the northeast a cold-temperate humid, mild continental conifer forest.

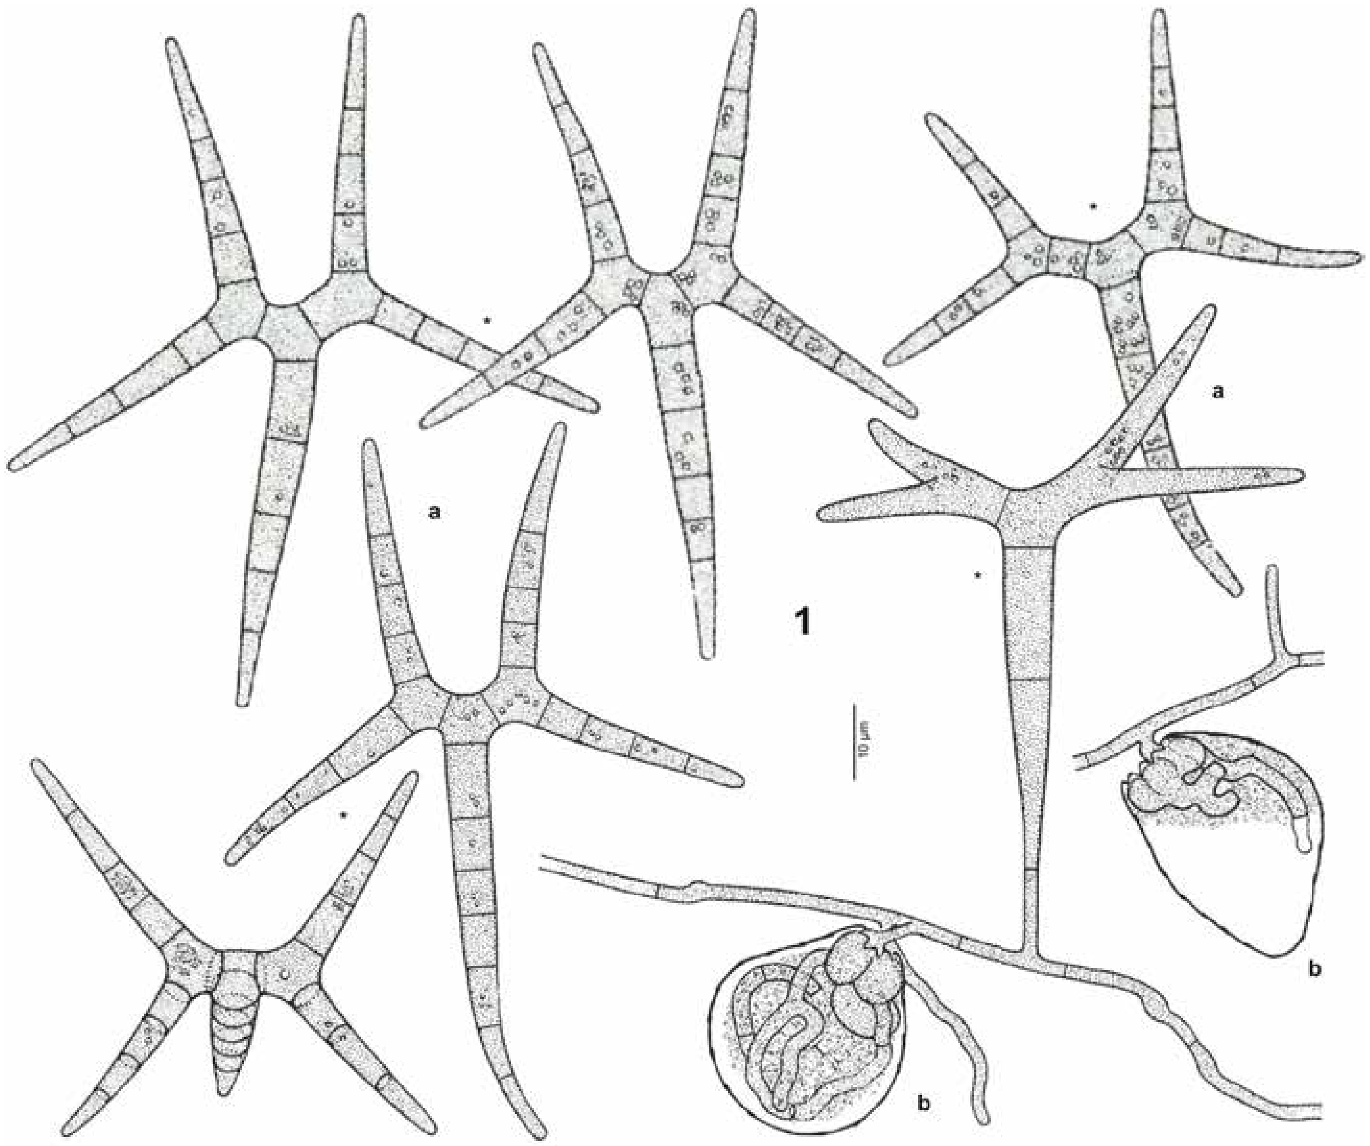

Plate 119. **1**: *Hyalorbilia quadridens* (holotype). – **a**. conidia (four in flattened condition under cover glass, lower right submature); **b**. testaceous rhizopods (*Euglypha laevis*) trapped by swollen protrusions. – From Drechsler (1962).

Hyalorbilia quadridens (Drechsler) Baral & E. Weber, in Baral et al., Mycol. Progr. 17 (1–2): 22 (2017) — Pl. 119

Basionym: *Triposporina quadridens* Drechsler, Sydowia 15(1–6): 19, pls 7–8 (1962) [1961]

≡ *Dwayaangam quadridens* (Drechsler) Subram., Kavaka 5: 96 (1978) [1977]

Etymology: according to the 4-armed (‘4-toothed’) conidia.

Typification: USA, Florida, Lakeland, herbaceous plant material, 12.IV.1959, C. Drechsler (holotype: illustration in Drechsler 1962: pls 7–8).

Description: — **TELEOMORPH**: unknown. – **ANAMORPH**: dwayaangam-like (isolated from herbaceous debris {T}). **Conidiophores** 10–12 × 1.8 µm, simple, non-septate, conidiogenesis terminal, singly. **Conidia** twice dichotomously branched in succession, *75–95 × 61–77 µm (when flattened), stipe 43–55 × 4.8–6.5 µm 5–6(–7)-septate, gradually tapered towards base, primary branches 6–11 × 4.5–6 µm, 0(–1)-septate, secondary branches *(20–)25–34 × 4–5.5 µm, (2–)3–4(–5)-septate, gradually tapered towards ends; containing one or several globose (?)SCBs 0.7–1.2 µm diam. in most of the cells. **Trapping organs**: capturing testaceous rhizopods (*Euglypha laevis*) by hyphal protrusions that form swollen lobes after capture within the aperture of the rhizopod.

Taxonomic remarks. In morphology of its staurosporous conidia the fungus unquestionably belongs to the *Orbiliomycetes*, and the detailed protologue leaves little doubt about its placement in *Hyalorbilia*. The capacity of capturing rhizopods by means of small, apparently adhesive protrusions seems to be unique in the genus *Dwayaangam* as currently circumscribed, which originally included only *D. quadridens*. Also Drechsler (1962) saw such a relationship when he wrote: ‘in its manner of taking prey the fungus displays close parallelism to *Dactylella passalopaga*’, a species here presumed to be the anamorph of *Hyalorbilia inflatula*. Drechsler’s drawing of living conidia shows groups of medium-sized drops which he illustrated also in *D. passalopaga*. These are very probably KOH-sensitve (SCBs), and are quite characteristic of *Hyalorbilia* (see, e. g., Pl. 59).

Ecology. Drechsler collected rotten herbaceous plant material from a grassy area near a lake in subtropical subhumid central Florida, predacious on testaceous rhizopods. The maize-meal-agar plate, in which the fungus finally developed, contained abundant mycelium of the plant pathogen *Pythium ultimum*, to which Drechsler added the collected plant material.

Specimens included. **USA**: **Florida**, ~23 km ENE of Lakeland, Lake Alfred, 40 m, from herbaceous plant material, predatory on *Euglypha laevis*, 12.IV.1959, C. Drechsler (**holotype**, doc. vid.).

Hyalorbilia tenuifusaria (Juan Chen, L.L. Xu, B. Liu & Xing Z. Liu) E. Weber & Baral, in Baral et al., Mycol. Progr. 17 (1–2): 15 (2017) — Pl. 3: f

≡ *Dactylella tenuifusaria* Xing Z. Liu, R.H. Gao, K.Q. Zhang & L. Cao, Mycol. Res. 100(2): 236 (1996), nom. inval., ICN Art. 40.7

≡ *Brachyphoris tenuifusaria* Xing Z. Liu, R.H. Gao, K.Q. Zhang & L. Cao ex Juan Chen, L.L. Xu, B. Liu & Xing Z. Liu, Fungal Diversity 26(1): 124 (2007)

Etymology: named after the shape of the slender, fusiform conidia.
Typification: China, Guizhou, Fanjingshan, forest soil, 25.VI.1994, X.Z. Liu (HMAS 70427, holotype; ex-type culture: CBS 617.95, sq.: DQ494371).

Description: — **TELEOMORPH**: unknown. – **ANAMORPH** (from Liu et al. 1996 & Chen et al. 2007c): brachyphoris-like (isolated from soil {T}). **Conidiophores** 8–67 × 1–4 µm, simple, densely septate, unbranched to strongly branched, conidiogenesis terminal, singly. **Conidia** unbranched, 88–120 × 4–6 µm, fusiform with tapered, filiform ends, straight, (9–)10–13(–14)-septate. **Trapping organs** forming short undifferentiated protrusions ~2–4 × 2–4 µm.

Taxonomic remarks. The capability of *H. tenuifusaria* to trap rhizopods by means of small, apparently adhesive protrusions (Liu et al. 1996, Chen et al. 2007c) supports a relationship with '*Dactylella*' *passalopaga* (?= *H. inflatula*). Since we have never seen such long conidia in any of the *Hyalorbilia* species studied, we assume that *H. tenuifusaria* represents a species of its own. Also Liu et al. (1996) compared it with '*Dactylella*' *passalopaga*, differing in distinctly longer conidia with more septa. The original drawing by Liu et al. shows conidia without contents, which leaves the question open whether they were studied in the living or dead state, while Liu et al.'s and Chen et al.'s photographs (at high magnification) clearly show dead conidial cells.

In the protologue of *Dactylella tenuifusaria* the holotype was given as 'HMAS 70427, CBS 617.95', for which reason the name was considered as invalid (P. Kirk pers. comm.). Chen et al. (2007c) unmistakably cited the single specimen HMAS 70427 as holotype by making the name valid.

Phylogeny. A sequence of the type strain gained by Chen et al. (2007a) comprises ITS (whether it possesses the S1506 intron is unclear) and an unofficial LSU sequence in the CBS database. In our analysis of the ITS region, the strain clustered unresolved in an unsupported clade containing *H. juliae*, together with various environmental isolates from soil and leaf litter from North America, Europe, Australasia, and Africa (Seychelles) (H17–H26), but with an over 20 % distance to any of them (Phyl. 5). In the combined ITS+LSU analysis (Phyl. 6), however, the support of this clade, which we call *juliae-tenuifusaria* clade, was strong (for *H. fusispora* see under that species, p. 400).

Ecology. *Hyalorbilia tenuifusaria* was isolated from soil in a evergreen mountain forest in subtropical humid (winter-dry) southern China.

Specimens included. **CHINA**: **Guizhou**, Fanjingshan, 1770 m, forest soil, predatory on rhizopods, 25.VI.1994, X.Z. Liu (HMAS 70427, holotype, doc. vid.; ex-type culture: CBS 617.95; sq.: DQ494371).

Hyalorbilia brevistipitata Bin Liu, Xing Z. Liu & W.Y. Zhuang, Nova Hedwigia 81: 147, fig. 1 (2005) — Pls 120–121

= *Brachyphoris brevistipitata* (Bin Liu, Xing Z. Liu & W.Y. Zhuang) Juan Chen, L.L. Xu, Bin Liu & Xing Z. Liu, Fungal Diversity 26: 120, 128 (2007), nom. inval., ICN Art. 41.5

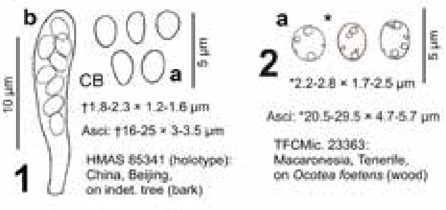

Plate 120. **1–2**: *Hyalorbilia brevistipitata*. – **a**. ascospores; **b**. ascus. – **2** redrawn from photo (see Pl. 121: 2c).

≡ *Dactylella brevistipitata* Bin Liu, Xing Z. Liu & W.Y. Zhuang, Nova Hedwigia 81: 148 (2005)

Etymology: refers to the very short conidiophores and the short apothecial stipes.
Typification: China, Beijing, indet. broad-leaved tree, 24.VI.2002, B. Liu (HMAS 85341, holotype of teleomorph; HMAS 86810 permanent slide culture, holotype of anamorph; ex-type culture: CBS 113946; sq.: AY514636, DQ656699, KT215221, HQ110702).
Misapplied name: Zhuang & Hyde (2001: 185), as *Pithyella* cf. *erythrostigma*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.1–0.7 mm diam., 0.08–0.14 mm thick, whitish to pale yellowish when fresh, pale yellowish-beige on drying, translucent, ± round, slightly to medium gelatinous, scattered to gregarious in small groups; disc flat, margin smooth or slightly uneven, not protruding; sessile or with a distinct obconical stipe 0.04–0.2 × 0.05–0.1 mm, superficial. **Asci** *20.5–29.5 × 4.7–5.7 µm {1}, †15.5–25 × 3–4.5 µm {3}, 8-spored, spores */†1–2-seriate, pars sporifera *12.5–15.5 µm long; **apex** (†) hemispherical to obtuse; **base** with short, thick stalk arising from croziers {1}. **Ascospores** *(2–)2.2–2.6(–2.8) × (1.7–)1.8–2.2(–2.5) µm {2}, †(1.5–)1.8–2(–2.3) × (1.1–)1.2–1.7(–1.8) µm {3}, subglobose to broadly ellipsoid(-ovoid); **SBs** 0.2–0.7 µm diam. {2}, globose, peripheral, ± bipolar, (2–)4–7(–10) per spore. **Paraphyses** apically uninflated to slightly clavate, terminal cell *9–20 × 2.6–3.2 µm {1}, †(1.5–)2–3 µm wide {3}, lower cells *6–8 × 2–2.7 µm {1}, sometimes branched at upper septum. **Medullary excipulum** 20–35 µm thick, of dense. slightly gelatinized textura intricata. **Ectal excipulum** at base 60–90 µm thick, at flanks 15–45 µm thick, of thin-walled, horizontally oriented t. angularis-prismatica, slightly gelatinized (common walls *0.5–1 µm thick), cells *13–19 × 5.5–9 µm {1}, †5–15 × 2.5–5 µm {2}, 6–14 µm thick at margin, marginal cells *7–17 × 3–6 µm {1}. **Anchoring hyphae** *2.5–3.5(–4) µm wide, wall 0.2–0.3 µm. **SCBs** in marginal excipulum globose; **VBs** in terminal and lower cell medium refractive, elongate. **Exudate** over paraphyses 0.3–0.8 µm thick, ± continuous to cloddy, hyaline. — **ANAMORPH**: brachyphoris-like (data from Liu et al. 2005b, from ascospore isolate {1}). **Conidiophores** reduced, simple, 1.5–5(–10) × 2–4 µm, 1.5–3 µm wide at apex, non-septate, monoblastic or sympodial (with 1–3 additional scars resembling nodules). **Conidia** unbranched, narrowly fusoid, tapering evenly towards the blunt apex and base, usually straight, occasionally slightly curved, especially at the distal end, †23–52 × 3–4 µm, 3–5-septate.

Habitat: lying on the moist ground, on decorticated or corticated, 20–250 mm thick branch and log of *Ocotea foetens* {1}, indet. angiosperm tree {T}, on bark {1} or wood {1}; on very rotten stems of bamboo on or close to old pyrenomycete {1}. **Further associated**: none observed. **Desiccation tolerance**: unknown (probably slightly desiccation-tolerant). **Altitude**: 120–775 m a.s.l. **Geology**: China: volcanic & felsic plutonic rock; Tenerife: volcanic sedimentary deposits, tephritic and phonolitic mafic flows. **Phenology**: II, VI–VII.

Taxonomic remarks. *Hyalorbilia brevistipitata* is characterized by very small, ovoid to subglobose or almost globose ascospores with about 2–10 small, peripheral, ± symmetrically arranged (bipolar) SBs, also by rather small asci, and by a brachyphoris-like anamorph with unbranched conidia. In contrast, the similar *H. erythrostigma* and *H. ulmi* contain a single, distinctly larger, eccentric SB in the living

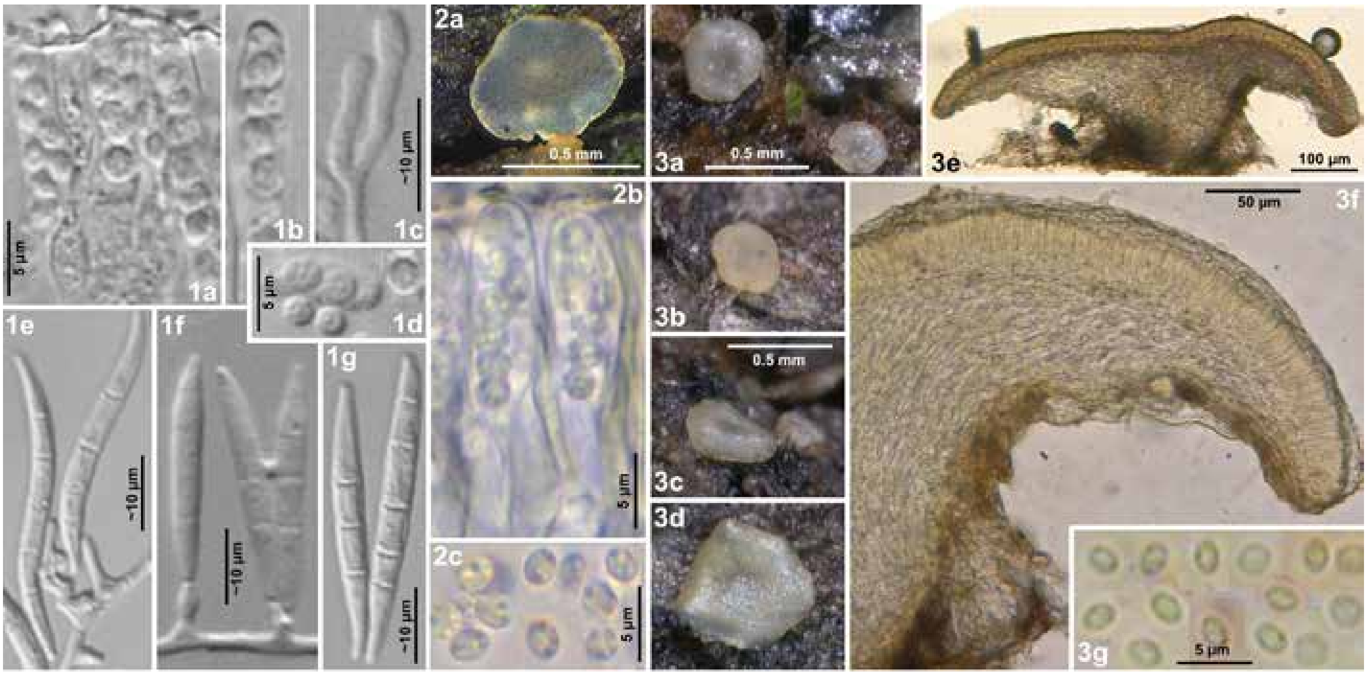

Plate 121. **1–2**: *Hyalorbilia brevistipitata*; **3**: *H.* cf. *brevistipitata*. – **2a**. fresh apothecium, **3a–d**. rehydrated apothecia; **3e–f**. apothecia in median section; **1a–b**, **2b**. asci; **1c**. paraphysis; **1d**, **2c**, **3g**. ascospores; **1e–g**. conidia and conidiophores (in culture). – Living state, except for **1c**, **e–g**, **3e** (in H_2O), asci in **1a–b**, **3f–g** (in KOH). – **1a–g**: from Liu et al. (2005b, DIC), **2a–c**: phot. L. Quijada (p.p. from Quijada et al. 2014a). — **1a–g**. HMAS 85341 (holotype): China, Beijing, on indet. tree; **2a–c**. TFC Mic. 23363: Macaronesia, Tenerife, on *Ocotea*; **3a–g**. H.B. 9276a: Ethiopia, on *Lobelia*.

spores, and the apothecia were mainly found on xeric instead of hygric substrates. *H. erythrostigma* further differs in larger asci and spores and in a trinacrium-like anamorph, and *H. ulmi* in slightly longer and narrower, more ellipsoid-ovoid spores, while its anamorph is unknown.

A collection from Australia mentioned under *H. erythrostigma* has spores very similar in size and shape, but here a single SB could be discerned as faint eccentric region in several spores (Pl. 126: 10).

Besides ascus and spore size, Liu et al. (2005b) separated *H. brevistipitata* from *H. erythrostigma* by flat instead of convex apothecia, and by short instead of long apothecial stipes. However, in the present concept of *H. erythrostigma* the apothecia varied strongly in shape of discs and length of stipes, and also the asci and spores vary to some extent in both size and shape. Therefore, the morphological differences between the two species are much less sharp than the authors believed.

The above description is based on the protologue of both morphs (Liu et al. 2005b), a copy of which can be found in Liu (2006: 27), and on our examination of a slide of the teleomorph from Beijing kindly supplied by B. Liu. The protologue of the teleomorph represents a mixture of the holotype from Beijing and a paratype from Hong Kong on bamboo, reported by Zhuang & Hyde (2001) as *Pithyella* cf. *erythrostigma*.

Liu et al. (2005b) described the spores as 'broadly ellipsoid to almost globose' (Latin diagnosis), while the given size in the English description suggests perfectly globose spores [*1.8–2 × 1.8–2 µm in water, †1.5–1.8 × 1.5–1.8 µm in CB_L]. The given spore size refers to the holotype, whereas spore measurement by Zhuang & Hyde (l.c.), who figured broadly ellipsoid-ovoid spores (though stating 'ovoid to subspherical'), were not included in the protologue. The present examination of a preparation of the holotype (Pl. 120: 1) revealed broadly ellipsoid to ovoid spores and suggests that Liu et al.'s illustration of ± globose living spores on their fig. 1D–E refers to spores seen more or less in top view. Only the upper left spore in fig. 1E (see Pl. 121: 1d) looks broadly ellipsoid and their size can be evaluated as *2.6 × 2.2 µm, while the remaining spores look globose or almost so and measure *2–2.3 × 1.8–2 µm according to the scale. B. Liu (pers. comm.) considered this ellipsoid spore as aberrant. Yet, also those spores inside asci in fig. 1 F–I (Pl. 121: 1a–b) tend to be broadly ellipsoid.

Liu et al. reported a single globose eccentric spore body 0.5 µm diam. in each spore, although on their fig. 1E–F (Pl. 121: 1a–d) the spores appear to contain several small peripheral SBs. Until further collections of *H. brevistipitata* are documented in the living state, we here characterize the living ascospores of this species as consistently multiguttulate due to several peripheral SBs of ~0.3–0.5 µm diam., in contrast to one eccentric SB 0.6–0.8 µm diam. in *H. ulmi*.

The asci in the protologue of *H. brevistipitata* are given as (†)18–25 × 3–3.5 µm, which again appears to refer solely to the holotype, although the few asci seen in the permanent slide were found to measure only †16 × 3–3.5 µm (Pl. 120: 1). In Liu et al.'s (2005b) fig. 1G–M, however, the scale is probably erroneous because the asci would measure †16–18 × 2.5 µm, which is in disagreement with both the description and the scale on their fig. 1F. In the specimen from Hong Kong the asci measured †15–17 × 3–3.8 µm, evaluated according to the scale in Zhuang & Hyde (2001: fig. 7) and the original sketch to this drawing made by a drawing tube (W.Y. Zhuang pers. comm.), although they are given as 19–21 × 3.3–4 µm in their description. Judging from the concordant spore width, the scale appears to be correct, and the ascus length of 19–21 µm could be erroneous, at least asci of that length were not figured.

The specimen from Hong Kong appears to fit the type, but it was only studied in the dead state, therefore, it is unknown whether the living spores contained several or only one spore body. A record from Macaronesia examined in the living state by L. Quijada (pers. comm.) concurs quite well with the holotype in ascus and spore size, though the asci tend to be wider. The living spores consistently contained 2–5(–7) peripheral SBs with a size of 0.2–0.7 µm, sometimes in a bipolar arrangement (Quijada et al. 2014a: fig. 2, Pls 120: 2; 121: 2).

Not included collection. A collection from Ethiopia (Pl. 121: 3) closely resembles *H. brevistipitata* in ascus [†(19–)23–24.5 × 3.2–3.5(–4.5) µm] and spore size [†2–2.2(–2.4) × 1.6–1.8(–2) µm, broadly ellipsoid to ovoid], but the size and number of SBs in the spores is unknown because it was only studied in the dead state.

Anamorph. In pure culture of an ascospore isolate of the holotype of *B. brevistipitata*, Liu et al. (2005b) obtained an anamorph which they named *Dactylella brevistipitata*. In the similar *H. erythrostigma* and *H. multiguttulata*, on the contrary, we presume a trinacrium-like anamorph. Chen et al. (2007c) combined *D. brevistipitata* in *Brachyphoris* and stated that it is similar in morphology to *B. oviparasitica* and *B. helminthodes*. Although the latter two species are parasites of nematodes or fungal spores, tests with nematode eggs and oospores were negative in *B. brevistipitata* (Liu et al. l.c., Chen et al. l.c.).

Some of the scale bars in Liu et al. (l.c.) might be inexact, for instance, the conidia in fig. 2G–H measure 31–44 × 4–4.5 µm according to the scale, while those in fig. 2B measure 29–33 × 3 µm. It appears questionable whether the ex-type strain still exists at CBS, since it does not appear in the database, and also queries for the ITS or LSU region do not show it.

Phylogeny. Sequences were available from the ex-type strain (ascospore isolate 1144 fide X.Z. Liu pers. comm.) of *B. brevistipitata* (SSU, ITS, LSU) and from the not included specimen from Ethiopia (SSU, 5.8S, ITS2, LSU, from apothecia). In the ex-type strain the S1506 intron is absent, while the Ethiopian sequence does not cover the 3-end of SSU and also lacks much of the 5'-end of ITS. The ex-type strain was sequenced by B. Liu (AY514636, DQ656699) and simultaneously by G. Hagedorn (KT215221). Both sequences include the ITS and LSU D1–D2 domain. The LSU was also sequenced by X.Z. Jiang et al. (HQ110702, D1–D3). These rDNA sequences fully concur in the overlapping parts, except that Liu's ITS2 shows many gaps and ambiguities downstream of the motif GGGCACAG, and his LSU 1 insert in the D1 domain, both obviously being sequencing errors.

In addition to the mentioned morphological differences in the teleomorph and anamorph, the available molecular data indicate that *H. brevistipitata* is not closely related to *H. erythrostigma*: in the ITS region the distance lies in the range of ~27–33 % and in the LSU at 11–15 %. Also B. Liu (pers. comm.) found that the two Chinese specimens referred by him to *H. erythrostigma* (one of them was examined in the present study: Pl. 126: 4) strongly differ in the ITS region from the type of *H. brevistipitata*. Even in the 5.8S region 7 nucleotides differ (pos. 64, 83–84, 98, 140, 148, 155), including the signature GAGCGTC at the 3'-end of 5.8S (GAGCGT**G** in *H. erythrostigma*, see Tab. 18). Three further positions in the 5.8S of *H. brevistipitata* (pos. 122, 133–134) differ only from European *H. erythrostigma*.

The specimen from Ethiopia clustered with *H. brevistipitata* in a strongly (ITS) or weakly (ITS+LSU) supported clade (Phyls 5–6) but with 8 % distance in the ITS2, 5 deviating nt and 1 gap in the LSU (D1–D2), and 1 nt in the SSU (V8). In the 5.8S it fully matches both the type strain and *H. oviparasitica*, but no other available sequence of *Hyalorbilia*. In Phyls 6 and S5 (ITS+LSU; LSU) *H. brevistipitata* s.l. clustered with strong support as a sister clade to *H. oviparasitica*. Also Liu et al. (2005b) and Chen et al. (2007c) found that *H. brevistipitata* and *H. oviparasitica* are genetically closely related but different enough to be separated at the species level. *H. brevistipitata* actually differs from *H. oviparasitica* by 12.5–16 % in the ITS region, and the Ethiopian sample even more when comparing the available ITS2 region (for details see under *H. oviparasitica*, p. 411).

In the 99 nt of the V8 region by which SSU sequences of *H. oviparasitica* s.l. overlap with most available orbiliaceous SSU sequences, *H. brevistipitata* (A**CT**ATCCTTGG) differs by 1 nt from *H.* cf. *brevistipitata* (A**CC**ATCCTTGG). Both deviate by 2 nt from *H. oviparasitica* s.l and a majority of *Hyalorbilia* spp. which have A**TA**ATCCTTGG (in *H. tortuosa* A**TA**ATCCTTG**A**), and by 4 nt from *H. erythrostigma* (A**CA**ATCCTT**AA**).

Ecology. *Hyalorbilia brevistipitata* was found on decaying, hygric twigs and branches of broad-leaved trees as well as on rotten bamboo. In all collections the substrate was lying on the moist ground in a wet environment. The apothecia in the holotype grew on bark without a clear connection to a pyrenomycete (B. Liu pers. comm.), whilst in the paratype from Hong Kong they grew on or close to an old pyrenomycete. The collections originate from warm-temperate and subtropical humid (winter-dry) forests in eastern and southeastern China, and from the thermomediterranean humid laurel forest (*Lauro novocanariensis-Perseetum indicae*) in Tenerife, Macaronesia. The sample from the Ethiopian highlands was on a herbaceous stem of *Lobelia* very close to old pyrenomycetes, in a warm-temperate humid, evergreen afromontane forest. Based on the genetic similarity to *H. oviparasitica*, *H. brevistipitata* might also be a parasite on nematode eggs. However, Liu et al. (2005b) did not note any parasitism when testing their culture with nematode eggs (the genus of the used nematode is not stated).

Specimens included. **CHINA**: **Beijing**, **Mentougou**, 23 km WNW of Beijing, Xian Shan (Fragrance Mt.), 450 m, branch of angiosperm tree, on bark, 24.VI.2002, B. Liu (B.L. 6167, HMAS 85341, **holotype** of *H. brevistipitata*, H.B. 7809 ø; X.Z.L. 1144, HMAS 86810 dried culture, **holotype** of *B. brevistipitata*, CBS 113946 ex-type culture, anam. cult.; sq.: AY514636, DQ656699, KT215221, HQ110702). – **Hong Kong**, 8 km SE of Fanling, Tai Po Kau Forest Stream, ~SE of Lai Chi Hang, ~120 m, on indet. pyrenomycete on indet. bamboo, 15.VII.1998, D.Q. Zhou (HMAS 74869 = W.Y.Z. 2447, doc. vid.). — **MACARONESIA**: **Canary Islands**, **Tenerife**, Santa Cruz de Tenerife, Anaga, 3.3 km ESE of Taganana, El Pijaral, 775 m, log of *Ocotea foetens*, on wood, 14.II.2012, L. & C. Quijada (TFC Mic. 23363, doc. vid.).

Not included. **ETHIOPIA**: **Oromia**, 22 km WSW of Addis Ababa, 10 km NW of Sebeta, Menagesha Suba State Forest, southern part, 2500 m, on stem of *Lobelia giberroa*, 26.III.2010, U. Lindemann (U.L. 0310-17 ø, H.B. 9276a; sq.: KY463701, KT222440).

Hyalorbilia oviparasitica (G.R. Stirling & Mankau) E. Weber & Baral, in Baral et al., Mycol. Progr. 17 (1–2): 15 (2017)

Basionym: *Dactylella oviparasitica* G.R. Stirling & Mankau, Mycologia 70(4): 777 (1978)

≡ *Brachyphoris oviparasitica* (G.R. Stirling & Mankau) Juan Chen, L.L. Xu, B. Liu & Xing Z. Liu, Fungal Diversity 26(1): 79 (2007)

Etymology: named after the ability to parasitize nematode eggs.

Typification: USA, California, Parlier, Sorenson ranch, roots of *Prunus persica*, from eggs of *Meloidogyne* sp., X.1976, G.R. Stirling (BPI 418238 [formerly BPI 71878], holotype, dried culture ['isolate S']; ?ex-type culture in CBS 379.84).

Misinterpretation of *H. oviparasitica*: Smith & Jaffee (2009) = *H.* aff. *multiguttulata* (strain DoUCR50).

Description: — **TELEOMORPH**: unknown. — **ANAMORPH**: brachyphoris-like (data from Stirling & Mankau 1978 and Chen et al. 2007c, from nematodes). **Conidiophores** reduced, simple, 2–10(–

28) × 2.5–3 µm, tapering to 1–2 µm at apex, non-septate, monoblastic or sometimes sympodial (with one additional scar). **Conidia** unbranched, narrowly fusoid, medium tapered towards obtuse apex and truncate base, straight, *(31–)40–60(–65.5) × (2.7–)3.5–5 µm, (4–)6–7(–9)-septate.

Habitat: in soil and nematode cysts, parasitic in nematode eggs, fourth stage juveniles, and females. **Altitude**: -40–+900 m a.s.l.

Taxonomic remarks. *Hyalorbilia oviparasitica* is the type species of the genus *Brachyphoris* and is only known from its anamorph. Because we did not have the opportunity to study this species, we here refer to the descriptions of Stirling & Mankau (1978) and Chen et al. (2007c) (see also Seifert et al. 2011: pl. 195A and p. 217–219). The species differs from the anamorph of *H. brevistipitata* in slightly longer, consistently ± straight conidia.

H. oviparasitica was originally isolated from infected eggs of the nematode *Meloidogyne* from soil in different peach orchards of central California. The conidia in the holotype measured *31–60 × 2.7–5 µm, with (4–)6–7 septa, whereas in the paratypes Stirling & Mankau (l.c.) observed longer conidia up to *51–81 × 3.3–6 µm. Isolate S produced millions of conidia under optimum conditions, whereas isolates K and C showed only few conidia (Stirling ined., thesis, J.O. Becker pers. comm.). Since the conspecificity of these strains was not affirmed by molecular data, we refrained from including the larger measurements in the description. Two strains from Stirling & Mankau's laboratory, which are not exactly identical in the ITS rDNA, exist in official culture collections (ATCC 38908 and CBS 379.84). Whether the latter is an ex-type isolate is not fully certain.

Uncultured DNA isolates of this species were also obtained from juveniles and adult females of *Heterodera schachtii* in sugar beet soil in southern California: at Riverside (DoUCR60) and the Imperial Valley (various UCR numbers, Witte et al. 2014), and from manure treated soil in southern India (NBAII DOP1). Three culture isolates from nematode eggs of *Globodera rostochiensis* were obtained in a potato field in the Netherlands at a single site and day in 1985 deposited at CBS 347–349.85. From all isolates other than *Meloidogyne* no morphological data were available. In fact, all strains obtained from *Heterodera* 'did not produce conidia on any media or conditions we have tested', including the aberrant strain UCR50 mentioned below (J.O. Becker pers. comm.).

Chen et al. examined the authentic Californian isolate CBS 379.84 and the three Dutch CBS cultures, and described the conidia as *40–65.5 × 3.5–5 µm, with 5–9 septa. Contrary to the protologue which gives a conidiophore length of 'rarely more than 2 µm', Chen et al. observed 3–28 µm long conidiophores but figured them scarcely longer than 10 µm. From which culture their photos were taken was not stated and cannot now be clarified (J. Chen pers. comm.).

Type studies. The type strain was preserved as dried culture and slides at BPI (see BPI database). A living culture from '*Meloidogyne* sp. egg masses' was deposited by G.R. Stirling at ATCC 38908 with the remark 'type strain: no' (see ATCC website), and one from 'California, nematode egg' by R. Mankau at CBS 379.84 in 1984 with the remark 'authentic' in the CBS database but 'type' by Chen et al. (2007c) and in GenBank (NG_064136). The history of these two living strains could not be clarified, but it seems probable that also CBS 379.84 was from *Meloidogyne*. The strain from which the sequences AY185771 (ITS) and AY185772 (SSU) were obtained by Yin et al. (2003) was received by J.O. Becker (pers. comm.) from R. Mankau's culture collection but was later lost when an incubator malfunctioned. The perfect match in the ITS region between this lost culture and the ATCC strain, for which ITS and LSU sequences are included at the ATCC website, might suggest that both had the same origin. That ATCC 38908 represents an ex-type strain seems unlikely because of the negative statement at the ATCC website.

Chen et al. (2007c) appears to be in error when stating that the type strain, from which the type specimens at BPI derive, was obtained by R. Mankau in June 1984: in fact it was isolated by G.R. Stirling in X.1976. The database of the US National Fungus Collection at Beltsville (BPI) gives this information, together with the new numbers of the type isolates, which were mentioned by Chen et al., and the corresponding old numbers used in the protologue. Chen et al. considered CBS 379.84 as ex-type culture of *Dactylella oviparasitica*. This strain was actually deposited at CBS by R. Mankau in 1984, according to the CBS database. However, in the BPI database no mention is made of this CBS strain, nor of the ATCC culture.

Phylogeny. Eight ± complete ITS sequences of *Hyalorbilia oviparasitica* were available, which appear to refer to seven different strains (three from a locality in Netherlands on *Globodera rostochiensis*, four from two different regions in California on *Meloidogyne* sp. and *Heterodera schachtii*, and one from India). SSU (V4–V8) exists for one Californian strain (ATCC 38908, on *Meloidogyne*), LSU (D1–D3) for two Californian strains (ATCC 38908, on *Meloidogyne*; CBS 379.84, on ?*Meloidogyne*) and three from the Netherlands (CBS 347–349.85, on *Globodera*). 15 further sequences, obtained from *Heterodera* in the Californian Imperial Valley by Witte et al. (2014), comprise only a large part of 5.8S and a short part of ITS2 (KM250092–KM250106).

The distance among the complete ITS sequences lies at 0–2.5 %, irrespective of whether strains of one or different continents are compared. For instance, the lowest distance of 0–0.5 % is observed between ATCC 38908 from California, CBS 349.85 from the Netherlands, and NBAII DOP1 from India. The highest distance of 2.5 % is noted between the Californian CBS 379.84 and DoUCR60. Between CBS 379.84 and ATCC 38908 the distance is 1.5 %. Variation occurs mainly in the ITS2, whereas in the ITS1 only 1–2 nt differ as a maximum among the seven strains. The 15 incomplete sequences likewise vary somewhat in the short part of ITS2. In the LSU the five sequences were identical.

H. oviparasitica formed with some other taxa the strongly supported *oviparasitica-multiguttulata* clade in all of our analyses (Phyls 5–6, S6). Also the phylogenetic analyses of the ITS region by Liu et al. (2005b) and Yang et al. (2012b) showed that isolates from California and the Netherlands (erroneously 'China' in Yang et al.) are conspecific and clustered as a supported clade sister to *Hyalorbilia brevistipitata*. A distance of 12.5–16 % is observed between *H. oviparasitica* and *H. brevistipitata* in the ITS region. This high distance comes from a strongly deviating ITS1 region (23–26 %; 0.4 % variation within *H. oviparasitica*), whereas the ITS2 differs only by 8–12 % (1–5 % variation within *H. oviparasitica*). The distance between *H. oviparasitica* and *H.* cf. *brevistipitata* from Ethiopia, for which only 5.8S+ITS2 was available, ranges at 15.5–18.5 % in the ITS2. For the distance to *H. multiguttulata* see p. 416.

A separate clade is formed by another Californian culture isolate from *Heterodera schachtii* (DoUCR50, also called

'UCR-50' or 'strain 50'), uploaded under the name *Dactylella oviparasitica* and originating from the same sugar beet field as DoUCR60 (J.O. Becker pers. comm.). This was named '*Dactylella oviparasitica*-like' by Yin et al. (2003) and is referred to as *Hyalorbilia* aff. *multiguttulata* here (see also under *H. multiguttulata*, p. 416). From the same field various further ITS DNA isolates from *Heterodera schachtii* are found in GenBank (DACITS2–DACITS6, Yin et al. 2003), which are identical with DoUCR50 (max. 2 nt or 2 gaps difference; Phyl. 5). The homogeneity of this clade and its distance to *Hyalorbilia oviparasitica* (10.5–14 %) strongly suggests a species of its own.

SSU (V4–V8) was available for 12 strains of *H.* aff. *multiguttulata* (AY123746–57, AY123763). Differences are absent among these sequences and in comparison with the one SSU sequence of *H. oviparasitica*, except that *H. oviparasitica* possesses the S943 intron with 400 nt, but not *H.* aff. *multiguttulata*. Two nucleotides in the overlapping V8 region permit distinction from *H. brevistipitata* (see p. 410).

LSU (D1–D3) was available for one strain of *H.* aff. *multiguttulata* (DoUCR50, EF446019, JQ638669), which differs from both *H. oviparasitica* and *H. brevistipitata* by 2.5–3 % in the D1–D2 domain. The distance between the latter two species is with 0.4 % unexpectedly low (1 nt in D1, 1 nt in D2). Despite the 2.5–3 % distance, *H. oviparasitica* and *H.* aff. *multiguttulata* concur at the two mentioned deviating positions. In the D3 domain *H. oviparasitica* and *H. brevistipitata* differ by 3 nt, and here *H.* aff. *multiguttulata* and *H. brevistipitata* surprisingly fully concur.

Ecology. *Hyalorbilia oviparasitica* was isolated from eggs as well as fourth-stage juveniles and adult females of different nematodes on which it parasitizes. The fungus was able to act as a biocontrol agent by reducing the population density of its prey and establish thereby a nematode-specific disease-suppressive soil (Yin et al. 2003, Yang et al. 2012b). It is so far known from irrigated peach orchards in warm-temperate semiarid central California and from sugar beet fields in subtropical semiarid (hot-summer mediterranean) southern California, from a potato field in oceanic temperate humid Netherlands, and from farm yard manure treated soil in the savannah climate of tropical monsoon-dominated southern India. In the peach orchards it preys on the root-knot nematode *Meloidogyne* sp., in the sugar beet field on the beet cyst nematode *Heterodera schachtii*, and in the potato field on the potato cyst nematode *Globodera rostochiensis*.

Based on the molecular finding that *H. multiguttulata* may occur in soil, it can be speculated that also *H. oviparasitica* is able to produce apothecia on dead plant substrate.

Sequenced specimens. **USA**: **California**, central California, San Joaquin Valley, ~25 km SE of Fresno, Parlier, Sorenson ranch, 100 m, roots of *Prunus persica*, on eggs of *Meloidogyne*, X.1976, G.R. Stirling (isolate S, BPI 418238 [old number BPI 71878], **holotype**, dried culture; BPI 418236, 418237 [old number BPI 71879 for both], **isotypes**, dried culture or slide; conid. isol., doc. vid.); – (?)ibid., on nematode eggs, undated (CBS 379.84, ?ex-type strain, X.Z. Liu 1420, conid. isol.; sq.: AY776168, HQ110703, NG_064136). – 2 km SE of Parlier, Kearney Agricultural Research Station, 105 m, on eggs of *Meloidogyne*, undated (isolate K, conid. isol., doc. vid.). – ?SE of Fresno, Chandler ranch, 95 m, on eggs of *Meloidogyne*, undated (isolate C, conid. isol., doc. vid.). – ibid., unlocalized, on eggs of *Meloidogyne*, undated (ATCC 38908, conid. isol.; sq.: ATCC, AY185771, AY185772). – southern California, Riverside, 4.7 km ENE of Riverside, 2 km WSW of UCR, Agricultural Operations, 300 m, sugar beet field 9E, roots of *Beta vulgaris*, from parasitized females of *Heterodera schachtii*, ~2009, J.I. Yang (DoUCR60, mol. extr.; sq.: JQ638670). – ibid., as uncultured soil fungus (mol. extr., KM250092–KM250105). – Imperial Valley, Brawley, -30–+40 m, various sugar beet fields, from parasitized females of *Heterodera schachtii* (mol. extr.; sq.: KM250092–KM250106). — **NETHERLANDS**: **Gelderland**, Wageningen, Mierenbos, 45 m, on eggs of *Globodera rostochiensis*, 9.VI.1985, D. Hugo (CBS H-3748, H-3749, myc. only; CBS 347.85; sq.: AY514637; CBS 348.85, X.Z. Liu 1536; sq.: DQ494372, HQ110704; CBS 349.85; sq.: DQ494373, MH873576). — **INDIA**: **Karnataka**, Bangalore, 900 m, soil with farmyard manure, V. 2010 (NBAII DOP1, mol. extr.; sq.: JF923815, JX403725).

Hyalorbilia biguttulata Baral, M.L. Wu & Y.C. Su, in Wu et al., Fungal Diversity 25: 239, figs 16–26 (2007) — Pls 122–123

Etymology: named after the two large spore bodies in the ascospores.

Typification: Taiwan, Liouguei, branch of indet. angiosperm, 27.VIII.2005, Y.C. Su (TNM F20071, holotype).

Description: — **TELEOMORPH**: **Apothecia** fresh (0.25–)0.3–0.5(–0.6) mm diam., 0.12–0.15 mm high (receptacle 0.08–0.1 → 0.05 mm), pale yellow-chlorinaceous to cream-ochraceous, translucent, ± round, hardly to distinctly gelatinous, (sub)gregarious; disc flat to slightly convex, margin indistinct, not protruding, smooth; with a very short, broad obconical base, superficial; dry light ochraceous-buff. **Asci** *26–31 × 5–5.8 µm {1}, †21–27(–32) × (3.5–)4–5(–5.7) or (5–)6–7(–7.5) µm {2}, 8-spored, spores (*/†) biseriate, at lower end almost uniseriate, pars sporifera *16–19 µm long; **apex** (†) hemispherical (subconical to slightly truncate); **base** with or without a short and thick stalk, arising from croziers (mostly no perforation seen) {2}. **Ascospores** *(3.3–)3.6–5(–5.7) × (2.2–)2.4–2.7(–2.9) µm {2}, †3.3–5.2 × (2–)2.2–2.7 µm {2}, broadly ellipsoid to very slightly fusoid († also slightly limoniform), homopolar, both ends rounded to obtuse; **SBs** *0.8–1.2(–1.5) µm diam. {2}, globose, 1 at each end, closely attached to wall or at a short distance, with 1(–2) further smaller SBs and 0–3 minute LBs in each half. **Paraphyses** apically slightly (to medium) clavate-capitate, terminal cells *3.5–4.5 µm wide {1}, †19–25 × 2.5–4.5(–5.3) µm {2}, lower cells †5–7 × 1.5–3 µm {2}. **Medullary excipulum**, ~20–50 µm thick, of dense, ± non-gelatinized textura prismatica(-angularis), indistinctly to medium sharply delimited. **Ectal excipulum** of (†) thin-walled to slightly gelatinized, horizontally oriented t. prismatica from base to margin, ~50–70 µm thick near base, cells †10–27 × 8–15 µm

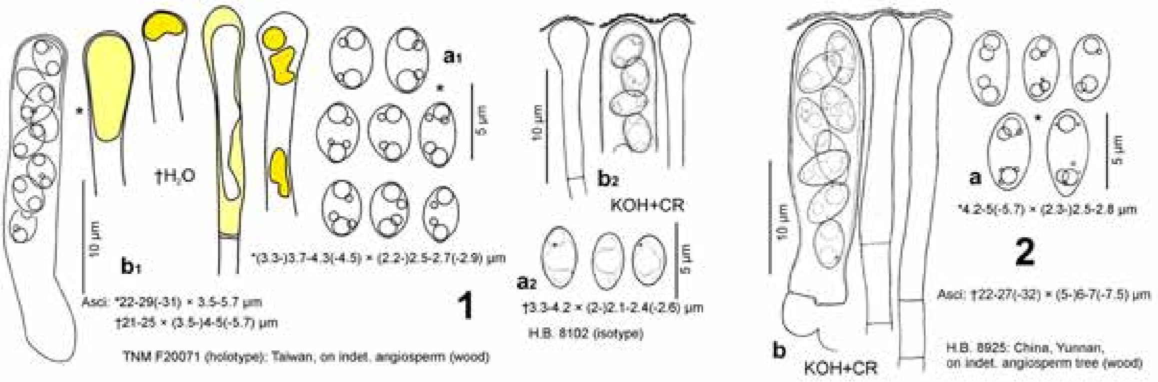

Plate 122. **1–3**: *Hyalorbilia biguttulata*. – **a**. ascospores; **b**. asci and paraphyses. – **1a**$_1$, **b**$_1$: from Wu et al. (2007).

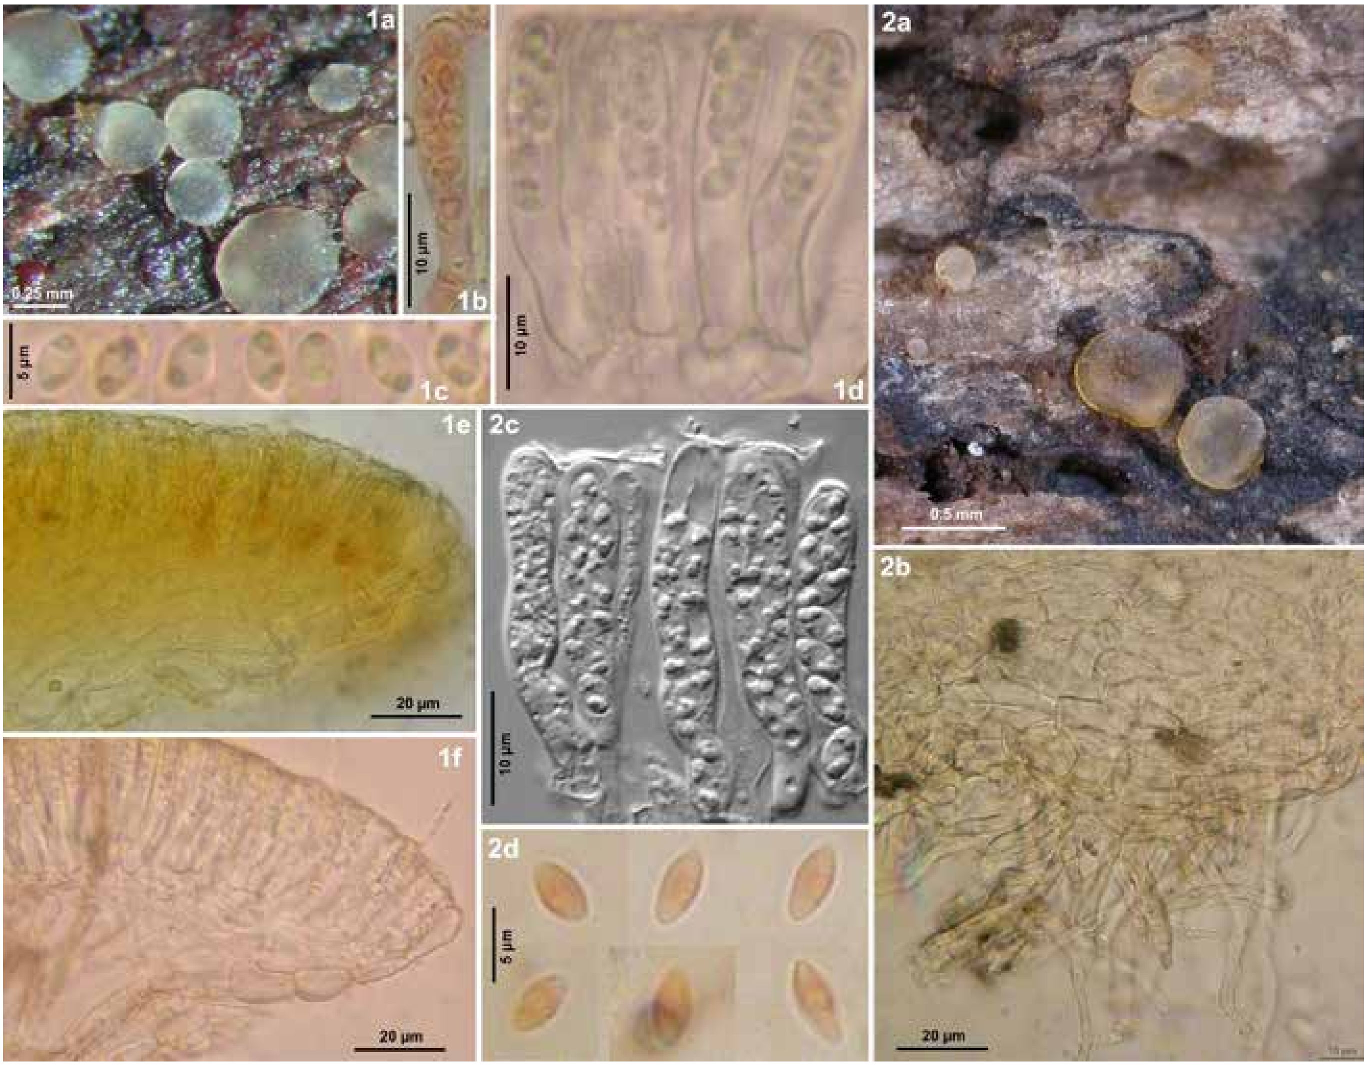

Plate 123. **1–2**: *Hyalorbilia biguttulata*. – **1a**. fresh apothecia; **2a**. rehydrated apothecia; **1e–f**. marginal ectal excipulum in median section; **2b**. ectal excipulum near base, with anchoring hyphae (median section); **1b**, **d**, **2c**. asci and paraphyses; **1c**, **2d**. ascospores. – Living state, except for **1b**, **e**, **2b**, **d**, asci in **2c** (**1e** in KOH+IKI, **2b** in H_2O, **1b** and **2d** in KOH+CR). – **1a**, **c–d**, **f**: from Wu et al. (2007, holotype). – **2c**: phot. H.Y. Su. — **1a–f**. TNM F20071/H.B. 8102 (holo-/isotype): Taiwan, on indet. angiosperm; **2a–d**. H.Y.S. glgs-1/H.B. 8925: China, Yunnan, Baoshan, on indet. angiosperm.

{2}; 10 µm thick near margin, marginal cortical cells †13–18 × (3–)4–7.5 µm {2}, clavate, thin-walled. **Anchoring hyphae** abundant at base, radiating, †2–4.5(–5.7) µm wide, walls 0.2–0.5(–0.7) µm thick {2}. **VBs** in living terminal cells of paraphyses slightly refractive, pale yellow to orange (deeper in dead state), globose to elongate. **Exudate** over paraphyses and marginal excipulum 0.2 µm thick, continuous, finely granular-warted, at margin as distinct small angular warts. — **ANAMORPH**: unknown.

Habitat: collected on the very wet ground, corticated, ~5–20 mm thick branches of indet. broad-leaved trees {2}, on 0.2 mm deep medium to very decayed wood {2}, sometimes on blackened areas, no algae. **Associated**: ?*Capronia* sp. {1}. **Desiccation tolerance**: intolerant, after 5–6 weeks some spores still alive. **Altitude**: 800–1845 m a.s.l. **Geology**: Proterozoic metamorphic rock, Paleogene sedimentary rock. **Phenology**: VIII.

Taxonomic remarks. Among the species with globose to broadly ellipsoid spores, *H. biguttulata* is readily recognized in the living state by ascospores with two large polar SBs, besides 2–3 smaller SBs near to them. In the dead state, however, the characteristic spore contents are only very difficult to discern. The closest relative appears to be *H. multiguttulata*: here the SBs also occur at both spore ends, but they are all of the small size and occur in higher number. Contrary to *H. biguttulata*, the spores of *H. multiguttulata* are almost globose. In an intermediate Chinese specimen included in *H. multiguttulata* (Pls 124: 3; 125: 5) the SBs are less in number and have about the same size as in *H. biguttulata*, but also here the spores are almost globose. *H. erythrostigma* and *H. anonyma* sharply differ in having a single eccentric SB.

Variation. A collection from Yunnan (Pl. 123: 2) is considered here to be conspecific with the type of *H. biguttulata*, although it differs in longer spores and the SBs being less closely associated with the spore ends, also in distinctly wider asci.

Not included collections: A sample from eastern England on *Cytisus* was studied by E. Batten. The spores are only slightly smaller (*2.6–4.2 × 1.8–2.4 µm), but their 1–3 medium-sized guttules were not tested for whether they disappear in dead spores.

Ecology. *Hyalorbilia biguttulata* was found on ± decayed wood and bark of hygric branches of unidentified angiosperm trees. The holotype is from a tropical humid monsoon-influenced climate in southern Taiwan. The collection from Yunnan was in a montane subtropical humid (winter-dry) evergreen broad-leaved forest at the southern end of Hengduan Shan, the southeastern extension of Himalaya. In the type some apothecia grew in close association with a ?*Capronia* and in the Yunnan collection over blackened areas.

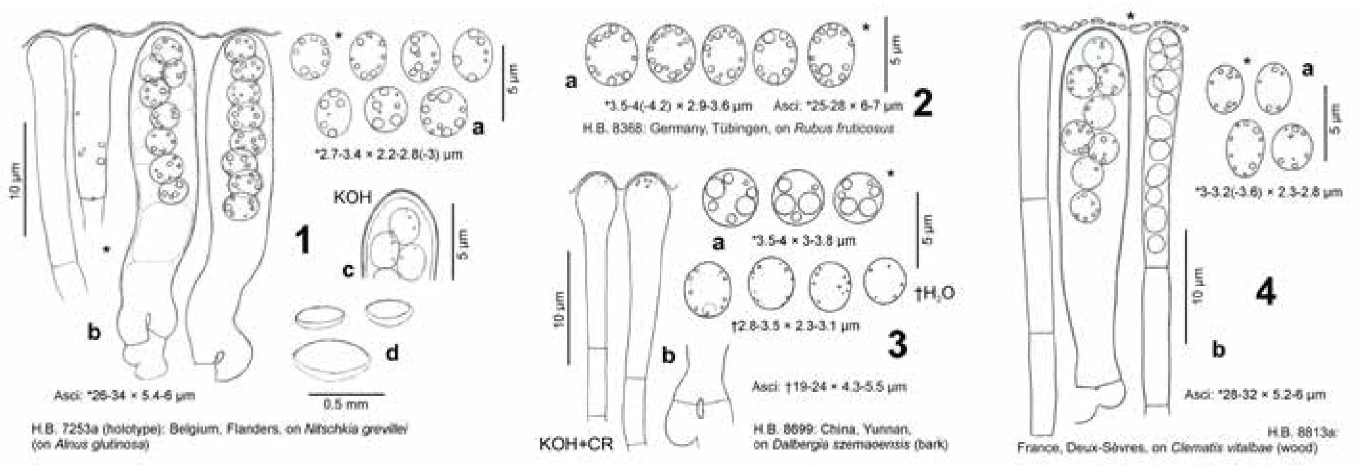

Plate 124. **1–4**: *Hyalorbilia multiguttulata*. – **a**. ascospores; **b**. asci and paraphyses, ascus bases with croziers; **c**. ascus apex; **d**. apothecia (fresh).

Specimens included. **CHINA**: **Taiwan**, **Kaohsiung**, 54 km NE of Kaohsiung, 4.5 km SE of Liouguei, Shanping Natural Education Center, 800 m, branch of indet. angiosperm, on wood, 27.VIII.2005, Y.C. Su (TMUE S050827T2, TNM F20071 **holotype**, doc. vid.; H.B. 8102 **isotype**). – **Yunnan**, **Baoshan**, Tengchong, 52 km SW of Baoshan, 31 km SE of Tengchong, Gaoligongshan, 1845 m, branch of indet. angiosperm, on wood, 4.VIII.2008, X.J. Su, H.Y. Su & X.N. Zhao (H.Y.S. glgs-1, CBCD, H.B. 8925).

Not included. **GREAT BRITAIN**: **East England**, **Suffolk**, 3.7 km ESE of Halesworth, NNW of Wenhaston, Bicker's Heath, 10 m, branch of *Cytisus scoparius*, on wood, 16.IV.2006, S. Francis, vid. E. Batten (E.B. '4667' ø, doc. vid.).

Hyalorbilia multiguttulata Baral & B. Declercq, **sp. nov.**, MB 813457 — Pls 124–125

Etymology: referring to the fact that a number of small spore bodies occur in the ascospores.

Typification: Belgium, Vlaanderen, Wachtebeke, branch of *Alnus glutinosa* (on *Nitschkia grevilli* and on bark), 23.XI.2002, B. Declercq (ex H.B. 7253a, M-0276415, holotype).

Latin diagnosis: *Differt ab* Hyalorbilia erythrostigmate *ascosporis vivis pluria corpuscula refringentia continentibus.*

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated 0.1–0.9 mm diam., 0.08–0.13 up to 0.19–0.26 mm high (receptacle 0.05–0.11 → 0.03–0.07 mm), whitish to pale (yellowish-)chlorinaceous-amber or greyish-cream, ± translucent, round to slightly undulating, slightly gelatinous, scattered to subgregarious in small groups; disc flat (to slightly convex), margin thin or thick, 0–15 µm protruding, smooth; sessile or with a distinct cylindrical stipe 0.035–0.07 × 0.05–0.09 up to 0.2 × 0.3 mm, superficial. **Asci** *(22–)24–34(–37.5) × (4.7–)5–6.5(–7) µm {5}, †(18.5–)20–25(–30) × (4–)4.3–5.3(–5.6) µm {5}, 8-spored, spores *1–2-seriate, pars sporifera *20–23 → 14–18 µm long; **apex** (†) hemispherical to subconical; **base** unstalked, with croziers {8} with or without small perforation. **Ascospores** *(2.5–)3–3.7(–4.2) × (2.2–)2.3–3.5(–3.8) µm {8}, †2.5–3.3(–3.6) × 2–3.1 µm {4}, subglobose to nearly globose, also broadly ellipsoid; **SBs** *0.3–0.4 µm {5} or 0.3–0.8 µm {3} or 0.7–1.5 µm {1} diam., ~2–6 in each spore half, ± globose, often closely attached to wall (here often ± flattened); with a few minute LBs. **Paraphyses** apically uninflated to slightly or medium clavate-capitate, terminal cells *11–22 × 2.2–3.5 µm {2}, †14.5–18 {1} × (2.5–)3–4.5(–5.5) µm {2}, lower cells *9–12.5 × 2–2.5 µm {1}, †6–8 × 1.3–1.5(–2) µm {1}; unbranched at upper septum. **Medullary excipulum** only present in centre, 15–30 µm thick, of dense textura intricata-prismatica-globulosa, non-gelatinized, very indistinctly delimited. **Ectal excipulum** at base of thin-walled to sometimes slightly to medium gelatinized, oriented t. globulosa-angularis, inner parts of ± obliquely upwards oriented t. prismatica, 50–200 µm thick, cells *5–15 {3} or (8–)15–30(–37) {2} × 4–12 µm {4}, at flanks 10–15 up to 35–60 µm thick, of horizontal t. prismatica(-globulosa), cells */†7–22 × 4–10 µm {3}, thin-walled; 10–15 µm thick near margin, marginal cortical cells cylindrical, *6–12 × 3.5–5 µm {1}, †8–10 × 2.5–4 µm {2} or †4.5–12 × 4.5–6.5 µm {1}, or clavate-pyriform, */†10–18 × 5–8 µm {3} (6–10 µm wide in surface view), thin- or firm-walled. **Anchoring hyphae** sparse to abundant, */†2–4(–5) µm wide (at insertion up to 5–7 µm), walls 0.2(–0.3) µm thick {6}. **VBs** globose to angular, low- to medium refractive {1}, also absent. **Exudate** over paraphyses 0.2(–0.3) µm thick, continuous (smooth to slightly rough), or 0.3–0.7(–1.2) µm thick, cloddy, very pale chlorinaceous; over margin and flanks finely punctate to cloddy, hyaline to pale yellow. **— ANAMORPH**: unknown (but see below).

Habitat: lying on shady, moist ground {2} or collected 1–1.8 m above the ground {2}, on corticated or decorticated, 1–5 cm thick branches of *Alnus glutinosa* {1}, *Carpinus betulus* {1}, *Clematis vitalba* {1}, *Dalbergia szemaoensis* {1}, *Populus* sp. {1}, *Ulmus* sp. {1}, indet. angiosperm {1}, stem of *Rubus fruticosus* agg. {1}, on bark {3} (periderm & bast, also on inner surface) and wood {3}; on rotten *Fomes fomentarius* {1}, living mature perithecia of *Nitschkia grevillii* {1}, old stroma of *Diatrype* sp. {1}; wood up to 5 mm deep very decayed and furrowed, with beetle galleries, sometimes on dark brown detritus, also on scar area or broad clefts of periderm, strongly greyed, ± algae-covered. **Further associated**: *Calycina* sp. {1}, *Eutypella quaternata* {1}, *E. scoparia* {1}, *Hyalorbilia japonica* {1}, *Hypnum cupressiforme* {1}, *Karstenia rhopaloides* {1}, *Lophiostoma compressum* {1}, *Orbilia binchuanensis* {1}, *O. breviaristata* {1}, *O. clavuliformis* {1}, *Physcia* sp. {1}, *Porella platyphylla* {1}, *Pyrenopeziza rubi* {1}, *Tremella* sp. {1}. **Desiccation tolerance**: some mature asci still viable after 2 weeks, basal excipular cells and spores after 5 months. **Altitude**: 8–452 m a.s.l. (Europe), 1850–2700 m (southern China). **Geology**: Cambrian wacke, Devonian-Carboniferous rock, Middle Jurassic calcareous clay, Keuper (Knollenmergel), Cretaceous flysch, Tertiary molasse; mica schist, serpentinite, mafic volcanic rock. **Phenology**: IV–VI, X–XI.

Taxonomic remarks. *Hyalorbilia multiguttulata* closely resembles *H. erythrostigma* in size and shape of the ascospores. The species sharply differs in the presence of several rather small, scattered SBs, all being closely attached to the spore wall. In *H. erythrostigma*, only one large eccentric SB is found in each living spore which is not visibly attached to the spore wall (exceptionally by a fine filum). The close attachment of all SBs in the spores of *H. multiguttulata* was only visible when observing living free spores floating in the medium. Further distinguishing characters between the two species are quite wanting, even in the presumed anamorph. For the differences to the closely related *H. biguttulata* see p. 413. *H. brevistipitata* possesses smaller spores which contain a very similar pattern of minute SBs (Pl. 121: 1a, d, 2b–c).

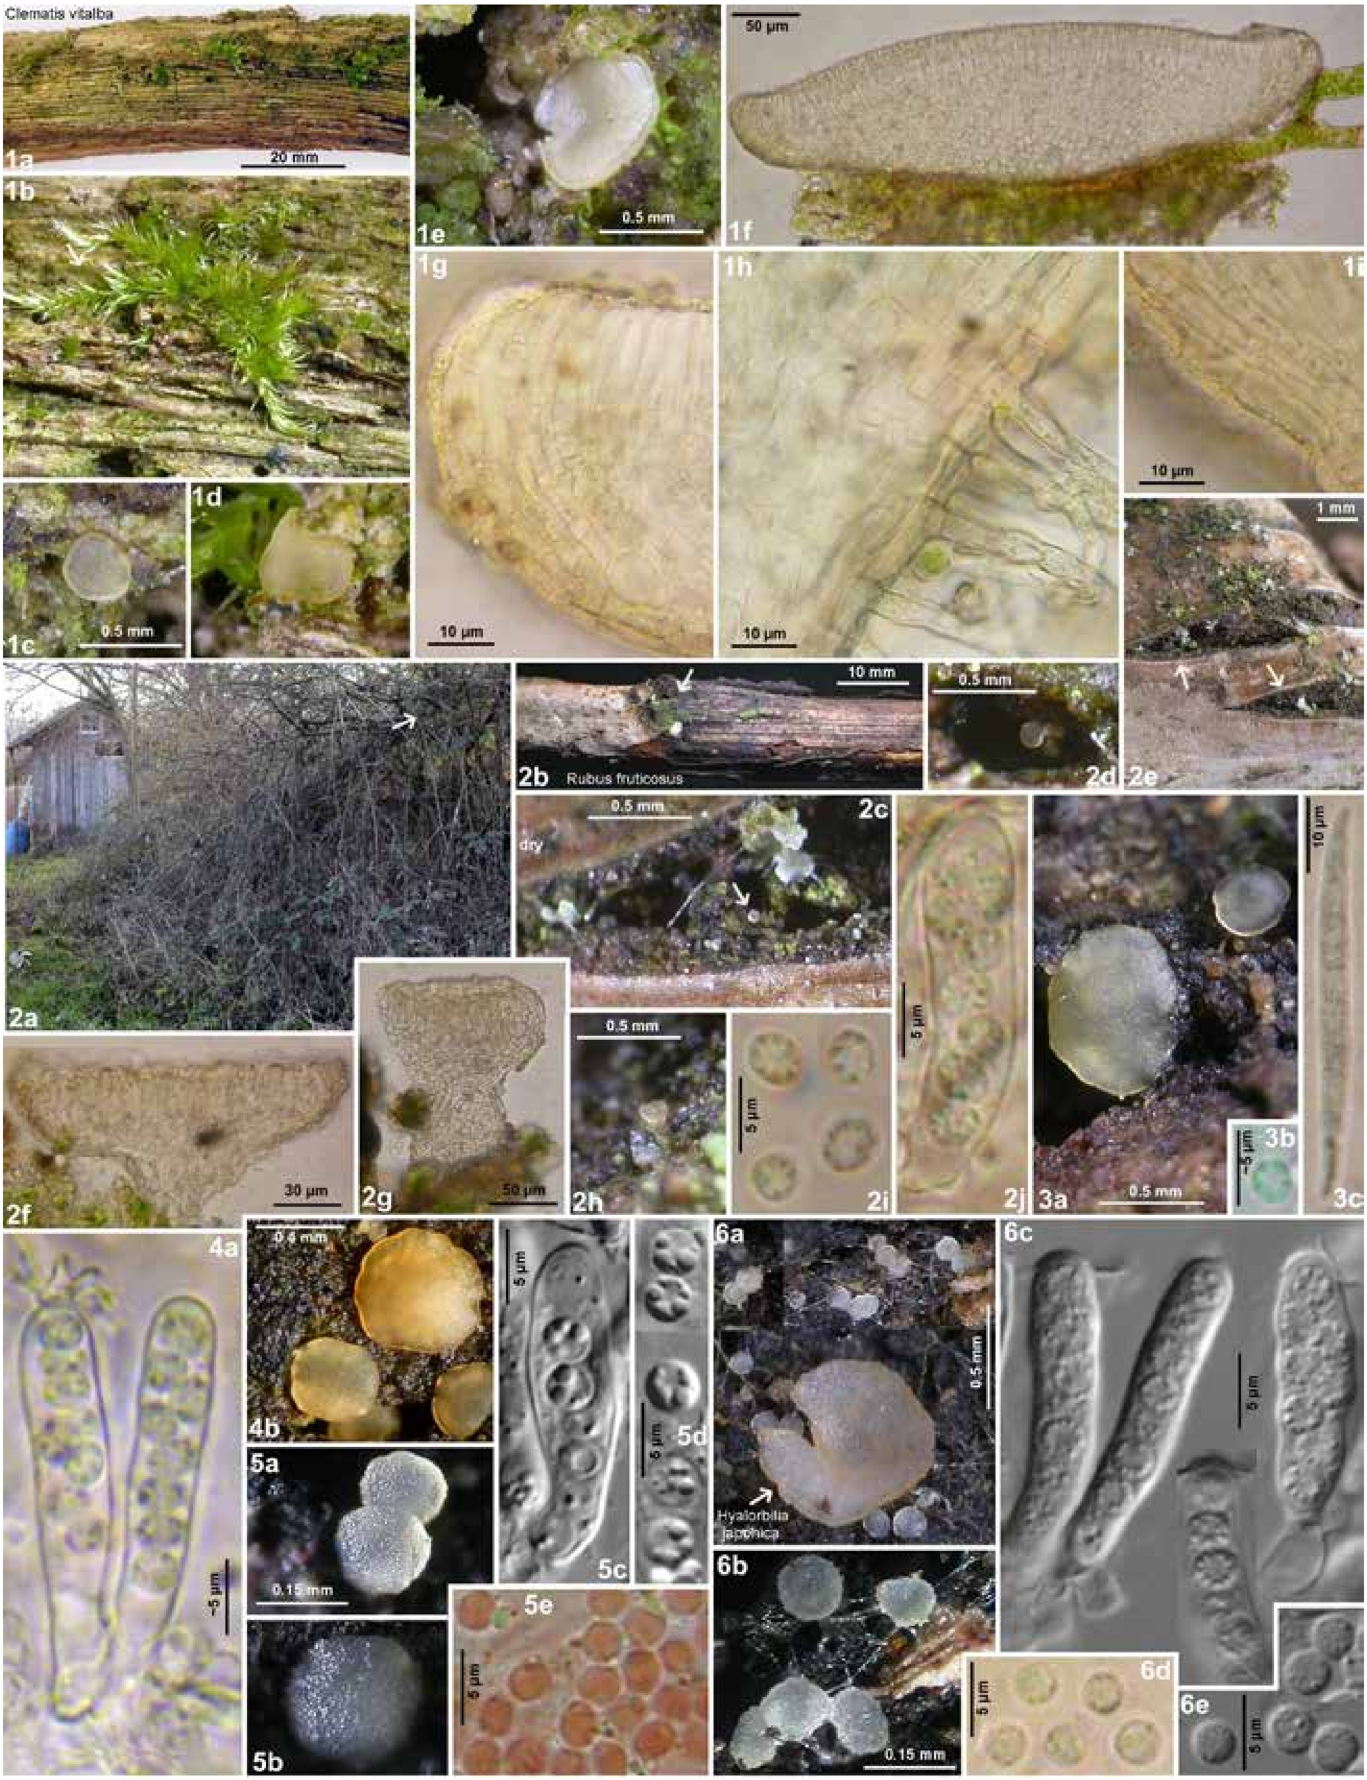

Plate 125. **1–6**: *Hyalorbilia multiguttulata*. – **2a**. old *Rubus fruticosus* growing over *Salix purpurea*; **1a–b**. decorticated xeric branch of *Clematis vitalba*, with *Hypnum cupressiforme* and *Porella platyphylla*; **2b**, **e**. dead corticated xeric stems of *Rubus fruticosus*; **4b**. fresh apothecia; **1c–e**, **2d**, **h**, **3a**, **5a–b**, **6a–b**. rehydrated apothecia; **2c**. dry apothecium; **2g**. lateral view of apothecium (squash mount); **1f**, **2f**. apothecia in median section; **1g**. id., marginal ectal excipulum; **1h–i**. id., ectal excipulum at lower flanks (**1h** with anchoring hyphae); **2i–j**, **3b**, **4a**, **5c–e**, **6c–e**. asci and ascospores; **3c**. conidium from substrate. – Living state, except for **6d–e** (in H_2O); **5e** (KOH+CR); asci in **5c**, **6c**. – **5c–d**: phot. H.B. 8979b: China, Dali, on indet. angiosperm.

Variation. The seven collections here referred to *H. multiguttulata* differ in apothecial size, ranging from 0.1–0.3 up to 0.4–0.9 mm. Similarly, the thickness of the apothecia strongly varies because of a very different height of the ectal excipulum. The holotype is intermediate concerning apothecial size, but has a rather thin, small-celled ectal excipulum. The collections on *Clematis* and *Ulmus* differ from the others in narrower, more cylindrical marginal cortical cells, the former also in smaller SBs, the latter in rather small spores (*2.5–3 × 2.5–3 µm). Also in the sample on *Fomes* (IVV: 22.XI.2018) the spores were rather small (*2.8–3 × 2.4–2.7 µm) and contained only a few SBs, while the marginal cortical cells were intermediate.

A Chinese specimen on bark of *Dalbergia* (Pls 124: 3; 125: 4) closely resembles European *H. multiguttulata* in its almost globose spores, but differs in fewer, distinctly larger SBs (0.7–1.5 µm diam), also rather large, especially wide spores. Three further specimens from the same locality (7.VI. and 17.VII.2007, on bark of unidentified broad-leaved trees) were not documented in the living state (H. Su pers. comm.). The collection on *Dalbergia* is somewhat intermediate to *H. biguttulata*, from which it differs in much wider, globose spores and not regularly bipolarly arranged SBs. Another Chinese specimen (Pl. 125: 6) has smaller SBs and herein fits well European *H. multiguttulata*. We have included it in the description, although some paraphyses were medium capitate and, therefore, distinctly wider (up to †4–5.5 µm) than found in European material.

Anamorph. A pure culture of *Hyalorbilia multiguttulata* was not obtained in the present study, because the ascospores did not easily germinate on our agar media, and the germinated spores early stopped growing. In two collections we found conidia on the natural substrate near apothecia. In the sample on *Ulmus* (Pl. 125: 3c) a single phragmoconidium was seen (*51 × 3 µm, 6-septate) that resembles conidia of the closely related *H. brevistipitata* or *H. oviparasitica*, whereas in the sample on *Rubus* (Pl. 124: 2) trinacrium-like conidia occurred, some of which are thought to belong to *H. erythrostigma* (Pl. 127: 6). Cultures belonging to the environmental DNA isolate from soil in California (dm2s_a1) have not been obtained, therefore, morphological data of the anamorph is lacking.

Not included collections. Two records from Riverside (California), one cultured, the other only as DNA isolate, were reported by Smith & Jaffee (2009) under the name *Dactylella oviparasitica*. Their molecular data place them closer to *H. multiguttulata*, but the high distance prevents to include them in this species. They are referred to as *H.* aff. *multiguttulata*, because any morphological data has not been obtained.

Phylogeny. An ITS sequence was gained from apothecia of the sample on *Ulmus* (Bretagne, H.B. 9850, Pl. 125: 3, see also IVV). It lacks the S1506 intron and clustered in the strongly supported *oviparasitica-multiguttulata* clade (Phyl. 5), though with 15–17% distance to *H. oviparasitica* and 10.5% to *H.* aff. *multiguttulata*. Two uncultured DNA extracts from Californian soil (dm2s_a1, dm4w_a8) and an unlocalized strain (1070) comprise partial 5.8S and ITS2, the former two also LSU. Two of them deviate from *H. multiguttulata* and from each other merely by 1 nt in the ITS2, which suggests that *H. multiguttulata* occurs also in North America, whereas isolate dm4w-a8 (H15) shows a much higher distance to either of these taxa.

When comparing the 5.8S region, *H. multiguttulata* and *H.* aff. *multiguttulata* concur but deviate from *H. oviparasitica* and *H. brevistipitata* s.l. and any other *Hyalorbilia* at pos. 134 (Tab. 18), and from *H. erythrostigma* at 6 positions. In the LSU (434 nt), *H. multiguttulata* (EF446003) differs from *H. brevistipitata* by ~3% and from *H. erythrostigma* by ~11%. The very high molecular distance to *H. erythrostigma* confirms the high taxonomic importance that spore body characters in living ascospores provide.

Ecology. *Hyalorbilia multiguttulata* was found on rotten bark and wood of hygric branches or logs of *Alnus*, *Populus*, and *Ulmus*, and of a xeric branch of *Clematis* and stem of *Rubus*, in supra- to mesotemperate and mesosubmediterranean humid, atlantic western, and subcontinental central Europe. The holotype was collected on the ground of a wet but drained *Populus-Acer-Alnus* forest plantation with *Urtica*. The two paratypes on *Rubus* and *Clematis* were found 1–1.8 m above the ground, suggesting that *H. multiguttulata* is desiccation-tolerant and has a wide host range. In the holotype, some apothecia grew on perithecia of *Nitschkia grevillii* which, however, did not show any sign of damage to their hymenia. The Serbian samples were on rotten, ± xeric *Fomes* and *Diatrype* on fallen *Carpinus* and *Fagus* branches and logs. The two south Chinese collections were on bark lying on the moist ground, in subtropical humid (winter-dry) evergreen broad-leaf forest. The Californian soil isolate was from a mild-maritime humid coastal area.

H. aff. *multiguttulata* was isolated from *Heterodera schachtii* in a sugar beet field in subtropical semiarid (hot-summer mediterranean) southern California. An improved isolation technique of the fungus was developed, in which soil samples from sugar beet fields are infested by greenhouse-reared juveniles of the nematode, and females are later picked from the roots for DNA extraction (J.O. Becker pers. comm.).

Specimens included. **BELGIUM**: **Vlaanderen**, **Oost-Vlaanderen**, 15 km NE of Gent, 2.5 km SSE of Wachtebeke, Puyenbroeck, 8 m, on *Nitschkia grevillii* and bark of branch of *Alnus glutinosa*, 23.XI.2002, B. Declercq (ex H.B. 7253a M-0276415, **holotype**; B.D. 02083 **isotype**). — **FRANCE**: **Bretagne**, **Ille-et-Vilaine**, 7 km E of Rennes, 2.2 km SE of Cesson-Sévigné, Forgé, 47 m, branch of *Ulmus*, on wood, 24.V.2013, J.P. Priou (J.P.P. 13120 ø, H.B. 9850, anam. substr.; sq.: KT222345). – **Poitou-Charentes**, **Deux-Sèvres**, 13.5 km N of Melle, 2 km SW of La Mothe-St.-Héray, La Dame de Chambrille, 100 m, branch of *Clematis vitalba*, on wood, 17.IV.2008, S. Helleman (H.B. 8813). — **GERMANY**: **Baden-Württemberg**, Tübingen, 5 km NE of Tübingen, 0.6 km S of Pfrondorf, Obere Mähder, 395 m, stem of *Rubus fruticosus*, 20.XI.2006, H.O. Baral (H.B. 8368a ø). — **AUSTRIA**: **Wien**, 5 km SSW of Wien, SE of Meidling, Wienerberg, 225 m, log of *Populus*, on wood, 29.XI.2013, R. Moosbeckhofer, vid. B. Wergen (H.B. 9865). — **SERBIA**: **Vojvodina**, Fruška Gora, 13 km S of Novi Sad, 6 km NNW of Irig, Iriški venac, W of WWII memorial, 440 m, on *Fomes fomentarius* (on *Fagus sylvatica* log), 22.XI.2018, D. Savić (FG-944, doc. vid.). – 11.5 km S of Novi Sad, 5.7 km NNW of Irig, 452 m, branch of *Carpinus betulus*, on *Diatrype*, 26.IX.2019, D. Savić (doc. vid.). — **CHINA**: **Yunnan**, **Dali**, 42 km NNE of Dali, Jizushan Nature Reserve, 2700 m, branch of indet. angiosperm, on bark, 20.X.2008, X.M. Gao, H.Y. Su & X.J. Su (H.Y.S. jz-3, CBCD, H.B. 8979b, mixture in M0276443 [type of *O. binchuanensis*]). – **Yuxi**, Tonghai, 35 km SE of Yuxi, ~2 km S of Tonghai, Xiushan Forest Park, ~1850 m, branch of *Dalbergia szemaoensis*, on bark, 7.VI.2007, J.W. Guo & S.F. Li (J.W.G th2-12(2), YMFT, H.B. 8699). — **USA**: **California**, central California, ~30 km WSW of Santa Rosa, Bodega Bay, from soil (dm2s_a1, as *Brachyphoris* sp. 1, mol. extr., non vid.; sq.: EF446003). — **Unlocalized**: from soil (1070, as uncultured *Orbiliales*, mol. extr., sq.: MF482281)

Not included (**O**. **aff**. ***multiguttulata***). **USA**: **California**, southern California, 4.7 km ENE of Riverside, 2 km WSW of University of California, Agricultural Operations, sugar beet field 9E, 300 m, roots of *Beta vulgaris*, isolated from parasitized females of *Heterodera schachtii*, ca. 2003, R. Olatinwo (DoUCR50, myc. only, as *D. oviparasitica*; sq.: AY970525, EF446019, JQ638668, JQ638669). – ibid. (soil from field 9E placed in cups in greenhouse), on females of *H. schachtii* (UCR, DACITS2–6, as uncultured soil fungus, mol. extr.; sq.: AY123746–57, AY123763, AY185766–AY185770).

Phenology of *H. erythrostigma* within Europe											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
7	6	4	7	2	3	4	2	4	5	3	3

Taxonomic remarks. *Hyalorbilia erythrostigma* is characterized by small, subglobose ascospores with a single, eccentric, globose, comparatively large SB, and by minute, subhyaline to pale cream or yellowish, often stipitate apothecia growing on ± decayed pyrenomycetes, jelly basidiomycetes, or plant substrate. The morphologically very similar but ecologically different *H. orbiliicola* grows parasitically on the margin of *Orbilia* apothecia and mainly differs in much shorter, ± globose to subglobose VBs in paraphyses and marginal cells. However, molecular data indicate that *H. erythrostigma* is still heterogeneous.

H. erythrostigma may also be confused with *H. anonyma*, *H. brevistipitata*, *H. biguttulata*, and *H. multiguttulata*. *H. anonyma* merely deviates in a few gradual characters and is, therefore, here only tentatively separated at the species level. *H. brevistipitata* differs in smaller spores that contain several small peripheral SBs per spore, and in unbranched conidia. Also *H. biguttulata* and *H. multiguttulata* differ in the contents of the living spores, with either two large or several small SBs, respectively. From dead material the latter three species can hardly be distinguished, although the difference in spore contents is highly consistent and striking in well-developed living specimens. Therefore, the distinction at the species level is justified. Since the protologue of *Peziza erythrostigma* is devoid of vital characters, the identity of the holotype could only be resolved from the presence of remnants of SBs in the dead spores, which were discerned as very faint, eccentric, transparent regions (Pl. 126: 2a lower row).

In order to fix the name, a specimen from Luxembourg on *Diatrype bullata* on a *Salix* branch (ex H.B. 9077a, Pl. 127: 5), from which a sequence was gained, is herewith designated as **epitype** of *H. erythrostigma*.

Variation. Among the collections here referred to *H. erythrostigma*, some variation especially in size and length/width ratio of ascospores and asci, size of SBs, and length of apothecial stipes was noted. Yet, no reliable correlation was discovered between apothecial micromorphology and the inhabited substrate (pyrenomycetes, basidiomycetes, angiosperm substrate). Exceptionally narrow asci (*3.9–4.1 µm, †3.2–3.8 µm) were measured in the samples from Vizcaya and Tenerife (on pyrenomycetes), and in that from Tenerife spore size was with *2.2–2.5 × (1.5–)1.7–2.1 µm at the lower range (IVV: 14.IX.2014). In the holotype on *Chaetosphaerella phaeostroma*, variation in spore size was noted; however, this might originate from different preparation methods (unheated KOH vs. heated KOH+CR, Pl.126: 2a).

Based on the few DNA data from Europe, samples on bark and wood possibly belong to a species different from those on pyrenomycetes. Between two samples from Luxembourg (on *Diatrype* on *Salix*, epitype, IVV: H.B. 9077a; on *Clematis* bark, IVV: G.M. 2017-11-19.4) a rather high ITS distance is observed (see below), correlated with a different SB size (1–1.5 µm vs. 0.8–1 µm diam.), although the spores are of equal size (*2.5–3 × 2–2.4 vs. *2.7–3 × 2–2.2 µm, respectively). However, similarly small SBs (0.8–1.1 µm) have been observed in two Austrian samples on *Tilia* bark and *Diatrypella* (Pl. 126: 5, 7).

In the holotype the apothecia showed the longest and narrowest stipes (Pl. 126: 2d), unlike most of the other specimens studied in which the stipes were either shorter and wider, or ± absent. Yet, the presence and length of stipes might depend on the structure of the substrate: no distinct stipes are formed when growing on naked wood and bark, while the long stipes in the holotype appear to be due to growth among the dark setae of *Chaetosphaerella*. Distinct stipes of about the same height and width have mainly been seen in collections on stromatic pyrenomycetes, but sometimes also on naked wood.

The epithet '*erythrostigma*' and the remark 'pale red' in the protologue misleads to imagine a red discomycete. However, all recently collected apothecia were rehydrated nearly hyaline to light chlorinaceous-cream, and dry yellowish(-orange). Also in the examined holotype the apothecia were pale yellow when rehydrated and golden yellow-amber when dry.

Not included collections. Two Australian specimens are not included in the description. One was on an unidentified climber (Pl. 126: 9) and had comparatively large spores (*2.5–3.3 × 2–2.6 µm) with SBs visibly attached by a short filum, and the croziers were without perforation (here no associated conidia were seen). A more abundant sample which differs in smaller spores was only studied in the dead state; the associated conidia were small and ± symmetrical (Pls 126: 10; 128: 3). In a few spores a single SB could be discerned as a faint eccentric region. From *H. ulmi* this sample differs in shorter, more subglobose spores and in larger apothecia, and from *H. brevistipitata* in spore guttulation, although this feature is very difficult to assess in dead spores. Vital studies on further collections from Australia are necessary in order to clarify spore contents and species limits in this group, and to find out whether conidia with asymmetric arms growing on *Orbilia* spp. belong to a species different from European *H. orbiliicola*.

Records of *H. erythrostigma* from eastern Asia were reported by Liu (2006, Fujian, Pls 126: 4; 128: 1), Guo et al. (2014b, Yunnan and Zhejiang), and Ekanayaka et al. (2018, Thailand). Liu's two samples on *Nitschkia acanthostroma* have short-stalked apothecia of 0.1–0.2 mm diam., rather short asci (†16–22 × 3.6–3.8 and 20–23 × 3.8–4.2 µm), and spores of †2.2–2.6 × 1.8–2.4 and 2.5–2.7 × 1.8–2.4 µm (Liu 2006 and present study). Guo et al.'s three samples (on *Dalbergia* bark, sometimes on black fungi) have sessile to short-stipitate apothecia 0.1–0.3 mm and spores *2.5–3.3 × 2–2.3 µm with large eccentric SB. Ekanayaka et al.'s sample (on *Annulohypoxylon*) was described with apothecia 0.38–0.43 mm diam. with a prominent stipe and rather small spores (†1.7–2.3 × 1.6–2.2 µm), whereas ascus size (†30–33 × 3–3.5 µm) fits *H. erythrostigma*. Because of strong deviations in the DNA data, we refrained from including southeastern Asian collections in the description.

For two collections from South America (Peru), Matsushima's *Orbilia trinacriifera* and *Trinacrium angamosense*, see under Type studies and Anamorph, respectively.

Anamorph. Only a few detached conidia of the presumed trinacrium-like anamorph could be observed on the natural substrate (pyrenomycetes) in three samples (Peru: Pl. 126: 6; Luxembourg: Pl. 127: 5d; Spain: IVV: 27.VII.2017). This anamorph can hardly be distinguished from that of *H. orbiliicola*. In a German sample on *Rubus* (Pl. 127: 6) very similar conidia were observed near apothecia of *H. multiguttulata*, and we assume here that these conidia belong to *H. erythrostigma*, because *H. multiguttulata* more probably

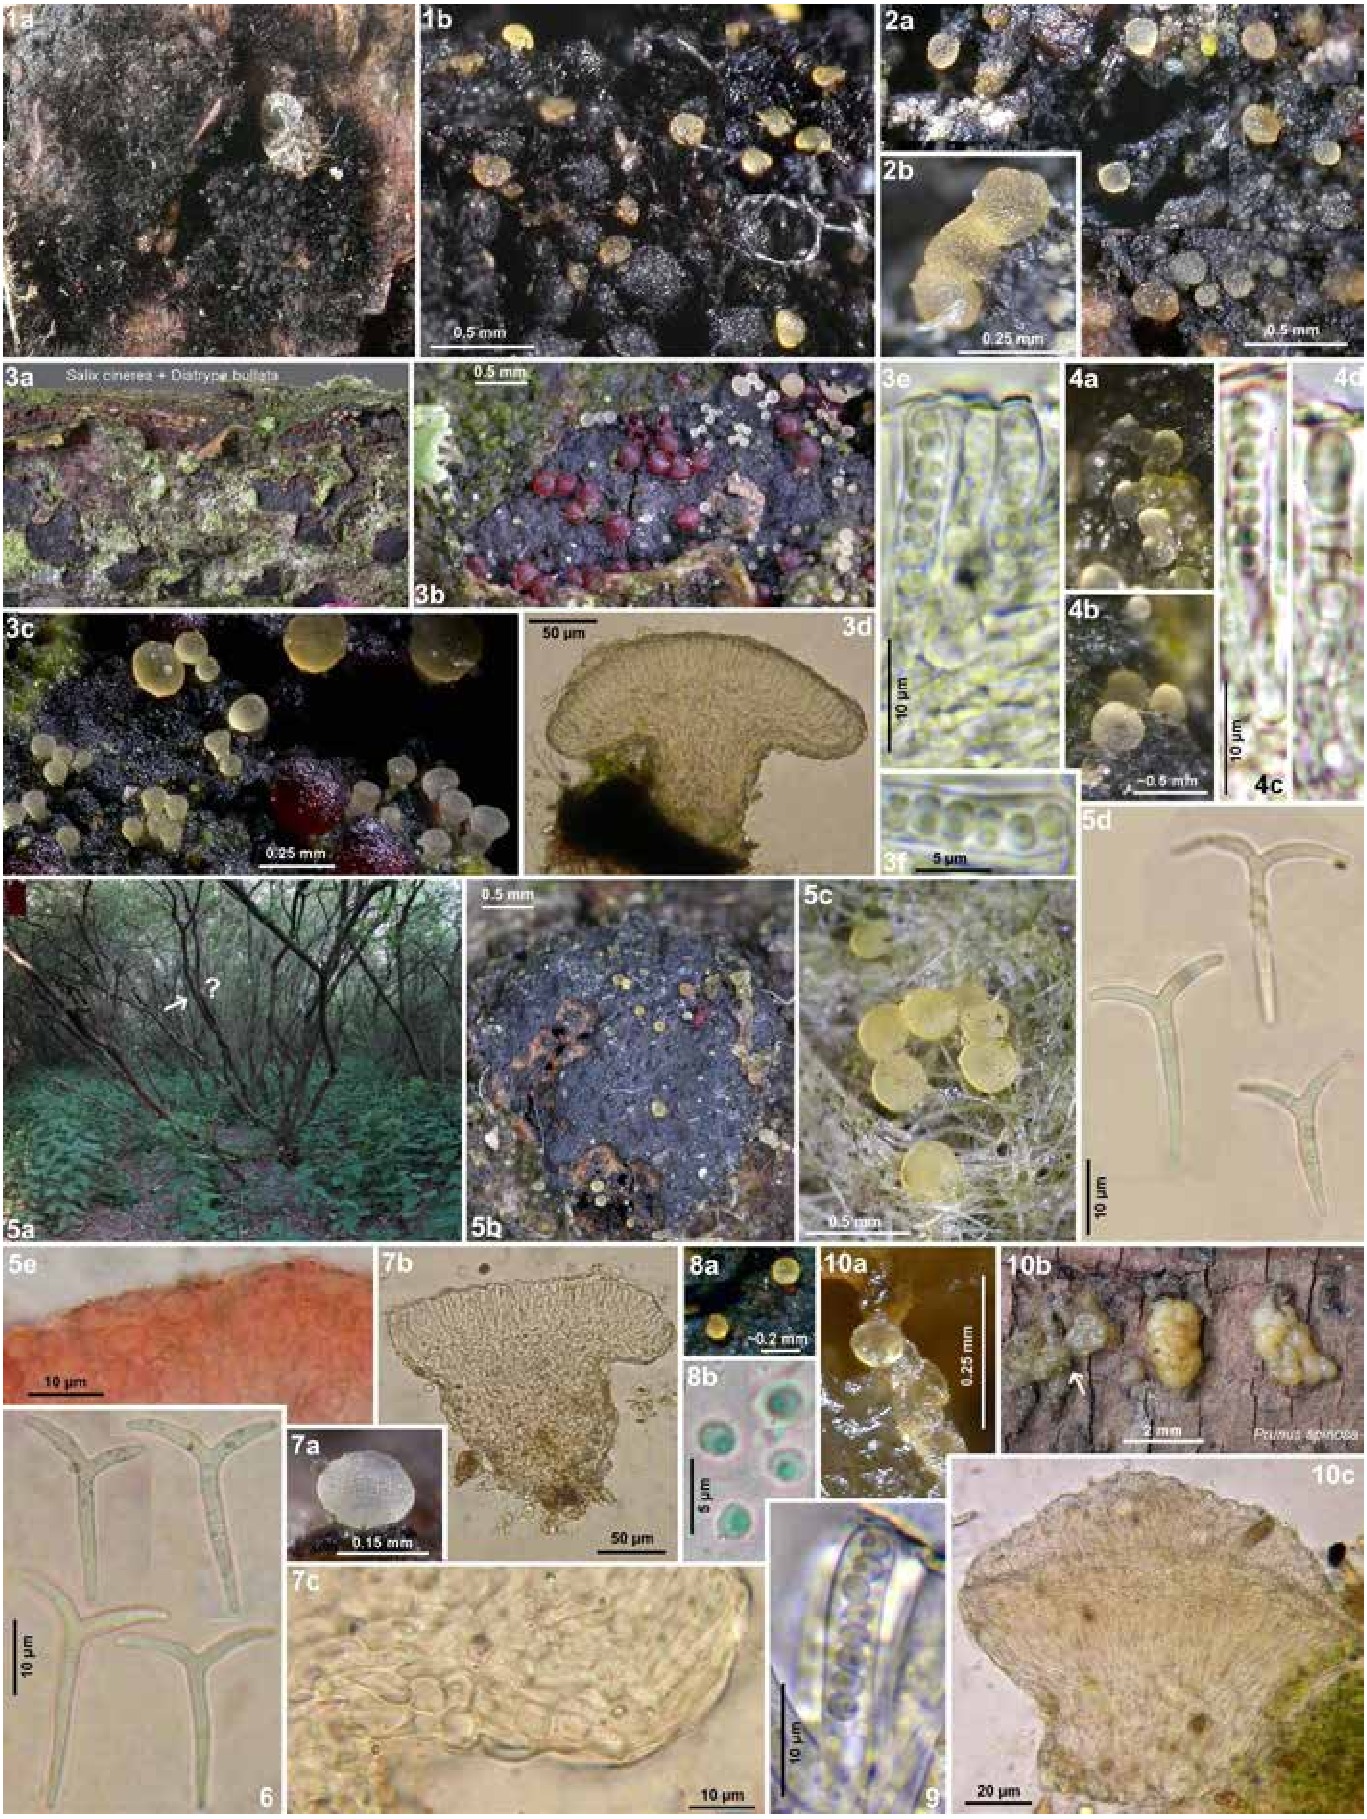

Plate 127. 1–10: *Hyalorbilia erythrostigma*. – **5a**. *Salicetum* with *Urtica* (same site as Pl. 130: 1); **1a**. bark with *Chaetosphaerella phaeostroma* (dry); **1b**, **2a–b**, **3a–c**, **4a–b**, **5b–c**, **7a**, **8a**, **10a–b**. rehydrated apothecia growing on *Sordariomycetes* or *Sebacinales*; **10c**. apothecium in lateral view (squash mount); **3d**, **7b**. apothecia in median section; **7c**. id., ectal excipulum at margin and flanks; **5e**. margin in top view; **3e**, **4c**, **9**. asci; **4d**. marginal paraphysis; **3f**, **8b**. ascospores; **5d**, **6**. conidia from substrate. – Living state, except for **5e** (in CR); **7b–c**, **10c** (in KOH), lower left conidium in **5d**. – **4a–c**: phot. H.B. 6605: Peru, Cordillera Blanca, on *Eutypa* (on

possesses phragmoconidia and *H. orbiliicola* so far never occurred parasitic on *Hyalorbilia* apothecia. No conidiophores could be seen in any of these samples. In those from Peru and Spain the sparse conidia had 4-septate stipes, a feature so far not observed in *H. orbiliicola*, whereas in those from Luxembourg and Germany they had 2–3-septate stipes as in *H. orbiliicola*. In the sample from Luxembourg on *Diatrype*, *H. orbiliicola* on *O. eucalypti* occurred at a distance of ~10 cm on the same *Salix* branch, nevertheless, the figured conidia (Pl. 127: 5d) were found near apothecia on *Diatrype*.

Trinacrium angamosense Matsush., described from Peru on palm petioles (Pl. 22: b), very probably belongs in the *H. erythrostigma* aggregate, but its synonymy with *H. erythrostigma* or *H. orbiliicola* is uncertain. Also *Trinacrium parvisporum* (see Pl. 22: c), described by Matsushima (1987) from basidiocarps of *Tremella* in Taiwan, could be a synonym of *H. erythrostigma*, although the two arms often show some asymmetry.

In the not included small-spored Australian collection on indet. climber (Pl. 126: 10) a few rather small conidia (†14–18 × 11–22 µm) were observed on the substrate close to the presumed teleomorph (Pl. 128: 3j). In one conidium the arms are downwards curved, whereas in others they are straight or curved upwards (not shown); however, this depends on which branch is considered to be the stipe. A mixture of different *Orbilia* spp. was observed in this sample (*O. mammifera*, *O. neocomma*, *O. paracaudata*, *O. scandens*, *O. subfabacearum*), and the connection between them and the different observed anamorphs was difficult to assess.

Nomenclature and type studies. ***Peziza erythrostigma*** Berk. & Broome is a later homonym of *P. erythrostigma* Mont. and thus illegitimate. Phillips (1887) was the first to transfer Berkeley & Broome's epithet to another genus in which there is no earlier competing homonym. Therefore, Phillips' combination must be taken as a nomen novum based on the same type as Berkeley & Broome's illegitimate name (Art. 58.1, Turland 2018).

The holotype from Batheaston (Somerset) was described and figured with convex apothecia and rather long, mostly curved stipes composed of large prismatic cells (Berkeley & Broome 1866). Clearly, the illustrated individual cells are macroscopically only visible when using the strong magnification of a compound microscope. Cooke (1871) and Phillips (l.c.) merely copied the protologue. Cooke's statement (in Phillips) that the fungus is hairy must be an error.

In the holotype in K, Korf & Zhuang (1987) found the asci slightly larger [†27–33(–40) × 3.7–5 µm] than in the present study of the same specimen, whereas the given spore size (†2–3.5 × 1.8–2.5 µm) concurs very well. Spore shape in *H. erythrostigma* was always described and figured as subglobose or broadly ellipsoid (Berkeley & Broome l.c., Phillips l.c., Dennis 1972: 473, Korf & Zhuang l.c., present study). The spores were always completely smooth (Pl. 126: 2a) in concordance with Korf & Zhuang (1987) who stated that they are not distinctly marked, unlike the type species of *Pithyella* which has globose warted spores.

When Matsushima (1995: pl. 20 fig. F-841, pl. 21 figs F-842–844, pl. 34 figs P-335–337, pl. 35 figs P-338–340) described ***Orbilia trinacriifera*** from palm leaves in Peru, he obviously overlooked the strong similarity with *H. erythrostigma*. The type collection was reexamined from a living culture kindly sent by T. Matsushima in 1996. This contained many overmature *Trinacrium* conidia (Pl. 126: 8j) and densely gregarious, living, immature apothecia of 0.1–0.15 mm diam. with excipulum and paraphyses covered by a warted exudate (Pl. 126: 8b, d). During further incubation the apothecia did not produce asci and ascospores. The microfeatures (strongly gelatinized apothecia, small angular warts of the exudate, excipulum of horizontal t. prismatica) clearly refer the species to the genus *Hyalorbilia*. The protologue describes the ectal excipulum of t. globulosa (Pl. 128: 2a), a feature which was also seen once in a European specimen of *H. erythrostigma* (Pl. 127: 7c).

A micrograph of the hymenial elements provided by Matsushima (l.c., pl. 35 fig. 338; see Pl. 128: 2b) shows living mature asci which contain living subglobose spores with large globose eccentric SBs. Ascus size evaluated from this plate is about *24–26 × 4 µm and spore size *2.5–2.8 × 1.7–2 µm, with SBs 0.9–1.2 µm diam. Another photo (l.c., pl. 34 fig. 337) shows free, dead spores without SBs. Different photos in his electronic publication (Matsushima 2005) show living spores inside dead asci. SB size can here be evaluated as 1–1.3 µm diam. when taking the scale bar as 10 µm instead of the erroneous 20 µm. In the protologue the asci are given as 23–30 × 2.5–4 µm, and the spores as uniguttulate, 2–3 µm, with a length/width ratio of 1:0.7–1:0.8, which means a spore width of 1.5–2.3 µm. Obviously, ascus dimensions in the protologue include also dead asci. In ascus and spore width this specimen lies at the lower end of the range of *H. erythrostigma* and *H. orbiliicola* though fitting well these species.

The anamorph obtained by Matsushima (1995) in culture differs from that of European *H. erythrostigma* and *H. orbiliicola* in distinctly larger conidia with markedly wider arms and much wider stipes (Pl. 126: 8j left), which suggests that the conidia studied here from the living type culture were not secondarily inflated due to an overmature stage (Pl. 126: 8j right). Matsushima isolated his strain from leaves, perhaps from conidia growing on them but this was not stated, while the described apothecia and conidia developed in his agar culture. Since *H. orbiliicola* grows parasitic on apothecia of *Orbilia* spp., it cannot be excluded that the trinacrium-like conidia reported by him belong to a species of *Orbilia* that served as the host of *H. orbiliicola* or closely related species. The studied isolate would then be a mixture of two orbiliaceous species and would require lectotypification, while the true anamorph of *O. trinacriifera* (?= *H. orbiliicola*) could be *Trinacrium angamosense*, which was described from the same region and substrate (Peru, Colonia Angamos, palm petioles). On the other hand, the shape of the conidia described for *O. trinacriifera* fits well the *H. erythrostigma* aggregate, except that much wider conidial stipes [27–40 × 4.5–6 µm, (2–)3–4(–5)-septate] and arms (7–13 × 3–5 µm, 1-septate) suggest a species of its own.

When Matsushima (1995) described *O. trinacriifera*, he cited a '*Trinacrium* sp. MFC-6700' previously reported by him from Taiwan (Matsushima 1980). This *Trinacrium* he apparently considered as conspecific with that obtained in the *O. trinacriifera* culture, although it has longer, more downwards curved arms. Later, Matsushima (1993) described the new

H.B. 4663: Germany, Tübingen, on *?Tremellales* sp. (on *Prunus*).

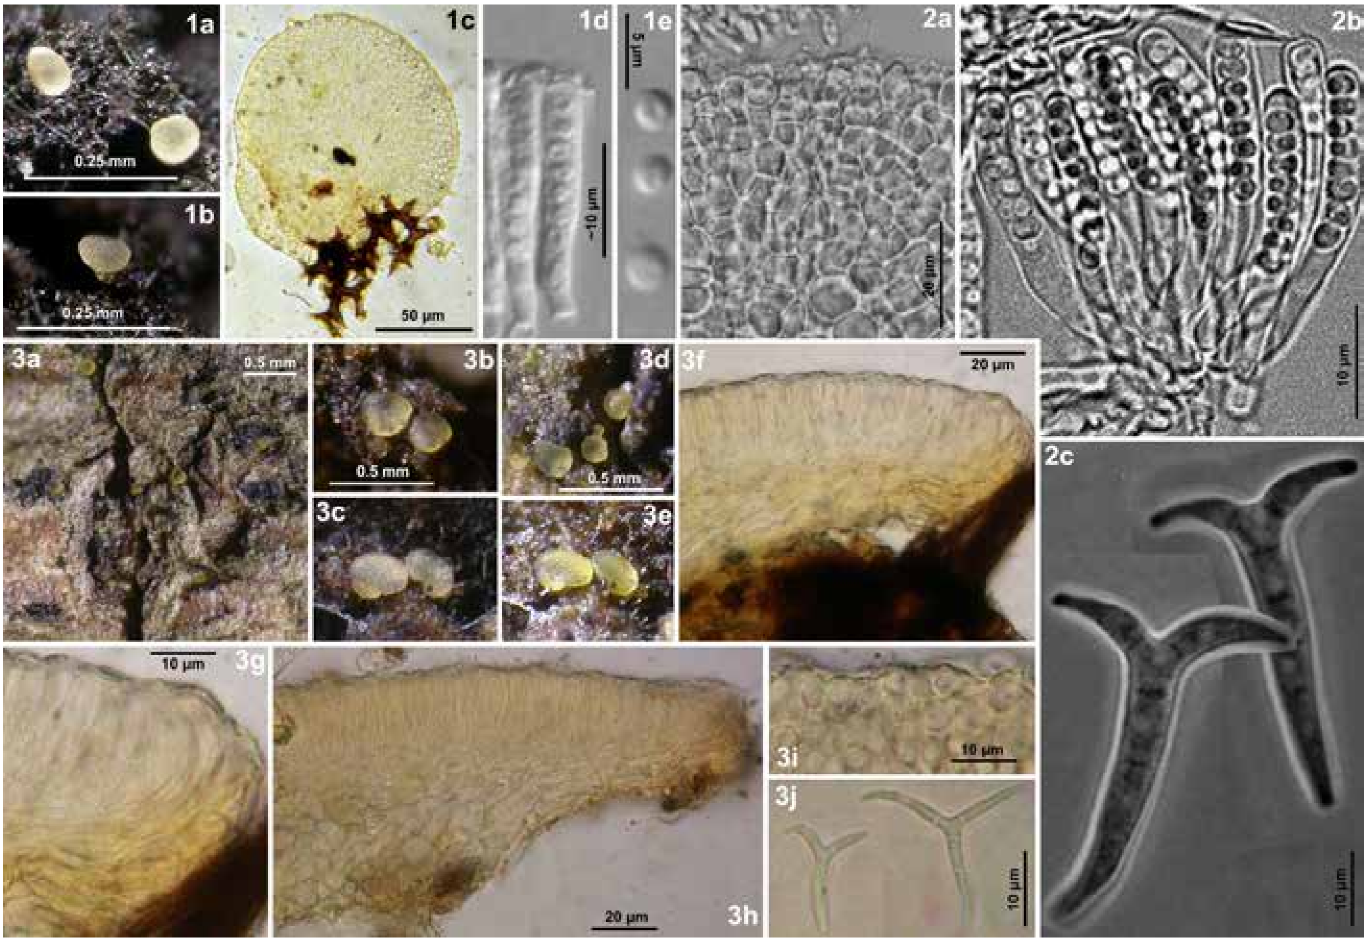

Plate 128. **1–3**: *Hyalorbilia* aff. *erythrostigma*. – **1a–b**, **3a–e**. rehydrated apothecia; **1c**. apothecium from below, with spiny hyphae of ?*Nitschkia acanthostroma*; **3f**, **h**. apothecia in median section; **3g**. id., marginal region; **2a**. ectal excipulum in external view; **3i**. margin in top view; **1d**, **2b**. asci; **1e**. ascospores; **2c**, **3j**. conidia (**2c** from pure culture, **3j** from substrate). – Dead state (**1d–e**, **3j** in H_2O; **1c**, **3f–i** in KOH), except for **2a–c**. – **1d–e**: from Liu et al. (2007b, fig. 5); **2**: from Matsushima (1995, 2005). — **1a–e**. B.L. 6427 (= H.B. 7808a): China, Fujian, on indet. angiosperm; **2a–c**. MFC-4P833 (holotype of *Orbilia trinacriifera*): Peru, Amazon basin, on indet. *Arecales* (petiole); **3a–j**. H.B. 6280g: Australia, Queensland, on indet. climber.

species *T. incurvum* based on an isolate from Peru, which he stated to be conspecific with that from Taiwan based on a very similar conidial morphology. It remains a mystery why Matsushima (1995) did not refer to *T. incurvum* as anamorph of *O. trinacriifera*, although citing the Taiwanese isolate as reference. The connection of *T. incurvum* to a teleomorph remains unsettled since very similar conidia with downwards curved arms were repeatedly observed by us as anamorph in several species from different sections of *Orbilia* (*O. ocellata* and related species, *O. corculispora*, *O. pilifera* and related species).

Misapplications. A British collection reported by Hawksworth & Sivanesan (1975), followed by Ellis & Ellis (1985), under the name *Orbilia euonymi* was described with 'globose' spores, which were found to be subglobose in the present reexamination (Pl. 126: 3). The specimen appears to fit *H. erythrostigma*. However, no trace of SBs was detected in the dead spores, therefore, it could well also be *H. multiguttulata*. Hawksworth & Sivanesan reported apothecia of 0.2–0.5 mm diam., but now only some with 0.12–0.17 mm diam. were found (rehydrated).

Phylogeny. Available rDNA data suggests that *H. erythrostigma* is an aggregate of several taxa. For the time being, we here present a concept which excludes the very similar *H. orbiliicola* but includes samples on pyrenomycetes and gelatinous basidiomycetes. Sequences were gained in the present study from five samples from Luxembourg on different substrates (*Diatrype*: ITS+LSU D1, Pl. 127: 5; *Exidia*: LSU D1–D3, IVV: 4.VII.2013; bark of *Clematis*: SSU+ITS+LSU D1–D4, IVV: 19.XI.2017, 23.XI.2017; wood of *Cornus*: ITS, 22.I.2019). Further sequences are those of Liu et al. (2006a) from two samples from Fujian, China (both on *Nitschkia*: ITS, one also LSU D1–D2, Pls 126: 4; 128: 1), all from apothecia. The S1506 intron is absent in four of them (that on *Exidia* does not cover the SSU region).

Rather high similarity is observed between some of these samples while others strongly differ. Those on bark/wood are completely identical; also the two on *Nitschkia* are identical in the ITS (some gaps and deviations at the 5'-end might be erroneous). The one on *Diatrype* shows an ITS distance of 5.7–6.2 % to those on bark/wood, whereas the *Nitschkia* samples differ by 9.7 % from that on *Diatrype* and by 11 % from those on bark/wood. In the LSU D1 domain only 1 nt differs between the *Diatrype* and *Exidia* sample, and 2–3 nt in comparison to those on *Clematis*. In the D2, however, 10 nt differ between *Exidia* and *Clematis* which is 0.7 % in the D1–D2, and the *Nitschkia* sample differs hereof by 3.2–3.5 % in this region. *H. orbiliicola* differs in the D1–D2 from *H. erythrostigma* s.l. by 5–5.2 % and from *H. latispora* by 13 %.

Also 1 nt in the V8 region of SSU (pos. 52, number according to Tab. 60) differs between samples on *Diatrype* (CGAGTA**C**) and *Clematis* bark or *Cornus* wood (CGAGTA**T**). **T** is typical of most orbiliaceous sequences whereas **C** was otherwise only observed in *H. brevistipitata* s.l., clones U1–3 and U5, *O. polyspora*, and series *Orbilia* p.p.maj.

Two environmental North American soil isolates from Illinois (2321, 3674) clustered with *H. erythrostigma*, but comprise only partial 5.8S and ITS2 (Phyl. 5). In the ITS2 region, the latter differs by 21–23 % from the former and all remaining strains of the *erythrostigma-orbiliicola* clade. KX194742 differs from European *H. erythrostigma* by 3.5 % (*Diatrype*) and 5.5 % (bark/wood), from Chinese *H. erythrostigma* by 10.5 %, and from *H. orbiliicola* by 12.5 % (between European and Chinese *H. erythrostigma* the distance is 9–12.5 %).All this appears to indicate that at least six different species of the *H. erythrostigma* aggregate are involved, three in Europe (including *H. orbiliicola*), one in China, and two in North America. This surprising result raises the question whether *H. anonyma* from Ecuador or the here in *H. erythrostigma* incorporated Peruvian samples (including the type of *O. trinacriifera*) might be conspecific with one of these North American strains.

Specific nucleotides. All ITS sequences of the *erythrostigma-orbiliicola* clade show three remarkable deviations from the current situation in ascomycetes: (1) the 3'-end of 5.8S (pos. 155) is GAGCGT**G** instead of GAGCGT**C** (Tab. 61); (2) the 5'-end of LSU is T**C**ACCT instead of T**G**ACCT; (3) 2 adjacent nucleotides in the 5.8S (pos. 83–84) have AAT**CT**AGT instead of AAT**TC**AGT or rarely AAT**CC**AGT (Tab. 61), with the exception that **CT** also occurs in five North American (California, Canada) and two Chinese (Changbaishan) soil isolates (clades H29–32) which clustered unresolved near the *erythrostigma-orbiliicola* and *Vermispora* clade (Phyl. 5). Another position in the 5.8S (pos. 64) is AG**G**TA, which also occurs in *H. latispora*, the uncultured H30–32, the *Vermispora* clade of *Hyalorbilia*, and the *Lecophagus* clade, whereas the core of *Hyalorbilia* concurs with *Orbilia* in having AG**T**TA (Tab. 61).

Phylogenetically, the *erythrostigma-orbiliicola* clade falls quite distant from the core of *Hyalorbilia*. When analysing the ITS region, it clustered unsupported sister to all the remaining taxa of *Hyalorbilia* (Phyl. 5). Even when restricting the analysis to 5.8S, the distance to other species of the genus, including *H. multiguttulata* (6 nt), is obvious. Also when analysing ITS+LSU or LSU, the *erythrostigma-orbiliicola* clade clustered, like *H. latispora*, unresolved between *Hyalorbilia* s.str. and the *Vermispora* clade (Phyls 6, S5).

Ecology. *Hyalorbilia erythrostigma* in the here circumscribed sense has a wider ecological amplitude than hitherto known. Previously the species was repeatedly recorded on senescent pyrenomycetes (including the type). In various of the here studied collections the apothecia grew on pyrenomycetes, particularly *Diatrypaceae*. For instance, Matočec et al. (2005), who unintentionally placed the species in *Orbilia*, listed a total of four Austrian samples on *Diatrypella* spp. In other samples the apothecia occurred on wood or bark without a visible association with other fungi, and in two samples they grew on basidiomata of *Exidia recisa* and ?*Tremellales* sp. *H. erythrostigma* was considered by Berkeley & Broome (1866) as a parasite.

The species aggregate was collected on ± xeric branches of various angio-, rarely gymnosperm trees and shrubs. The type of *O. trinacriifera* was isolated from rotten petioles of a palm. Collections are from atlantic to subcontinental, humid to rarely semihumid Europe, with a supra- to mesotemperate, more rarely oro- or thermotemperate and orosub- or mesomediterranean climate (see Map 19), where the species occurred, e. g., at sun-exposed borders of forests, thermophilous old shrubs or hedges in quarries, also more shady forests with *Alnus*, *Fraxinus*, *Frangula alnus*, and *Salix* (Luxembourg). Collections from South America are from an orotemperate (subalpine) subhumid *Polylepis* woodland in the Peruvian Andes and a tropical humid rainforest in the Amazon basin, and two environmental isolates of *H. erythrostigma* s.l. (2321, 3674) indicate occurrence in warm continental humid North America.

Map 19. Known distribution of *H. erythrostigma* in Europe and Macaronesia.

The not included collection from Macaronesia was in a lower mesomediterranean subhumid laurel forest (*Lauro novocanariensis-Perseetum indicae*, L. Quijada pers. comm.), and those from Australia occurred on bark and wood of decaying xeric branches of an unidentified climber in the tropical wet and dry (subhumid savannah) northeast, east of the Great Dividing Range (see Map 20). One Australian sample (H.B. 7276f) showed a strong drought tolerance, the medullary excipular cells being still viable after 4.25 years. Samples from Asia include the monsoon-dominated subtropical east of China and tropical north of Thailand.

Specimens included. **GREAT BRITAIN**: **South West England**, **Somerset**, ~5 km NE of Bath, Batheaston, ?100 m, indet. angiosperm (?*Rosaceae*), on *Chaetosphaerella phaeostroma*, 15.I.1859, [no collector,] (K, herb. Broome, holotype of *Peziza erythrostigma*, H.B. 5346 ø). – **Devon**, 35 km ESE of Plymouth, 0.9 km SSE of Slapton, Slapton Ley, north side of Lower Ley, 10 m, log of indet. angiosperm, on bark, 16.VIII.1973, D.L. Hawksworth (IMI 178289, as *O. euonymi*, 'decorticated', H.B. 5013 ø). — **NETHERLANDS**: **Noord-Brabant**, 4 km NNW of Boxmeer, 1.3 km NW of Beugen, W of Helbroek, De Vilt, 12 m, branch of *Quercus rubra*, on indet. pyrenomycete, 29.XI.2008, S. Helleman (S.H. 600, doc. vid.). — **BELGIUM**: **Wallonie**, **Luxembourg**, 8 km SE of Arlon, 0.7 km SE of Sterpenich, 325 m, branch of *Sambucus nigra*, on wood, 23.IV.2001, H.O. Baral (H.B. 6908a). — **LUXEMBOURG**: **Gutland**, **Luxembourg**, 5 km SSW of Luxembourg, N of Kockelscheier, Weier, 300 m, branch of *S. cinerea*, on *Diatrype bullata* and bark, 2.IX.2008, G. Marson (H.B. 8960a). – ibid., branch of *Salix caprea* × *cinerea*, on *Exidia recisa*, 4.VII.2013 (G.M. 2013-07-04.1, sq.: KT380064). – 5 km SE of Luxembourg, 1.5 km E of Itzig, Reimeschbaach, branch of *Cornus*, on wood, 22.I.2019, G. Marson (G.M. 2019-01-22.4, non vid., sq.: MN151402). – ibid., branch of *Salix*, on wood & bark, 28.I.2019, G. Marson (G.M. 2019-01-28.3, non vid.). – **Esch-sur-Alzette**, 5.7 km S of Luxembourg, 1 km SE of Kockelscheier, N of Uecht, 305 m, branch of *Salix*, on *Diatrype bullata*, 17.VI.2009, G. Marson (ex H.B. 9077a, M-0291773, anam. substr., epitype; sq.: KY463699, KT222441). – 1.2 km SSW of Hesperange, SW of Fentange, Wéineguecht, 277 m, branch of *Clematis vitalba*, on bark, 19.XI.2017, G. Marson (G.M. 2017-11-19.4; sq.: MH221046). – SE of Fentange, Wénkel, 265 m, branch of *C. vitalba*, on wood, 20.III.1994, G. Marson (ø). – **Echternach**, Petite Suisse, 7 km W of Echternach, 4 km SW of Berdorf, Schnellert, 230 m, branch of *Crataegus monogyna*, on

Diatrype stigma, 20.X.1996, G. Marson (H.B. 5641a). – 10 km WNW of Echternach, 1.2 km SW of Beaufort, Längt, 340 m, trunk of *Fagus sylvatica*, on bark, 3.II.2007, G. Marson (ø). – **Esch-sur-Alzette**, 4.2 km S of Bettembourg, 1.6 km E of Dudelange, 2.7 km NW of Zoufftgen, 298 m, branch of *Clematis vitalba*, on bark, 23.XI.2017, G. Marson (G.M. 2017-11-23.1; sq.: MH221047). — **GERMANY**: **Mecklenburg-Vorpommern**, 6 km NNW of Rehna, 1 km E of Roduchelstorf, 45 m, branch of *Corylus avellana*, on *Diatrypella ?favacea*, 21.I.2017, T. Richter (H.B. 10045). – **Nordrhein-Westfalen**, 4 km E of Duisburg, 1 km NW of Raffelberg, 35 m, on stem of *Sambucus ebulus*, 11.IV.2012, K. Müller (H.B. 9673). – 14 km NW of Brilon, 3 km NE of Warstein, 308 m, branch of ?*Corylus avellana*, on ?*Diatrype stigma* and bark, 28.IX.2012, S. Helleman (S.H. 724, doc. vid.). – **Baden-Württemberg**, Schönbuch, 4 km N of Tübingen, 0.7 km W of Bebenhausen, Mühlbach, 365 m, branch of *Prunus spinosa*, on ?*Tremellales* sp. and bark, 1.V.1992, H.O. Baral (H.B. 4663a). – ibid., 20.IV.1993 (H.B. 4872). – 5 km NE of Tübingen, S of Pfrondorf, Obere Mähder, 395 m, stem of *Rubus fruticosus*, 20.XI.2006, H.O. Hyalorbilia orbiliicola Baral, G. Marson, Polhorský & E. Weber, **sp. nov.**, MB 829493 — Pls 129–130, Map 20

Etymology: according to the parasitism on apothecia of *Orbilia* spp.

Typification: Slovakia, Žilina, Tvrdošín, Brezovica, on apothecia of *O. aurantiorubra* on branch of *Salix*, 31.XII.2017, A. Polhorský (ex A.P. 18/50, BRA-CR29844; sq.: MK028717).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.06–)0.1–0.15(–0.22)((–0.25)) mm diam. (immature 0.035–0.08 mm), in total 0.05–0.14 mm high (receptacle 0.05–0.065 mm), whitish-subhyaline to pale cream or yellowish, ± translucent, round (young globose), gregarious; disc flat, margin even, not protruding, exterior glabrous, sessile or often with a short stipe of 0.01–0.07 × 0.03–0.09 mm, superficial; dry whitish to light cream, slightly contracted. **Asci** *(26–)29–43 × (4–)4.5–5.5 µm {5}, †22–33(–38) × 3.5–5(–6) µm {3}, 8-spored, spores */†1(–2)-seriate, orientation in all directions, pars sporifera *15–22 µm long; **apex** (†) hemispherical to subconical or subtruncate; **base** ± unstalked or with a short, thick stalk, arising from croziers {2} with vertical slits 2–3 µm long. **Ascospores** *(2.5–)2.7–3.2(–3.5) × (2.2–)2.4–2.7(–2.8) µm {5}, †2–2.8 × 1.5–2 µm {2}, subglobose (to broadly ellipsoid), with a single globose, strongly eccentric **SB** (1–)1.2–1.4(–1.5) µm diam. {4}, very close to one end but not visibly attached; with 1–2 minute **LBs**. **Paraphyses** apically cylindrical to slightly or sometimes strongly clavate-capitate, terminal cells *7–10.5 × 2.2–3(–4) {2} µm, †1.7–3.2 µm wide {2}, lower cells *6–8 × 2–2.4 µm {2}, †4–5 × 1.5–2.2 µm, branched or unbranched near base. **Medullary excipulum** ~10–30 µm thick, of dense, thin-walled textura globulosa-angularis, indistinctly delimited. **Ectal excipulum** at stipe and flanks of thin-walled to slightly gelatinized t. globulosa-angularis or t. prismatica oriented parallel to outside or irregular, ~30 µm thick in stipe, ~10–15 µm thick at lower flanks, cells in stipe and lower flanks *6–12 × 3–8 µm {2}, †5–8 {2} or 7–19 {2} × (3–)4–8 µm {4}; towards margin 6–8 µm thick, marginal cortical cells *6.5–8 × 2.4–2.8 {1} or 10–13 × 3–4 µm {1}, cylindric-clavate, thin-walled. **Anchoring hyphae** not observed. **VBs** in apex of terminal cells of paraphyses ± globose, strongly refractive, 1.5–5 × 1.5–3.7 µm {2}, in marginal cortical cells 1.5–5 × 1.5–5 µm {2}; **LBs** sparsely present in paraphyses and ectal excipulum, minute, hyaline to pale yellowish. **Exudate** over paraphyses and ectal excipulum 0.3–0.8 µm thick, hyaline, continuous, externally smooth to finely rough. — **ANAMORPH**: trinacrium-like (both morphs from natural substrate {14}, molecular data from conidial isolate {1}, only anamorph observed {10}). **Conidiophores** projecting in abundance from margin or hymenium of host apothecia, */†10–30 × 1.5–2.8 µm {2}, ± flexuous-geniculate, unbranched, conidiogenous cells apparently monoblastic. **Conidia** branched (T-

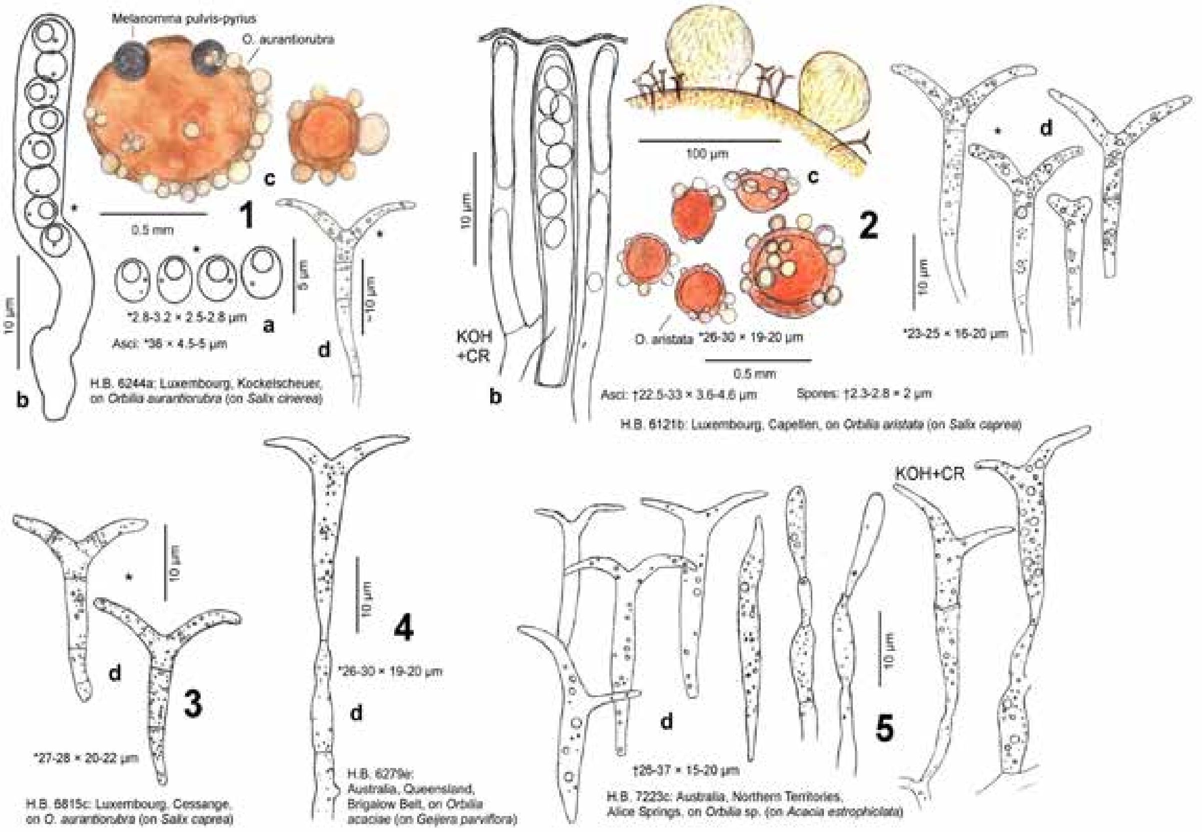

Plate 129. **1–3**: *Hyalorbilia orbiliicola*; **4–5**: *H.* aff. *orbiliicola*. – **a**. ascospores; **b**. asci and paraphyses; **c**. rehydrated apothecia growing on *Orbilia* spp.; **d**. conidia and conidiophores from substrate (*Orbilia* spp.)

to Y-shaped), 2-armed, branches gradually tapering towards ends, */†(14–)19–29(–35) × (13–)16–25 µm {7}, stipe *15–20(–25) × 2.2–3(–3.3) µm (†2–2.5 µm wide), 1–3-septate, arms *(5–)8–12 × 2–2.7 µm, 0–1(–2)-septate, of ± similar length (exceptionally asymmetrical), slightly to medium curved downwards but still pointing ± upwards or laterally.

Habitat: undisturbed, shady and moist but also thermophilous, deciduous or mixed forests, often with ruderal plants (*Rosa*, *Rubus*, *Urtica*), 1–2 m above the ground or rarely on the ground, xeric, decayed, corticated to partially decorticated, 10–50 mm thick branches of living or often dead trees and shrubs of *Cedrus atlantica* {1}, *Cercis siliquastrum* {1}, *Cornus* sp. {1}, *C. sanguinea* {1}, *Eucalyptus camaldulensis* {1}, *Larix decidua* {1}, *Picea ?glauca* {1}, *Punica granatum* {1}, *Salix* sp. {8}, *S. alba* {1}, *S. aurita* × *caprea* {1}, *S. caprea* {4/1}, *S. cinerea* {5/1}, *S. ?viminalis* {1}, *Spartium junceum* {1}; growing almost exclusively on living apothecia of *Orbilia aristata* {3/1}, *O. aurantiorubra* {13/1}, *O. eucalypti* {8}, *O. flagellispora* {1}, *O. ?gambelii* (or *O. albidorosea*?) {1}, *O. mali* {1}, *O. subaristata* {1}, *O. vinosa* {2}; host apothecia in holes of periderm or mostly on inner surface of bark (bast) being slightly to strongly detached (projecting or often ± large pieces hanging from branch), exceptionally on wood {1, on *Spartium* in beetle galleries}, green algae sparse to abundant. **Further associated**: *Allophylaria macrospora* {1}, *Caloplaca holocarpa* {1}, *Cistella ?chlorosticta* {1}, *Cryptocoryneum condensatum* {1}, *Cryptodiscus foveolaris* {1}, *Durella connivens* {1}, *Glyphium elatum* {1}, *Hyalorbilia erythrostigma* {2}, *H. subfusispora* {2}, *Hysteropatella elliptica* {3}, *Karstenia idaei* {1}, *K. rhopaloides* {1}, *Lecophagus ellipsoideus* {1}, *Melanomma ?pulvis-pyrius* {1}, *Mollisia ligni* {1}, *Orbilia aristata* {1}, *O. carpoboloides* {3}, *O. ?cejpii* {1}, *O. clavuliformis* {1}, *O. gambelii* {2}, *O. pleiogambelii* {1}, *O. spermoides* {1}, *O. subaristata* {2}, *O. subclavuliformis* {1}, *O. ?tremulae* {1}, *O. xanthoguttulata* {1}, *Rutstroemia punicae* {1}, *Sclerococcum* sp. {1}, *Trichopeziza perrotioides* {1}, *Unguiculariopsis* sp. {1}, *Xerombrophila crystallifera* {1}. **Desiccation tolerance**: after 15 months many cells of ectal excipulum still alive, conidia after 3.5 months. **Altitude**: 8–1447 m a.s.l. **Geology**: Buntsandstein, Keuper (gypsum), Lower Jurassic sandstone and shale (sometimes covered by Pleistocene loess), Cretaceous & Oligocene limestone & calcareous marl, flysch, Tertiary molasse, Quaternary sand; migmatite & gneiss. **Phenology**: throughout the year (long-lived).

Phenology of *H. orbiliicola* (teleomorph and/or anamorph)											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
2	2	5	1	3	3	3	3	3	3	3	1

Taxonomic remarks. *Hyalorbilia orbiliicola* is very similar to *H. erythrostigma* and mainly differs in its unusual habitat, apothecia of *Orbilia* spp., also in consistently short apothecial stipes and in much shorter, ± globose to subglobose VBs in paraphyses and marginal excipular cells (strongly elongated in *H. erythrostigma*). The two species even concur in their conidia which were frequently observed on the natural substrate in *H. orbiliicola* but rarely in *H. erythrostigma*. Due to its special habit of growing on the apothecial margin of *Orbilia*, the minute apothecia of *H. orbiliicola* may at first glance be mistaken for marginal teeth of the host.

Anamorph. Trinacrium-like conidia have been observed by us in close association with the apothecia in about half of the collections (Pls 129: 1–5; 130: 5, 6b; 131: 1–5). Like the apothecia of the *Hyalorbilia*, the short conidiophores emerge from the margin of the host apothecia. That the trinacrium-like anamorph belongs to the host fungus (mainly *Orbilia aurantiorubra* and *O. eucalypti*) rather than to the parasite can be excluded since these two host taxa produce very different conidia in pure culture (vermispora- and dicranidion-like, respectively). The connection between apothecia and anamorph was eventually proved by molecular data (see

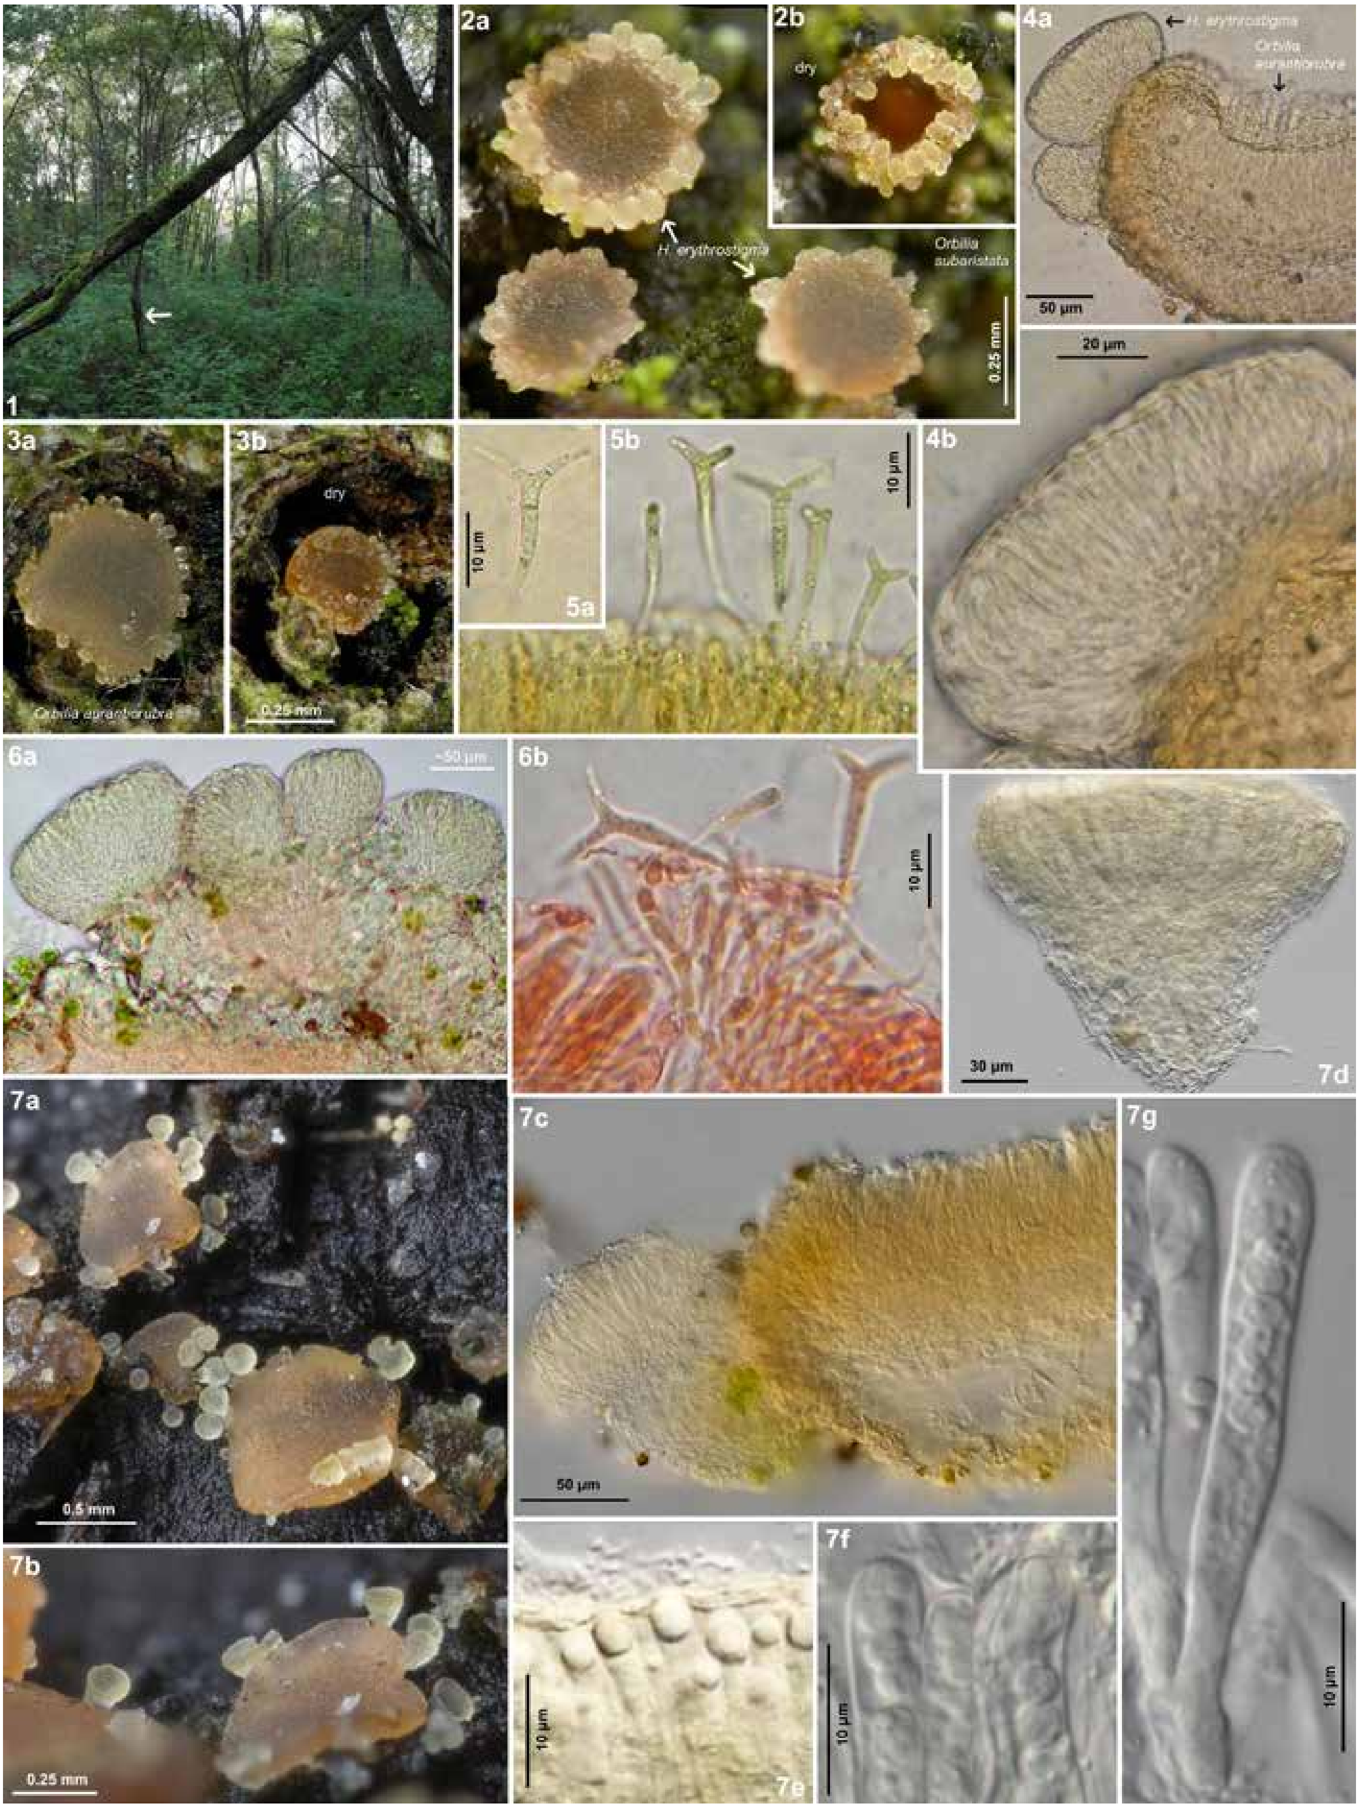

Plate 130. **1–7**: *Hyalorbilia orbiliicola*. – **1**. Shady forest with *Salix cinerea* × *caprea*, large piece of detached bark hanging from broken trunk; **2a–b**, **3a–b**. whitish immature apothecia of *Hyalorbilia* on margin of orange apothecia of *Orbilia* spp. (rehydrated and dry); **7a–b**. id., mature (rehydrated); **4a–b**, **7c**. apothecia in median section (with host apothecium); **6a**. id., squash mount; **7d**. apothecium in median section; **7e**. subglobose VBs in cells of marginal ectal excipulum; **7f–g**. asci with ascospores; **5a–b**, **6b**. conidia and conidiophores arising from host apothecia. – Living state: **7c–g**, dead state: **4a–b**, **5a** (in KOH), **5b** (in KOH+IKI), **6b** (in KOH+CR). – **7a–g**: phot. A. Polhorský. — **1**. 13.X.2010: Luxembourg, Kockelscheier, on *Orbilia aurantiorubra* (on *Salix*); **2a–b**. 28.III.2007: ibid., Mersch, on *O. subaristata* (on *Cornus*); **3a–b**. 7.VII.2011: ibid., Bridel, on *O. aurantiorubra* (on *Salix*); **4a–b**. below). This anamorph closely resembles that observed in *H. erythrostigma* which merely differs in a slight tendency to form longer stipes and more septa in stipes and arms. For the questionable *Orbilia trinacriifera* see discussion under *H. erythrostigma* (p. 421).

H*. cf. *orbiliicola (conidia symmetrical, Pl. 131: 5). In an Australian sample a single apothecium of 0.06 mm diam. was found growing on *Orbilia neocomma* (H.B. 8608a). It closely concurs with European *H. orbiliicola* in size of asci (†19–22 × 4–5 µm) and spores (†2–2.8 × 1.7–1.8 µm) (both unillustrated). Yet, the associated conidia differ in their smaller size (†14–17 × 13.5–15.5 µm) due to shorter stipes and more straight arms, therefore, this collection is doubtfully conspecific.

H*. aff. *orbiliicola (conidia ± asymmetrical, Pls 129: 4–5; 131: 1–4). In seven Australian populations of different *Orbilia* spp. (*O. acaciae*, *O. bicknellensis*, *O.* aff. *myriella*, *O. pleioserpens*, immature *Orbilia* spp.), trinacrium-like conidia abundantly emerged from the host apothecia. Contrary to the above sample, the 2 conidial arms are predominantly curved and of distinctly different size, thus showing a more or less strong asymmetry. Furthermore, the rather thick stipes are non- or only 1-septate and the 2 strongly attenuated arms always non-septate. Compared to European *H. orbiliicola*, the conidia tend to be longer and their arms shorter (total size */†22–40 × 10–20 µm, stipe */†15–29 × 2.5–4 µm, arms */†5–10 × 1.2–2.2 µm).

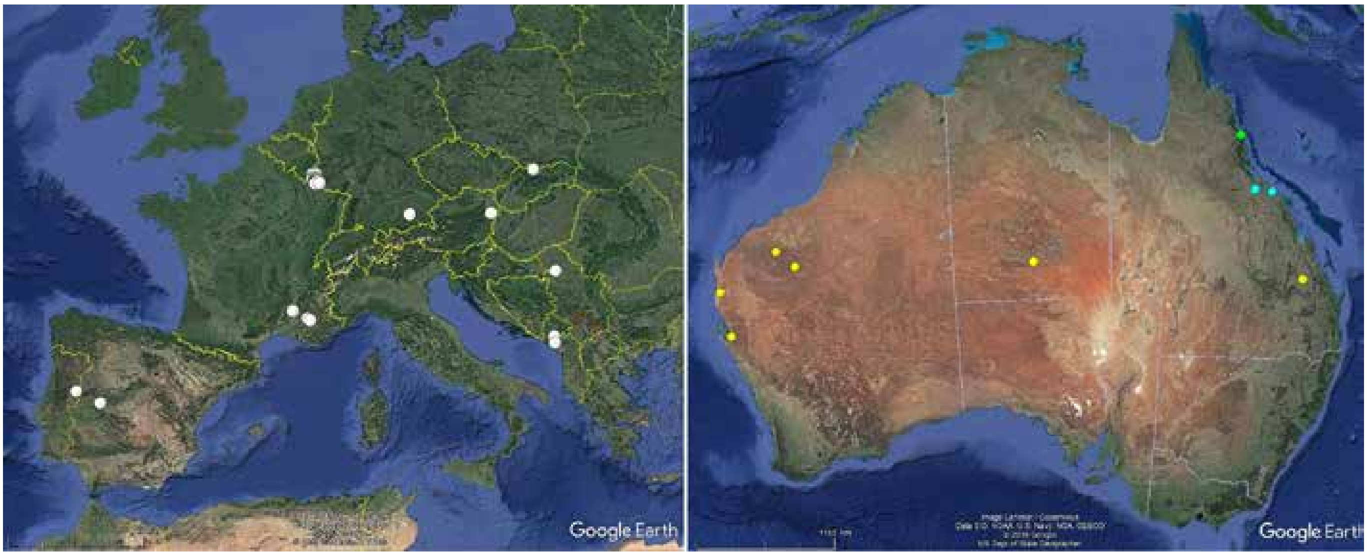
Only in one of these samples (on *Orbilia acaciae*, IVV: H.B. 6279e) a few apothecia occurred in association with the conidia. These differ from *H.* cf. *orbiliicola* in larger asci (†29–35 × 5–5.8 µm) and spores (globose, *3–3.5 µm diam.). The spores did not contain SBs, perhaps because of immaturity.

Both the paucity of septa and the asymmetry of conidial arms are quite unusual features when comparing typical *H. orbiliicola* or the form genus *Trinacrium* as a whole. Together with the presumed slightly deviating teleomorph in H.B. 6279e, Australian populations with asymmetrical conidia might belong to a different, closely related species in which apothecia are rarely formed. However, a slight conidial asymmetry was also sometimes observed in European samples, e.g., from Montenegro (20.II.2016) or Austria (27.I.2013) (IVV).

In *Trinacrium parvisporum* (see Pl. 22: c) the two arms also frequently differ in length but the conidia are mostly multiseptate.

Very similar asymmetrical conidia as in *H.* aff. *orbiliicola* were reported by Hudson & Ingold (1960) for an unidentified aquatic hyphomycete on rotten leaves in Jamaica [as '*Heliscus* (?)']. Comparable conidia were described in the coelomycetous genus *Cornutispora* Piroz. (Pirozynski 1973, Punithalingam 2003). However, the conidia of *H.* aff. *orbiliicola* are freely formed, not within yellowish- to dark brown pycnidia as in *Cornutispora*. In the eight known species of *Cornutispora* the pycnidia occur on ascomata of the rhytismatalean genus *Therrya* (type species) or on lichens. Moreover, the conidia always possess a basal arm-like downward extension.

Phylogeny. Sequences from apothecia were gained of a sample from Luxembourg (Howald, on *O. eucalypti* on *Cornus*, ITS+LSU D1–D3) and one from Slovakia (ITS, on *O. aurantiorubra* on *Salix*). Another sequence derives from abundant conidia in another sample from Luxembourg (Dudelange, on *Salix*, ITS+LSU D1–D6), but here also apothecia of *H. orbiliicola* were present, therefore, it cannot fully be excluded that only DNA from conidia came into the extract. All sequences lack the S1506 intron and fully concur in the ITS region, also the two LSU sequences are identical in the overlapping D1–D3 domain. The ITS/LSU D1–D2 distances to the different strains of *H. erythrostigma* are 6.3/4.9 % (China), -/4.2 % (*Exidia*), 8/4.4 % (bark & wood and Illinois clone), and 10/4.4 % (*Diatrype*).



Map 20. Known distribution of *H. orbiliicola* s.str. in Europe (left) and of *H. orbiliicola* s.l. and *H.* cf. *erythrostigma* in Australia (right): white = *H. orbiliicola*, green = *H.* cf. *orbiliicola*, yellow = *H.* aff. *orbiliicola*, cyan = *H.* cf. *erythrostigma*.

H. orbiliicola clustered with *H. erythrostigma* in a strongly supported clade when analysing ITS, LSU, or both in combination (Phyls 5, 6). A very rare exception is observed in the 5.8S of *H. orbiliicola*: at pos. 145 it has A whereas any other *Orbiliomycetes* (including *H. erythrostigma*) has G. A comparable proportion in the occurrence of A and G at pos. 145 is observed within the *Helotiales*.

Ecology. According to the numerous records it can be concluded that *Hyalorbilia orbiliicola* is an obligate parasite growing on the margin of living, desiccation-tolerant apothecia of different species of *Orbilia*. The minute apothecia grew abundantly together with the conidiophores on the margin, rarely the hymenium, of living, often rather intact apothecia of *Orbilia* spp. Often a majority of the *Orbilia* population were infected, but sometimes only 20–30 %. The asci of the host apothecia were often not fully developed or sometimes even absent. We were unable, however, to detect hyphae of the *Hyalorbilia* in the host tissue, or haustoria in the marginal excipular cells of the host apothecia on which the *Hyalorbilia* apothecia superficially insert.

Collections included in *H. orbiliicola* comprise supra- to orotemperate humid central Europe and northeastern North America, and orosub- to mesomediterranean, humid to semihumid southern Europe. The not included Australian records occurred on apothecia of different *Orbilia* spp. on decaying xeric branches, but usually only the anamorph was present. The population with ± symmetrical conidia was from the tropical humid (wet and dry) northeast, while those with ± asymmetrical conidia are from subtropical arid to semiarid western and central Australia (e.g., in eucalypt open woodlands) and one from subtropical subhumid (winter-dry savannah to monsoon climate) eastern Australia east of the Great Dividing Range (see Map 20).

Specimens included. **LUXEMBOURG**: **L'Oesling**, **Redange**, 10 km W of Ettelbruck, 1.5 km NW of Grosbous, near Bruch (an der Wark), 400 m, on *Orbilia eucalypti* on bark of *Salix cinerea*, 26.III.2001, G. Marson (H.B. 6990c, anam. substr.). – ibid., on *O. aurantiorubra* on bark of *Salix*, 24.IV.2001, G. Marson & H.O. Baral (ø, anam. only). – ibid., on *O. aurantiorubra* on bark of *S. cinerea*, ?26.III.2001, G. Marson (H.B. 6991b ø, anam. substr.). – **Gutland**, **Diekirch**, 3.5 km ESE of Ettelbruck, 1.7 km SE of Ingeldorf, Jongeboesch, Béibert, 353 m, on *O. aurantiorubra* on bark of *Salix*, 18.VI.2001, G. Marson (ø, anam. only). – **Mersch**, 5.3 km SE of Mersch, 3 km NNE of Lorentzweiler, Lëtzert, 395 m, on *O. subaristata* on bark of *Cornus sanguinea*, 28.III.2007, G. Marson (ø). – **Capellen**, 1.7 km SSE of Eischen, 1.5 km ENE of Clairefontaine (Belgium), Aechels, at river Eisch, 310 m, on *O. eucalypti* on bark of *Salix ~caprea*, 15.VII.2000, G. Marson (H.B. 6726a, anam. only). – 5 km NW of Capellen, 1 km NNW of Koerich, Haereboesch, Carrière, 300 m, on *O. aristata* on bark of *S. caprea*, 8.V.1998, G. Marson (H.B. 6121b, anam. substr.). – 5 km NNW of Luxembourg, 1.2 km E of Bridel, Gipsweieren, 260 m, on *O. aurantiorubra* on *S. cinerea*, 15.V.2004, G. Marson (ø). – ibid., ~7.VII.2011, G. Marson (ø). – **Luxembourg**, 3.5 km S of Luxembourg, 1 km SW of Howald, 295 m, on *O. eucalypti* on bark of *Cornus*, 30.X.2014, G. Marson (G.M. 2014-10-30.1, anam. substr.; sq.: MK473404 [from apothecia]). – 4.5 km SW of Luxembourg, SW of Cessange, Bois de Cessange, on *O. aurantiorubra* on bark of *Salix caprea*, 5.XI.2000, G. Hyalorbilia anonyma (Rehm) Baral, **comb**. **nov**., MB 813453 — Pl. 132

Basionym: *Pezizella anonyma* Rehm, Hedwigia 34, Beibl.: (165) (1895)
≡ *Mollisiella anonyma* (Rehm) Rehm, Hedwigia 44: 9 (1905)
≡ *Helotiopsis anonyma* (Rehm) Höhnel, Österr. Bot. Z. 63: 301 (1913) (superfluous combination by Sherwood & Korf, Mycotaxon 3: 323, 1976)
≡ *Pithyella anonyma* (Rehm) Korf & W.Y. Zhuang, Mycotaxon 29: 4 (1987)

Etymology: not explained by the author.

Typification: Ecuador, Quito, branch of *Melastoma*, VII.1892, G. v. Lagerheim (Rehm Ascomyc. 1115b, S-F10640, lectotype, designated by Sherwood & Korf 1976).

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.3 mm diam., pale yellowish-chlorinaceous to bright honey-yellow, ± gregarious; disc ± flat, margin even; stipe very distinct, 0.1–0.5 × 0.1–0.2 mm. **Asci** †40–53 × 3.8–4.8 µm, 8-spored, spores (†) uniseriate; **apex** (†) hemispherical, firm-walled (0.4 µm thick); **base** with medium long, ± thick stalk, apparently simple-septate but with crozier-like connection (anastomosis) between the asci (no typical crozier observed). **Ascospores** †3–4 × 2.4–2.8 µm, subglobose to broadly ellipsoid, rarely ovoid; **SBs** (†) visible as a very inconspicuous, ± globose, eccentric region 1.5–2 µm diam.; with 2–6 minute **LBs**. **Paraphyses** apically uninflated, terminal cells †13–28 × 1.2–2.3 µm, lower cells †8–14 × 1–1.7 µm, unbranched. **Medullary excipulum** forming vertical chains of globose-prismatic cells †5–9 × 5–7 µm giving rise to paraphyses. **Ectal excipulum** in stipe of non-gelatinized textura prismatica-porrecta, cells †17–30 × 6–10 µm, at lower flanks of strongly gelatinized horizontal t. angularis-prismatica, cells †~4–10 × 3–5 µm, common walls 1–3 µm thick; near margin of less gelatinized t. porrecta, marginal cortical cells in median section †~10–15 × 1.5–3 µm. **Anchoring hyphae** abundant at base, long, radiating, †(1.5–)2.5–3.5(–4) µm wide, walls 0.2–0.3 µm thick, often moniliform, densely septate. **Exudate** over paraphyses, margin and flanks 0.2–0.3 µm thick, continuous, smooth. **— ANAMORPH**: unknown.

Habitat: on gall- or canker-like, light ochre-brown, warted, 2–3 mm thick stromata of (?immature) '*Valsaria crenata* Rehm' [in sched., = *V. baccharidis* (Pat.) Rehm 1895: 164], on a corticated, 7 mm thick undecayed branch of *Melastoma* sp. **Associated**: thallose liverwort. **Desiccation tolerance**: unknown. **Altitude**: ~2830 m a.s.l. **Phenology**: VII (tropical belt).

Taxonomic remarks. In concordance with Korf & Zhuang (1987), we here accept *H. anonyma* as a species distinct from *H. erythrostigma*, although we are not sure about whether it is more than only a marginal population of that species. Korf & Zhuang did not mention the differential characters between the two taxa. Judging from their illustration of *Pithyella erythrostigma* and the description of *Helotiopsis anonyma* in Sherwood & Korf (1976), the differences were apparently seen in the marginal excipulum being hyphoid and gelatinized in *H. anonyma* but wide-celled and thin-walled in *H. erythrostigma*, perhaps also in a longer apothecial stalk and shorter asci in *H. erythrostigma* (the difference in spore shape is due to an error, see below).

Examination of the fully mature, abundant lectotype material in S revealed that *H. anonyma* differs in exceptionally long asci, narrower marginal cortical cells of the ectal excipulum, rather narrow, uninflated apices of paraphyses with longer individual cells, and slightly longer ascospores. Another specimen from South America (Peru, Pl. 126: 6) was assigned by us to *H. erythrostigma* because of much shorter asci, smaller spores, wider paraphyses (2–4 µm), and wider marginal cortical cells (†10–12 × 3–5 µm).

A further distinguishing character could lie in the ascogenous hyphae, which appear to arise from croziers with a slit-like perforation as in *H. erythrostigma*, but the downward protuberance at the beginning of crozier formation (see Pl. 126: 2, 6) was not seen here. Rather, the ascus formation appears to be of the simple-septate type, except that an anastomosis is formed between the asci near their base. Further research is necessary on this peculiarity, which might well have been overlooked in other species of *Hyalorbilia*.

An indistinct bluish IKI-reaction which turned negative at higher concentration was observed in the region of the medullary excipulum. This reaction is probably due to the presence of carotenoids. Korf & Zhuang (1987) were unsure whether the spores are smooth or finely warted. Yet, as in *H. erythrostigma* it was impossible in the present study to see any trace of spore markings under oil immersion. A large globose eccentric SB could be discerned as a very faint region in the dead spores.

Rehm (1895) gave the asci as 45 × 5 µm and thought they were immature, but later (1905) he gave a size of 45–50 × 5 µm and found globose spores 3 µm diam., uniseriate. The apothecia are described as 0.1–0.5 mm diam., with a short and thin stipe, yellowish-hyaline, dry turning amber. Sherwood & Korf (1976) designated the here examined duplicate in S as lectotype, but studied also an isolectotype in NY. Their description in part relies on Rehm's, and also includes globose spores 2–3 µm diam., in disagreement with the present result of broadly ellipsoid spores.

Rehm (1905) compared *Mollisiella anonyma* with *Pseudohelotium apicale* (Berkeley & Broome) Sacc. Korf & Zhuang (1987) transferred both species to *Pithyella* Boud., and accepted Boudier's placement of *Pithyella erythrostigma* in that genus. They considered *Pithyella apicalis* as 'at best critically distinct' from the type species of *Pithyella*, *P. hypnina* (Quél.) Boud., and thought the genus to belong to the *Helotiales* (see p. 209).

Not included collection. O. Ceska (pers. comm.) studied a collection on an *Alnus* branch from Newfoundland (eastern Canada) with apothecia growing mainly on old stromata (IVV: 23.VIII.2017). This deviates in longer spores of *(4–)4.5–5(–5.5) × (2–)2.5–3 µm with a rather small SB at one end. A trinacrium-like conidium with very narrow stipe and arms was observed, which resembles those of *H. erythrostigma*.

Ecology. *Hyalorbilia anonyma* grew abundantly on deformations of the bark caused by *Valsaria baccharidis* on branches of *Melastoma* sp. The collection derives from a subtropical humid highland climate in the northwest of South America. Both the host fungus and the inhabited branch are very slightly decayed, indicating that *H. anonyma* could be a hyperparasite.

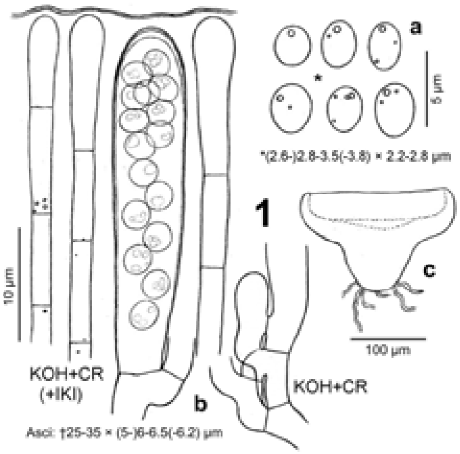

Plate 133. **1**: *Hyalorbilia pleioerythrostigma*. – **a**. ascospores; **b**. ascus and paraphyses, ascus base with croziers; **c**. apothecium in median section.

Specimens included. **ECUADOR**: **Pichincha**, La Sierra, ~4.5 km SSW of Quito, San Jorge, ~2830 m, branch of *Melastoma*, on deformations of bark, VII.1892, G. v. Lagerheim (S-F10640, Rehm Ascomyc. 1115b, **lectotype**, H.B. 6435 ø).

Not included. **CANADA**: **Newfoundland**, 8 km NW of Stephenville, Table Mt., 312 m, branch of *Alnus alnobetula*, on bark and old pyrenomycete, 23.VIII.2017, O. & A. Ceska (anam. substr., doc. vid.).

Hyalorbilia pleioerythrostigma Baral, **sp**. **nov**.,

MB 813454 — Pls 133–134

Etymology: named after the 16-spored asci and the resemblance to *H. erythrostigma*.

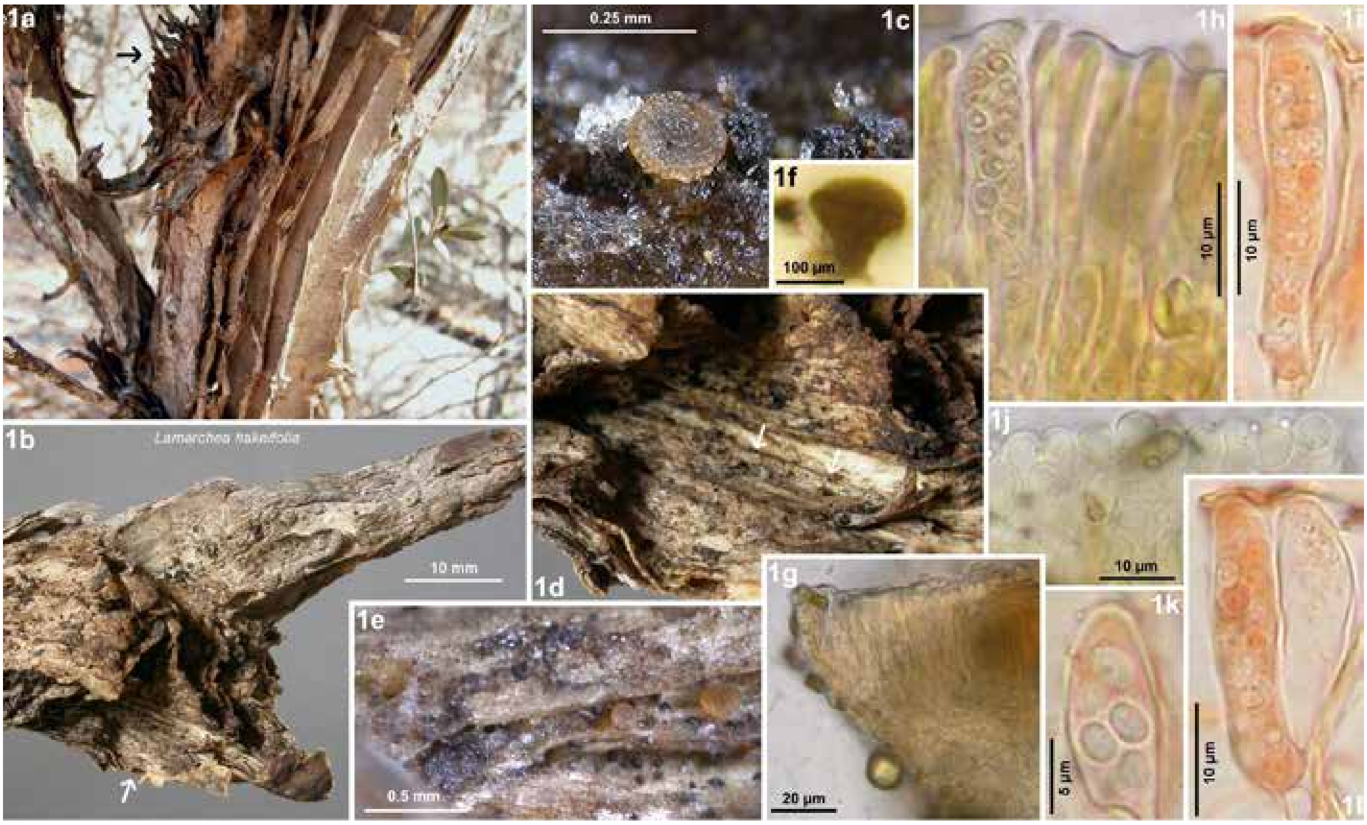

Plate 134. **1**: *Hyalorbilia pleioerythrostigma*. – **1a**. living trunk of *Lamarchea hakeifolia* in semiarid acacia shrubland; **1b**. detached xeric bark; **1c–e**. rehydrated apothecia; **1f**. apothecium in lateral view; **1g**. apothecium in median section; **1j**. margin in top view; **1h–i**, **l**. asci and paraphyses; **1k**. ascospores. – Dead state (**1j** in KOH; **1h** in KOH+IKI; **i**, **k–l** in CR) except for **1g** (with some living cells). — **1a–l**. H.B. 9020 (holotype): Western Australia, Geraldton, on *Lamarchea*.

Typification: Western Australia, Yalgoo, Toolonga, trunk of *Lamarchea hakeifolia*, 8.XI.2007, G. Marson (ex H.B. 9020b, MEL 2389274, holotype).

Latin diagnosis: *Apothecia in statu rehydratata 0.15–0.25 mm diam., pallide ochraceo-aurantiaca, margine subglabro. Asci 16-spori. Ascosporae *2.6–3.8 × 2.2–2.8 µm, subglobosae, guttulis paucis minutis continentes. Habitat ad corticem siccum valde putridum trunci vivi erecti* Lamarcheae hakeifoliae *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.25 mm diam., 0.13 mm high (receptacle 0.06 → 0.05 mm), pale cream-rose-orange, slightly translucent, round, non-gelatinous, singly or very scattered; disc flat, margin distinct, 5 µm protruding, ± rough; with a ± cylindrical stipe 0.07 × 0.09 mm, superficial but also in small clefts. **Asci** †25–35 × (5–)6–6.5(–7.2) µm, 16-spored, spores †2–4-seriate; **apex** (†) hemispherical to slightly conical, thin-walled (wall 0.4 µm thick); **base** unstalked, arising from croziers with or without a slit-like perforation. **Ascospores** *(2.6–)2.8–3.5(–3.8) × 2.2–2.8 µm, †2.5–3 × 2–2.5 µm, subglobose to broadly ellipsoid; **SBs** absent (?), with a few **LBs** 0.1–0.5 µm diam. **Paraphyses** apically slightly to medium clavate, terminal cells †8–15 × 2.5–3.7 µm, lower cells †8–9 × 1.6–2.2 µm; unbranched at upper septum, firmly agglutinated in gel. **Medullary excipulum** 10 µm thick, of non-gelatinized textura angularis, indistinctly delimited. **Ectal excipulum** in stipe of (†) thin-walled t. globulosa, 80 µm thick, cells *10–15(–18) × 7–11 µm; at flanks of indistinctly horizontally oriented t. globulosa-angularis-prismatica, cells *6–13 × 5–9 µm, in surface view of t. prismatica, cells †5–10 × 3–6 µm, marginal cortical cells */†9–17 × 4–7.5 µm, thin-walled. **Anchoring hyphae** sparse, †2–5 µm wide, walls 0.2–0.3 µm thick, radiating. **SCBs** and **VBs** unknown. **Exudate** over paraphyses and marginal excipulum 0.2–0.6 µm thick, continuous, smooth, hyaline, lying over gel. — **ANAMORPH**: unknown.

Habitat: collected 0.5–1.5 m above the ground, corticated, 10–18 cm thick living trunk of *Lamarchea hakeifolia* sp., on very decayed, ± detached bark, strongly greyed, no algae. **Associated**: *Capronia* spp. {2}, *Claussenomyces* sp., *Orbilia austroobtusispora*, *O. gemma*, *O. kingsiana*, *O. lamarcheae*, *O. myriolilacina*, *O. pseudoflagellispora*, *O. ?pubescens*, *Ostropales*, *Symbiotaphrina desertorum*, *Xerotrema* sp. **Desiccation tolerance**: excipular cells and some ascospores still viable after 16.5 months. **Altitude**: 190 m a.s.l. **Geology**: Cretaceous sedimentary rock (red-brown sand). **Phenology**: XI (southern hemisphere).

Taxonomic remarks. *Hyalorbilia pleioerythrostigma* closely resembles *H. erythrostigma* except for the 16-spored asci and the fact that no SBs were seen in the living ascospores. Since only a few living spores could be found, it is possible that they were not fully mature. However, some dead asci with apparently mature dead spores were seen in the examined apothecia, therefore, the population seems to be well developed.

Ecology. The very sparse, minute apothecia of *H. pleioerythrostigma* were detected on detaching xeric bark of a vital trunk of *Lamarchea hakeifolia* in a semiarid subtropical acacia open shrubland of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, NW Coastal Hwy, 190 m, trunk of *Lamarchea hakeifolia*, on bark, 8.XI.2007, G. Marson (ex H.B. 9020b, MEL 2389274, **holotype**).

Hyalorbilia latispora Baral, G. Marson & P. Perz, **sp. nov.**, MB 813460 — Pls 135–136

Etymology: referring to the short ascospores.

Typification: Netherlands, Noord-Brabant, Tilburg, stem of *Senecio*, 11.X.2004, L. Rommelaars (ex H.B. 7592b, M-0276413, holotype).

Latin diagnosis: Hyalorbiliae rotiferae *similis*, *sed ascosporae distincte latiores.*

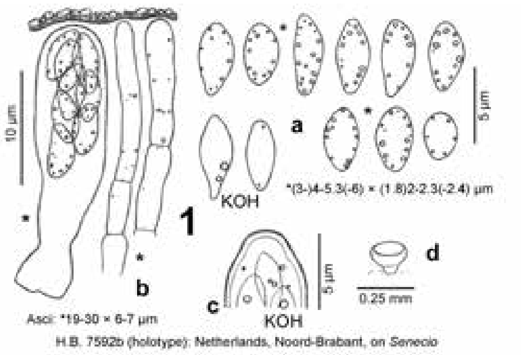

Plate 135. **1**: *Hyalorbilia latispora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium (fresh).

Description: — **TELEOMORPH**: rehydrated 0.12–0.22 mm diam., 0.07 mm high (receptacle 0.035 mm), whitish, translucent, round, scattered; disc flat, margin thin, not protruding, smooth; subsessile or with distinct stipe, superficial. **Asci** *18–25(–30) × 5.5–6.5(–7) µm {5}, †18–27(–31) × 4.5–5.9 µm {2}, 8-spored, spores *3–4-seriate, pars sporifera *11–14 µm long; **apex** (†) hemispherical to distinctly conical; **base** with short, thick stalk, with croziers {3}, with or without perforation. **Ascospores** *(3–)4–5.5(–6) × (1.8–)2–2.3(–2.5) µm {6}, †(3–)3.7–5(–5.5) × 1.6–2.2 µm {1}, broadly (cylindric-) ellipsoid to fusoid or fusiform, ends obtuse (to subacute), base rarely shortly attenuated, sometimes ± inequilateral; **SBs** 0.15–0.25 µm diam., globose, ~3–5 in each half, oriented at the periphery {5}; with a few minute, rarely medium-sized LBs. **Paraphyses** apically uninflated or slightly clavate, terminal cells *11–14 × 2–3 µm {1}, lower cells *5–8.5 × 1.7–2 µm {1}; unbranched at upper septum. **Medullary excipulum** not examined. **Ectal excipulum** at base and flanks of non-gelatinized t. angularis-prismatica, cells *8–11 × 4–7 µm {1}, horizontally oriented at flanks; 5 µm thick near margin, of t. prismatica, cortical cells *3–3.5 {T} or †4.5–6.5 µm {1} wide, in some populations ± protruding and hair-like, *~12–15 × 5–8.5 µm, ± conical, firm-walled (0.3–0.5 µm thick) {2}. **Anchoring hyphae** sparse, *1.3–2.3 µm wide, walls 0.2 µm thick {1}. **Exudate** over paraphyses and margin 1–2 µm thick, continuous, with coarse adhering granules. — **ANAMORPH**: curucispora-like (from ascospore isolate {1}). **Culture**: ascospores shot on agar tardily germinating, hyphae very slow-growing, *1.5–3 µm wide. **Conidiophores** short, not clearly seen. **Conidia** *11–12(–13.7) × 9.5–12 µm, with two ‘arms’ and two ‘legs’ (rarely one arm branched), legs lying in a plane vertical to the arms; upper arms curved downwards, actual length *5–8 × 2.5–3.3 µm, legs straight, bent downwards at their insertion, *6.5–9 × 2.5–2.8 µm, arms and legs 0–1-septate, with a few 0.5–1.2 µm large LBs and some smaller ones; one of the two arms has a truncate end and is in fact the conidial stipe by which the conidium was attached to the conidiophore.

Habitat: 0–1 m above the ground, on ~15 mm thick branches of *Clematis vitalba* {2}, on bark {2}; cupule (pericarp) of *Fagus sylvatica* {1}, stems of *Rubus fruticosus* {2}, stems of *Senecio* sp. {1}. **Associated**: *Hyalorbilia subfusispora* {2}, *Karstenia rhopaloides* {1}, *Lecophagus ellipsoideus* {2}, *Orbilia aristata* {1}, *O. breviaristata* {1}, *O. clavuliformis* {1}, *O. eucalypti* {1}, *O. filiformis* {1}, *O. obtusispora* {1}, *O. pleioeuonymi* {1}, *O. quaestiformis* {1}, *O. ungulata* {1}, *O. vinosa* {1}, *O. vitalbae* {2/1}, *Pyrenopeziza* sp. {1}, old pyrenomycete {1}; little greyed, algae absent or medium abundant. **Desiccation tolerance**: fully tolerant for at least 1 day. **Altitude**: 12–837 m a.s.l. **Geology**: Keuper (Knollenmergel), Lower Jurassic sandstone and shale; granite/granodiorite & gneiss. **Phenology**: I, VII–VIII, X–XI.

Taxonomic remarks. *Hyalorbilia latispora* is tentatively separated from *H. rotifera* by its wider, rarely distinctly heteropolar ascospores. The presence of spore bodies might be a further distinctive feature, but these were not consistently absent in *H. rotifera*, and not clearly seen in the specimen on *Fagus* cupule. *H. latispora* is also similar to *H. subfusispora*, but differs in shorter spores which never contain SBs larger

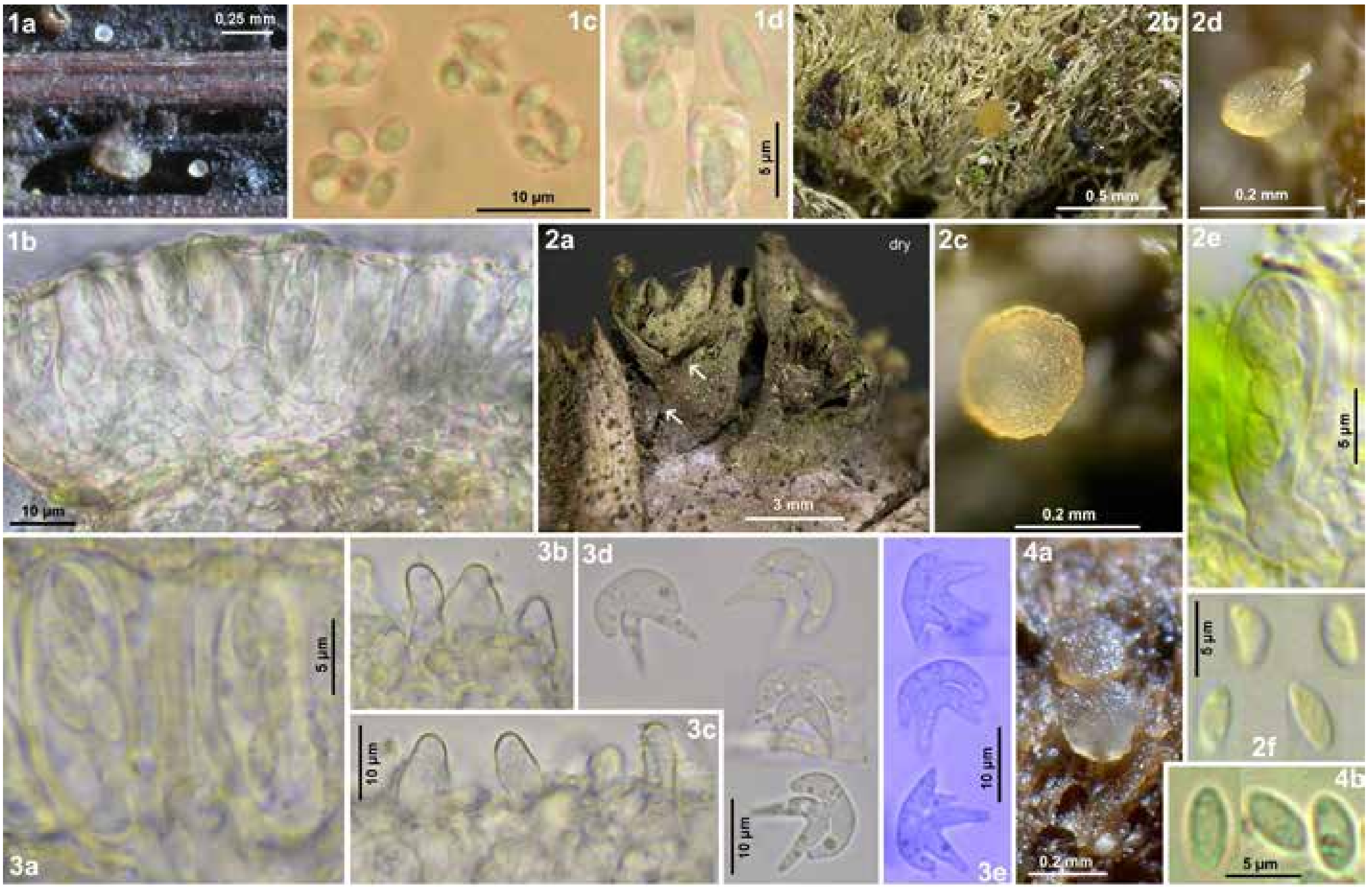

Plate 136. **1–4**: *Hyalorbilia latispora*. – **1a**, **2c–d**, **4a**. fresh apothecia; **2a–b**. dry apothecia 1b. apothecium in median section; **3b–c**. hair-like protuberances at the margin; **2e**, **3a**. asci; **1c–d**, **2f**, **3a**, **4b**. ascospores (**1c**: recently ejected and still in groups); **3d–e**. conidia from pure culture (**3e** in CRB). – Living state. – **4a–b**: phot. P. Perz. — **1a–c**. H.B. 7592b (holotype): Netherlands, on *Senecio*; **2a–f**. 27.I.2007: Luxembourg, Echternach, on *Rubus*; **3a–e**. G.M. 2013-11-16.3: Luxembourg, Dudelange, on *Clematis*; **4a–b**. P.P. 20100817-1: Poland, on *Fagus* cupule.

than 0.3 µm. For a very sparse similar collection on bark of *Ilex* see under *H. subfusispora* (Pls 116: 9; 117: 15).

Variation. The marginal cells seen in the holotype were distinctly narrower than in the specimen on *Fagus* cupule. Distinctly protruding, conical, firm- to thick-walled (0.2–0.5 µm) marginal cells were observed in the collections on *Rubus* (Germany) and *Clematis*. The ascospores vary somewhat in shape between (cylindric-)ellipsoid to fusoid-fusiform, but only slightly in size: *4.2–5.2 × 1.8–2.4 µm (*Clematis*), *(3.3–)3.8–5.5 × 2–2.5 µm (*Fagus*), *4–5.2 × 2–2.4 µm (*Rubus*, Luxembourg), *5–6 × 2–2.3 µm (*Rubus*, Germany).

Anamorph. Conidia were formed in the very slow-growing ascospore isolate from *Clematis* (Pl. 136: 3d–e; fig. 3x in Baral et al. 2017b erroneously as H.B. 9902c [= G.M. 2014-07-25.1]). They resemble *Curucispora flabelliformis* as described by Ando (1993). The apothecium from which the isolate originates was at first thought to be *Lecophagus ellipsoideus* which grew in association, but the narrow hyphae in the culture contradict this identity, and a sequence from apothecia sampled the next year from the same area and substrate confirmed identity of the culture with *H. latispora.*

Similar curucispora-like but slightly larger conidia were observed on *Ulmus* bark in association with *O.* cf. *frangulae* (Luxembourg, Holtz, IVV: 7.V.1999). Gönczöl & Révay (2006: figs 9–12) and Révay & Gönczöl (2010: fig. 13) figured very similar conidia as ‘unknown sp. 2’, collected from rainwater from Germany (Tübingen) on *Fagus* and *Prunus*, and from Hungary (Királyrét, Budapest) on *Quercus*, *Fagus*, *Chamaecyparis*, *Cupressus*, *Picea*, and *Taxus*, but with ~1.5–2× larger size. Gönczöl & Révay’s figures suggest to believe that all extremities lie in one plane. The conidia of the present culture, however, are clearly 3-dimensional, with the 2 ‘legs’ lying in a plane vertical to that of the ‘arms’. When viewed under the light-microscope, pressure by the cover slip forces such conidia in a 2-dimensional form.

Phylogeny. Sequences were taken from the ascospore isolate of the *Clematis* sample from 2013 and from apothecia sampled on *Clematis* in 2014, comprising ITS and LSU. The S1506 intron is absent in both. In the ITS they differ by 1.2% (5 nt in ITS1 and 3 nt in ITS2), while in the overlapping D1 domain of LSU they concur.

H. latispora clustered unresolved among *Hyalorbilia* s.str., the *Vermispora* clade, and the *erythrostigma-orbiliicola* clade (Phyls 5–6, S5), though with a very high distance in the ITS region (~27–31%). Even in the LSU the distance to any other species of *Hyalorbilia* lies in the range of ~10–14% (614 nt). Also in Baral et al. (2017b) *H. latispora* clustered unresolved within the *Hyalorbilia-Vermispora* clade.

Specific nucleotides. In the 5.8S *H. latispora* concurs at three characteristic positions with the *Vermispora* clade (pos. 30, pos. 64 [3’-end of Orb5.8s1F], pos. 98), which would support a relationship with this group (Tabs 18, 56). At pos. 64 and 98 it concurs also with *H. erythrostigma*/*orbiliicola*, and at pos. 140 only *H. erythrostigma*/*orbiliicola* concur with the *Vermispora* clade. In contrast to this, *H. latispora* and *H. erythrostigma*/*orbiliicola* concur at pos. 11 and 85 with *Hyalorbilia* p.p.maj., where the *Vermispora* clade differs (Tab. 61).

Ecology. The mostly very sparse apothecia of *Hyalorbilia latispora* appear to be plurivorous. The known hosts include herbaceous stems and woody branches as well as cupules. The collections were mainly on xeric substrate, except for the *Fagus* cupule that was lying on the moist ground. The collection sites comprise subatlantic to subcontinental, cold- to orotemperate humid areas. The two samples on stems of *Rubus fruticosus* each comprised only a single apothecium. The others were on herbaceous stems of *Senecio*, on *Fagus* cupule, and on a *Clematis* branch. In the collections on *Rubus* and *Clematis* from Luxembourg the similar *H. subfusispora* was present. The locations of the two *Clematis* samples were 160 m away from each other along a railway track bordered by a thermophilous forest stripe.

Specimens included. **LUXEMBOURG**: **Gutland**, **Echternach**, 4 km SW of Echternach, 1.5 km E of Scheidgen, N of Michelshaff, S of Seidemuer, 320 m, stem of *Rubus fruticosus*, 27.I.2007, G. Marson (ø). – **Esch-sur-Alzette**, 4.2 km S of Bettembourg, 1.7 km E of Dudelange, along railway, 290 m, branch of *Clematis vitalba*, on bark, 16.XI.2013, G. Marson (G.M. 2013-11-16.3, anam. cult.; sq.: MK493158). – ibid., branch of *C. vitalba*, on bark, 25.VII.2014, G. Marson (G.M. 2014-07-25.1, H.B. 9902c ø; sq.: KT222386). — **NETHERLANDS**: **Noord-Brabant**, 6 km SW of Tilburg, 5 km E of Gilze, Kaaistoep, 12 m, on stem of *Senecio*, 11.X.2004, L. Hyalorbilia hergiswiliana Baral, Polhorský, D. Savić & E. Weber, **sp. nov.**, MB 813959 — Pls 137–138

Etymology: named after the village close to the type locality, Hergiswil (Luzern).
Typification: Switzerland, Hergiswil, branch of *Acer pseudoplatanus*, 15.VIII.2006, H.O. Baral (ex H.B. 8235b, M-0276492, holotype)

Latin diagnosis: Hyalorbiliae rotiferae *similis sed ascosporae leniter breviores et latiores, asci longiores, excipulum ectale textura globulosa, cellulae marginales angustiores, apothecia majores;* Hyalorbiliae latisporae *similis sed ascosporae leniter minores, absque corpusculis refringentibus KOH-sensitivis, asci angustiores, apice subtruncato. Habitat ad lignum putridum rami sicci* Aceri, Corni, Koelreuteriae *in zona oro- ad mesotemperata humida Europae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.3(–0.55) mm diam., 0.11–0.18 mm high (receptacle 0.045–0.09 mm), pale greyish(-rosaceous) to cream or light reddish-brownish, medium translucent, round or sometimes elongated, scattered; disc slightly concave to slightly convex, margin indistinct or distinct, not protruding, smooth; sessile on an obconical base or with a stipe of up to 0.085 × 0.1 mm, superficial but ± immersed in algal layer or in clefts in outer wood layer. **Asci** *(25.5–)27–35(–38) × 4.3–5.5 µm {3}, †21–26 or 28–37 × 3.6–4.7(–5.3) µm {T}, 8-spored, spores *2–4-seriate, pars sporifera *10–15 µm long; **apex** (†) slightly to medium truncate (never indented or laterally inflated), hemispherical in side view, thin-walled {2}; **base** sessile or with short to medium long, thick, ± flexuous stalk, often h-shaped, often forming croziers {2} with or without small to large slit-like perforation. **Ascospores** *(3.2–)3.5–4.2(–4.4) × (1.6–)1.8–2(–2.1) µm {3}, ellipsoid to fusoid, sometimes fusoid-clavate, apex obtuse, base sometimes attenuated, straight to slightly inequilateral; **SBs** apparently absent, some spores with 1–4 minute **LBs** {2}. **Paraphyses** apically uninflated to slightly or sometimes medium capitate, terminal cells *(13–)16–24 {2} × (2–)2.5–3.5(–4.5) µm {3}, †11–24 × 2–2.7 µm {T}, lower cells *5–9 × 1.8–2.7 µm {2}, †3–6 × 1.5–2 µm {T}; branched or unbranched at upper septum. **Medullary excipulum** hyaline, 35–50 µm thick, of dense, small-celled, non-gelatinized textura intricata, medium sharply delimited from ectal excipulum. **Ectal excipulum** hyaline {T} or with light reddish-ochre cortex, of (†) thin-walled t. globulosa(-prismatica) at base and lower flanks, 30-60 µm thick near base, cells *7–15(–18) × 5–11 µm {T} or *5–8 × 4–6 µm {2}; 30–50 µm thick at lower flanks, irregularly vertically oriented; 15–20 µm thick at mid flanks, indistinctly oriented at ~20–50°; 10–15 µm thick at margin, of t. porrecta oriented at 0–10°, marginal cortical cells *5–10 × 2.5–3(–4) {2} or †9–11 × 2–3 µm {T}; flanks covered by a 3–6 µm thick layer of *2–3(–3.5) µm wide hyphae. **Anchoring hyphae** very sparse, †1.3–2.5 µm wide, walls 0.2–0.3 µm thick {2}. **SCBs** in paraphyses {1} and upper part of medullary excipulum {T} globose, 1–1.5 µm diam., slightly to strongly refractive, disappearing in KOH; **VBs** absent {2} or medium refractive, roundish to elongate {1}. **Exudate** over paraphyses 0.1–0.4 µm thick, smooth or rough-granular, continuous, hyaline, loosely attached, over margin and flanks pale yellowish-chlorinaceous, 0.1–0.3 µm thick, smooth to warted. **— ANAMORPH**: dicranidion-like (presumed, observed on natural substrate {T}). **Conidiophores** unbranched, ~*10–20 × 1.8–2 µm {T}; **conidia** *32–58 × 11–20 µm, 2(–3)-armed, Y-shaped, when 3-armed then sometimes 1 reflexed (K-shaped), stipe *11–20 × 2–3 µm, 1–4-septate, arms *18–36 × 2.8–4 µm, 2–7-septate, containing some small peripheral LBs {T}.

Habitat: collected 0.1–1.8 m above the ground, decorticated, 2–5 cm thick branches of *Acer pseudoplatanus* {1}, *Cornus mas* {1}, *Koelreuteria paniculata* {1}, exposed, ± deeply strongly decayed wood {3}, sometimes in old beetle galleries, in abundant biofilm of

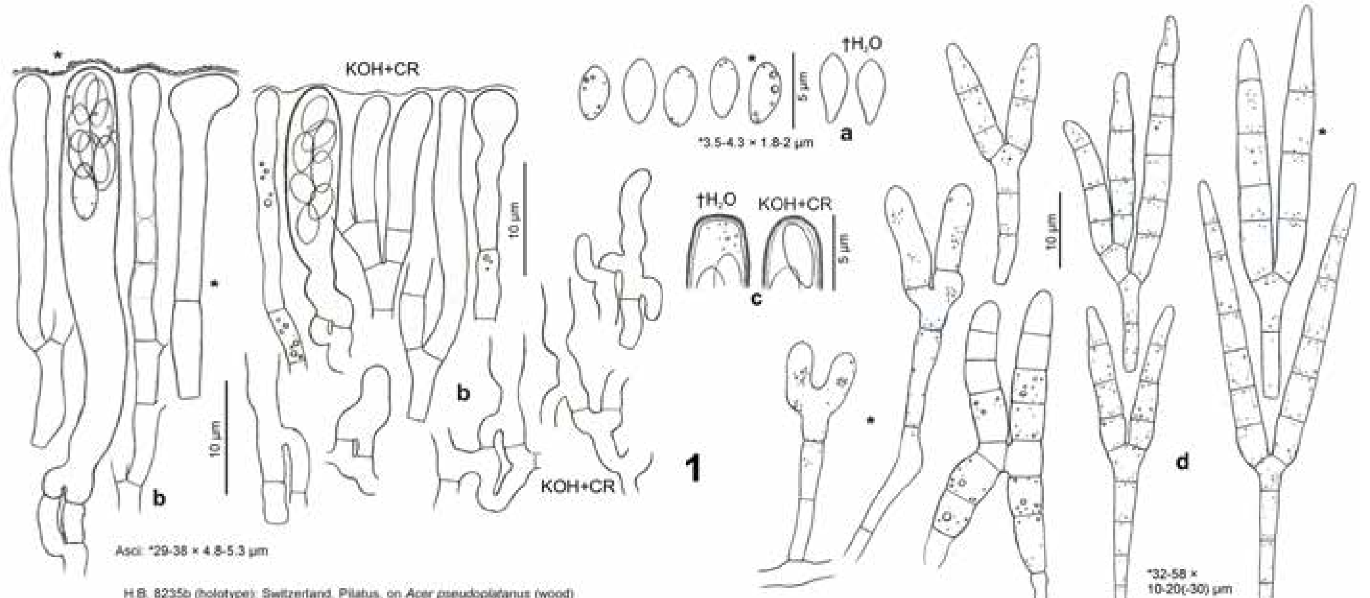

Plate 137. **1**: *Hyalorbilia hergiswiliana*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. conidia (found on associated apothecia of *O. vinosa*).

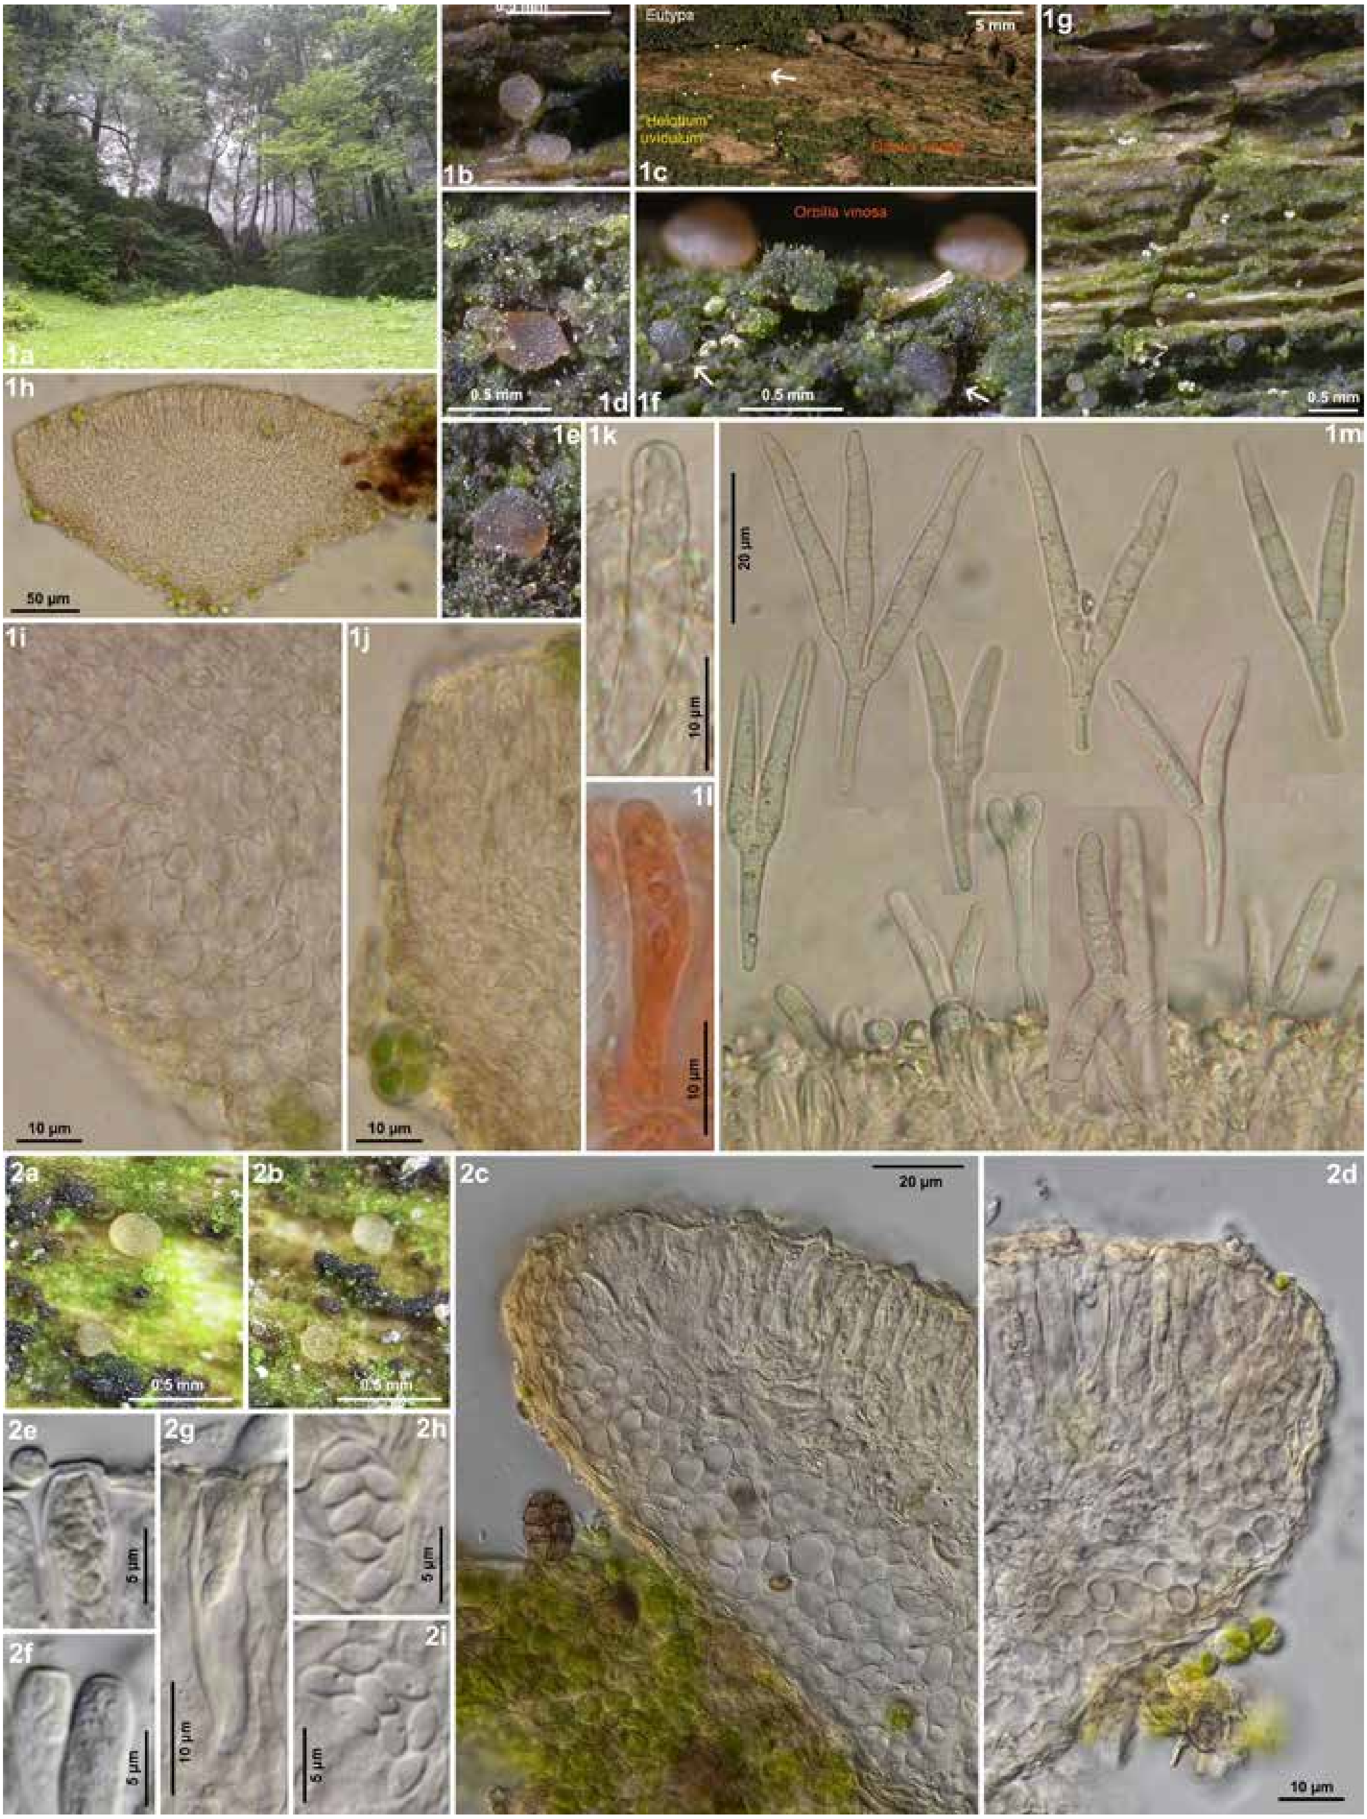

Plate 138. **1–2**: *Hyalorbilia hergiswiliana*. – **1a**. montane *Aceri-Fraxinetum* with *Asplenium scolopendrium*; **1c**. detail of decorticated rotten mesic branch of *Acer pseudoplatanus*, associated with *O. vinosa* and '*Helotium*' *uvidulum* (apothecia marked by dots, white = *H. hergiswiliana*); **1b**, **d–g**, **2a–b**. rehydrated apothecia (in **1f** associated with two apothecia of *O. vinosa*); **1h**. apothecium in median section; **1i**. id., ectal excipulum at lower flanks; **1j**, **2c–d**. id., ectal excipulum at flanks and margin; **1k–l**, **2g**. asci (and paraphyses); **2e–f**. ascus apices; **2h–i**. ascospores within dead asci; **1m**. conidia growing on hymenium of *O. vinosa*. – Living state, except for **1l** (in KOH+CR), **2e**, **f** (in H_2O), asci in **2h–i**. — **1a–m**. green algae (*Pleurococcus*) and brown hyphae. **Associated**: '*Helotium*' *uvidulum* {2}, *Orbilia aprilis* {1}, *O. montigena* {2}, *O. vinosa* {1}. **Desiccation tolerance**: fully viable for almost 3 weeks. **Altitude**: 132–890 m a.s.l. **Geology**: Cretaceous micrite (Schrattenkalk) & flysch, fluviatile sediment (sandy gravel). **Phenology**: V, VIII–IX.

Taxonomic remarks. *Hyalorbilia hergiswiliana* is only known from the holotype from Switzerland and the paratype from Slovakia. It particularly resembles *H. latispora* and *H. rotifera*, the former differing in slightly larger ascospores containing several minute peripheral SBs and in wider asci, the latter in shorter asci, slightly longer and narrower ascospores, a more prismatic, horizontally oriented ectal excipulum at the flanks, and wider marginal cortical cells. Both species differ from *H. hergiswiliana* in some of their asci having a somewhat conical apex (dead state), in shorter terminal cells of paraphyses, and smaller, more whitish apothecia.

Because of the partially bifurcate ascus base and occasional absence of croziers, and the ectal excipulum being composed at the lower flanks of textura globulosa(-prismatica) with an irregular vertical orientation, the species was also compared with series *Orbilia*, particularly *O. frangulae*. However, the finely warted exudate over the paraphyses, the occurrence of croziers, and the consistent absence of shoulders and indentations at the ascus apex point to a *Hyalorbilia*. Apart from this, *O. frangulae* differs in smaller spores, narrower asci, and in larger apothecia. Also in the presumed anamorph the two species are similar. *O. cejpii* differs in shorter spores with a small spore body and in much narrower asci.

Anamorph. In the holotype dicranidion-like conidia formed on very short conidiophores (Pls 137: 1d; 138: 1m) were observed emerging from the hymenium of *Orbilia vinosa*, which grew in close association with apothecia of *H. hergiswiliana*, sometimes only 0.3 mm away. The apothecia of *H. hergiswiliana* are smaller and less pigmented than those of the associated *O. vinosa* (Pl. 138: 1f). In the Slovakian sample *O. montigena* grew at ~5 mm distance from *H. hergiswiliana*, but here only trinacrium tothii-like conidia of unclear relationship were found on the natural substrate (A. Polhorský pers. comm., IVV: 18.V.2019).

Not included collections. In 11 further records of *O. vinosa* s.l. from various regions of Europe, very similar dicranidion-like conidia were observed, either on the apothecia or nearby on the plant substrate, but no apothecia of *H. hergiswiliana* were observed (see specimen list below). In spite of their close morphological match they are not included in the description of *H. hergiswiliana*. Gönczöl & Révay (2003: figs 1–4, as *Dwayaangam* sp.) illustrated the same type of conidia from a treehole in a trunk of *Fagus sylvatica* in the Börzsöny mountains in Hungary.

The occurrence of such dicranidion-like conidia with *O. vinosa* apothecia suggests at first glance that they belong to *O. vinosa* rather than *H. hergiswiliana*. However, in some of these collections, very differently shaped conidia occurred in addition: trinacrium tothii-like conidia in five samples of *O. vinosa* (e.g., Pl. 261: 1, type sample of *H. hergiswiliana*), and dwayaangam-like conidia in two samples of *O. arachnovinosa* (e.g., Pl. 269: 6) and one of *O. angiosubvinosa* (Pl. 267: 2). Trinacrium tothii- and dwayaangam-like conidia were assured in pure culture as anamorph of *O. vinosa* and *O. subvinosa*, respectively, which supports our hypothesis that the above dicranidion-like conidia do not represent the anamorph of those apothecia on which they grew. Instead, they seem to belong to a parasitic orbiliaceous fungus, possibly *H. hergiswiliana*. In a similar way, apothecia and conidia of *Hyalorbilia orbiliicola* specifically grow as a parasite on apothecia of *Orbilia* spp.

Phylogeny. A sequence was gained by A. Polhorský (pers. comm.) from apothecia of the Slovakian paratype of *H. hergiswiliana*, which comprises ITS (S1506 intron absent) and LSU D1–D4. In ML analyses (not shown) it clustered unresolved in *Hyalorbilia*, and also BLAST search for ITS yields solely that genus, though with only 37% query cover as a maximum, except for one sequence with 52%. Distances to other species of *Hyalorbilia* lie in the range of ~29–32% for ITS (p-distances evaluated with MEGA7) and 12% for LSU. An insert occurs in the ITS1 similar as in the genotype of *H. inflatula* with broad marginal cells, though being difficult to align. In its aberrant conservative motifs GAGC**A**TC (3'-end of 5.8S) and TGA**T**CT (5'-end of LSU) *H. hergiswiliana* resembles *H. erythrostigma* and *H. orbiliicola*, which likewise differ from almost any other orbiliaceous species in a further variant of these motifs (see p. 122 and Tab. 18).

The sequence that appeared on top with a 52% query cover was an environmental clone isolated from a *Picea* log in Sweden (GenBank HQ611287; ITS, S1506 intron absent). It shows the very same two aberrant motifs and clustered medium supported with *H. hergiswiliana*, though differing by a 21% and numerous gaps; therefore, it is named *H.* aff. *hergiswiliana* here. In the Orb5.8s3F primer this sequence concurs with *H. hergiswiliana*, whereas in the Orb5.8s1F primer it shows the predominant orbiliaceous variant, and in the 4 first nucleotides of ITS2 it concurs, unlike *H. hergiswiliana*, with *H. latispora* and others (Tabs 18, 20). In the LSU *H. hergiswiliana* shows the Orb28s2R motif of the core clade of *Hyalorbilia*, which does not occur in any other clades of *Hyalorbilia* or other orbiliaceous genera (Tabs 19).

The ITS distance between *H. hergiswiliana* and *H. latispora* or *H. rotifera* lies around 30%. Also clone from Amazonas (U2, KY687852/3; SSU+ITS+LSU), which shares with *H. hergiswiliana* s.l. the motif GAGC**A**TC, clustered unsupported herewith by showing a 29% ITS distance. In our combined analysis of *Orbiliomycetes* (Phyl. 2) this clone clustered weakly supported within the *Hyalorbilia* clade, whereas in our 5.8S+LSU analysis (Phyl. 1) it nested unsupported sister to *Hyalorbilia*.

Ecology. In the three known samples, *Hyalorbilia hergiswiliana* occurred on xeric, decorticated, very rotten wood of angiosperm branches, always in association with members of *Orbilia* series *Hesperideae* (*O. aprilis*, *O. montigena*, *O. vinosa*), in two samples also with the macroscopically similar '*Helotium*' *uvidulum*. The sparse apothecia in the holotype, which were almost used up during examination, grew on the upper side of an eroded branch of *Acer* lying with little soil contact on the forest floor of a montane, shady, calcareous *Aceri-Fraxinetum* with *Asplenium scolopendrium* in the orotemperate humid calcarean northern Alps. In the Slovakian sample on *Cornus*, the apothecia grew on an attached branch in a thermophilous (xerophilous) pannonian oak grove with *Acer campestris* and many *Cornus* shrubs in the temperate humid Danubian lowlands near an oxbow but outside the floodplain. In the Serbian sample on *Koelreuteria*, the branch was recently fallen to the ground in a supratemperate humid *Quercus*/*Tilia*/*Acer* forest with planted gymno- and angiosperms, next to a road near the top of Fruška Gora mountain in the south of the Pannonian Plain.

The not included conidial records comprise thermoboreal to cold- or orotemperate humid but also orosub- to suprasubmediterranean (semi)humid regions. The uncultured clone from a *Picea* log is from hemiboreal humid lowlands of eastern Sweden.

Specimens included. **SWITZERLAND**: **Nidwalden**, 8.5 km SSW of Luzern, 2 km SW of Hergiswil, Renggpass, 890 m, branch of *Acer pseudoplatanus*, on wood (presumed anamorph on associated apothecia of *O. vinosa*), 15.VIII.2006, H.O. Baral (ex H.B. 8235b, M-0276492, **holotype**, anam. substr.). — **SLOVAKIA**: **Bratislava**, 10 km SE of Bratislava, 5 km S of Podunajské Biskupice, Topol'ové hony, 132 m, branch of *Cornus mas*, on wood (no anamorph seen on associated apothecia of *O. montigena*), 18.V.2019, A. Tena (ø, doc. vid.).
H. **aff.** ***hergiswiliana***: **SWEDEN**: **Uppsala**, 35 km WNW of Uppsala, around Knutby, ~30 m, log of *Picea abies*, before 2011, M.T. Banik (xan, 0618Banik_03D_20, uncultured clone; sq.: HQ611287).

Hyalorbilia ulmi Baral & E. Batten, **sp. nov.**, MB 813455 — Figs 139–140

Etymology: named after the substrate, *Ulmus minor*.
Typification: Great Britain, Suffolk, Halesworth, trunk of *Ulmus minor* (on pyrenomycete and on bark), 6.II.2005, E. Batten (ex E.B. 4586 & ex H.B. 7674, M-0276422, holotype).

Latin diagnosis: Hyalorbiliae erythrostigmati *similis sed asci breviores, ascosporae angustiores, corpusculo refringente minore.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.07–0.16 mm diam., (greyish-) whitish(-chlorinaceous), semitranslucent, round, scattered to subgregarious; disc slightly ± flat, margin not protruding, finely rough; subsessile or with distinct short stipe ~15 × 40 µm, superficial; dry yellowish-cream. **Asci** *14–17 × 4.2–5 µm, †(12–)14–16(–17) × (3–)3.5–3.7(–4) µm, 8-spored, spores (*/†) ± biseriate, some spores inverted (irregularly mixed), pars sporifera †9.5–11 µm long; **apex** (†) hemispherical; **base** with ± absent stalk, arising from croziers with small perforation. **Ascospores** *2.4–3.2 × 1.4–1.8 µm, †(1.8–)2.1–2.6(–3) × (1.2–)1.3–1.6(–1.8) µm, ellipsoid-ovoid, rarely (cylindric-)ellipsoid or fusoid, both ends obtuse (rarely subacute), straight; **SBs** *0.6–0.8 µm diam., globose, 0.4–0.5 µm away from apex (attachment invisible), with 1-2 minute LBs. **Paraphyses** apically uninflated to slightly (rarely medium) clavate-capitate, terminal cells †11–14 × 1.8–2.5 µm, sometimes strongly inflated to a width of 5–8 µm, lower cells †3.8–4.7 × 1.3–2(–4) µm; branching not seen. **Medullary excipulum** not studied. **Ectal excipulum** of (†) ± thin-walled, horizontal textura angularis(-prismatica) at lower flanks, cells †8–15 × 4–12 µm, cubical; marginal cortical cells †13–18 × 4–7.5(–9) µm (3–6 µm wide in section). **Anchoring hyphae** not studied. **VBs** unknown. **Exudate** over paraphyses 0.1–0.2(–0.3) µm thick, finely granular, continuous, loosely attached, over margin smooth to granular. — **ANAMORPH**: unknown.

Habitat: 20 cm above the ground, on loose bark at base of a trunk of *Ulmus minor*, on remnants of stromatic pyrenomycete. **Associated**: abundant conidia of ?*Diplodia* below apothecia. **Desiccation tolerance**: after 1 week only some cells of ectal and medullary excipulum were viable. **Altitude**: 13 m a.s.l. **Geology**: Pleistocene till (sand & gravel). **Phenology**: II.

Taxonomic remarks. *Hyalorbilia ulmi* resembles *H. erythrostigma* in many respects, but differs in shorter asci, narrower spores, smaller SBs, also in some of the paraphyses being extraordinarily wide. Because the spores with their eccentric SBs have an elongate shape, they tend to be oriented with their SBs either up- or downwards rather than in all directions as in *H. erythrostigma*, which is an exceptional feature

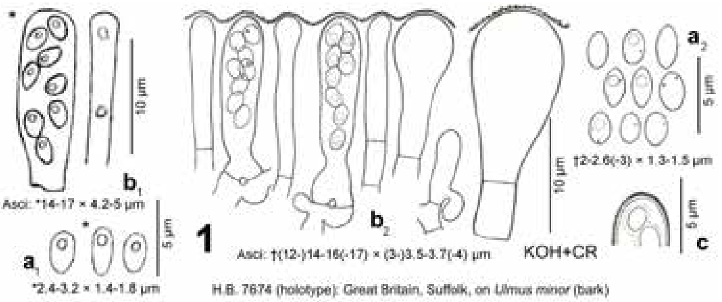

Plate 139. **1**: *Hyalorbilia ulmi*. – **a**. ascospores; **b**. asci and paraphyses, ascus bases with croziers; **c**. ascus apices. – **1a$_1$**, **b$_1$**: del. E. Batten.

within *Hyalorbilia*. *H. brevistipitata* differs in multiguttulate, partially subglobose spores and a hygric habitat. Two somewhat intermediate collections from Australia and Africa are treated as *H.* cf. *erythrostigma* (Pls 126: 10; 128: 3) and *H.* cf. *brevistipitata* (Pl. 121: 3).

Ecology. *H. ulmi* grew on an old stromatic pyrenomycete which occurred on bark at the base of a standing tree of *Ulmus minor*, in oceanic, cold-temperate humid eastern England.

Specimens included. **GREAT BRITAIN**: **East England**, **Suffolk**, 4 km ESE of Halesworth, km NE of Wenhaston, path to Bicker's Heath, 10 m, on pyrenomycete and bark of trunk of *Ulmus minor*, 6.II.2005, E. Batten (ex H.B. 7674, M-0276422, **holotype**; E.B. 4586, K(M) 147142, **isotype**, doc. vid.).

Hyalorbilia resinae Baral, **sp. nov.**, MB 813465 — Pls 141–142

Etymology: named after the habitat, old resin of conifers.

Typification: Luxembourg, Mensdorf, branch of *Larix*, on resin, 5.III.2007, G. Marson (ex H.B. 8443a, M-0276416, holotype).

Latin diagnosis: Hyalorbiliae rotiferae *similis sed ascosporae angustiores, in statu vivo cum duobus corpusculis refringentibus minutis, paraphyses ad apicem partialiter valde inflatae. Habitat ad resinam nigram ramorum vulneratorum siccorum coniferarum in zona hemiboreale et temperata humida Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.08–0.18 mm diam., (0.03–)0.05–0.09 mm high [receptacle (0.03–)0.04–0.05 → 0.03–0.04 mm], whitish to very pale chlorinaceous, translucent, round, scattered to gregarious in small groups; disc flat, margin thin, 0–10 µm protruding, very finely to distinctly rough; sessile or with distinct stipe 0.02–0.05 × 0.05–0.06 mm, superficial, partially semiimmersed in black hyphomycete or biofilm, dry very pale yellowish or whitish-cream. **Asci** *16–22 {1} × 5–6.5(–7) µm {3}, †(13–)15–23(–26) × (4–)4.3–5.5(–6) µm {4}, 8-spored, spores *(2–)4-seriate, pars sporifera *9–13.5 µm long; **apex** (†) hemispherical to medium conical; **base** sessile or with short, thick, partially constricted stalk, with croziers {4}, partially with small, round to elongate perforation. **Ascospores** *(3.5–)4–5.3(–6) × 1.3–1.6(–1.8) µm {3}, †4.2–5.2 × (1.2–)1.3–1.4 µm {1}, subcylindrical to ellipsoid, sometimes fusoid-clavate, ends (rounded to) obtuse, straight to slightly inequilateral, rarely medium curved; **SBs** *0.2–0.25 µm {1}, globose, 1 at each end, also absent {2}. **Paraphyses** apically very slightly to medium or sometimes strongly clavate-capitate, terminal cells *9–13 × 3.5–5 µm {1}, †(5–)7–11(–13) × 1.8–3.3(–4.5) µm {3}, lower cells *7–9 × 1.8–2.3 µm {1}, †(2.5–)4–7 × 1.5–2(–2.5) µm {3}, sometimes branched at upper septum. **Medullary excipulum** 5–10 µm thick, non-gelatinized, partially distinctly delimited. **Ectal excipulum** of not or very slightly gelatinized, indistinctly (at mid flanks also horizontally) oriented textura (globulosa-)angularis from base to margin, 10–50 µm thick near base, cells */†(5–)6–10(–12.5) × (4–)5–7(–9.5) µm {3}; cells at flanks *~6–8 × 6–8 µm; 7–15 µm thick at margin, marginal cortical cells */†(7–)9–12(–15) × 5–8(–9) µm {4}, clavate-vesiculous, partially ± protruding, sometimes with angular outline or forming nipple-like protuberances 1–3 × 1.7–2.5 µm. **Anchoring hyphae** sparse to rather abundant at base, †1.5–3(–4) µm wide (at insertion 4–5 µm), walls 0.2((–0.3)) µm thick {4}. **SCBs** in paraphyses and ectal excipulum absent; **LBs** in excipular cells sometimes present. **Exudate** over paraphyses and excipulum 0.1–0.3 µm thick, continuous, ± smooth, on marginal cells also finely rough, very pale chlorinaceous. — **ANAMORPH**: brachyphoris-like (presumed, from natural substrate {2}). **Conidiophores** unknown. **Conidia** *(38–)47–62(–73.5) × (4.2–)4.5–6.5(–6.8) µm, fusiform, (4–)5–6(–8)-septate.

Habitat: fallen (lying ± close to ground) {3} or still-attached at 1–3 m above the ground {1}, corticated, 3–30 mm thick, partially living twigs and branches of *Larix* sp. {3}, *Picea abies* {1}, in large wounds (swollen to 25–50 mm) or on small thin patches of resin {2}, also on slightly decayed bark without resin close to apothecia {2}, resin blackened by a thick layer of a hyphomycete, green algae present or absent. **Associated**: *Ciliolarina* sp. {1}, *Cosmospora rishbethii* {1}, *Lachnum virgineum* {1}, *Lophium mytilinum* {2}, *Microthyrium abietis* {1}, *Mytilinidion gemmigenum* {1}. **Desiccation tolerance**: fully tolerant for at least a few days. **Altitude**: 50–370 m a.s.l. **Geology**: Lower Carboniferous sediment, Lower Jurassic sandstone; quartzite. **Phenology**: III, V.

Taxonomic remarks. *Hyalorbilia resinae* resembles *H. rotifera*, a species which differs in consistently uninflated or only scarcely inflated paraphyses, partially wider, fusoid ascospores, and in growing on angiosperm substrate. In spore shape *H. resinae* resembles *H. oreadum*, which differs in less inflated paraphyses, narrower marginal cortical cells, narrower spores and asci, and larger apothecia.

Variation. The paraphyses show a remarkable variability in their apical inflation, even within an apothecium. In the samples from Germany and Poland they are partially very strongly capitate, whereas this is much less so in the holotype (from Luxembourg) and the find from Norway. Also the cortical cells near the margin vary among the collections: they may project distinctly, and some of them tend to become angular and may form short protrusions (Pl. 142: 2e–g, 3e) similar as observed in a specimen of *H. juliae* (Pls 106: 7h; 107: 2d–f). In the other features the four included collections concur very well. In some asci of the holotype the spores were ellipsoid and measured *3.2–3.8 × 1.6–2 µm, but these seem to represent atypical spores; also a few oversized free spores (†6.5–6.8 × 1.4–1.6 µm, Pl. 141: 2a right) were observed which possibly arose from asci with a reduced spore number.

Anamorph. Brachyphoris-like conidia were abundantly seen on the natural substrate in the specimen from Norway (K. Homble pers. comm., Pl. 142: 3f). A similar conidium was found on the substrate in the German sample.

Ecology. *Hyalorbilia resinae* grew on old blackened resin of wounds, also on bark, of ± undecayed, dead or still-living twigs and branches of *Larix* and *Picea* in supratemperate humid,

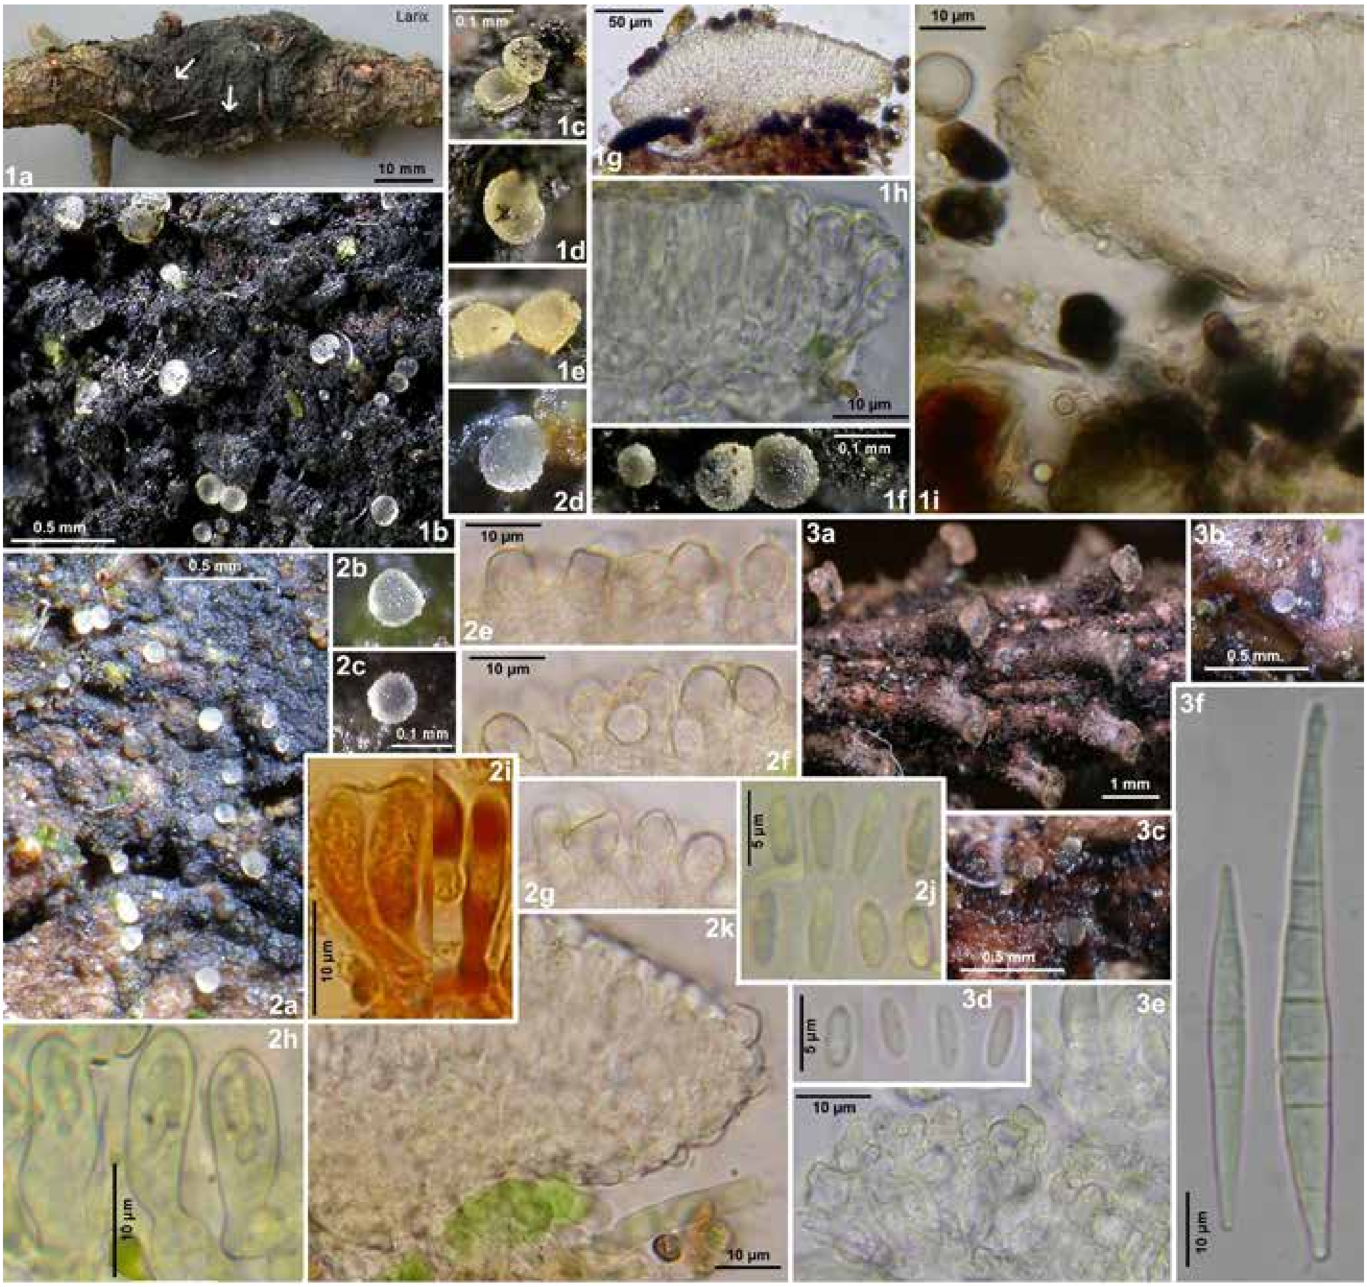

Plate 142. **1–3**: *Hyalorbilia resinae*. – **1a**. living *Larix* branch with blackened resinous wound; **3a**. fallen twig of *Picea abies;* **1b–f**, **2a–d**, **3b–c**. rehydrated apothecia; **1g**. apothecium in median section; **1h–i**, **2k**. id., marginal (and basal) part; **2e–g**, **3e**. marginal cortical cells (**2e–g** in top view); **2h–i**. asci (**2i** right immature); **2j**, **3d**. ascospores; **3f**. conidia (from substrate). – Living state, except for **1g**, **2e–g** (in H_2O); **1i**, **2k** (in KOH); **2i** (in KOH+IKI). – **2a**, **h**, **j**: phot. P. Perz; **3f**: phot. K. Homble. — **1a–i**. H.B. 8443a (holotype): Luxembourg, Mensdorf, on *Larix*; **2a–k**. H.B. 9169: Poland, Szczecin, on *Larix*; **3a–f**. H.B. 9687: Norway, Arendal, on *Picea*.

subcontinental central and in hemiboreal northern Europe. The vegetation includes shady mixed conifer forests. The sample from Luxembourg was on a still-attached xeric branch, whereas the others were on the ground, that from Poland even from a hygric habitat. Yet, also in the xeric collection the apothecia did not well withstand repeated rehydration.

Specimens included. **NORWAY**: **Aust-Agder**, 4.5 km WSW of Arendal, 1.5 km NW of Vrengen, Sagmyr, 50 m, twig of *Picea abies*, on bark, 9.V.2012, T.H. Dahl (H.B. 9687, anam. substr.). — **POLAND**: **West Pomerania**, 20 km SE of Szczecin, 1.7 km NE of Dobropole Gryfińskie, Puszcza Bukowa, 88 m, branch of *Larix*, on bark, 21.III.2009, P. Perz & G. Domian (H.B. 9169). — **GERMANY**: **Hessen**, Oberes Lahntal, ~5 km NW of Biedenkopf, ?1.5 km N of Wallau, Hainbachtal, 370 m, branch of *Larix*, on resin, 1.V.2000, L.G. Krieglsteiner & H.O. Baral (H.B. 6631a, anam. substr.). — **LUXEMBOURG**: **Gutland**, **Grevenmacher**, 14 km ENE of Luxembourg, 1.5 km E of Mensdorf, Widdebierg, 349 m, branch of *Larix*, on resin, 5.III.2007, G. Marson (ex H.B. 8443a, M-0276416, **holotype**).

Hyalorbilia herbicola Baral, Priou & Perz, **sp**. **nov**., MB 813458 — Pls 143–144

Etymology: named after the growth on herbaceous stems and culms.
Typification: France, Morbihan, La Gacilly, stem of *Reynoutria sachalinensis*, 12.VI.2008, J.P. Priou (ex H.B. 8880, M-0276410, holotype).

Latin diagnosis: Hyalorbiliae rotiferae *similis*, *sed asci et ascosporae angustiores*, *ascosporae subcylindricae. Habitat in caules uvidos herbarum in zona temperata humida Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.1–0.16 mm diam., 0.05–0.07 mm high (receptacle 0.03–0.04 mm), whitish, ± translucent, round, slightly non-gelatinous, scattered to gregarious; disc flat to slightly convex, margin indistinct, smooth; sessile or with a stipe 0.01–0.02 × 0.04–0.045 mm, superficial. **Asci** *(13.5–)15–28(–31) × 4.5–5.2 µm {2}, †18–24 × 3.8–4.2 µm {1}, 8-spored, spores *4-seriate, pars sporifera *10–14 µm long; **apex** (†) hemispherical to subconical; **base** unstalked or with short, thick stalk, with croziers {2}, with perforation. **Ascospores** *(3.2–)3.5–5(–5.5) × (1.1–)1.2–1.3(–1.4)

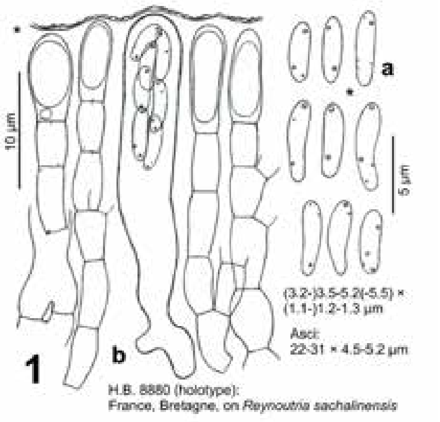

Plate 143. **1**: *Hyalorbilia herbicola*. – **a**. ascospores; **b**. asci and paraphyses.

µm {2}, subcylindrical to slightly ellipsoid-clavate, both ends rounded to obtuse, straight to slightly (rarely medium) curved; **SBs** *0.2–0.4 µm, globose, 1 at each end, also absent (perhaps always LBs?). **Paraphyses** apically uninflated, sometimes slightly clavate to ellipsoid or lageniform, terminal cells */†(4–)7–9(–10) × 2.5–3(–3.8) {1}, lower cells *(2–)3–6(–7.5) × 2–3 µm {1}, †1–5 × 2–3 µm {1}. **Medullary excipulum** ~15 µm thick, of thin-walled, non-gelatinized textura globulosa, very indistinctly delimited. **Ectal excipulum** at base of 25 µm thick, (†) thin-walled t. globulosa-angularis, cells *6–11 × 5–8.5 µm {1}, †5–9 × 4–7 µm {1}, at flanks of horizontal t. prismatica-angularis, cells †(3–)5–8 × 5–6 µm, 8–10 µm thick at margin, marginal cortical cells (*)/†(5–)8–10(–12) × 4–5.3(–6) µm {2}. **Anchoring hyphae** sparse, †1.5–3 µm wide, walls 0.2 µm thick {1}. **VBs** in paraphyses (very) slightly refractive, hyaline. **Exudate** over paraphyses 0.2–0.5 µm thick, very pale yellowish, continuous, finely rough, over excipulum smooth, pale yellow. **— ANAMORPH**: unknown (but see below).

Habitat: lying on the moist ground, on 1 cm thick stem of *Reynoutria sachalinensis* {1}, culm of *Phleum pratense* {1}, ungreyed but with some blackish patches, without algae. **Associated**: *Hyalorbilia ?juliae* {1}, *Lophiostoma* sp. {1}. **Desiccation tolerance**: only the spores survived for 1 day in the herbarium. **Altitude**: 4–570 m a.s.l. **Geology**: Upper Cretaceous calcareous clay-, marl- & limestone, flysch; quartzite & granite. **Phenology**: VI, VIII.

Taxonomic remarks. *Hyalorbilia herbicola* closely concurs with *H. rotifera*, from which it merely differs in distinctly narrower asci and ascospores, with the spore width not overlapping, also in growing on hygric herbaceous substrate. The spores of the lignicolous *H. oreadum* are also very similar though even slightly narrower. *H. oreadum* further differs from both taxa in distinctly larger and thicker apothecia, much larger, more elongate excipular cells at lower flanks, and distinctly longer terminal cells of paraphyses, also in the arrangement of the spores in the living asci (in *H. oreadum* strictly 4-seriate in two superimposed bundles). The latter feature is unknown for the type of *H. oreadum* because the spore arrangement is not stable in the dead state.

Variation. The collection on *Phleum* differs from that on *Reynoutria* merely in slightly shorter spores (*3–4.3 × 1.1–1.3 µm, Pl. 144: 1d).

Not included collections. More fusoid were ascospores in a British sample by N. Aplin (pers. comm.) on a dead standing stem of *Digitalis* (*4.3–5.8 × 1.2–1.5 µm, apothecia up to 0.3 mm diam., IVV: 18.VI.2016) and two Serbian samples by D. Savić (pers. comm.) on stems of *Centaurea* and indet. *Apiaceae* (*3.8–4.9 × 1.1–1.3 µm, apothecia 0.08–0.22 mm, partially with a finely crenulate margin due to broad protruding marginal cells, IVV: 11.VI.2019, I.VII.2019). A single apothecium (0.16 mm diam) on angiosperm bark from Ethiopia (IVV: H.B. 9246b) resembles *H. herbicola*, but differs in slightly wider asci (†17–18 × 4–4.5 µm) and spores [*3.5–4.5(–5) × 1.3–1.5 µm, without SBs] and appears intermediate to *H. rotifera*.

Anamorph. A single brachyphoris-like conidium was found on *Phleum*: ± straight, narrowly fusoid, *63 × 2.3 µm, with ?7 septa. Very similar conidia were observed four times near apothecia of *H. rotifera*.

Ecology. *Hyalorbilia herbicola* was detected on hygric herbaceous mono- and dicot stems lying on the moist ground, in mesotemperate atlantic to cold-temperate subcontinental humid Europe. The type locality is a moist *Reynoutria* stand, while the paratype derives from a wet meadow close to a spring. On *Phleum* the apothecia grew very close to perithecia of a *Lophiostoma*. The not included collection from mesotemperate atlantic humid England was on a standing stem of *Digitalis* 10 cm above the ground, in close association with a *Pyrenopeziza*, in a tall herb vegetation on the bank of a pond. That from Ethiopia grew in association with *Orbilia aethiopica* on angiosperm bark in a warm-temperate humid, evergreen afromontane forest in the central plateau of the Ethiopian highlands.

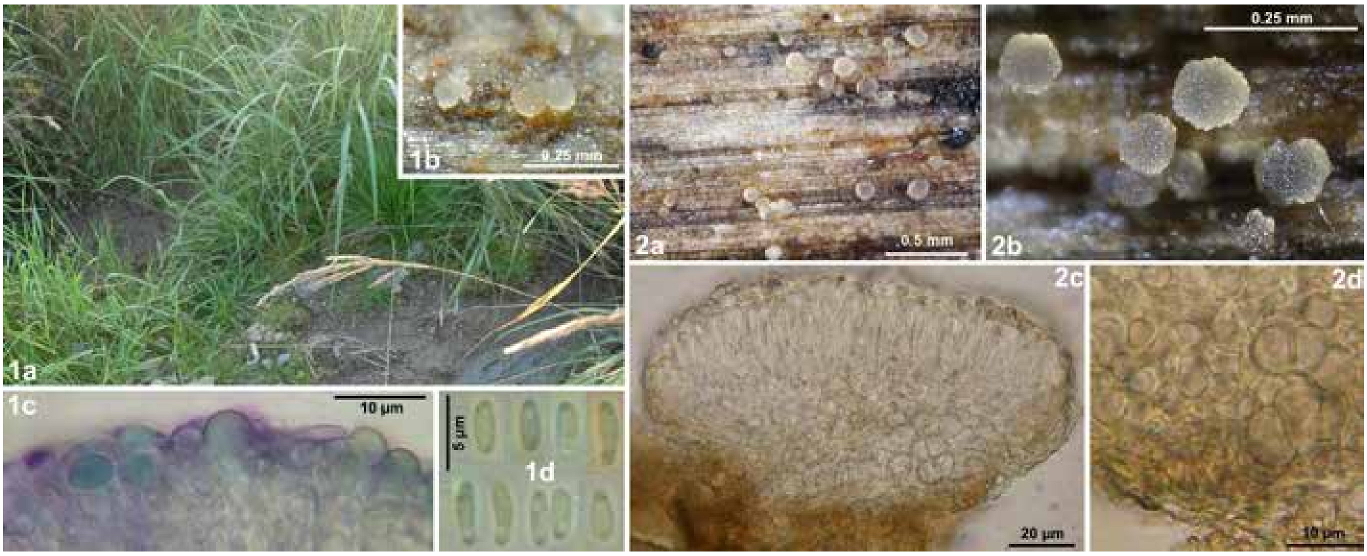

Plate 144. **1–2**: *Hyalorbilia herbicola*. – **1a**. wet meadow with *Phleum pratense*; **1b**, **2a–b**. fresh apothecia; **2c**. apothecium in median section; **2d**. id., central part in median section; **1c**. margin in top view; **1d**. ascospores. – Living state (**1c** in CRB). – **1a–d**: phot. Savić (FG-1098, doc. vid.). — **ETHIOPIA**: **Oromia**, 22 km WSW of Addis Ababa, 10 km NW of Sebeta, Menagesha Suba State Forest, 2500 m, branch of indet. angiosperm, on bark, 22.XII.2009, U. Lindemann (H.B. 9246b ø).

Hyalorbilia rotifera Baral & E. Batten, **sp. nov.**, MB 813459 — Pls 145–146

Etymology: *rotifera*: referring to the presence of an infected rotifer close to the apothecia in the holotype.

Typification: Great Britain, Suffolk, Halesworth, branches of *Ulex europaeus*, 27.III.2004, S.M. Francis & E. Batten (ex E.B. 4504 & ex H.B. 7507a, M-0276417, holotype).

Latin diagnosis: Hyalorbiliae subfusisporae *similis*, *sed apothecia minora*, *plerumque alba*, *ascosporae minores*, *partim basaliter curvatae*, *in statu vivo corpuscula refringentia plerumque carentes.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.05–)0.08–0.16(–0.19) mm diam., 0.05–0.06 mm high (receptacle 0.035 mm), whitish, sometimes very pale amber-yellowish, translucent, round, slightly gelatinous, scattered to gregarious; disc flat, margin thin, not protruding, smooth; sessile or often with indistinct obconical stipe, superficial; dry pale yellowish-cream or rosaceous. **Asci** *19–30 {5} × (4.8–)5.2–5.8(–6.2) µm {5}, †15–24(–32) × (4.2–)4.5–5.5(–6) µm {6}, 8-spored, spores *3–4-seriate, pars sporifera *15 → 11–12 µm long; **apex** (†) hemispherical or obtuse-subconical; **base** with or without medium long, thick, flexuous stalk, with croziers {4} (some with perforation). **Ascospores** *(4–)4.5–5.5(–6) × (1.4–)1.6–1.8(–2) µm {4}, †(3.5–)4.5–5.5(–6) × 1.3–1.7 µm {5}, (fusiform- to) (ellipsoid-)fusoid(-clavate), apex obtuse to subacute, base slightly to sometimes strongly attenuated, partially inequilateral or slightly curved towards base; **SBs** consistently absent {4}, rarely present {1}, minute, globose; with a few minute, rarely medium-sized LBs towards each end. **Paraphyses** apically uninflated, sometimes slightly to medium clavate-capitate, terminal cells †5.5–14 × (1.8–)2–2.5(–2.8) µm {2}, lower cells †3.5–7 × 1.8–2 µm {2}; not or rarely branched at upper septum. **Medullary excipulum** 10 µm thick, non-gelatinized, of medium loose, horizontally oriented textura prismatica-porrecta, medium sharply delimited. **Ectal excipulum** near base of (†) not or slightly gelatinized, indistinctly vertically oriented t. angularis, 30 µm thick, cells †8–11 × 5–8 µm {1}; at flanks of horizontal t. prismatica-globulosa, cells *6–11 × 4–10 µm, 10 µm thick near margin, marginal cortical cells */†(6–)7–12(–14) × (3–)4–8(–9) µm {6}, clavate to vesiculous, thin-walled. **Anchoring hyphae** sparse to medium abundant, */†1.8–3 µm wide, walls 0.2 µm thick {1}. **Exudate** over paraphyses 0.1–0.3 µm thick, continuous, smooth to finely rough, sometimes with scattered, loosely adhering granules; over margin and flanks 0.1 µm, smooth. — **ANAMORPH**: brachyphoris-like (presumed, from natural substrate {4}). **Conidiophores** not observed. **Conidia** unbranched, narrowly fusoid, slightly to medium curved (falcate to helicoid), especially towards ends, *44–60 {1} or 62–77.5 {1} × 2.1–2.5(–3) µm {2}, †44–56 × 1.6–2 µm {3}, ~3–6-septate, with several minute LBs in each cell, sometimes also with larger guttules.

Habitat: collected 0.5–2 m above the ground, corticated or partially decorticated, 7–38 mm thick branches or 5–30 cm thick standing trunks of *Cornus* ?*sanguinea* {1}, *Corylus* ?*colurna* {1}, *Fagus sylvatica* {5}, *Salix* sp. {2}, *S. caprea* {1}, *S.* ?*cinerea* {1}, *Sambucus nigra* {1}, *Ulex europaeus* {1}, on slightly to strongly decayed bark {12} (periderm {1} and bast {4}), rarely on wood {1}, often on inner surface or on edges of detaching bark, also in old scars of side twigs, slightly greyed to strongly blackened, with or without a few to many green algae. **Associated**: *Cryptodiscus* sp. {1}, *Glyphium elatum* {1}, *Hyalorbilia erythrostigma* {2}, *H. juliae* {2}, *H. subfusispora* {2}, *Hysteropatella elliptica* {1}, *Karstenia idaei* {1}, *Lachnum* sp. {1}, *Melanomma pulvis-pyrius* {1}, *Mollisia* sp. {2}, *Orbilia aristata* {2}, *O. auricolor* {1}, *Pyrenopeziza* sp. {1}, *Unguiculariopsis* ?*rehmii* {1}. **Desiccation tolerance**: mature asci still viable for at least 6 days. **Altitude**: 15–417 m a.s.l. **Geology**: Buntsandstein, Keuper (Stubensandstein), Lower Jurassic sandstone & marl, Pleistocene sand & gravel. **Phenology**: I–V, IX, XI.

Taxonomic remarks. *Hyalorbilia rotifera* is characterized by very small, usually whitish apothecia and small, (ellipsoid-) fusoid(-clavate) ascospores. From the similar *H. subfusispora* with partially larger and more chlorinaceous apothecia, *H. rotifera* differs in shorter and narrower spores which are sometimes slightly curved near the base. *H. latispora* differs in wider, broadly fusoid spores, and *H. resinae* in partially narrower spores besides a tendency to strongly inflated paraphyses and in growing on coniferous substrate. *H. oreadum* has larger apothecia and narrower spores. For the similar *H. herbicola* and *H. hergiswiliana* see there.

Variation. In the typical collections of *H. rotifera* (on bark of *Ulex* and *Fagus*) spore bodies could not be found in the living spores (all drops were KOH-resistant). In the sample on

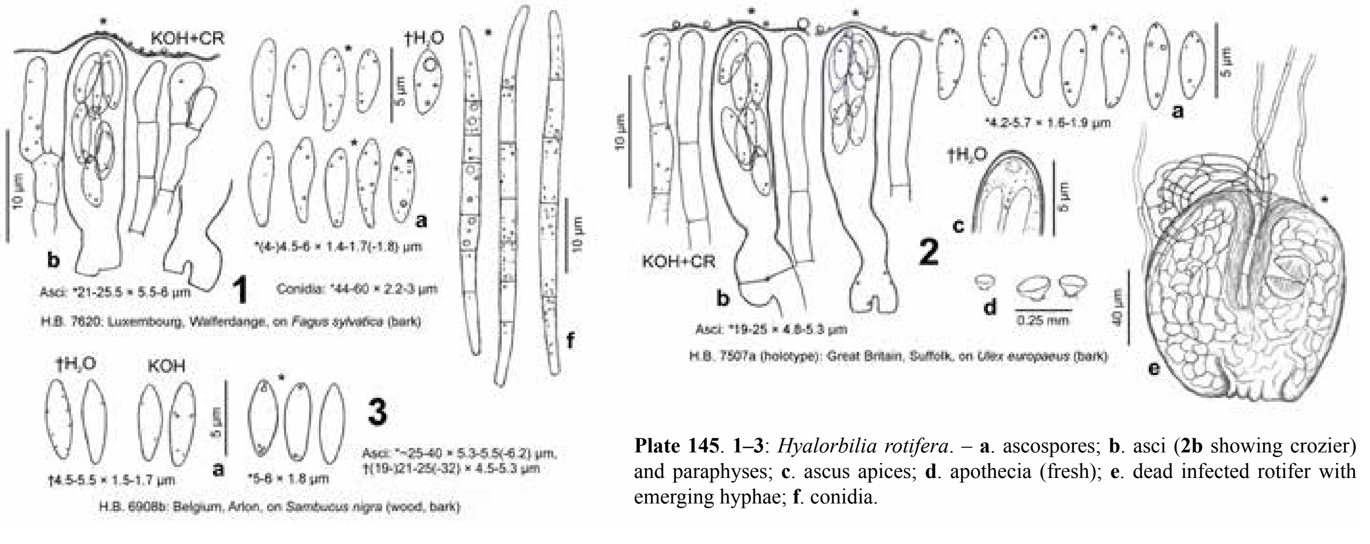

Plate 145. **1–3**: *Hyalorbilia rotifera*. – **a**. ascospores; **b**. asci (**2b** showing crozier) and paraphyses; **c**. ascus apices; **d**. apothecia (fresh); **e**. dead infected rotifer with emerging hyphae; **f**. conidia.

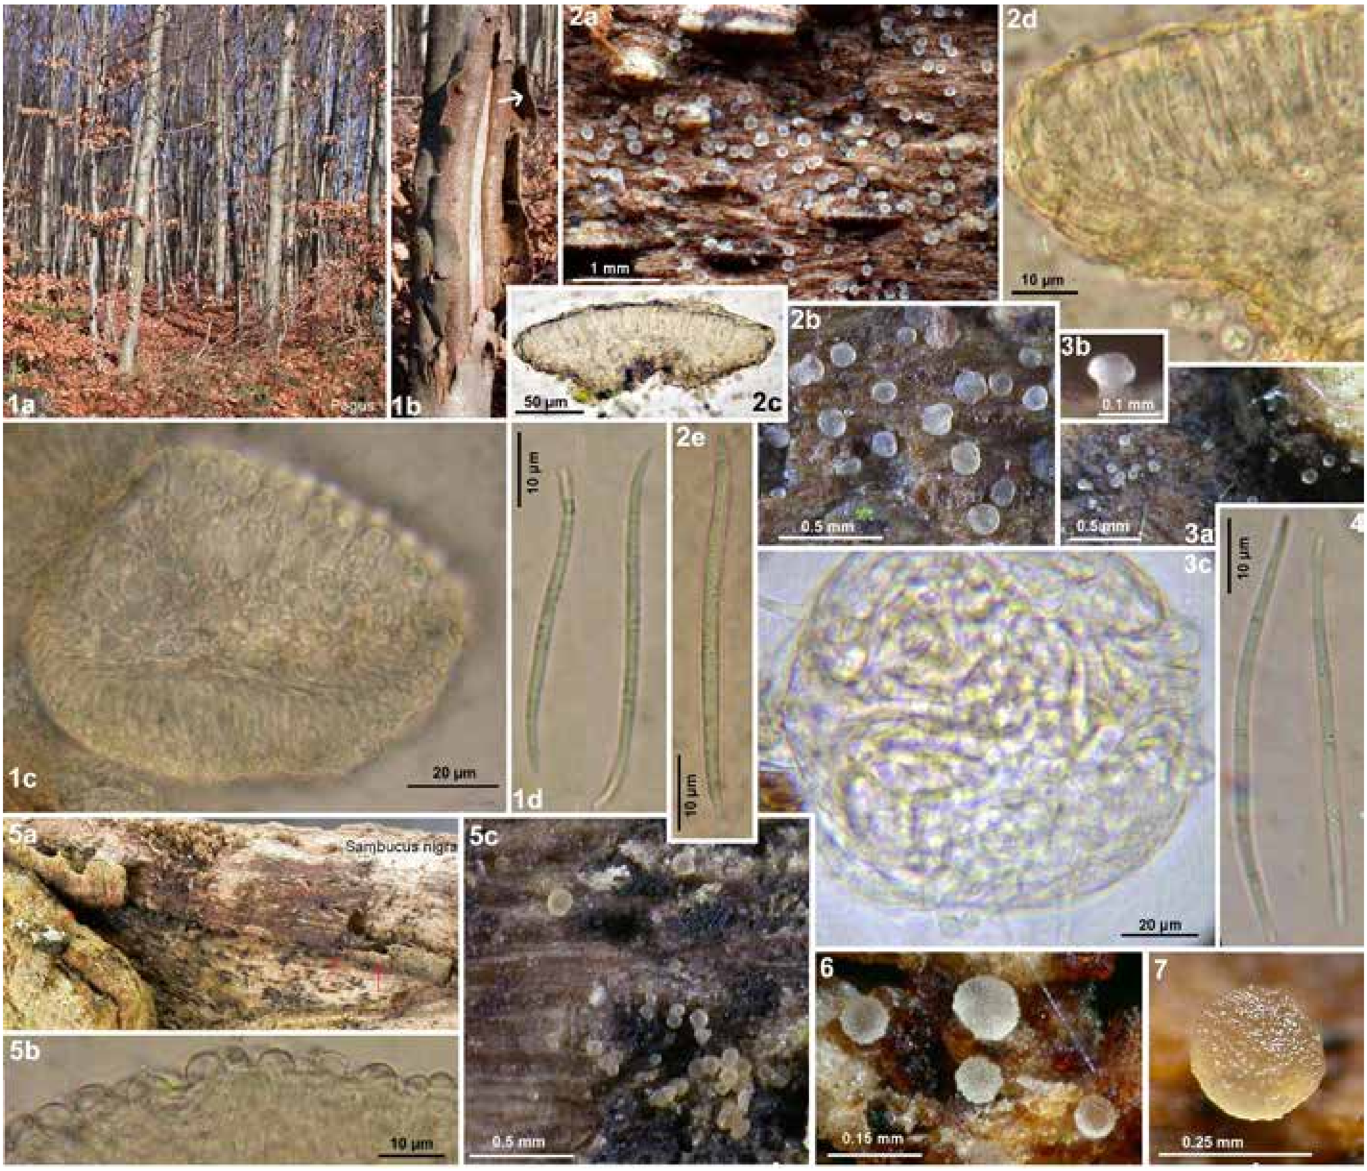

Plate 146. **1–7**: *Hyalorbilia rotifera*. – **1a**. young beech forest; **1b**. living *Fagus* with large wound; **5a**. decorticated xeric branch of *Sambucus nigra*; **2a–b**, **6**, **7**, **5c**. rehydrated apothecia; **3a–b**. fresh apothecia; **2c–d**. apothecia in median section; **1c**. apothecium in top view; **5b**. margin in top view; **1d**, **2e**, **4**. conidia from substrate; **3c**. dead rotifer colonized by assimilative hyphae. – Living state (in **1c** & **2d** only some asci and spores alive) except for **1d** (in H_2O); **4**, **5b** (in KOH). — **1a–d**. H.B. 7627b: Luxembourg, Walferdange, on *Fagus*; **2a–e**. H.B. 7620a: ibid., on *Fagus*; **3a–c**. H.B. 7507a (holotype): Great Britain, Suffolk, on *Ulex*; **4**. H.B. 6988b: Luxembourg, Ettelbruck, on *Salix*; **5a–c**. H.B. 6908b: Belgium, on *Sambucus*; **6**. 3.I.2010: Luxembourg, Waldhaff, on *Fagus*; **7**. 3.II.2007: ibid., Echternach, on *Fagus*.

wood of *Sambucus* a minute SB was present at each spore end and the asci were extraordinarily long. Here and in samples on bark of *Cornus* and *Salix* the spores were consistently straight and homopolar. In the type collection 4 free spores were figured by E. Batten (IVV: H.B. 7507a), all with a single elongate spore body ~0.8 × 0.2 µm in the wider end, but no such body could be observed when the material was received in the fresh and living state.

Among the samples from which sequences were gained, only that on *Corylus* bark was microscopically studied (IVV: 22.I.2019). It fits in ascus (*24–29 × 5.2–5.3 µm) and spore size (*4–5 × 1.7–2 µm inside living asci, indistinctly heteropolar, without SBs), but the conidia are with *62–77.5 × 2.1–2.3 µm longer than in the other four samples in which conidia were seen, although they show the same number of septa (3–6).

Anamorph. The flexuous, slender conidia of the presumed anamorph of *H. rotifera* (Pl. 145: 1f; 146: 1d, 2e, 4; see also IVV) resemble those of *B. helminthodes*, which differs in larger, more straight conidia (53–84 × 2.8–3.7 µm) and is known to infect oo- and zygospores.

In the type collection of *H. rotifera* a single infected rotifer was found close to an apothecium. The interior of the rotifer was colonized by *5–8 µm wide assimilative hyphae similar as in *Lecophagus*, but the emerging and external hyphae being much narrower (*2.5–3.5 µm) than in *Lecophagus*. Very probably these hyphae belong to the adjacent *Hyalorbilia* apothecia. That they belong to an orbiliaceous fungus is supported by the fact that their wall surface stains lilac in CRB.

Phylogeny. Sequences of *H. rotifera* were obtained from apothecia of two samples from Luxembourg, on *Salix* and *Corylus*, comprising ITS and LSU, one also SSU (V7–9). In the ITS they fully concur except for 1 nt in ITS2, but they differ in 1 nt in LSU D1 and 3 nt in LSU D2 (0.7 %). Another sequence was made from an undocumented sample (G.M. 2014-11-28.1) which by microscopy belonged to *H. subfusispora* (G.M. 2014-11-28.2). This deviates from the above by 5.2–5.4 % in

ITS but only 0.3–0.7 % in LSU. We presume here a mixture of two *Hyalorbilia* species. In all three sequences the S1506 intron is absent.

In our combined analysis (Phyl. 6), *H. rotifera* clustered in the strongly supported *Vermispora* clade, and here with boreal to subarctic North American environmental clones (V11–12) in a likewise strongly supported subclade. The three *H. rotifera* sequences formed a supported clade in NJ analyses of ITS, LSU, or ITS+LSU (not shown), which clustered sister to most of the environmental clones which include also some from alpine central Europe. *H. rotifera* shows to all these clones an 8–10.5 % ITS distance, but also among the clones a distance of up to 6.5–13.5 % occurs. When analysing LSU (D1–D2), *H. rotifera* showed a 1–3 % distance to these clones. Its ITS distance to *H. hergiswiliana* lies at ~30 %, and to *H. subfusispora* at 33–34 %.

Ecology. The sparse to abundant apothecia of *Hyalorbilia rotifera* were found on ± rotten bark (rarely wood) of dead xeric branches of various angiosperm trees and shrubs, also on the inner surface of bark detaching from large wounds of living trunks of *Fagus*. The collections are from cold-temperate humid, planar to colline areas in atlantic northwestern and subcontinental central Europe.

Specimens included. **GREAT BRITAIN**: **East England**, **Suffolk**, 4 km ESE of Halesworth, 0.4 km NNW of Wenhaston, Bicker's Heath, 15 m, branches of *Ulex europaeus*, on bark, 27.III.2004, S.M. Francis & E. Batten (E.B. 4504, ex H.B. 7507a, M-0276417, **holotype**). — **BELGIUM**: **Wallonie**, **Luxembourg**, 8 km SE of Arlon, 0.7 km SE of Sterpenich, 325 m, branch of *Sambucus nigra*, on wood & bark, 23.IV.2001, H.O. Baral (H.B. 6908b, anam. substr.). — **LUXEMBOURG**: **L'Oesling**, **Redange**, 10 km W of Ettelbruck, 1.8 km NW of Grosbous, Bruch (an der Wark), 380 m, branch of *Salix ?cinerea*, on bark, 27.V.2001, G. Marson (H.B. 6988b, anam. substr.). – **Gutland**, **Capellen**, 6.5 km ESE of Arlon, 1.3 km NW of Steinfort, Aechels, 330 m, branch of *Salix caprea*, on bark, 5.V.1998, H.O. Baral (ø). – **Luxembourg**, 6 km NNE of Luxembourg, 2 km E of Walferdange, Gréngewald, Croix de la Femme Morte, 412 m, trunk of *Fagus sylvatica*, on bark, 20.XI.2004, G. Marson (H.B. 7620a, anam. substr.). – ibid., trunk of *F. sylvatica*, on bark, 25.XI.2004, G. Marson (H.B. 7627b, anam. substr.). – 7 km NE of Luxembourg, Waldhaff, 417 m, trunk of *F. sylvatica*, on bark, 3.I.2010, G. Marson (ø). – 5.3 km NE of Luxembourg, 3 km NE of Kirchberg, 347 m, trunk of *Fagus sylvatica*, on bark, 28.XI.2014, G. Marson (G.M. 2014-11-28.1, non vid., sq.: MN15140). – 5 km SE of Luxembourg, 1.5 km E of Itzig, Reimeschbaach, 297 m, branch of *Salix*, on bark, 17.X.2015, G. Marson (G.M. 2015-10-17.1, non vid., sq.: MK493151). – ibid., branch of *Corylus ?colurna*, on bark and old pyrenomycete, 22.I.2019, G. Marson (G.M. 2019-01-22.1, sq.: MN151405). – **Echternach**, 10 km WNW of Echternach, 1.2 km SW of Beaufort (Befort), Längt, 340 m, trunk of *F. sylvatica*, on bark, 3.II.2007, G. Marson (ø). — **GERMANY**: **Baden-Württemberg**, 3 km NE of Tübingen, 1 km NE of Lustnau, Stauden, 400 m, branch of *Cornus ?sanguinea*, on bark, 15.IX.2001, H.O. Baral (ø).

Hyalorbilia fusarina (Burghouts & W. Gams) E. Weber & Baral, **comb. nov**., MB 830794 — Pl. 24: b

Basionym: *Vermispora fusarina* Burghouts & W. Gams, Mem. N. Y. bot. Gdn 49: 58 (1989) (Pl. 24: b)

Etymology: named after the phragmoconidia reminiscent of macroconidia of *Fusarium*.

Typification: Netherlands, Assen, on eggs of *Globodera pallida*, I.1984, Th. Burghouts (CBS 382.84, ex-type culture; dried material: holotype)

Description: — **TELEOMORPH**: unknown. — **ANAMORPH**: vermispora-like (data from Burghouts & Gams 1989 and Chen et al. 2007c: fig. 4). **Mycelial hyphae** 1–3 µm wide, hyaline. **Conidiophores** not differentiated from mycelial hyphae, arising mostly as lateral branches, simple or branched, repeatedly geniculate by proliferating in a sympodial manner, 17–80 µm long, 2.5–3 µm wide near the base, ending in a truncate, 1.5–2.5 µm wide scar. **Conidia** fusiform, curved and slightly beaked at the apex, 30–50(–55) × (3.5–)4–4.5(–5) µm, (2–)3(–4)-septate. Chlamydospores absent.

Habitat: Agricultural soil, isolated from nematode eggs of *Globodera pallida*. Known only from temperate subatlantic Europe.

Phylogeny. ITS sequences from three strains of the type collection were available for *H. fusarina*. A distance of 1.5–2 % is found among them although they were all gained from the same isolate. Considering this infraspecific variation which might include sequencing errors, the distance of 2.5–4.5 % between *H. fusarina* and *H. leguminacea* is comparatively low. In contrast, *H. fusarioides* differs from these three species by ~21–24 % and various gaps which cause strong optical divergence in the alignment. The 5.8S distance between the *Vermispora* clade and other clades of *Hyalorbilia* or other genera is surprisingly high, e.g., 3 % to *Lilapila*, 4.5–5 % to *Amphosoma*, 5–7 % to *Hyalorbilia* p.p.maj., and 6.5–7.5 % to *Lecophagus*.

Sequences of two strains of *H. fusarina* (CBS 382.84, 383.84A) comprise LSU D1–D4 and are identical in the D1–D3. Their D1–D3 distance to *H. leguminacea* is 0.9 % and to *H. spermatophaga* 2.5 %.

Specimens included. **NETHERLANDS**: **Drenthe**, Assen, isolated from eggs of *Globodera pallida* buried in agricultural soil, I.1984, Th. Burghouts (CBS 382.84, ex-type culture, conid. isol., doc. vid.; dried material: **holotype**; CBS 383.84A, CBS 383.84B), sq.: DQ494377– DQ494379, HQ110699–HQ110700.

Hyalorbilia leguminacea (Juan Chen, L.L. Xu, Bin Liu & Xing Z. Liu) E. Weber & Baral, **comb. nov**., MB 830795 — Pl. 24: a

Basionym: *Vermispora leguminacea* Juan Chen, L.L. Xu, Bin Liu & Xing Z. Liu, Fungal Diversity 26(1): 136 (2007)

Etymology: named after the pod-shaped conidia resembling fruits of legumes.

Typification: China, Fujian, soil, 2003, X.Z. Liu (HMAS 140512, holotype; ex-type culture: CGMCC 6.0291)

Description: — **TELEOMORPH**: unknown. — **Anamorph**: vermispora-like (data from Chen et al., 2007c: fig. 6). **Mycelial hyphae** 1.5–3 µm wide, hyaline. **Conidiophores** simple, ± straight, slightly geniculate by sympodial proliferation, 26–104 µm long, 1.5–3 µm wide near the base, gradually narrowed to 1–1.5 µm towards the apex. **Conidia** hyaline, cylindric-fusoid, pod-shaped, straight to slightly curved, *20–34 × 4–5 µm, (1–)3(–5)-septate.

Habitat: Isolated from soil. Known only from China.

H. leguminacea resembles *H. fusarina* but has distinctly shorter, more pod-shaped conidia. The scale bars in Chen et al. (2017c) are sometimes highly erroneous, those in fig. 6 E–F being probably the most reliable ones.

Phylogeny. ITS Sequences of the holo- and paratype of *H. leguminacea* were gained by Liu et al. (2005b, as *V. fusarina*) and also by Chen et al. (2007a), partially misidentified as *V. fusarina*. The five available ITS Sequences derive very probably from only three strains; also one sequence of LSU D1–D3 exists for one strain (AS6.0291). A distance of 0.5–1.2 % is found among the five strains, although the *H. leguminacea* strains derive from only three isolates. The S1506 intron is absent in two sequences of *H. leguminacea* (AY776169, AY776170), according to the used ITS5 primer.

Specimens included. **CHINA**, **Fujian**, from soil, 2003, X.Z. Liu (HMAS 140512, **holotype**; ex-type culture: CGMCC 6.0291, conid. isol., doc. vid., sq.: DQ494376, HQ110701). – ibid. (HMAS 140513, **paratype**; CGMCC 6.0290; sq.: DQ494375). (strains 786 = AY776169 and 333 = AY776170 probably also from holo-/paratype). – ?**Beijing**, undated, Yang et al. 2007 (CGMCC 3.6757, YXJ13-5, non vid., sq.: AY773447).

Hyalorbilia spermatophaga (Drechsler) E. Weber & Baral, **comb. nov.**, MB 830796 — Pl. 24: d

Basionym: *Dactylella spermatophaga* Drechsler, Phytopathology 28(1): 91 (1938)

≡ *Vermispora spermatophaga* (Drechsler) Juan Chen, L.L. Xu, Bin Liu & Xing Z. Liu, Fungal Diversity 26(1): 124 (2007)

Etymology: named after the habit of the fungus to consume oospores of oomycetes ('eating seeds').

Typification: USA, Maryland, Beltsville and Virginia, Arlington, on decaying plant remains, undated, C. Drechsler (holotype: illustration in Drechsler 1938)

Description: — **TELEOMORPH**: unknown. — **ANAMORPH**: vermispora-like (data from Drechsler 1938 and Chen et al. 2007c: fig. 7). **Mycelial hyphae** 1–2 µm wide, hyaline. **Conidiophores** hyaline, septate, simple or somewhat branched, slightly geniculate by sympodial proliferation, 27–75 µm long, 2.5–4 µm wide at the base, tapering to 1–2 µm at the apex. **Conidia** hyaline, fusiform, truncate at the base, straight or often slightly to medium curved at narrowly rounded apex, *(25–)35–65 × 3.5–5.5 µm, (2–)3(–4)-septate.

Habitat: Isolated from decaying plant remains or soil, parasitizing many species of *Pythiaceae* (mostly *Pythium* and *Phytophthora*).

Phylogeny. A sequence of the ITS and LSU region was available for a non-type strain of *H. spermatophaga* (CBS 255.76), which shows an ITS distance of 12.5–13 % to *H. fusarina* and 13 % to *H. leguminacea*. In *H. spermatophaga* the presence or absence of the intron is unknown because the ITS1 primer was used.

Specimens included. **USA**: **Maryland**, Beltsville, and **Virginia**, Arlington, decaying plant remains, on hyphae, conidia, zoosporangia, oogonia, and oospores of *Pythium* and *Phytophthora*, undated, C. Drechsler (**holotype** [illustration in C. Drechsler 1938], conid. isol., doc. vid.). – **Michigan**, East Lansing, on oospores of *Phytophthora megasperma* var. *sojae*, isol. by B. Sneh (CBS 255.76, non vid., sq.: DQ494374, HQ110698).

Hyalorbilia fusarioides (D.C. Harris) E. Weber & Baral, **comb. nov.**, MB 830797 — Pl. 17

Basionym: *Microdochium fusarioides* D.C. Harris, Trans. Br. mycol. Soc. 84(2): 358 (1985)

≡ *Microdochiella fusarioides* (D.C. Harris) M. Hern.-Restr. & Crous, in Hernández-Restrepo, Groenewald & Crous, Persoonia 36: 62 (2015) [2016]

Etymology: named after the conidium shape resembling macroconidia of *Fusarium*.

Typification: Great Britain, Kent, East Malling Research Station, *Malus* leaves on and in soil, on oospores of *Phytophthora syringae*, X.1980, D.C. Harris (IMI 218715, holotype; ex-type culture CBS 741.83).

Description: — **TELEOMORPH**: unknown. — **ANAMORPH**: vermispora-like (data from Harris 1995 and Hernández-Restrepo et al. 2015). **Mycelial hyphae** 1–2 µm wide, hyaline. **Conidiophores** simple or branched, septate, geniculate by sympodial proliferation, ~7–100(–150) µm long, 2–3 µm wide, ~1.5 µm at apex. **Conidia** hyaline, narrowly fusiform, tapered towards narrowly rounded apex and truncate base, slightly to medium curved (falcate), *30–60 × 2–3 µm, (1–)3(–5)-septate, dry but with a droplet of moisture at the mid-point of each conidium. **Chlamydospores** subglobose to ellipsoid, forming intercalary chains.

Habitat: Isolated from apple leaves on and in soil, parasitic on oospores of oomycetes (Harris 1985); DNA extract from maize roots. Known from temperate humid Great Britain and Germany.

Phylogeny. Sequences of three CBS cultures of the type isolate from apple leaves in East Malling (Kent, Great Britain) were gained by Hernandez-Restrepo et al. (2015), comprising ITS and LSU (D1–D3). Three 'uncultured *Vermispora*' DNA extracts from roots of maize near Göttingen (Niedersachsen, Germany) comprise ITS and LSU (D1). The S1506 intron is absent in all six sequences which are identical in their overlapping part, except for 1 nt in the ITS1 in two of the DNA extracts, therefore, they belong to *H. fusarioides*. Three further uncultured clones from the same maize field clustered also in the *Vermispora* clade but distant from the above: two (V1) in a clade with the three former *Vermispora* spp. (*H. fusarina*, *H. leguminacea*, *H. spermatophaga*), and one (V13) in a clade with clones V11–V12 and *H. rotifera* (see Phyl. 6, see also S6 & S7).

H. fusarioides shows a high ITS distance to the three former *Vermispora* species, ranging at ~21–24 %, compared to 2.5–13 % among the latter, although in the 5.8S region it differs from them by only 1 nt (pos. 142, Tab. 18). In the LSU D1–D3 *H. fusarioides* differs from the three former *Vermispora* species by 6.5–7.3 % (8.2–8.7 % in D1–D2), compared to 0.9–2.5 % or 1.2–2.6 % among the latter, respectively.

Specimens included. **GREAT BRITAIN**: **South East England**, **Kent**, 6 km WNW of Maidstone, East Malling Research Station, apple orchard, 25 m, *Malus* leaves on and in soil, on oospores of *Phytophthora syringae*, X.1980, D.C. Harris (IMI 218715, **holotype**, CBS 740.83, 741.83 [ex-type], 742.83, sq.: KP858975, KP858976, KP858977, KP859039, KP859041). — **GERMANY**: **Niedersachsen**, 4.5 km NW of Göttingen, Holtensen, 158 m, maize field, soil around roots of *Zea mays*, 2010–2011 (as Uncultured *Vermispora*, HG936894, HG936895, HG936896).

= *Pseudotripoconidium* Z.F. Yu & K.Q. Zhang, in Yu et al., Mycologia 103(1): 168 (2011) – Type species: *P. sinense* Z.F. Yu & K.Q. Zhang (series *Pseudotripoconidium*)

Etymology: see under the respective series.

Description: — **TELEOMORPH**: **Apothecia** hydrated ((0.07–)) (0.1–)0.2–2(–4)((–7.5)) mm diam., variously reddish-coloured (often orange or brick-red, also rose to pink), more rarely hyaline, yellow, blood-red, brownish or olive-black, translucent or not, round, sometimes ellipsoid or with undulating margin, soft-fleshed, rarely distinctly gelatinous, superficial to erumpent; disc ± flat, often also concave or convex, margin usually distinct, not or slightly, sometimes strongly protruding, smooth or finely crenulate, sometimes with short to long whitish teeth or hairs, developing gymnohymenial or sometimes cleistohymenial; exterior ± concolorous, broadly sessile to subsessile, also with an obconical to cylindrical stipe which is very rarely higher than wide. **Asci** *(24–)30–100(–140) × (2.8–)4–11(–15.3) µm, 8- up to 128-spored, spores uni- up to multiseriate, usually most or all asci with a varying percentage of the spores with an inverse orientation, usually the lower spores inverted, rarely the upper spores; **apex** (†) ± hemispherical in all viewing directions, or strongly truncate in front view (often with ± distinct shoulders) while hemispherical in profile view, thin-walled or with a distinct apical wall thickening †(0.4–)0.7–3(–6) µm thick (mostly with apical chamber), spores at maturity dehydrated and agglutinated to form a single body that is forcibly ejected through a slit-like apical pore; **base** ± narrowed to a thin or thick, often ± flexuous stalk of very variable length, usually forked at the base into 2(–3) branches (Y-, T-, L-, h- or H-shaped), some asci seemingly non-furcate (with one branch reduced to a septum at the lateral part of the ascus stalk). **Ascospores** *(1.8–)2.5–20(–30) × (0.6–)1–4(–6) µm, homopolar or slightly to strongly heteropolar in shape, sometimes with a distinct basal tail, highly diverse in shape (cylindrical, subulate, clavate, fusiform, ellipsoid, ovoid, globose, triangular, heart-shaped, sperm-shaped), straight or slightly to very strongly curved (reniform, falcate, geniculate, or helicoid), hyaline, smooth (very rarely warted), non-septate and uninucleate (very rarely 1–2-septate inside living asci); each spore containing a medium to strongly refractive **spore body** (SB) attached to the spore apex (rarely at subapex or lateral wall), SBs variously shaped (lens- to plug-shaped, globose, tear-shaped, ampulliform, rod-shaped, vermiform, filiform), either broadly attached to spore wall or apically narrowed to a wide or small point, sometimes with a fine, short to long, partially very delicate and then ± invisible filum, straight or flexuous to helicoid, sometimes uncinate; usually with a few small LBs (lipid content very low to low, very rarely medium); overmature spores 0–1-septate, vermiform SBs then strongly contracted and inflated, sometimes with a high lipid content (multiguttulate). **Paraphyses** apically uninflated or slightly to very strongly capitate or clavate, sometimes spathulate, lageniform, mammiform, or lanceolate, terminal cells either of ± equal length (desiccation-tolerant taxa), or distinctly or much longer than lower cells (predominantly desiccation-sensitive taxa), usually equalling or ± exceeding the dead asci, but often surmounted by the living asci; generally branched in their lower part, unbranched in upper part if with long terminal cells but rarely or frequently branched if with short terminal cells, anastomoses usually frequent in lower part, always absent in upper part. **Subhymenium** rarely clearly separated from the medullary excipulum, composed of anastomosing basal cells of paraphyses tightly woven with the branches of the furcate ascus bases. **Medullary excipulum** hyaline or very pale reddish, rarely olivaceous-brown, 10–20 up to 70–150(–200) µm thick, of loose to dense, thin-walled, rarely distinctly gelatinized textura intricata, composed of *(1.5–)2–3(–4)((–6)) µm wide hyphae, intermingled with some or many inflated globose to prismatic cells *5–15(–20)((–30)) × (4–)6–10(–16)((–27)), either sharply delimited from ectal excipulum or indistinctly so (if inflated cells very abundant), at lower or at least mid flanks sometimes forming a thin delimiting layer of t. porrecta. **Ectal excipulum** hyaline to very pale reddish, of non- or sometimes slightly to medium gelatinized, usually vertically or indistinctly oriented t. globulosa-angularis(-prismatica), either extending from base to margin, or replaced at mid flanks or margin by t. prismatica-porrecta oriented at a 0–50° angle to the surface, or rarely from base to margin of horizontally oriented t. (globulosa-)angularis(-prismatica), (10–)15–25 or usually 30–60 or up to 70–120(–220) µm thick near base, 10–30(–50) µm thick near margin, marginal cells thin- or sometimes thick-walled; **glassy processes** absent, less often present, 1–10 up to 30–100(–200) × (2–)3–4(–5) µm, often stratified, low- to high-refractive, solid, **hairs** rarely present, 10–100 or up to 200(–300) × (3–)4–7(–9.5) µm, cylindrical or slightly moniliform, thin- or thick-walled, septate, processes and hairs free or ± coherent to form a fimbriate to lacerate or dentate margin. **Anchoring hyphae** sparse to abundant, sometimes seen around each apothecium as a white subiculum (in dry state), *(1.5–)2–4(–6) µm wide, walls *0.2–0.4(–1.2) µm thick, sometimes forming a dense, hyaline, sometimes gelatinized t. intricata below apothecia. **SCBs** in paraphyses and ectal excipulum frequently present, either globose, hyaline, 1–3(–5) µm diam., low-refractive, or ring- to keyhole-shaped, medium refractive, hyaline to pale orange, 2–7(–11) µm diam. (often both types occurring mixed); **VBs** in desiccation-sensitive taxa often present as very low- to rather high-refractive, globose to elongate, hyaline, rarely yellowish or reddish vacuoles (1–)1.5–20(–25) × (1–)1.5–3(–4) µm, in strongly desiccation-tolerant taxa consistently absent; **carotenoids** in **LBs** [0.2–1(–2) µm diam.] of paraphyses, subhymenium and ectal excipulum (at flanks and especially margin) present in many taxa, pale to bright yellow-orange. **Exudate** over paraphyses, margin and flanks either sparse to absent (especially in desiccation-sensitive taxa), or abundant (especially in desiccation-tolerant taxa), forming a covering layer which is either ± continuous or broken into clods or granules, loosely adhering to a thin invisible gel layer, or firmly attached, sometimes forming thick glassy caps on each paraphysis, (medium to) strongly refractive, hyaline or pale to light yellow, 0.2–2(–5) µm thick over paraphyses, margin and flanks; paraphyses and asci usually more or less separable by pressure; gel between cells and on anchoring hyphae mostly distinctly lilac in **CRB**. — **ANAMORPH**: anguillospora-like, arthrobotrys-like, dactylella-like, dactylellina-like, descalsia-like, dicranidion-like, drechslerella-like, dwayaangam-like, gamsylella-like, helicoon-like, pseudotripoconidium-like, tridentaria-like, trinacrium-like, vermispora-like. **Mycelial hyphae** *2.5–7.5 µm wide, hyaline. **Colonies** hyaline/whitish to cream, yellowish, orange, rose, salmon or reddish-brownish. **Conidiophores** emerging from mycelial hyphae, rarely aggregated in synnemata, branched or unbranched in lower, middle or upper part, gradually narrower towards apex, (1.5–)7–400(–1500) µm long. **Conidiogenous cells** monoblastic or sympodial, partially with denticles or nodules. **Conidia** either unbranched, cylindrical, ellipsoid, clavate, fusoid to fusiform, inversely pyramidal (with nipple-shaped protuberances, pseudotripoconidium-like), straight or slightly to strongly curved, also vermiform (anguillospora-like) or strongly coiled (barrel-shaped, helicoon-like), (0–)1–17(–21)-septate; or branched (descalsia-, dicranidion-, dwayaangam-, tridentaria-, trinacrium-like), mostly multiseptate, arms cylindrical or ± tapering, straight or curved. — Living cells containing small, rarely large **LBs**; large **glycogen** regions partially present (in unbranched conidia); wall surface mostly distinctly lilac in **CRB**. **Trapping organs**: some species with adhesive branches and arches (gamsylella-like), adhesive knobs and non-constricting rings (dactylellina-like), adhesive networks (arthrobotrys-like), or constricting rings (drechslerella-like).

Habitat: Saprobiontic on dead bark and wood (including resin), woody fruits, herbaceous stems of mono- and dicots, textile, fruitbodies of perennial basidiomycetes or pyrenomycetes, exceptionally on dung or bones, the substrate being usually decomposed (optimal to often final stage) or sometimes very undecayed; substrate permanently moist (hygric) or periodically dry (xeric, then frequently in tight association with green algae and black yeasts); sometimes capturing nematodes, rarely arthropods or rotifers, occasionally parasitic on pollen. **Desiccation tolerance**: mature asci intolerant or tolerating a few weeks up to ~3.5 years; excipular cells and ascospores between a few days and several years. **Distribution**: worldwide, in arctic-alpine, boreal-montane, temperate, subtropical and tropical, humid to arid climates, with the highest species number in the (sub)tropical (semi)arid regions.

Recognized subgenera: *Habrostictis*, *Hemiorbilia*, *Orbilia* (see also Tab. 62), with 434 recognized species plus 7 with provisional name and 74 unnamed species ('affinis'); numbers referring to species with known teleomorph.

Generic concept. In the here applied wide circumscription, the genus *Orbilia* includes about 90 % of the species of *Orbiliomycetes* with a known teleomorph. Unlike *Hyalorbilia*, *Orbilia* forms a very diverse though likewise monophyletic group. The genus is sharply delimited from *Hyalorbilia* by a large number of more or less consistent characteristics (see also Tab. 59). The most important are: (1) only 1 spore body (SB) in each ascospore (mostly in the spore apex), (2) apex of dead asci either hemispherical and thick-walled or truncate and thin-walled (only exceptionally hemispherical and thin-walled), (3) ascus base usually ± furcate, croziers consistently absent or exceptionally present in a few taxa, (4) paraphyses often capitate but also spathulate-mammiform to lanceolate or uninflated, not embedded in ample gel, and (5) an ectal excipulum at the lower flanks generally of textura angularis, often with vertically elongated prismatic cells. As a very rare exception, a few abnormal spores with 2 spore bodies, one at each end, were seen in some species of *Orbilia* (series *Lentiformes*, *Hesperideae*, *Serpentinae*, see p. 71). Such abnormal spores appear to reveal the origin of the genus from an ancestor which showed SBs at both spore ends (see p. 79).

The genus *Orbilia* is applied here in the circumscription as proposed by Baral (1994), Baral & Marson (2001), and Baral et al. (2017b). Prior to this, a different concept was in use in which the genus *Hyalorbilia* was included in *Orbilia*. On the other hand, some of the species assigned in the present study to *Orbilia* have been segregated hereof into three different genera: species with uninflated paraphyses in combination with a hairy or dentate margin were segregated in the genera *Hyalinia* (hairs solid, glassy) and *Orbiliaster* (hairs septate), whereas those with protruding spathulate paraphyses and a hairy margin were referred to *Habrostictis*.

The previous inclusion of *Hyalorbilia* in *Orbilia* is astonishing since this genus differs in several respects from the generally accepted key characteristics of *Orbilia* which comprise capitate paraphyses, furcate ascus bases, and isodiametric excipular cells. On the other hand, *Hyalorbilia* possesses strongly conglutinate hymenial elements, a feature which is often stressed as typical of *Orbilia* though being actually absent in most species of that genus.

A total of six teleomorph-typified genera and a large number of anamorph-typified genera are considered to be synonymous with *Orbilia* in the present circumscription. Among the teleomorph-typified genera, the type species of *Orbiliaster* and *Orbiliella* belong to section *Arthrobotrys* of subgenus *Orbilia*, that of *Radotinea* probably falls in section *Hemiorbilia* of subgenus *Hemiorbilia*, that of *Hyalinia* belongs to section *Aurantiorubrae* of subgenus *Habrostictis*, while *Habrostictis* (= *Cheilodonta*) is reduced here to a subgenus and emended to include a large group (section *Habrostictis*) of predominantly newly described species. Prior to about 1950, quite a few species here accepted in *Orbilia* were considered to belong to helotialean genera, such as *Calloria*, *Helotium*, *Laetinaevia*, and *Mollisia*. For a history of the genus and its varying circumscription see p. 192 ff.

Considering the vast number of species recognized in this monograph and the high diversity in character combinations, a subdivision into several genera instead of subgenera and sections would be worth taking into consideration. However, according to our molecular phylogenetic analyses, several of the morphologically important characteristics occur scattered in rather distant groups within *Orbilia*, which complicates the preparation of keys to these infrageneric groups. As a consequence of a subdivision of *Orbilia* into several genera, molecular data would be required in order to place a species in one of these genera. Many of the microscopic characteristics did not clearly correlated with a phylogenetic group, hence do not permit recognition of the group by morphology alone. Therefore, we have accepted paraphyletic groups in several cases, based on striking morphological traits, for instance, we have defined section *Hemiorbilia* by a thick-walled hemispherical ascus apex although the group is only moderately supported, or series *Lentiformes* and *Phanosomates* are recognized based on the lens-shaped vs. lantern-shaped spore bodies, although our molecular data do not suggest such a split.

Diversity of teleomorph. Macroscopically, *Orbilia* encompasses a rather high diversity in both colour and shape. Most of desiccation-tolerant species show different shades of reddish colours (including orange, rosaceous and lilaceous), while some are yellow or ochraceous, and a few black. The margin is usually smooth or only slightly roughened, but in some species it is crenulate or fringed with whitish teeth or hairs. Desiccation-sensitive species are often whitish to pale cream, but also here yellow, orange, red, or rosaceous-lilaceous colours occur; the margin is usually smooth, but also here in some species hairy or toothed.

Particularly the microscopic features of the genus encompass a very high morphological diversity. Apart from differences in the apices of asci and paraphyses, a high variation in spore and SB shape and size is noted, the number of spores per ascus varies between 8 and 128, also the mentioned marginal fringe in some groups made up of septate hairs or glassy processes is remarkable. Organelles of the living cells of paraphyses and excipulum, i. e. vacuolar bodies (VBs) and cytoplasmic bodies (SCBs), play an important role in the classification, especially at the species or series level.

Nomenclature of teleomorph. When Fries (1836: 343) erected the genus *Orbilia* he provided little more than a reference to the two included species described by him earlier (Fries 1815: 165, 1822: 146). The brief statements that concern the new genus run as follows: '[apothecia] membranaceous-gelatinous, asci moniliform = *Orbilia*', and 'to *Orbilia* belong *P. leucostigma* and *P. xanthostigma* which much resemble the genus *Ascobolus*'. *Calloria*, a genus which was thought to be closely related to *Orbilia* during the following hundred years, was simultaneously described by Fries in the same paragraph as having a 'smooth hymenium and unchangeably persistent, clavate asci'. Fries' concept of *Calloria* must have been rather large, as he stated that 'to *Calloria* belong most of the small and gelatinous members of *Peziza*'.

The 'Dictionary of Fungi' (Hawksworth et al. 1996, Kirk et al. 2008) gives the year of valid publication of the genus *Orbilia* as 1849. In fact, Fries provided valid combinations into *Orbilia* only in 1849, whereas in 1836 he merely stated that the two species *Peziza leucostigma* and *P. xanthostigma* belong to the new genus. However, the same applies to *Calloria*, and that genus is listed in that Dictionary as 1836. According to ICN Arts 40.1, 40.3 (Turland et al. 2018), also *Orbilia* was validly described by Fries in 1836, because before 1958 the indication of a type was not necessary, and there is no requirement in the Code for making valid combinations into the new genus (P. Kirk pers. comm.).

Type material of the two species originally included in *Orbilia* by Fries has obviously not survived. His purely macroscopical diagnoses (see p. 1401) might even include the genus *Hyalorbilia*, but Fries' (1836, 1849) statement of moniliform asci as a generic character of *Orbilia* excludes *Hyalorbilia*. The word 'moniliform' should either refer to dead collapsed asci with a moniliform outline around the included 8 uniseriate spores, or to rows of spores inside disintegrated asci at an overmature stage. Either of these cases can only be provoked by short and thick spores as occur, e. g., in *O. eucalypti* and *O. leucostigma* or *O. xanthostigma*, but were never seen in *Hyalorbilia*, even in those taxa with subglobose spores. Species of *Orbilia* with cylindrical to filiform spores, such as *O. auricolor*, *O. epipora*, or *O. cardui*, can also be excluded from being used as neotypes of *Peziza leucostigma* and *P. xanthostigma*.

Clements & Shear (1931) were commonly believed to be the first having designated a lectotype of *Orbilia*. Their selection of *P. leucostigma* was followed by Nannfeldt (1932: 253) and later authors, although Nannfeldt did not mention Clements & Shear in this context. It was, therefore, a surprise to learn that in the rather unknown paper of Bachman (1909) on discomycetes of Ohio a number of genera were lectotypified. On p. 57 of this study, *O. xanthostigma* was given as the 'type species' of *Orbilia*, without further explanation. The interpretation of this species by Bachman was apparently that of *O. eucalypti*, but this does not affect the herewith effectuated lectotypification.

Because of the difficulty to interpret Fries' two originally included taxa, Nannfeldt selected *P. leucostigma* in the interpretation of Nylander (1869: 54) as 'neotypus' of *Orbilia*, but he did not designate a neotype specimen. In the present reexamination, material under the name *P. leucostigma* in the herbarium of P.A. Karsten was found to comprise four different species of *Orbiliaceae* (*H. inflatula*, *O. epipora*, *O. eucalypti*, *O. leucostigma*). Judging from the identification as *O. leucostigma*, all of them should have had colourless apothecia, which is no more evident after such a long time. Also *O. xanthostigma* was interpreted in the past century in quite different ways. In the present monograph two recent collections are designated as neotypes of *O. leucostigma* and *O. xanthostigma*.

Anamorph. Various anamorph-typified genera so far known to be connected to *Orbilia* contribute to the high morphological diversity of the genus. Previously, such genera have been defined by their conidial morphology and the type of conidiophore. In comparison with *Hyalorbilia* a much higher diversity of conidial types occur in *Orbilia*, which is the reason why in the past so many different genera have been recognized. These were based on conidial characters such as unbranched or branched, straight or curved, 0–1- or multiseptate, or presence vs. absence of a strongly enlarged middle cell. Also conidiophore morphology was used to define a genus, which included differences in conidiophore length and apical branching, such as presence of distinct denticles or nodules aggregated in nodes, or simple unbranched apices with a single conidiogenous locus at the tip (see p. 109 ff.).

Based on molecular data, so far only one group of anamorphs was modified in its generic circumscription within *Orbilia*. This group comprises predatory, mainly nematode-trapping taxa and is included here in section *Arthrobotrys* of subgenus *Orbilia*. The new circumscription typifies genera by their type of trapping organs, which were found to provide a more reliable morphological marker. The remaining anamorph-typified genera were continued to be characterized by conidial characters up to now, because trapping organs are unknown in almost all of them. Most of these genera are quite heterogeneous in their rDNA data, but they are difficult to redefine, because a purely molecular classification would make little sense in regard to application of their names. Merely *Pseudotripoconidium* was found to constitute a natural monophyletic group, based on its peculiar conidia and its long conidiophores with denticles at the tip. With the new nomenclatural rules (ICN, Turland et al. 2018) these genera are now considered as synonyms of *Orbilia* in the broad concept of the genus. They are mostly difficult to define regarding their type species for which authentic DNA data is usually unavailable.

A striking correlation between morphology and desiccation tolerance of the anamorph can be noted: intolerant species generally have unbranched straight conidia being usually formed on long conidiophores, whereas tolerant species have either branched or unbranched conidia formed on more or less short conidiophores, the conidia being mostly curved when unbranched (C-shaped). However, the two ecological groups form taxonomic entities only to a certain degree, mainly because intolerance to drought appears to be an apomorphy within the genus that developed in different evolutionary lines.

A simplified survey on the anamorphs of *Orbilia* can be given as follows (for a detailed report of the genera and species see p. 214 ff.): long conidiophores characterize section *Arthrobotrys*, C-shaped conidia (vermispora-like) are typical of section *Aurantiorubrae* but also occur in section *Lentiformes*, scolecosporous conidia (anguillospora- and helicoon-like) are mainly found in section *Helicoon*, Y-shaped conidia (trinacrium-like) are very common in sections *Habrostictis* and *Hemiorbilia* and in series *Piliferae* of section *Aurantiorubrae*, but also occur in section *Lentiformes* and other groups, dicranidion-like conidia occur in sections *Lentiformes*, *Aurantiorubrae* and *Orbilia*, and higher-branched conidia occur especially in series *Hemiorbilia* of section *Hemiorbilia* (dwayaangam-like) and series *Microsomates* of section *Orbilia* (arachnoid type) (see Baral et al. 2017b fig. 1).

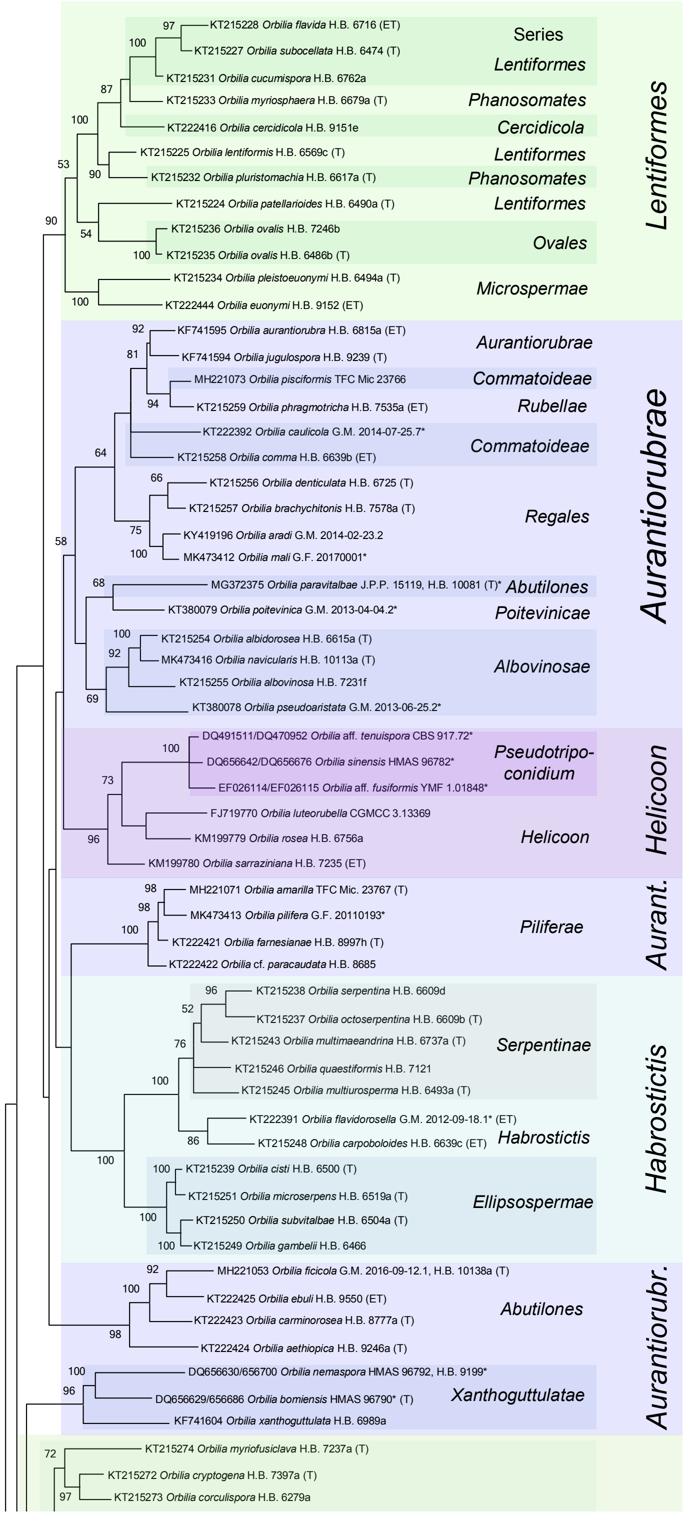
Despite a high conidial diversity within *Orbilia*, groups of clearly recognizable teleomorph-typified species often possess very similar or even indistinguishable anamorphs, mainly with trinacrium- and vermispora-like conidia. For instance, a frequently recorded anamorph is *Trinacrium robustum* agg., which we found to be connected to about 36 different teleomorph-typified species of *Orbilia*, mainly of section *Habrostictis*, but also of sections *Hemiorbilia* and *Lentiformes*. Some of these connections remain to be proved by pure culture, but evidence for a connection exists for all three mentioned infrageneric groups. Due to the frequent lack of type cultures, molecular data from authentic specimens could be gained only in some cases, therefore, the identity of many of these anamorph-typified species remains unsettled.

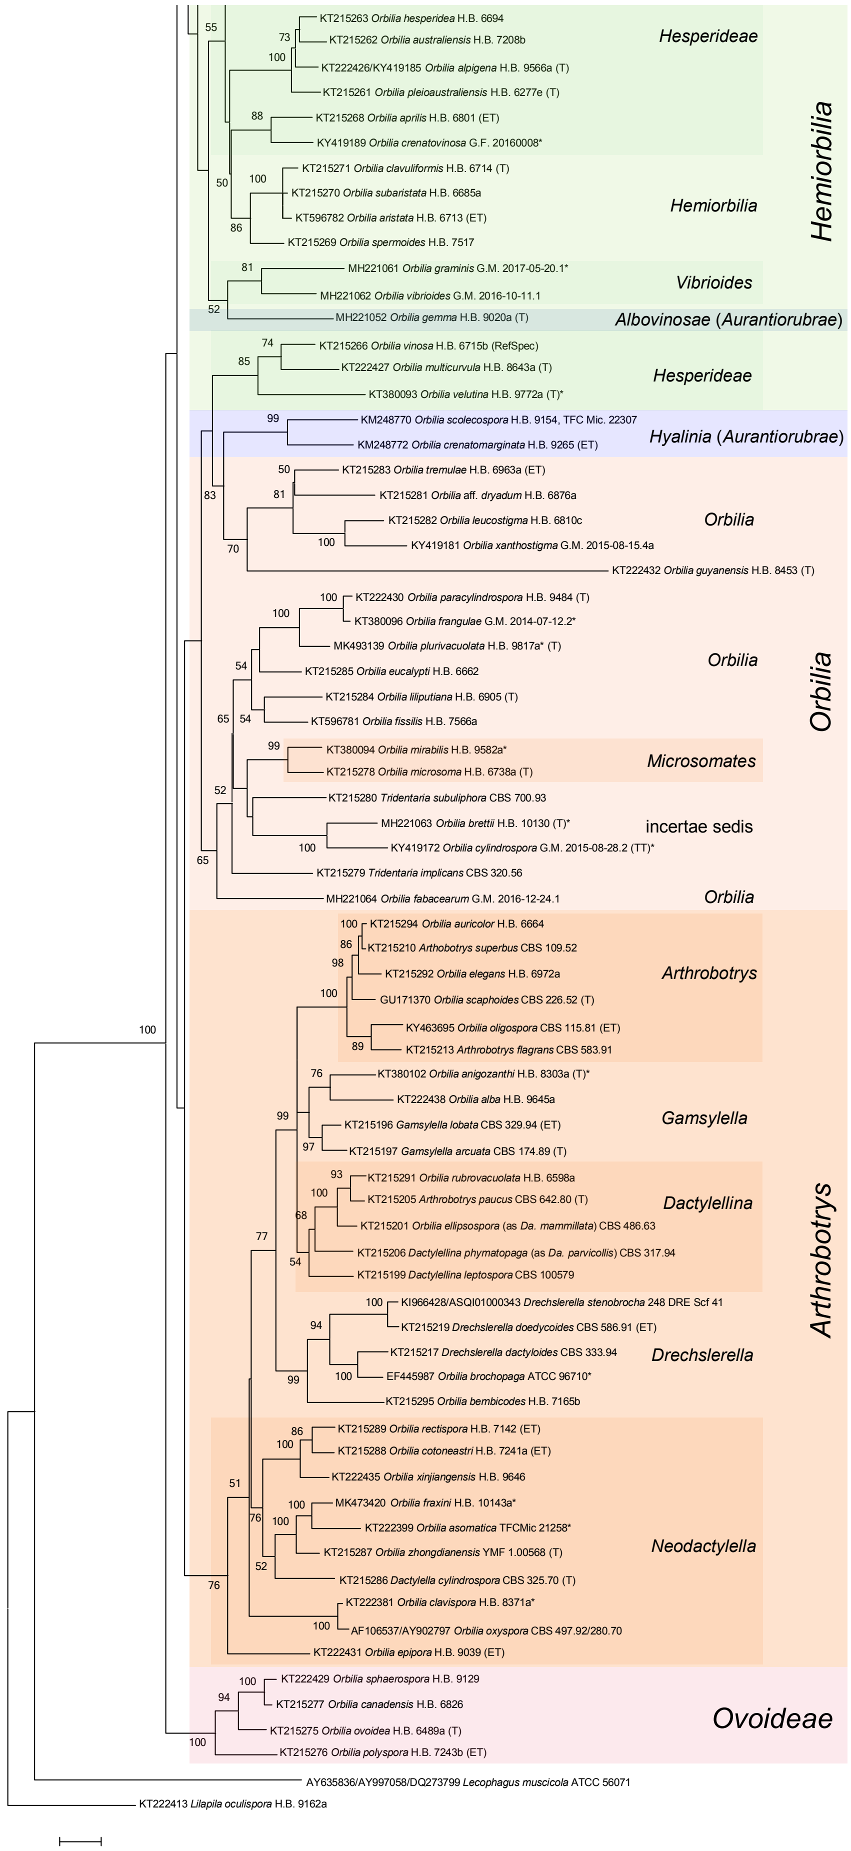
The frequent occurrence of different types of conidia in one isolate complicates the application of names of anamorphs as well as the use of anamorphs as markers of infrageneric groups. For example, trinacrium-like anamorphs often form some unbranched conidia which resemble those of *Dactylella*, except that they are formed on short conidiophores. Also higher-branched conidia (descalsia- and dwayaangam-like) may occur mixed with trinacrium-like conidia in one isolate. Similar problems are caused by the inconsistent presence of microconidia in anamorphs with unbranched conidia. In some taxa, microconidia are not sharply differentiated from macroconidia, and they may sometimes constitute the predominant or only conidia formed in pure culture.

Phylogeny within *Orbilia*. Most published molecular phylogenetic analyses of the genus *Orbilia* are focused on members of section *Arthrobotrys* and particularly nematode-trapping species. Various such analyses, e.g., by Hagedorn & Scholler (1999) and Yu et al. (2011), include a maximum of only two further sections of *Orbilia*, *Helicoon* and *Orbilia*. Some studies provide a more balanced data set in regard to the sections that they represent. For instance, Zhang et al.'s (2015) neighbour joining ITS tree of ~30 species regarding the position of *O. laevimarginata* includes five more or less supported clades: sections *Arthrobotrys*, *Aurantiorubrae*, and *Helicoon*, and series *Hyalinia* and *Xanthoguttulatae*. Liu et al. (2006a) present analyses of ITS (parsimony, ~30 spp.) and LSU (neighbour joining, ~20 spp.), which include members of seven or six sections, respectively. Here, it was mainly section *Helicoon* which received high support in the ITS tree, and the nematode-trapping taxa of section *Arthrobotrys* which were well-supported in the LSU tree. The analysis of Magyar et al. (2017a) comprises 20 *Orbilia* species in eight sections, all of which forming monophyletic clades. However, except for the highly supported section *Arthrobotrys* which here included only nematode-trapping taxa, bootstrap values were low within *Orbilia* and, therefore, not shown at most nodes.

As already stated under the class *Orbiliomycetes*, about 100 species of *Orbilia* have been included in the ML analysis of SSU+ITS+LSU done with RAxML (Baral et al. 2017b, erroneously as 'SSU+5.8S+LSU'). Comparable to the entire class, the backbone phylogeny within the genus remained unresolved and the question unanswered which subgenus or section is the ancestral one. The main tree topology actually changed among the different best trees of this analysis. Six strongly supported clades were recognized that represent six sections within the genus *Orbilia*: *Arthrobotrys*, *Habrostictis*, *Helicoon*, *Lentiformes*, *Ovoideae*, and *Orbilia*. Two further sections, *Hemiorbilia* and *Aurantiorubrae*, were not supported: the former formed a monophyletic clade and the latter was paraphyletic, being composed of six strongly supported subclades. These six clades were included in one section for morphological reasons, although they clustered unresolved without any supported affinities between them. Five of them were recognized at the series level: *Abutilones*, *Albovinosae*, *Hyalinia*, *Piliferae*, and *Xanthoguttulatae*. The sixth clade included four series: *Aurantiorubrae*, *Regales*, *Rubellae*, each with only 1–2 species, and the paraphyletic series *Commatoideae*.

The present ML analysis of the same gene region done with MEGA6 (Phyl. 7) shows largely a similar tree topology, with one main exception: series *Hyalinia* clustered medium supported sister to a clade of section *Orbilia* (with *O. leucostigma*, *O. xanthostigma* and *O. tremulae*), whereas in Baral et al. (2017b) it clustered unresolved in the highly paraphyletic section *Aurantiorubrae* of subgenus *Habrostictis*.





Phylogenetic analysis 7. Phylogram of genus *Orbilia* inferred from ML analysis of SSU (V8–V9)+ITS1-5.8S-ITS2+LSU (D1–D2) rDNA dataset (131 sequences, 2000 positions, aligned with MAFFT), using the GTR+G+I model in MEGA6 (100 replicates). The tree is rooted with *Lilapila oculispora* and *Lecophagus muscicola*. RefSpec = reference specimen, T = type, ET = epitype, TT = topotype, * = SSU ± absent.

Table 62. Synoptic table of selected characters for the infrageneric groups of *Orbilia* (for futher details see Tab. S3): **ascus apex**: h = hemispherical, t = truncate, – = thin-walled, + = thick-walled (often with ocular chamber); **dome**: – = thin-walled, + = thick-walled; **ascus base**: T-shaped, Y-shaped, H-shaped (with one blindly ending branch), etc.; **spore number**: high numbers are estimated; **inverse orientation**: lmh = low/medium/high number of spores inverted; **inverted spores**: L = lower spores inverted, U = upper spores inverted; **VBs**: + = vacuolar bodies present; **SCBs**: g = globose, c = crystalloid; **glassy processes**: + = present at margin; **septate hairs**: + = present at margin; **SBs**: g = globose, l = lens-shaped, t = tear-shaped, v = vermiform/filiform, p = plug-shaped, f = with filum, r = rod-shaped; **SB attachment**: a = apical, s = subapical, l = lateral; **spore shape**: g = (sub)globose, e = ellipsoid, cy = cylindrical, cl = clavate, f = fusoid/fusiform, o = ovoid/

Specific nucleotide positions. Only a few positions in the rDNA have been found that are more or less characteristic for the genus *Orbilia*. The combination of 2 adjacent nucleotides in the SSU V8 region is unique: pos. 141–142 is AT**AT**CT, whereas other orbiliaceous taxa with available SSU have AT**TC**CT or rarely AT**A**CCT (Tab. 60). In the 5.8S and LSU D1–D2 domain no characteristic nucleotide positions have been found.

In the region of the '*Orbiliales*-specific' primers (Smith & Jaffee 2009), a majority of *Orbilia* spp. either concur with a majority of *Hyalorbilia* spp. (Orb5.8s1F), or with *Lilapila* and *Mycoceros* (Orb5.8s3F) or *H. erythrostigma* and *H. orbiliicola* (Orb28S2R). However, a small minority of *Orbilia* spp. deviate in the latter two regions, where they mainly provide unique motifs. Also in stem-loop B8 near the 3'-end of 5.8S the motifs occurring in *Orbilia* are very diverse and without a nucleotide characteristic for the genus, although all these motifs do not occur in other orbiliaceous genera, except for a few *Orbilia* spp. which concur with some members of the *oviparasitica-multiguttulata* clade of *Hyalorbilia* (Tabs 18–19).

Plesiomorphic characters in *Orbilia*. Hypotheses on the plesio- or apomorphy of characters are given under each organ in the two morphology chapters about teleomorphs and anamorphs. A summary is presented under the class (p. 253). To establish sound hypotheses on the evolution of characters is still premature and must await more comprehensive molecular studies.

Ecology. The large genus *Orbilia* exhibits a very wide ecological diversity. The inhabited substrate includes bark and wood, herbaceous stems, perennial basidiomycetes, pyrenomycetes, exceptionally on dung or other residues of obovoid, t = with a tail, h = heart-shaped or triangular; **spore tail**: + = present, – = absent; **spore curvature**: 0 = straight, 3 = strongly curved; **spore apex**: r = rounded, o = obtuse, a = (sub)acute to acuminate; **paraphysis apex**: 0 = uninflated, 4 = very strongly inflated; **paraphysis shape**: c = capitate/clavate, s = spathulate/lageniform/lanceolate, m = mammiform; **apothecial colour**: hy = hyaline/white, red = reddish (orange, rose), yel = yellow, li = lilaceous, bl = black-olivaceous; **desiccation tolerance of apothecia**: t = desiccation-tolerant, s = desiccation-sensitive, a = semiaquatic; **anamorph**: an = anguillospora-like, ar = arthrobotrys-like, art = arthropod-like, d = dactylella-like, da = dactylellina-like, de = descalsia-like, di = dicranidion-like, dw = dwayaangam-like, ga = gamsylella-like, h = helicoon-like, ps = pseudotripoconidium-like, td = tridentaria-like, tr = trinacrium-like, v = vermispora-like.

animals, and soil. A wide range of climatic regions is colonized, and a majority of taxa are found in semiarid to arid vegetation types. In contrast to *Hyalorbilia*, desiccation tolerance of apothecia is, therefore, often much higher. Parasitism on other fungi is not known with certainty, but parasitism on eggs and adults of various invertebrates (nematodes, rotifers, arthropods) is typical of four series of section *Arthrobotrys*, but as yet unknown with certainty in any other infrageneric group of *Orbilia*. Taxa being predacious on testaceous rhizopods might occur in series *Orbilia*: *Dicranidion dactylopagum* is possibly connected to the *O. leucostigma* aggregate, while some other predacious species currently placed in *Dactylella*, *Tridentaria*, and *Trinacrium* are of unclear phylogenetic relationship. Species of the latter three genera are also known to prey on oospores (see p. 214 ff.). Finally, parasitism on pollen seems to be a common feature of *Orbilia*.

Subgenus *Hemiorbilia*

Orbilia subgenus ***Hemiorbilia*** Baral, Syst. Ascomycetum 13: 118 (1994) – Type species: *Orbilia occulta* (Rehm) Sacc.

Description: — **TELEOMORPH**: **Apothecia** hydrated rose to (ochraceous-)orange or brick-red, also olivaceous-black, margin glabrous or crenulate, denticulate to dentate, or hairy, sessile or short-stipitate. **Ascus apex** (†) hemispherical to slightly (rarely medium to strongly) truncate, with apical wall thickening, rarely thin-walled, often with distinct apical chamber; **base** T-, L-, Y-, or h-, exceptionally H-shaped; **Ascospores** and **SBs** variously shaped. **Paraphyses** apically uninflated or slightly, rarely strongly capitate-clavate. — **ANAMORPH**: descalsia-like, dicranidion-like, dwayaangam-like, trinacrium-like, vermispora-like. **Trapping organs**: unknown.

Key to subgenera, sections (and series) of *Orbilia*

1. Spore bodies (SBs, only visible in living ascospores) lens- to plug-shaped, wider than tall (rarely distinctly taller than wide due to a basal prolongation), widest part above where they are affixed to the spore wall, here (0.7–)1–2(–3) µm wide; spores ellipsoid-oblong or clavate, apex rounded; SCBs never crystalloid; apothecial margin always without glassy processes; apothecia always desiccation-tolerant
series *Lentiformes* (section *Lentiformes*, subgenus *Hemiorbilia*), p. 459

1. SBs globose, tear-shaped, rod-shaped, vermiform, only exceptionally wider than tall (rarely absent), either not visibly connected to the spore wall, or narrowly attached, i.e., apically attenuated (if not attenuated then SBs max. 0.8 µm wide at their widest part 2

2. Apex of dead asci hemispherical to slightly truncate, shape only slightly depending on the viewing direction, thick-walled (min. †0.5–1 µm), especially when immature, rarely also some asci thin-walled and strongly truncate; apex of paraphyses uninflated but also slightly to medium inflated, never uniformly spathulate to mammiform; apothecia always desiccation-tolerant .... (subgenus *Hemiorbilia*) 3

2. Apex of dead asci usually medium to strongly truncate in front view (sometimes centrally indented and/or laterally inflated by forming 2 shoulders), hemispherical in profile view, thin-walled (†~0.2–0.4 µm) 5

3. SBs ± abruptly divided into an inflated, mostly tear- to stomach-shaped, also vermiform, rod-shaped or nearly globose lower part and a fine (rarely thick) filum of about the length of the inflated part (but also much shorter); crystalloid SCBs present only in series *Cercidicola*; apothecial margin always without glassy processes or hairs ....
.... **series *Phanosomates*** (p. 505), ***Cercidicola*** (p. 501), **and *Microspermae*** (p. 528, section *Lentiformes*)

3. SBs vermiform, subulate, tear-shaped, ampulliform, rarely globose, apically gradually narrowed to a small or wide point, filum absent or very short; crystalloid SCBs present or absent................4

4. Ascus apical wall immature †(2–)3–4(–6) µm thick; rough exudate often provoking a warted hymenium and radial ribs at the margin; crystalloid SCBs absent; asci (32–)64–128-spored; Australia................ **series *Vibrioides* p.p.** (p. 746)

4. Ascus apical wall immature †0.5–2.5(–3.5) µm thick (if 2.5–4.8 µm then asci < 32-spored); exudate never forming warts on the hymenium; crystalloid SCBs present or absent; asci 8–128-spored (if SBs ± globose see also section *Ovoideae*) ....
.... **section *Hemiorbilia***, **series *Vibrioides* p.p.**

5. SBs filiform to vermiform or subulate, apically narrowed to a small point, sometimes divided into an inflated lower part and a long filum, often flexuous to curled, total length of SBs min. 1/3 of spore length, length/width ratio ~4–10(–20) ....(subgenus *Habrostictis*) 6

5. SBs globose, ellipsoid, tear-, plug- or rod-shaped (rarely absent), apically narrowed to a small or wide point, filum either invisible or absent to very short, total length of SBs max. 1/3 of spore length, length/width ratio ~1–4 8

6. Apothecia ± desiccation-sensitive, white, pale lilaceous-rosaceous, yellow- to ochre-orange, with a smooth, rarely crenulate margin; asci 8-spored; crystalloid SCBs absent, VBs usually present; spores *2.6–17 × 0.8–2.2 µm; paraphyses clavate-capitate, terminal cells 2.5–6 × longer than lower cells .... **section *Helicoon*** (p. 953)

6. Apothecia desiccation-tolerant, pale to bright yellowish-ochraceous to usually orange-red or rose(-lilaceous), with a smooth or ± hairy margin; asci 8–128-spored; crystalloid SCBs present or absent, VBs mostly absent; spores *3.3–19.5 × 0.9–5 µm; paraphyses clavate-capitate or spathulate-lageniform, mammiform, or lanceolate, terminal cells (0.2–)0.5–1.5(–3)× longer than lower cells 7

7. Asci 8–128-spored; spores *(3.3–)4–17(–19.5) × (1.3–)1.6–4(–5) µm; terminal cells of paraphyses (0.2–)0.5–1.5(–3)× as long as lower cells................ **section *Habrostictis*** (p. 1012)

7. Asci 8-spored; spores *4.8–11 × 0.9–2.3 µm; terminal cells of paraphyses (1–)2–3 × as long as lower cells................
................**series *Abutilones*** (section *Aurantiorubrae*), p. 885

8. SBs apically narrowed to a usually wide point, rod- to pear-shaped or ampulliform, 1.2–2(–4) × 0.4–1.3 µm; asci 8-spored; apothecia rose-orange, desiccation-tolerant................9

8. SBs apically narrowed either to a small point, with or without a very short, often invisible filum, or to a wide point and then SBs max. 1.2(–1.4) µm long, or absent................10

9. Spores *3.7–7.5 × 2.2–3.3 µm, ellipsoid-ovoid to broadly fusoid-clavate, l:w ratio < 3; anamorph dicranidion-like ....
................**series *Ovales*** (section *Lentiformes*), p. 498

9. Spores *5–11 × 1–3 µm, fusoid-clavate, l:w ratio > 3 or spores with a tail; anamorph trinacrium-like with curved-down arms....
.... **series *Piliferae*** (section *Aurantiorubrae*), p. 915

10. SBs plug-shaped, also tear- to dumbbell-shaped or ampulliform, rarely subglobose, 0.3–1.2(–1.4) × 0.25–0.8(–1.2) µm, attached by a wide point, rarely by a filum; glassy processes and exudate caps on paraphyses mostly present; asci 8–64-spored; apothecia orange to rose, always desiccation-tolerant .... **series *Microsomates*** (section *Orbilia*), p. 1295

10. SBs (if present) globose to broadly tear-shaped, with or without short, ± thin or invisible filum 11

11. Spores *(1.3–)1.7–3.8(–4.3) µm wide, globose to ovoid, ellipsoid-fusoid, clavate, or subcylindrical, straight or curved only near base; SBs globose to broadly ellipsoid-ovoid, (0.6–)0.7–1.5(–1.9) µm wide; terminal cells of paraphyses (0.5–)1–2(–3)× as long as lower cells; asci 8–128-spored; apothecia orange to rose or lilaceous, rarely ochraceous, always desiccation-tolerant .... **section *Ovoideae*** (p. 1241)
If paraphyses ± mammiform, spores ± clavate, with or without tail, anamorph trinacrium-like see *O. pilifera* (p. 918) and *O.* aff. *farnesianae* (p. 925, series *Piliferae*, section *Aurantiorubrae*).

11. Spores *0.8–2.5(–3) µm wide; SBs (0.2–)0.3–0.8(–1.3) µm wide, sometimes absent; terminal cells of paraphyses (1–)2–4(–6)× as long as lower cells................12

12. Spores predominantly < *6.5 µm long................13

12. Spores predominantly > *6 µm long................14

13. SBs globose to broadly tear-shaped, centrically oriented in spore apex (or absent); asci 8(–16)-spored; conidia unbranched (dactylella-like) or branched (dicranidion-like), never with inflated cells ..... **section *Orbilia*** (p. 1292, see also series *Neodactylella*, section *Arthrobotrys*)

13. SBs globose to rod-shaped, often ± eccentrically oriented in spore apex; conidia unbranched, often with inflated cells .... **series *Drechslerella*** (p. 1623), ***Gamsylella*** (p. 1610), and ***Dactylellina*** (p. 1584, section *Arthrobotrys*)

14. Spores consistently distinctly helicoid (curved in 3 dimensions), apex subacute to acute, rarely rounded to obtuse; SBs 1.5–4.5 µm long, broadly to narrowly tear-shaped or subulate to filiform, rarely ellipsoid to globose and without visible connection to spore wall 15

14. Spores straight to falcate (curved in 2 dimensions), sometimes with basal appendage or slightly helicoid.. 16

15. Apothecia desiccation-tolerant, with yellow to orange-red colours (rarely whitish), margin smooth to crenulate; anamorph vermispora- or dicranidion-like (with curved, C-shaped or U-shaped conidia, conidiophores very short)... ....**series *Aurantiorubrae*** (p. 833) and ***Xanthoguttulatae*** (p. 848, *xanthoguttulata-succulenticola* clade, section *Aurantiorubrae*)

15. Apothecia desiccation-sensitive or only slightly tolerant, whitish, yellowish or brownish, margin smooth to distinctly dentate; anamorph dactylella-like (with ± straight conidia, conidiophores short to very long) .... **series *Hyalinia*** (p. 868) and ***Xanthoguttulatae*** (p. 856, *nemaspora-vermiformis* clade, section *Aurantiorubrae*)

16. Spores consistently slightly to strongly falcate (C-shaped), rarely very indistinctly helicoid, *(6–)7–13(–15) × (0.8–)1–1.5(–1.7) µm, apex rounded to obtuse; SBs (0.8–)1–2.3(–2.6) µm long, globose to filiform; apothecia predominantly desiccation-sensitive...... .... **section *Arthrobotrys*** (p. 1432)

16. Not with this combination of characters, if spores falcate then ± constricted or geniculate in basal part and/or with acute apex 17

17. Apothecia desiccation-tolerant, with yellow, orange or rose to lilaceous colours; spores *6–15(–19) × (0.6–)1–2.5(–2.8) µm, apex rounded to acute.. **section *Aurantiorubrae*** (p. 769)
If SBs absent see *O. asomatica* (p. 1487, series *Neodactylella* of section *Arthrobotrys*), if SBs eccentrical and rod-shaped see *O. anigozanthi* (p. 1619, series *Gamsylella* of section *Arthrobotrys*); if apothecia desiccation-sensitive see also section *Helicoon* (p. 953).

17. Apothecia predominantly ± desiccation-sensitive, whitish, yellowish or brownish, rarely orange; spores *6–11.5 × 1–1.7(–2) µm, apex rounded to obtuse, rarely subacute .... **section *Arthrobotrys*** (p. 1432)

Habitat: xeric wood and bark of gymno- and angiosperms (including resin), also caulicolous or foliicolous, from subarctic to tropical, humid to arid climates. All species desiccation-tolerant.

Recognized sections: *Lentiformes* and *Hemiorbilia*, with 111 recognized species plus 2 with provisional name and 16 unnamed species (‘affinis’).

General remarks. The present circumscription of subgenus *Hemiorbilia*, which is mainly based on morphological criteria, includes two sections: *Lentiformis* and *Hemiorbilia*. The main feature common to most of its members is the more or less thick-walled, hemispherical to slightly truncate ascus apex (often with apical chamber) when studied in the dead state. However, this type also occurs in a few members of section *Ovoideae* of subgenus *Orbilia*. All members of subgenus *Hemiorbilia* have desiccation-tolerant apothecia with a reddish, rarely black colour. The paraphyses are usually not or only slightly inflated at the apex, and are never spathulate-mammiform or lanceolate-lageniform. Frequently they are covered by a thick layer of exudate. H-shaped ascus bases were only very rarely seen. Ascospore and SB shape are highly diverse.

Although series *Ovales* shows the characteristics of series *Orbilia* of subgenus *Orbilia*, including thin-walled truncate ascus apices, capitate paraphyses, and a dicranidion-like anamorph, the single species of this series, *O. ovales*, is included in section *Lentiformes* owing to its molecular data. Also section *Ovoideae* appears to form a transition between the two subgenera. It is characterized by predominantly globose to broadly tear-shaped, rarely ampulliform SBs, and predominantly or exclusively thin-walled ascus apices, but includes a few aberrant species in which thick-walled apices predominantly or exclusively occur (*O. clavipisca*, *O. lilacina*, *O. eremaeae*). On the other hand, we have included some members with ampulliform to globose SBs in section *Hemiorbilia* (e.g., *O. myriomuscula* and *O. sarothamni*). Molecular data are required in order to clarify relationships of such critical taxa in the future.

Section delimitation. Section *Lentiformes* is characterized by the consistent absence of crystalloid SCBs (except for *O. cercidicola*) and glassy processes. Most of its members possess quite characteristic, either lens- or lantern-shaped SBs. Series *Vibrioides* of section *Hemiorbilia* concurs in the absence of crystalloid SCBs and glassy processes. It differs in a strongly thickened ascus apical wall and (in some taxa) subapically inserted SBs, and is macroscopically more or less recognizable by a pruinose to prominently warted hymenium and exterior due to a sulphur-yellow exudate on the protruding paraphyses and excipular cells. In the rest of the large section *Hemiorbilia* crystalloid SCBs and glassy processes are often present, the spores tend to have a basal tail, and the SBs similarly tend to be subapically or laterally inserted in some species.

Anamorphs. Members of sections *Lentiformes* and *Hemiorbilia* form either stauroconidia (predominantly trinacrium-like, in *Lentiformes* also dicranidion-like, in *Hemiorbilia* also descalsia- and dwayaangam-like) or curved phragmoconidia (vermispora-like). Taxa with predatory capabilities are unknown within subgenus *Hemiorbilia*.

Phylogeny. Subgenus *Hemiorbilia* as proposed by Baral (1994) is adopted here based on the hypothesis that the striking morphology of the hemispherical, thick-walled ascus apex observed in sections *Lentiformes* and *Hemiorbilia* represents a character of high taxonomic importance which could be plesiomorphic within *Orbilia*. It would appear logical that these two sections form different lineages of more basal, ancient relationships, forming a paraphyletic group which nevertheless traces back to a common ancestor. This hypothesis implies that the thin-walled truncate ascus apex of subgenus *Orbilia* developed by reduction from the hemispherical thick-walled ascus apex of subgenus *Hemiorbilia*. Section *Ovoideae* represents an intermediate assemblage of taxa that morphologically stands somewhat between these two groups, and series *Ovales*, which shares most characters of series *Orbilia*, appears to represent a convergent lineage that emerged within section *Lentiformes*,

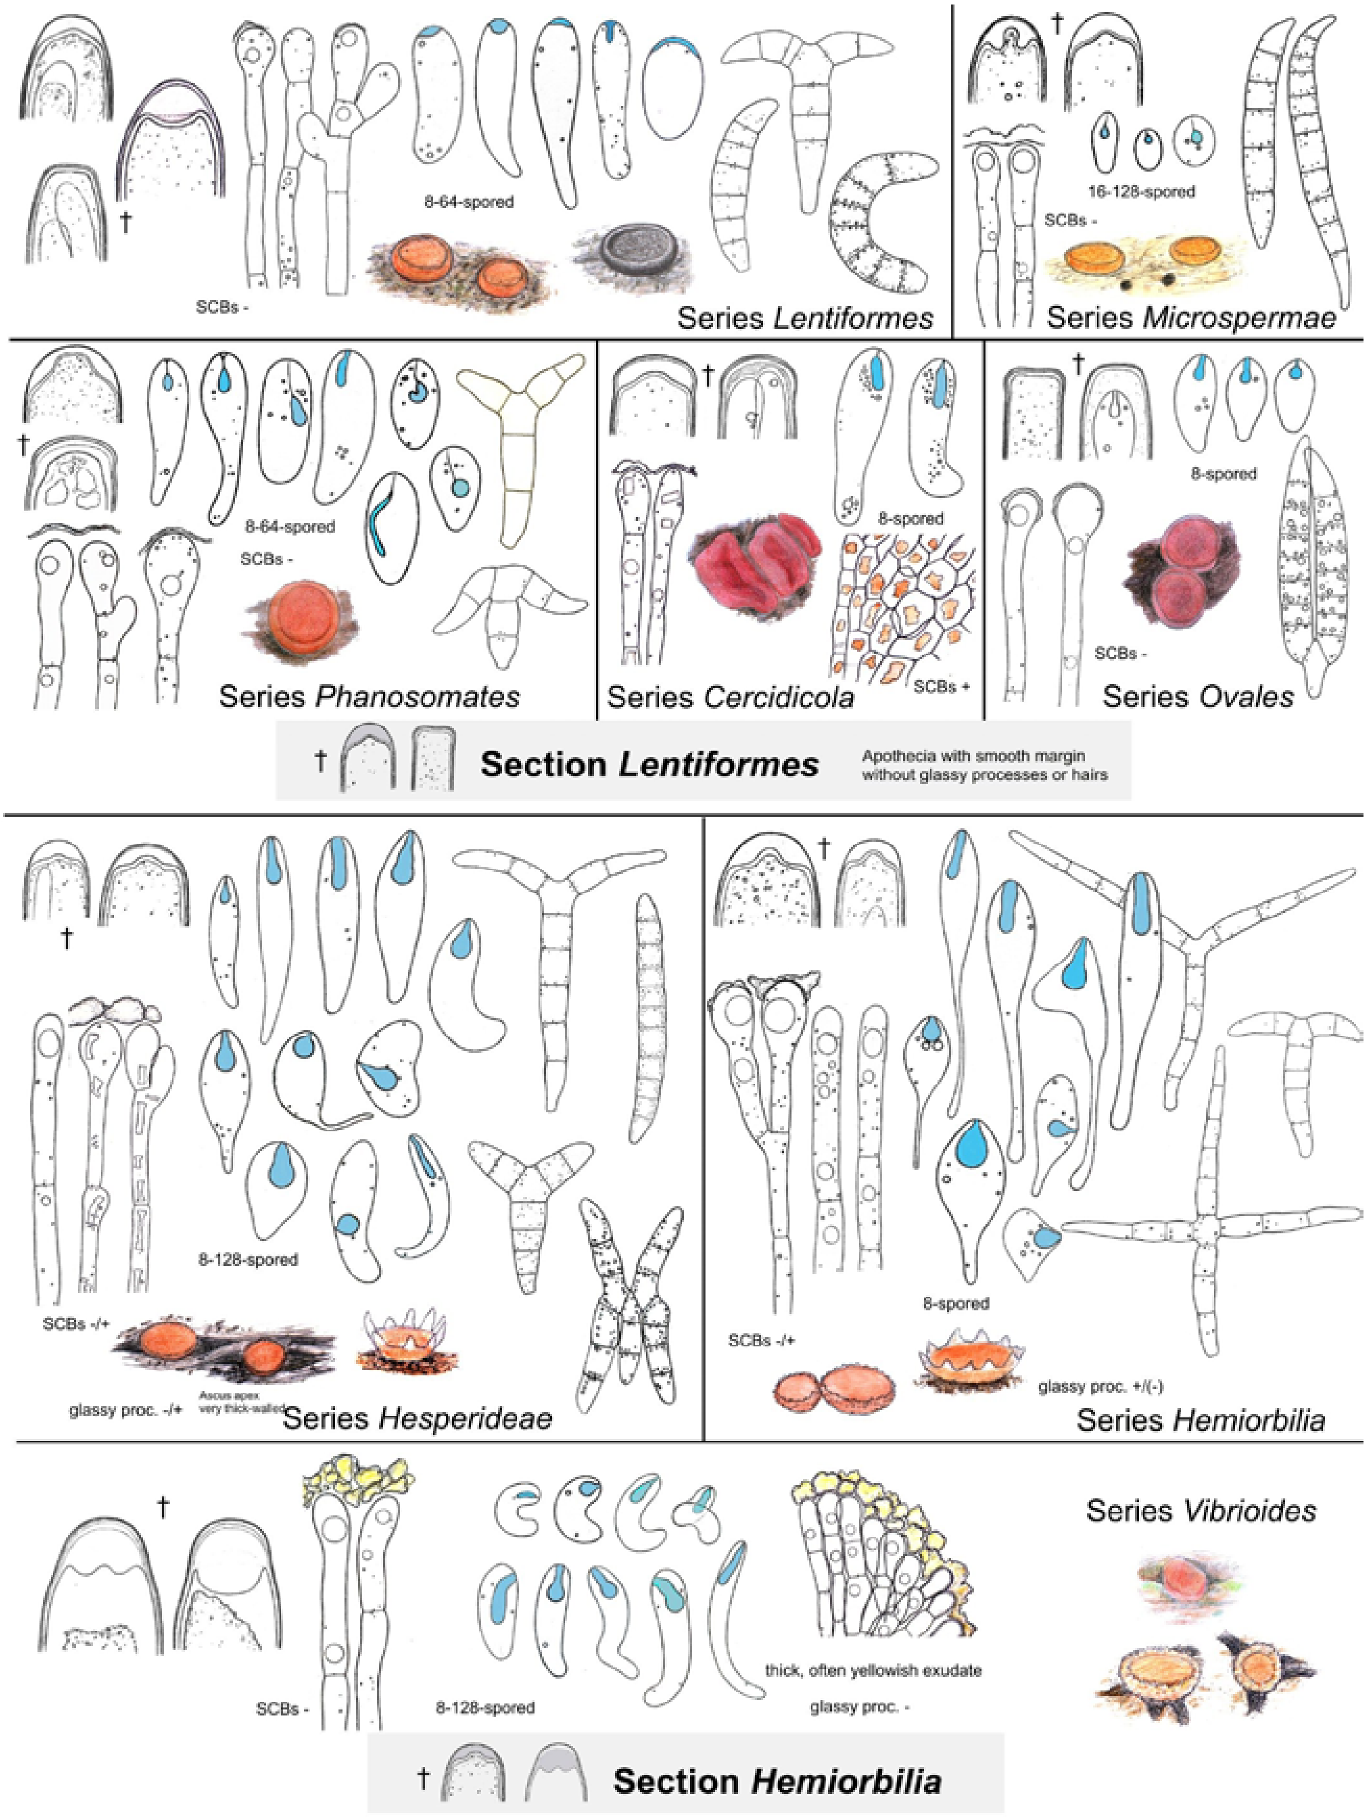

Plate 147. *Orbilia* subgenus *Hemiorbilia*, comprising sections *Lentiformes* and *Hemiorbilia*.

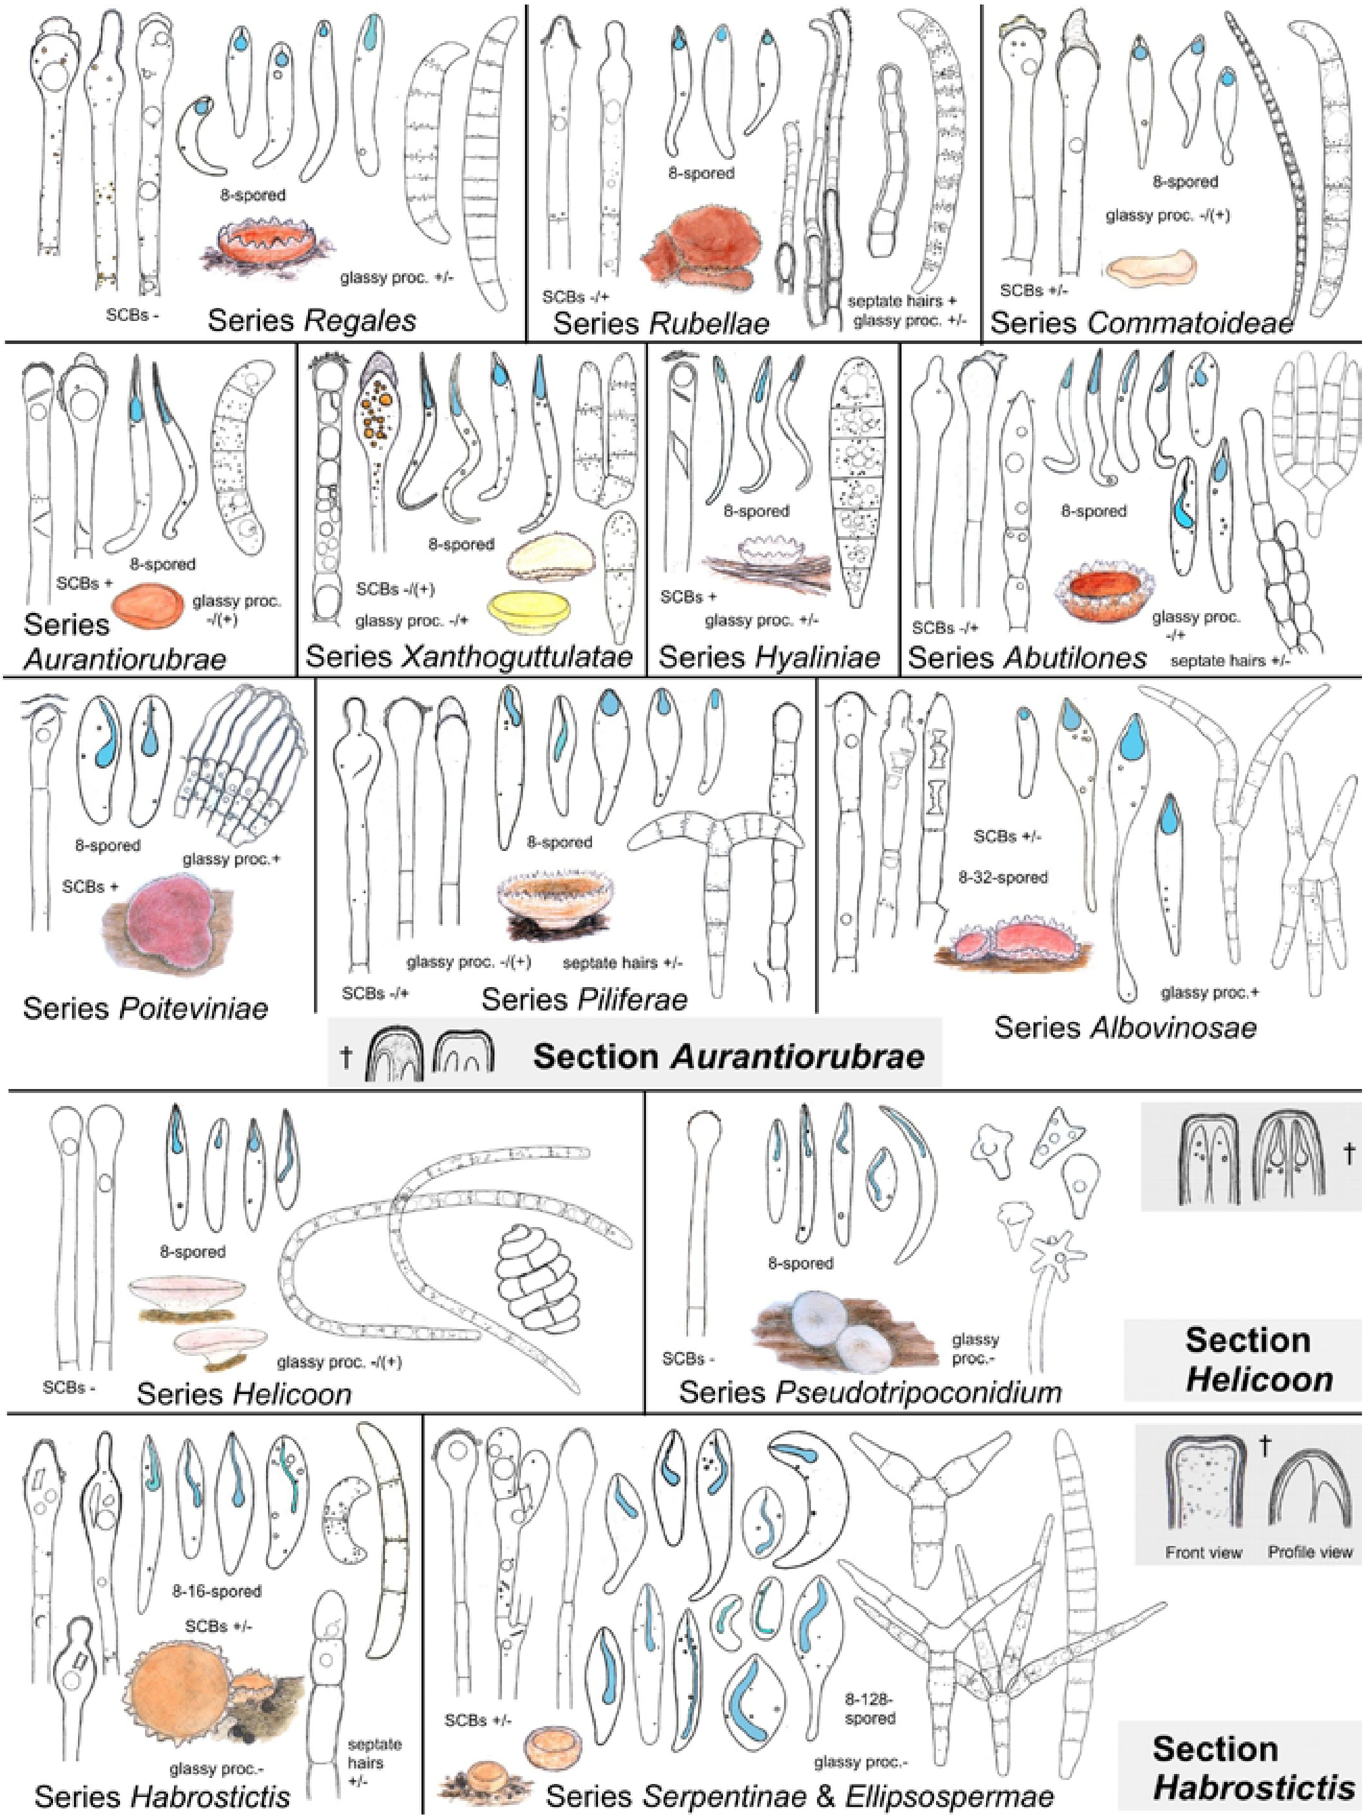

Plate 148. *Orbilia* subgenus *Habrostictis*, comprising sections *Aurantiorubrae*, *Helicoon*, and *Habrostictis*.

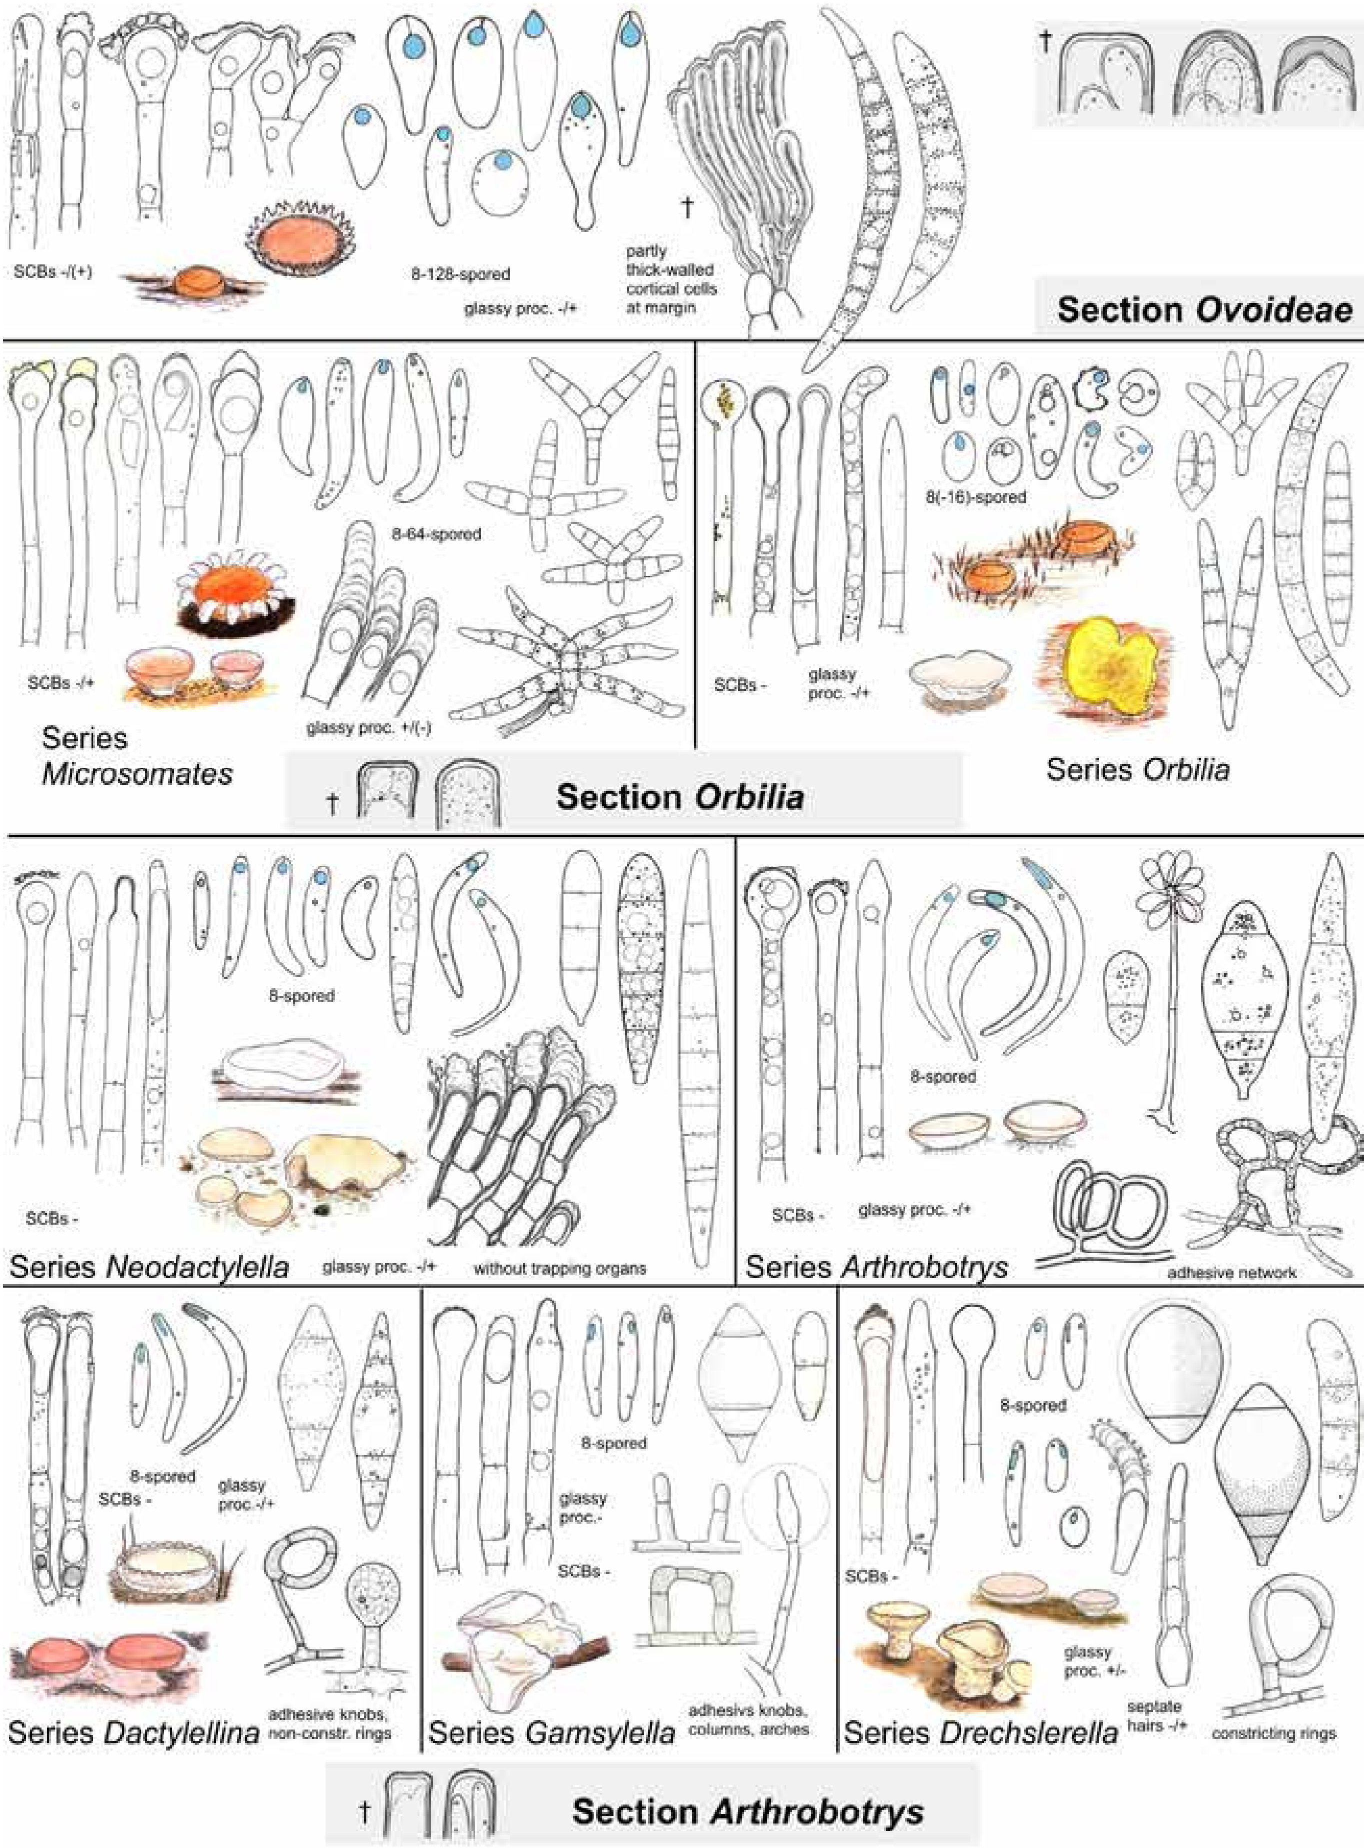

Plate 149. *Orbilia* subgenus *Orbilia*, comprising sections *Ovoideae*, *Orbilia*, and *Arthrobotrys*.

whereas series *Orbilia* appears to show closer molecular affinities with section *Hemiorbilia*.

In the phylogenetic analysis of rDNA presented in Baral et al. (2017b) the two sections of subgenus *Hemiorbilia* (*Lentiformes* and *Hemiorbilia*) appear in a paraphyletic position. Subgenus *Orbilia* formed a more basally positioned paraphyletic group, and subgenus *Habrostictis* a more terminally positioned paraphyletic group. However, the bootstrap support of this arrangement is absent to low, therefore, the result varies from one tree to another.

Specific nucleotide positions. No molecular motifs being characteristic of subgenus *Hemiorbilia* have been discovered in any of the frequently recorded regions of nuclear rDNA. However, the two included sections with DNA data show a few rather consistent nucleotide positions by which they can be distinguished from each other (see there).

Ecology. All species of subgenus *Hemiorbilia* are desiccation-tolerant and grow on xeric substrate from arctic-alpine to tropical and from humid to arid regions.

Section *Lentiformes*

Orbilia subgenus ***Hemiorbilia*** section ***Lentiformes*** Baral & E. Weber, **sect. nov.**, MB 814998 – Type species: *Orbilia lentiformis* Baral & G. Marson

Latin diagnosis: *Apothecia sessilia vel subsessilia, rosea ad aurantiaca vel atroolivacea, margine laevi, raro parum crenulato. Asci 8- ad 128-spori, apice in statu emortuo hemisphaerico, interdum truncato, tenui- vel crassitunicato, basi stipite bifurcato. Ascosporae subglobosae, ovoideae, ellipsoideae, cylindricae vel clavatae, apice rotundato vel obtuso, in statu vivo prope apicem corpusculum refringens lenti-, obturamenti-, bacilli- vel lanterniformem continentes. Paraphyses non vel leniter, raro valde clavato-capitatae. Excipulum ectale marginem versus cellulis vivis plerumque corpuscula globosa continentibus, absque processis vitreis.*

Description: — **TELEOMORPH**: **Apothecia** (0.08–)0.15–0.9(–1.3) mm diam., rose to orange, also olivaceous-black, (sub)sessile, disc ± flat, margin smooth, rarely slightly crenulate. **Asci** *(26–)40–100(–140) × (4–)5–11(–15.3) µm, 8- up to 128-spored, (0–)1/8–**1/4–1/2**–3/4(–4/4) of lower spores inversely oriented; **apex** (†) ± hemispherical (irrespective of viewing direction) or sometimes rather strongly truncate, rarely distinctly shouldered (series *Ovales*), thin-walled or with apical wall thickening [immature †0.8–2(–4) µm thick] with apical chamber; **base** L-, T-, Y- or h-, exceptionally H-shaped. **Ascospores** *(2.2–)3–17(–22) × 1.5–5(–6) µm, ovoid to subglobose, cylindric-ellipsoid, or ellipsoid- to fusoid-clavate, apically rounded to obtuse, sometimes with a thick tail, straight to slightly, rarely strongly curved (especially near base); **SBs** apically attached, either lens- to plug- or calotte-shaped, or ± lantern-shaped, sometimes of an intermediate type. **Paraphyses** uninflated or only slightly clavate-capitate at the apex, rarely strongly so (mainly series *Ovales*), terminal cells (0.3–)0.5–1.5(–2)× longer than lower cells. **Ectal excipulum** at flanks of textura (globulosa-) angularis(-prismatica), cells isodiametric or vertically elongated, near base *(5–)7–20(–26) × (3–)5–13(–20) µm, (†) thin-walled to slightly or rarely strongly gelatinized, common walls †0.4–1(–2) µm thick, near margin of t. angularis-prismatica to t. porrecta oriented at a high to low angle; **glassy processes** or **hairs** consistently absent. **Anchoring hyphae** (1.5–)2–3.5(–5) µm wide, walls 0.2–0.4(–1) µm thick. **SCBs** globose, rarely crystalloid (series *Cercidicola*); **VBs** consistently absent; **carotenoids** in **LBs** not observed. **— ANAMORPH**: vermispora-, trinacrium- or dicranidion-like. **Conidiophores** unbranched, hyphoid or forming chains of short inflated cells, *3–35 µm long. **Conidiogenous cells** monoblastic or sympodial, often with denticles. **Conidia** septate, unbranched (phragmosporous), often ± curved, or branched (staurosporous), with two arms and one stipe. **Trapping organs**: none observed.

Habitat: lignicolous, caulicolous, foliicolous, all taxa desiccation-tolerant.

Recognized series: *Cercidicola*, *Lentiformes*, *Microspermae*, *Ovales*, and *Phanosomates*, with 30 recognized species plus 2 with provisional name and 1 unnamed species ('affinis').

Taxonomic remarks. In the present concept, section *Lentiformes* includes five series: *Lentiformes*, *Ovales*, *Cercidicola*, *Phanosomates*, and *Microspermae*. It comprises almost exclusively taxa with hemispherical ascus apices, often with a slight or distinct, congophilous apical wall thickening. However, considerable variation in the ascus apex was noted in quite a few species of series *Lentiformes* and *Phanosomates*, even within a population: although the apices typically were hemispherical or only slightly truncate and with a distinctly thickened wall, sometimes with apical chamber, in some of the examined apothecia the apices were medium to strongly truncate, though never shouldered, and often also without an apical wall thickening.

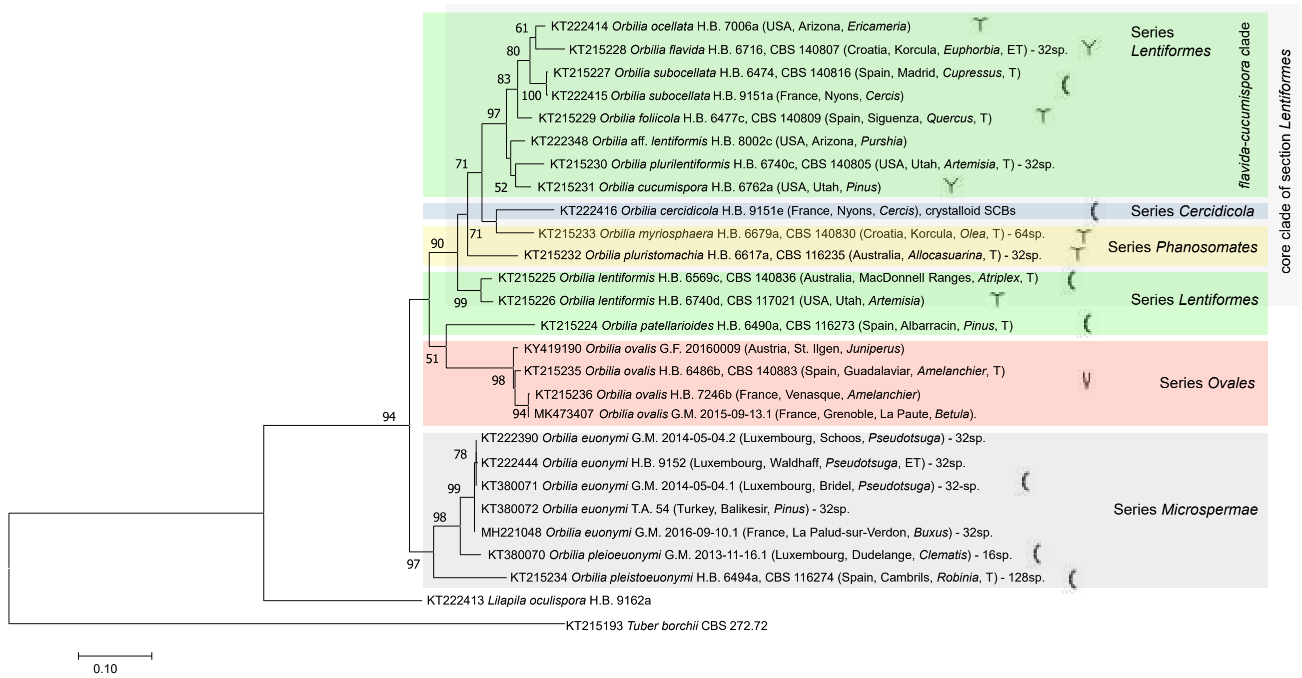
Further characteristics include paraphyses with a more or less equal cell length and usually uninflated apices, the absence of both crystalloid SCBs and glassy processes, and reddish or sometimes black, consistently desiccation-tolerant apothecia. Only two species sharply deviate from this set of characteristics: series *Ovales* with the single species *Orbilia ovalis* shows strongly truncate, shouldered, thin-walled ascus apices and capitate paraphyses with the terminal cells often longer than the lower cells, and series *Cercidicola* with the single species *O. cercidicola* deviates from all others in the presence of striking crystalloid SCBs.

Series delimitation. Two very different main types of SBs occur within section *Lentiformes*, according to which we distinguish the two more species-rich series of this group. Accordingly, series *Lentiformes* is characterized by quite unique lens-shaped, very broadly attached spore bodies (a species with very similar but smaller SBs, *O. microlentiformis*, is tentatively placed in series *Microsomates* of subgenus *Orbilia*), whereas members of series *Phanosomates* possess completely different, lantern-shaped SBs, which are narrowly attached by a short to long, very thin filum. Four species with ascospores and SBs similar to series *Phanosomates* but smaller are affiliated in series *Microspermae*.

O. cucumispora, *O. macroasca*, *O. cercidicola* and *O. ovalis* form a morphological transition between these two types of SBs: *O. cucumispora* shows a tendency to the lens-shaped type and is, therefore, assigned to series *Lentiformes*. The latter three resemble more the lantern-shaped type, deviating by SBs with a rather thick connecting part, but are placed in three different series. The very thin, calotte-shaped SBs in *O. pileosoma* (series *Lentiformes*) represent an extreme variant of the lens-shaped type.

Anamorph. Conidial diversity within section *Lentiformes* includes unbranched, phragmosporous (vermispora-like) and branched, staurosporous conidia (trinacrium-, rarely dicranidion-like). In series *Lentiformes* both vermispora- and trinacrium-like anamorphs occur, whereas in series *Phanosomates* only trinacrium-like conidia are known and in series *Microspermae* exclusively large phragmoconidia. In series *Ovales* a dicranidion-like anamorph and in series *Cercidicola* a vermispora-like anamorph are presumed (both series only with one species).

Phylogeny. Sequences were gained from 18 taxa that clustered in section *Lentiformes*, comprising ITS and LSU (D1–D2, rarely



Phylogenetic analysis 8. Phylogram of section *Lentiformes* inferred from combined ML analysis of SSU (V8–V9)+ITS1-5.8S-ITS2+LSU (D1–D2) rDNA dataset (27 sequences, 1720 positions, aligned with MUSCLE) using the K2+G model in MEGA7 (500 replicates). The tree is rooted with *Lilapila oculispora* and *Tuber borchii*. Asci 8-spored except when otherwise stated; T = type, ET = epitype.

D3 or more) and mostly also SSU (V8–V9, exceptionally also V1–V7). The S1506 intron is absent in all of them, except for *O. myriosphaera* of series *Phanosomates* and most sequences of series *Microspermae*. Based on analyses of SSU+ITS+LSU, section *Lentiformes* forms a strongly supported monophyletic clade (Baral et al. 2017b, Phyl. 7). The phylogenetic placement of the clade within the large genus *Orbilia* never received any support. In some trees it was found at the base of the genus in sister position to all remaining groups, while in that in Baral et al. (2017b) it diverged rather terminally after most other sections.

Phyl. 8 gives a combined phylogenetic analysis of section *Lentiformes* based on the three available gene regions. Seperate analyses of the ITS and LSU are added as supplementary information (Phyls S9 [ITS] and S11 [LSU]). All these analyses suggest that different types of ascus apices and spore bodies occur within this group. A close relationship between series *Lentiformes* and series *Phanosomates* was already presumed based on a similar shape of ascus apex, ascospores, paraphyses, and SCBs. However, despite the sharp morphological difference between lens- and lantern-shaped SBs in the two series, strains representing these two types did not cluster in distinct clades. Instead, species with lens-shaped SBs occur intermingled in a clade with those with lantern-shaped SBs. Moreover, *O. patellarioides* (with lens-shaped SBs) always clustered distant from the other taxa with this spore body type. Also *O. lentiformis* formed with a majority of series *Lentiformes* only in the combined analysis a strongly supported clade, which is referred to as 'core clade of section *Lentiformes*' here. Although the two morphologically defined groups turned out to be paraphyletic in all of our analyses of different rDNA gene regions, we prefer to maintain our classification system of two larger series based on spore body morphology, because it would seem here more logical that evolution went in one direction, i. e., at a single event from one spore body type to another. This circumscription has at least the advantage of easy series recognition without molecular data. However, it requires living ascospores because the lantern-shaped SBs are impossible to see in herbarium material.

Placement of *O. ovalis* (series *Ovales*) in section *Lentiformes* is surprising, as its microscopic characteristics, including the presumed anamorph, would refer it to subgenus *Orbilia*, in particular to series *Orbilia*. However, compared to the high molecular distance between *O. patellarioides* and the core clade of section *Lentiformes*, *O. ovalis* is not more distantly related to those and even shows a tendency to cluster with *O. patellarioides*. However, its morphology is very different from any member of section *Lentiformes*, including its thin-walled truncate ascus apex. Because of the high molecular distance to any member of the genus *Orbilia*, *O. ovalis* is here recognized here in a series of its own. On the other hand, we have retained *O. patellarioides* in series *Lentiformes* because it shows the typical morphology of that series.

In all mentioned analyses, series *Microspermae* formed a ± well-supported clade of its own that stands distant from the core of section *Lentiformes*. This placement was unexpected, as it closely resembles series *Phanosomates* in spore body shape, except for much smaller ascospores and SBs. Mainly because of our molecular data we here recognize a separate series for it.

A majority of series *Lentiformes* clustered in a ± strongly supported clade, here referred to as *flavida-cucumispora* clade, which comprises six species with lens-shaped SBs but also *O. cucumispora* which has elongate, plug-shaped SBs intermediate to series *Phanosomates*. However, *O. lentiformis*, which is morphologically difficult to delimit from *O. ocellata*, surprisingly clustered in a clade of its own distant from the *flavida-cucumispora* clade, though still in the core clade of section *Lentiformes* (in Phyl. S9 it formed a medium supported clade with *O. pluristomachia*).

The two species of series *Phanosomates* with available sequences clustered as a paraphyletic group within the core clade of section *Lentiformes*, though monophyletic in a weakly supported clade in Phyl. S8. *O. cercidicola* resembles series *Phanosomates* in SB morphology and actually clustered in a ±

Key to series of section *Lentiformes*

1. SBs often wider than tall, broadly affixed to apical spore wall, here (0.6–)1–2(–3) µm wide, lens-, calotte-, or plug-shaped, never apically distinctly narrowed; asci 8- up to 64-spored .... **series *Lentiformes***, p. 459
1. SBs never wider than tall, rod- to lantern-shaped, apically narrowed to a small or max. 0.5 µm wide point 2

2. Asci 8-spored, apices (†) thin-walled, strongly truncate in front view, ± distinctly shouldered; terminal cells of paraphyses 1.5–2(–3)× longer than lower cells, apically slightly to strongly inflated .... ***O. ovalis*** (**series *Ovales***), p. 498
2. Asci 8- up to 128-spored, apices (†) thick- or thin-walled, hemispherical or truncate in front view but never with shoulders; terminal cells of paraphyses (0.3–)0.5–1.5(–2)× longer than lower cells, apically not or slightly, rarely strongly inflated 3

3. Living paraphyses and excipular cells containing crystalloid SCBs (orange in excipulum); asci 8-spored; ascospores *(11–)12.5–17(–18.7) × (3.5–)3.7–4.5(–5) µm, often distinctly curved; bark of *Cercis* & *Ulmus*, semihumid, mediterranean or continental Europe .... **series *Cercidicola***, p. 501
3. Paraphyses and excipular cells only with globose, hyaline SCBs; asci 8- up to 128-spored 4

4. Spores *(2.2–)2.5–4(–5.5) × 1.5–2.5(–3) µm (exceeding 2.5 µm in width only when 16-spored); SBs mainly 1–1.8 × 0.2–0.6 µm; asci 16- up to 128-spored, apex (†) hemispherical, with apical thickening .... **series *Microspermae***, p. 528
4. Spores *(3.7–)4.5–15(–17.3) × (2.4–)2.8–4.8(–6) µm (< 3.2 µm wide only when 32–64-spored); SBs mainly 2–4 × 0.5–1.3 µm; asci 8- up to 64-spored, apex thin- or thick-walled, hemispherical or sometimes truncate .... **series *Phanosomates***, p. 505

weakly supported clade with *O. myriosphaera* in Phyls 8, S9. Yet, we prefer to place it in a series of its own because it has conspicuous reddish crystalloid SCBs unlike any other member of section *Lentiformes*, and a different excipulum texture.

Specific nucleotide positions. Molecular motifs in the SSU V8–V9, ITS, or LSU D1–D3 specific to the entire section *Lentiformes* have not been found. Two positions in the LSU separate it from a majority of remaining *Orbilia* spp. (see also under section *Hemiorbilia*, p. 544), but concur with most basal orbiliaceous genera, suggesting a common ancestry for these groups and an apomorphy for the remaining *Orbilia* spp.: all members of section *Lentiformes* have TGCAGCTC**T**AA at pos. 292 of D1 and GAGG**A**CCGCG at pos. 591 of D2, whereas most remaining members of *Orbiliomycetes* have TGCAGCTC**A**AA (including *Hyalorbilia* p.p.maj.) and GAGG**T**CCGCG (including *H. erythrostigma*, *H. orbiliicola*, *H. tortuosa*, and *Mycoceros*), respectively. As an exception, *O. xanthoguttulata*, *O. succulenticola*, and *Gamsylella arcuata* concur with section *Lentiformes* at pos. 292, and *O. pseudoaristata* at pos. 591. In the SSU V8–V9 pos. 70 is unique for series *Lentiformes, Phanosomates*, and *Cercidicola* (AGG**G**TTG), except for *O. patellarioides* which has AGG**T**CTG like other *Orbilia* spp., especially of section *Hemiorbilia*, series *Abutilones*, and series *Orbilia*, while most remaining *Orbilia* spp. have AGG**T**TTG.

Series *Lentiformes*

Orbilia subgenus ***Hemiorbilia*** section ***Lentiformes*** series ***Lentiformes* –** Type species: *Orbilia lentiformis* Baral & G. Marson

Etymology: named after the lens-shaped spore bodies.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.12–)0.2–0.5(–1) mm diam., either orange to rose or black-olivaceous, sessile, ± smooth. **Asci** *(47–)55–120(–138) × (5.5–)6.5–12(–13) µm, 8- up to 64-spored, about half or often only 1/8–1/3 of lower spores inverted; **apex** (†) hemispherical to rather strongly truncate, never indented nor laterally inflated, hemispherical in profile view, thin-walled or often with an (immature) †0.8–2(–4) µm thick dome, then often with apical chamber; **base** L-, T-, Y-, h-, rarely H-shaped. **Ascospores** *5–19 × 1.7–4.5 µm, ovoid, ellipsoid, cylindrical or often clavate, straight to ± strongly curved near base; **SBs** *(0.3–)0.5–1.2(–1.6) × (0.6–)1–2(–3) µm, rarely 0.2–0.4 or 2–3.5 µm high, lens- to broadly plug-shaped, also with a central prolongation (T-shaped) or rod-shaped, rarely forming a very thin calotte-shaped layer, broadly affixed to apical wall, never narrowed towards apex; frequently with 2 groups of **LBs**. **Paraphyses** uninflated at the apex or only slightly to medium, rarely strongly clavate-capitate, terminal cells 0.4–1.5(–2)× longer than lower cells, sometimes branched near apex. **SCBs** always globose. **Exudate** (0.2–)0.5–2(–6) µm thick, continuous, rough-cloddy or granular, loosely to firmly attached, hyaline to pale yellowish, also dark (bluish-)olive(-brown). — **ANAMORPH**: vermispora-like, trinacrium-like. **Conidiophores** ~7–30 µm long, partially branched. **Conidia** *(11–)15–54 × 4–7.5 µm (in situ and actual length) when phragmosporous, (1–)3–7(–11)-septate, straight or slightly to strongly curved; *20–56 × 10–64 µm when staurosporous, Y/T-shaped, arms straight or slightly bent downwards. **Conidiomata** only observed in *O. purshiae* (uncertain).

Habitat: wood and bark of both gymno- and angiosperms (including resin), foliicolous, or caulicolous, temperate to subtropical, humid to semiarid, always desiccation-tolerant.

Recognized species: 13, plus 1 unnamed species (‘affinis’).

Taxonomic remarks. Series *Lentiformes* is easily recognized by its very broadly attached, usually lens-shaped spore bodies in the ascospore apex, which are often also visible in herbarium material (in water or MLZ, in water sometimes retaining their refractivity). Four of the included species sharply differ from the remaining in very dark, blackish-olivaceous apothecia, therefore, they can easily be confused by macroscopy with lichenized fungi, or members of *Patellariales*. *O. cucumispora* is exceptional in its T- to rod-shaped SBs, whereas *O. pileosoma* has a very special type of SB that forms a very thin and broad, calotte-like layer. Variation in the ascus apex between hemispherical/thick-walled and truncate/thin-walled was noted in *O. lentiformis*, *O. pleiolentiformis*, *O. ocellata*, and *O. foliicola.*

Species delimitation. High variation in spore size and curvature is noted in most of the here accepted species. This variation is even seen within a population, and particularly within a single ascus, and makes species delimitation quite difficult. Also the SBs vary somewhat within a given population, especially in height. Species of the *O. lentiformis* complex (including *O. ocellata*, *O. subocellata*, and *O. foliicola*) are very difficult to separate based on teleomorph morphology, but appear to be separable by their anamorph and by molecular data.

Anamorph. Either unbranched or branched conidia are formed in culture. The former are mostly vermispora-like,

Key to species of series *Lentiformes*

1. Apothecia dark olivaceous or black due to a blue-green-olivaceous, ~1–5 µm thick exudate 2
1. Apothecia pale to bright orange or rose, exudate hyaline to pale yellowish 5

2. Asci 16-spored; spores ellipsoid-obovoid, *4.8–7(–8) × (3.2–)3.5–4.5 µm; SBs forming a thin (0.2–0.4 µm) hemispherical callotte at the spore apex; wood of gymnosperms, boreal to cold-temperate humid western North America .... ***O. pileosoma***, p. 468
2. Asci 8-spored; spores more elongate; SBs lens- to plug-shaped, 0.4–1.6 µm tall 3

3. Asci *8.5–10 µm wide (†7.3–9.5 µm), apical wall of immature asci †1.5–3.3 µm thick; SBs 0.8–1.6 µm tall, plug-shaped, with very prominent edges at the inner prolongation; spores *(8.3–)12–16(–17) × (2.8–)3–3.8(–4.2) µm, base mostly tapered and curved; wood of *Purshia* (*Rosaceae*), temperate subhumid to semiarid western North America .... ***O. purshiae***, p. 466
3. Asci *6–8 µm wide (†5–7.2 µm), apical wall of immature asci †0.9–1.5 µm thick; SBs 0.4–1.2 µm tall; wood of gymnosperms (mostly *Pinus*) 4

4. Spores *(7.5–)9–13(–14.5) × (2.6–)3–3.6(–3.8) µm, mostly strongly clavate, with a short, ± curved tail; SBs lens-shaped, 0.4–1 µm tall; orosubmediterranean humid Europe, mesomediterranean semihumid Macaronesia .... ***O. patellarioides***, p. 461
4. Spores *(9–)10–13.5 × (1.8–)2–2.6 µm, cylindrical, base not or only slightly narrowed and curved; SBs predominantly plug-shaped, 1–1.2 µm tall; boreal humid western North America .... ***O. atrolentiformis***, p. 464

5. SBs rod- to plug-shaped (T-shaped), taller than wide (1.5–3.5 × 0.6–1 µm), apically mostly abruptly widened; spores *(11–)13–19(–22) × 4–5.2(–5.7) µm, often ± dumbbell-shaped; asci 8-spored; apothecia pinkish-rose; bark & wood of gymnosperms, (oro)temperate (sub)humida western North America .... ***O. cucumispora***, p. 494
5. SBs lens-shaped, wider than tall (0.2–1.8 × 1–2.5 µm) 6

6. Asci 64-spored, *120–138 × 10.7–12.5 µm; spores *7–12 × 2.8–3.7 µm; apothecia 0.5–1 mm diam.; bark of *Cercis*, mesosubmediterranean semihumid southern Europe .... ***O. myriolentiformis***, p. 494
6. Asci max. 32-spored, mainly *60–105 × 7–11 µm; apothecia 0.15–0.65 mm diam. 7

7. Asci 32-spored 8
7. Asci 8–16-spored 9

8. Spores *(3.8–)5–8(–9.7) × (2–)2.2–2.8(–3) µm; asci *(54–)60–84(–92) × (6.7–)7–8.8(–9.3) µm; herbaceous stems, also bark & wood of angiosperms, temperate to thermomediterranean (semi)humid Europe and cool-maritime northwestern North America .. ***O. flavida***, p. 487
8. Spores *7–10.5(–11.3) × (2.8–)3–3.6(–4) µm; asci *(60–)70–105(–120) × (8.4–)9–11(–12) µm; bark & wood of angiosperm shrubs, boreal humid to temperate semiarid western North America .... ***O. plurilentiformis***, p. 492
If SBs only partly broadly attached and ± subglobose, compare *O. multicreosoteris* (section *Ovoideae*, p. 1275).

9. Asci 16-spored; spores *(6–)7–12(–15) × (2.4–)2.7–3.7(–4.4) µm; wood & bark of angiosperms, herbaceous stems, temperate to subtropical, humid to arid southern Europe, western North America and central Australia .... ***O. pleiolentiformis***, p. 484
9. Asci 8-spored 10

10. Spores *5.7–12.3 × 1.7–2.4 µm; asci *~4.5–5.5 µm wide, apex strongly truncate, without dome; marginal excipulum with short glassy processes .... see ***O. microlentiformis*** (series *Microsomates*), p. 1300
10. Spores *2.8–5.5 µm wide; asci *(6–)7–10(–11.5) µm wide, apex hemispherical to slightly truncate, with ± distinct dome (usually †0.5–1.4 µm thick); marginal excipulum without glassy processes 11
If spores *2.3–3.2 µm and asci *5–6 µm wide, see *O.* cf. *ocellata* on inflorescence of *Asteraceae* (p. 480).

11. Spores predominantly strongly tapered at base, here either tail-like or strongly curved 12
11. Spores predominantly slightly to medium tapered at base, here rarely tail-like, straight to slightly curved 13

12. Spores straight to slightly curved, often with tail-like base, *8.8–12.8 × 3–3.5 µm; SBs lens-shaped; ascus apical dome †0.8–1.2 µm thick; wood of *Pinus*, southern Europe .... ***O. patellarioides*** (rare reddish form), p. 461
12. Spores strongly curved at base, not tail-like, *11–17.5 × 3–4 µm; SBs plug-shaped; ascus apical dome †1.5–2 µm thick; wood of *Purshia*, western North America .... ***O. purshiae*** (rare reddish form), p. 466

13. On leaves of *Quercus ilex* agg.; spores *(7–)8–12.5(–15.5) × 3.3–4.2 µm; mediterranean Europe .... ***O. foliicola***, p. 482
13. On wood and bark of angiosperms (rarely gymnosperms) 14

14. Spores *(7–)8–12(–13) × (2.8–)3.2–4(–4.5) µm; asci *(47–)54–68(–76) × (6.5–)7–8.5(–9.2) µm; conidia trinacrium-like; subarctic to subtropical humid to semiarid Europe, North America, Asia .... ***O. ocellata***, p. 476
14. Asci *(8–)8.5–9.5 µm wide or wider 15

15. Spores *(9–)10–13(–14) µm long; asci up to *9(–9.7) µm wide; conidia vermispora-like; (sub)mediterranean Europe ......***O. subocellata***, p. 481
15. Spores *(10–)12–17(–19) µm long; asci up to *10.5(–11.5) µm wide; conidia vermispora- or trinacrium-like; boreal to subtropical, humid to arid, worldwide but absent in central Europe .... ***O. lentiformis***, p. 470

slightly to strongly curved phragmoconidia, the latter Y-shaped, trinacrium-like stauroconidia. In one case vermispora-like conidia were observed in orange ?sporodochia on the natural substrate (*O. purshiae*). The two types of conidia appear to characterize species of the above-mentioned *O. lentiformis* complex (see Tab. 63).

Phylogeny. Our combined phylogenetic analyses of SSU+ITS+LSU (Phyls 7–8) and separate analyses of ITS or LSU (S11) show that series *Lentiformes* is paraphyletic. Nevertheless we maintain it here because of the striking similarity in SB morphology among the species (see under Section *Lentiformes*, p. 458). The two species with black apothecia, for which sequences were available (*O. patellarioides*, *O. purshiae*), clustered separate from those with reddish apothecia but did not form a supported clade.

Specific nucleotide positions. No specific molecular motifs could be detected that are unique for members with lens-shaped SBs. When including series *Phanosomates* and *Ovales*, however, the group deviates in the ITS1 at pos. 1 as ATCATTA**A** vs. ATCATTA**C** in series *Microspermae* and ATCATTA**T** in series *Cercidicola*.

Ecology. Thirteen of the 14 taxa known within series *Lentiformes* occur on ligneous substrate (wood and bark), but some of them may also grow on herbaceous substrates or leaves. Four species were exclusively recorded on gymnosperms (*O. patellarioides*, *O. cucumispora*, *O. atrolentiformis*, *O. pileosoma*), though the latter two were only 1–2 × collected. *O. lentiformis* and *O. subocellata* grow mainly on angiosperms, but occasionally on gymnosperms. Within Europe, *O. flavida* is the most commonly recorded species of this series. It is the only one which was predominantly collected on herbaceous stems. *O. lentiformis*, *O. ocellata*, and *O. pleiolentiformis* were occasionally found on herbaceous substrate. Several species were recorded from different continents, including Europe, Macaronesia, North America, Asia, and Australia. *O. lentiformis* and *O. ocellata* also occur in Asia and northern Africa, moreover *O. lentiformis* and *O. pleiolentiformis* in Australia. Five species were so far only found in the Rocky Mountains and Colorado Plateau of North America and three only in the mediterranean belt of Europe. Among the latter is *O. foliicola* which is exceptional in growing on coriaceous leaves of *Quercus ilex* agg.

Species with blackish-olivaceous apothecia

Orbilia patellarioides Baral & G. Marson, **sp. nov**., MB 814370 — Pls 150–151, Map 21

Etymology: referring to the macroscopical similarity to species of the genus *Patellaria*.

Typification: Spain, Teruel, Frías de Albarracín, branch of *Pinus sylvestris*, 26.IX.1999, G. Marson & H.O. Baral (ex H.B. 6490a, M-0276552, holotype; ex-type culture: CBS 116273; sq.: KT215224).

Latin diagnosis: *Apothecia in statu rehydratata atroolivacea, 0.25–0.85 mm diam. Asci 8-spori, apice rotundati, leniter crassitunicati. Ascosporae *7.5–14.2 × 2.6–3.7 µm, profunde clavatae, ad basim valde attenuatae, plus minusve curvatae, in statu vivo prope apicem corpusculum refringens lentiformem, perlate affixum continentes. Paraphyses ad apicem non vel modice inflatae, exsudato valido atroolivaceo tectae. Habitat ad lignum putridum, raro corticem, ramorum siccorum arborum coniferarum in zona orosubmediterranea Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.85(–1.3) × 0.25–0.75(–0.9) mm, 0.14–0.23 mm high, black (rarely bright orange), round to elliptical, large apothecia sometimes somewhat lobate, scattered to densely gregarious; disc flat (to slightly convex), somewhat shining though finely rough, margin thin or thick, 0–10 µm protruding, (very) finely rough; sessile or subsessile with an indistinct pseudostipe ~20–50 × 170–200 µm immersed in algal layer, superficial, sometimes erumpent from small slits; dry with thicker, distinctly protruding margin. **Asci** *54–90(–105) × 6–7.5(–8) µm {7}, †(40–)50–73(–85) × 5.3–7.2 {4}, 8-spored, spores 2(–3)-seriate, (0–)1–3(–5) lower spores inversely oriented {10} (rarely mixed), pars sporifera *(27–)29–39 → 25–26 µm long, †(32–)38–50 µm; **apex** (†) ± hemispherical irrespective of the viewing direction, dome *0.4–0.7 µm thick, †1–1.5 → 0.8–1.4 µm thick {4}, often with apical chamber, emptied asci sometimes with an olivaceous (in KOH more ochraceous) apical wall; **base** with short to very long, flexuous, ± thick stalk, L- to Y-shaped. **Ascospores** *(7.5–)9–13(–14.5)((–17)) × (2.6–)3–3.6(–3.8) µm {10}, †7.5–13.5 × 2.4–3.6 µm {2}, free spores rarely with a septum close to the apex {1}, clavate, apex rounded (to obtuse), base mostly strongly attenuated, often with a distinct tail 1–3(–5) × 1.3–1.8 µm, straight or often slightly to strongly curved or geniculate in lower part, rarely hooked; **SBs** 0.4–1 × 1.4–2 µm {6}, lens-shaped, apically broadly attached; with 2–12 subapically grouped **LBs** 0.1–0.4(–0.7) µm) diam. and a few ones towards base. **Paraphyses** apically uninflated or slightly (to medium) capitate, some sublageniform, partially flexuous, terminal cell *9.5–27(–31) × 1.7–4 µm {4}, †1.6–3.5 µm wide, lower cells *(4–)6–20(–23) × 1.5–2.3(–2.5) µm {4}, †1.2–1.6 µm wide; rarely branched at upper septum, apices somewhat glued together, hymenium light olive. **Medullary excipulum** hyaline to pale rose, 30–50 µm thick, of dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a pale olive or hyaline, ~4–15 µm thick layer of subparallel hyphae. **Ectal excipulum** of (*) thin-walled to slightly, (†) distinctly gelatinized, pale to light olivaceous-brown or bluish-olivaceous, dark olive towards margin, of vertically oriented t. globulosa-angularis(-prismatica) from base to lower flanks, 20–90 µm thick near base, cells *5–16 × 4–11 µm {4}, common walls †0.5–1.5 µm thick, appearing glassy-gelatinous in dead state; 20–50 µm thick at lower flanks; 20–35 µm at mid flanks, of t. (angularis-)prismatica(-porrecta) oriented at a 45–90° angle, cells *5–14 × 3–7 µm {3}, at margin 25–30 µm thick, oriented at 20–45(–90)°, marginal cortical cells *4–11(–15) × 2–4(–7) µm {3}. **Anchoring hyphae** sparse to abundant, hyaline, *1.5–4 µm wide, wall 0.2–0.4 µm thick {3}, forming a dense, hyaline t. intricata ~10–100 µm thick. **SCBs** in paraphyses (0–)1(–2), rarely many globose or ellipsoid, 1–2 µm diam., at mid flanks and margin 2–2.8 µm diam. **Exudate** over paraphyses dark olive to bluish-olive, cloddy, 1–5 µm thick, ± loosely attached; over margin and flanks bright to dark (brass-)olive or blue-green, rough-cloddy, 1–6 µm thick, more olive-brown with age; especially in outer region of ectal excipulum with dark brass-olive, very finely granular intercellular exudate; dark olive clods KOH-resistant, turning deep yellowish-(brass-)grey-brown, ample acetic acid restores blue-green pigment in full strength. — **ANAMORPH**: vermispora-like (from ascospore isolate {2} and natural substrate {4}). **Conidiophores** strongly reduced, repeatedly branched. **Conidiogenous cells** *~7–10 × 3–3.5 µm. **Conidia** unbranched, strongly to very strongly curved (C-shaped), rarely slightly helicoid, *(17–)21–30(–35) × (4.5–)5–6.5(–7.5) µm (~25–45 µm actual length) {5}, †20–28 × 5–6 µm {1}, 3–9(–11)-septate, often germinating to form further conidia.

Habitat: collected 1.5–3 m above the ground, on dead, mostly decorticated, 10–80 mm thick, still-attached branches of *Larix ?decidua* {1}, *Pinus* sp. {4}, *P. canariensis* {1}, *P. sylvestris* {8/3}, on 0.1–0.5 mm deep slightly to often strongly decayed wood {17}, rarely bark {1}, sometimes broken (splitted) areas, often in beetle galleries, also close to cankers with sparse resin flow but not clearly associated with resin, wood covered by a layer of sparse to abundant green algae and brown hyphae. **Associated**: *Ciliolarina laricina* {1}, *Claussenomyces olivaceus* {1}, *Coniochaeta malacotricha* {1}, *Dacrymyces* sp. {2}, *Hypogymnia physodes* {1}, *Lophium mytilinum* {1}, *Melanelia glabratula* {1}, *Mytilinidion ?gemmigenum* {1}, *Orbilia aristata* {1}, *O. coniferarum* {1}, *O. cylindrospora* {2}, *O. delphinus* {1}, *O. euonymi* {2}, *O. ?ocellata* {1}, *O. sphaerospora* {3}, *O. subcylindrospora* {1}, *O. subtrapeziformis* {1}, *O. subvinosa* {11}, *O. trapeziformis* {1}, *O. vinosa* {2}, *Parmelia* sp. {3}, *Pseudevernia furfuracea* {1}, *Pseudohelotium sordidulum* {2}, *Sarea resinae* {1}, *Usnea* sp. {1}. **Desiccation tolerance**: fully viable for at least 3 months; after 12 months some mature asci and many ascospores still intact. **Altitude**: 860–1830 m a.s.l. **Geology**: Middle & Upper Jurassic and Cretaceous marl & limestone, Pleistocene silt & gravel; trachybasalt. **Phenology**: II, IV, VII–X (throughout the year, long-lived).

Taxonomic remarks. *Orbilia patellarioides* is easily recognized by its dark olive exudate and clavate ascospores

with lens-shaped spore bodies. The ascospores resemble those of *O. ocellata* but differ in their attenuated, tail-like base. Two other North American species with black apothecia resemble *O. patellarioides* even microscopically: *O. atrolentiformis* differs in narrower, basally scarcely attenuated spores with more plug-shaped SBs, *O. purshiae* in somewhat larger spores with distinctly plug-shaped SBs, and in thicker ascus apical domes.

Variation. Little variation could be observed among the collections of *O. patellarioides*, except for the spores which strongly vary in their actual length, also from slightly to strongly curved. A few spores were seen in which the basal tail looked like a hook, being curved by almost 180° (Pl. 151: 1r). In a single collection (Pl. 150: 4, holotype) the black apothecia grew in close association with what is perhaps only a colour variant of *O. patellarioides* (Pl. 150: 3): minute apothecia (0.2–0.3 mm) showed the orange colour of *O. ocellata* but the spore shape of *O. patellarioides*. The microfeatures between black and orange apothecia closely concurred except that, in the orange variant, the exudate formed merely a ~1 µm thick, refractive, very pale yellowish, granular layer lying over hyaline gel. Possibly, these orange apothecia belong instead to *O. ocellata* in which basally tapered spores sometimes occur, though not in that frequency. Similar colour variants were noted in *O. purshiae* and *Amphosoma atroolivaceum*.

Anamorph. The curved (C-shaped) conidia of *O. patellarioides* are not untypical within section *Lentiformes*, but show an extraordinary width coupled with a strong curvature. Only in *O. pileosoma*, *O. subocellata* and series *Microspermae* were similar ± curved phragmoconidia observed. The conidia of *O. patellarioides* resemble those of *Lecophagus navicularis* in shape, being only slightly smaller. Yet, mycelium and conidia of *O. patellarioides* did not contain cubical SCBs, also the mycelial hyphae of *Lecophagus* are about three times as wide.

Phylogeny. Sequences were taken from an ascospore isolate (ex-type culture) from Frías de Albarracín (SSU V8–V9, ITS, LSU D1–D2) and from apothecia of a sample from Le Labouret (SSU V7–V9, ITS, LSU D1–D6). In the overlapping gene regions the two strains are fully identical, although the two sites are 730 km apart.

O. patellarioides clustered unresolved and outside the core clade of section *Lentiformes* (Phyls S9 [ITS], S11 [LSU]) or in our combined analysis (Phyl. 8) weakly supported with *O. ovalis*, with a very high ITS/LSU D1–D2 distance to other members of series *Lentiformes*, the lowest percentage being to *O. lentiformis* s.l. (~19%/3.8–4.3%) and *O. ovalis* (19–20%/4.3–5%), that to *O. purshiae* 22%. Molecular affinities between *O. patellarioides* and *O. ovalis* (series *Ovales*) appear to exist also in the very conservative 5.8S region, where the two species are fully congruent, whereas other members of section *Lentiformes* show 1–2 deviating nucleotides.

Ecology. *O. patellarioides* grows, often in abundance, on ± rotten wood of dead, decorticated, still-attached branches of gymnosperms, predominantly *Pinus sylvestris*. The macroscopically hardly different *Claussenomyces olivaceus* was once found in association. *O. patellarioides* seems to be rather common in calcareous altimontane mountain ranges of southern Europe, with a humid, orosubmediterranean, rarely orotemperate (Savoie) or nearly suprasubmediterranean climate. The vegetation includes more or less open pine forests at north-exposed slopes or plateaus, sometimes with *Buxus sempervirens*, *Genista*, and *Juniperus oxycedrus*. In Tenerife (Macaronesia) it was found in a south-exposed, lower mesomediterranean semihumid *Pinus canariensis* forest (*Sideritido solutae-Pinetum canariensis*, L. Quijada pers. comm.).

Map 21. Known distribution of *O. patellarioides* in Europe and Macaronesia.

Specimens included. **FRANCE**: **Rhône-Alpes**, **Savoie**, 40 km NNE of Briançon, 3.8 km SSW of Termignon, Le Châtel, 1270 m, branch of *Pinus* (?) *sylvestris*, on wood, 5.VIII.1995, G. Marson (H.B. 5321a). – **Drôme**, 20 km SW of Serres, 8 km WNW of Ballons, Col de Perty, 1300 m, branch of *Pinus sylvestris*, on wood, 23.VIII.1996, G. Marson (ø). – **Provence-Alpes-Côte d'Azur**, **Hautes-Alpes**, 20 km NW of Gap, 0.7 km E of Les Coutières, Col du Festre, 1390 m, branch of *Larix* ?*decidua*, on wood, 23.VIII.2000, G. Marson (H.B. 6761a). – **Alpes-de-Haute-Provence**, 22 km NE of Digne-les-Bains, 1.6 km NE of Le Labouret, Col du Labouret, 1250 m, branch of *Pinus*, on wood & bark, 24.X.1992, G. Marson (H.B. 4821 ø, G.M. 4924). – 1.4 km NNE of Le Labouret, 1350 m, branches of *P. sylvestris*, on wood, 30.VIII.2015, G. Marson (G.M. 2015-08-30.2, sq.: MH091027). – 8 km SE of St.-Julien-du-Verdon, 3 km NW of Soleilhas, Vauplane, 1600 m, branch of *Pinus*, on wood, 16.VII.1994, G. Marson (H.B. 5132a). – 10.5 km E of St.-André-les-Alpes, 2.3 km WNW of Annot, 2.6 km NE of Col de l'Iscle, 1145 m, branch of *P. sylvestris*, on wood, 16.VIII.2001, G. Marson (H.B. 7061b). – 6.5 km SE of Castellane, 0.8 km NW of La Bâtie, Col de Luens, 1080 m, branch of *P.* (?)*sylvestris*, on wood, 5.X.1993, G. Marson (ø). – **Alpes Maritimes**, 28 km N of Monte Carlo, ~2 km NE of Col du Turini, l'Authion, ~1830 m, branch of *Pinus*, on wood, 3.X.1993, G. Marson (H.B. 5143). – 19 km NNE of Grasse, 4 km NNE of Gréolières, Gréolières les Neiges, 1405 m, branch of *P. sylvestris*, on wood, 1.X.1993, G. Marson (H.B. 5001b, anam. substr. & cult.). – 24 km N of Nizza, 1.5 km WSW of Utelle, Madone d'Utelle, 1150 m, branch of *P. sylvestris*, on wood, 3.X.1993, G. Marson (H.B. 5142a). – **Var**, 11 km SSE of Moustiers-Ste.-Marie, 3 km SSE of Aiguines, Grand Plan de Canjuers, 860 m, branch of *P.* (?)*sylvestris*, on wood, 5.VIII.1999, G. Marson (H.B. 6729b, anam. substr.). – **Vaucluse**, 9.5 km NE of Bedoin, 1.5 km NW of Mont Ventoux, Mt. Serein, 1385 m, branch of *P. sylvestris*, on wood, 13.VIII.2009, G. Marson, H.O. Baral & B. Liu (H.B. 9173a, anam. substr.). – **Hautes-Alpes**, 27 km SE of Gap, 2.5 km NE of Montclar, Col St.-Jean, 1335 m, branch of *Pinus*, on wood, 6.X.1993, G. Marson (H.B. 5016b, anam. substr.). — **SPAIN**: **Aragón**, **Teruel**, Sierra de Albarracín, 40 km W of Teruel, 4.5 km W of Frías de Albarracín, 1615 m, branch of *P. sylvestris*, on wood, 26.IX.1999, G. Marson & H.O. Baral (M-0276552, **holotype**; **isotype** in H.B. 6490a; anam. cult., CBS 116273; sq.: KT215224; H.B. 6490e orange variant). – Sierra de Javalambre, 23 km SSE of Teruel, 1.8 km E of Camarena de la Sierra, 1585 m, branch of *P. sylvestris*, on wood, 1.IV.2012, R. Tena (R.T.L. 12040101). — **MACARONESIA**: **Canary Islands**, **Tenerife**, Vilaflor, 0.6 km ENE of Vilaflor, Las Lajitas, 1445 m, branch of *P. canariensis*, on wood, 19.II.2012, L. Quijada (TFC Mic. 23352, doc. vid.).

Orbilia atrolentiformis Baral & G. Marson, **sp. nov.**, MB 813483 — Pls 152–153

Etymology: referring to the black colour of apothecia and the ± lens-shaped spore bodies.

Typification: USA, Montana, Yellowstone, branch (or root?) of *Pinus contorta*, 5.VI.1996, G. Marson (ex H.B. 5741a, M-0276437, holotype).

Latin diagnosis: *Similis* Orbiliae patellarioidi *sed ascosporae angustiores*, *ad basim haud vel parum attenuatae*, *ad apicem corpusculo refringente magis incrassato*, *plerumque obturamentiforme*, *angulato*. *Habitat ad lignum putridum rami sicci* Pini contortae *in zona boreali humidi Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.8(–1) × 0.2–0.7 mm, 0.19–0.24 mm thick (receptacle 0.07–0.12 mm),

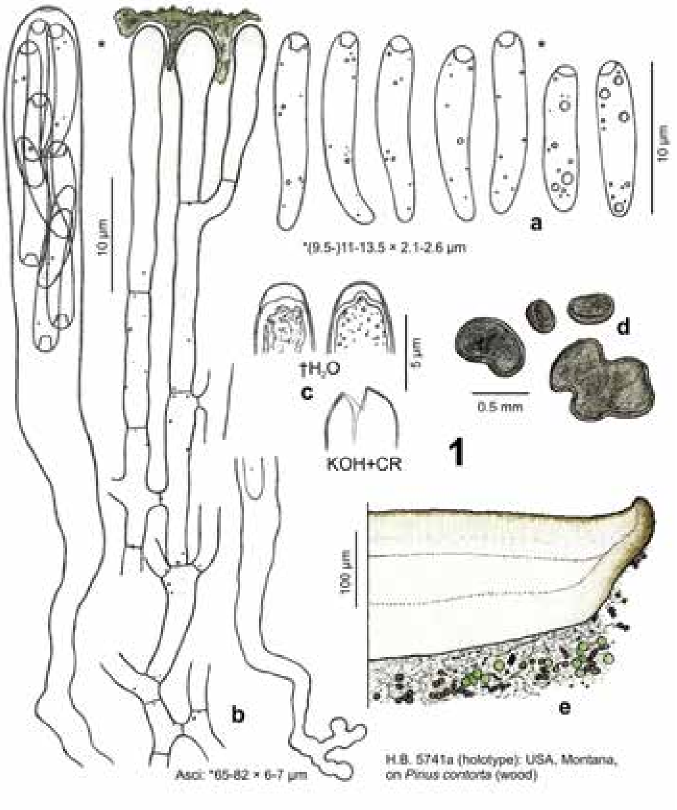

Plate 152. **1**: *Orbilia atrolentiformis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section.

olivaceous-black, young round to elliptical, ± undulating when large, scattered to gregarious in small groups; disc slightly concave to flat, finely rough, margin distinctly rising above disc, even; broadly sessile, sometimes with a distinct stipe 0.1–0.12 × 0.15–0.18 mm hidden in detritus, externally glabrous, shining, superficial to somewhat erumpent; dry with only slightly inrolled margin, disc remaining exposed. **Asci** *63–82 × 5.5–7 µm, †55–65 × 5–6 µm, 8-spored, spores 2–3-seriate, 2–3(–4) lower spores inversely oriented (rarely mixed), pars sporifera *25–35 µm long; **apex** (†) hemispherical to slightly truncate, dome immature †0.9–1.1 → 0.4–0.7 µm thick, sometimes with distinct apical chamber; **base** with long, thin, flexuous stalk, T-, L- to Y-shaped. **Ascospores** *(9–)10–13.5 × (1.8–)2–2.6 µm, †8–10.5 × 2.1–2.6 µm, (sub)cylindrical or (cylindric-)clavate, ends rounded, slightly attenuated near base, straight to slightly (or medium) curved towards the not or only slightly attenuated base; **SBs** 1–1.2 × 1.3–1.5 µm, lens- or often strongly plug-shaped, sometimes with inner edges, apically broadly attached; **LBs** sparse, minute, later increasing in size. **Paraphyses** apically uninflated to medium clavate, terminal cell 11–28 × 2.2–3.7 µm, lower cells 10–17 × 1.7–2.6 µm, sometimes branched near apex. **Medullary excipulum** hyaline, 60–110 µm thick, upper layer 40 µm thick, of dense small-celled texture, lower layer 20–70 µm thick, of a horizontal textura porrecta or loose t. intricata with inflated cells, sharply delimited. **Ectal excipulum** hyaline, of (*) thin-walled, (†) medium gelatinized (common walls 0.5–1 µm thick), vertically oriented t. angularis-prismatica from base to lower flanks, 30–80 → 20–40 µm thick, cells *9–23 × 8–12 µm, †5–10 × 5–9 µm, cortical cells very pale brownish; 20–25 µm thick near margin, at mid flanks of ± gelatinized t. prismatica oriented at a 30–70° angle to the surface, at margin of t. prismatica-porrecta oriented at 20–30°, bright to dark grey-brown-olive (mainly at the cortex), marginal cortical cells †7–11 × 2–5 µm. **Anchoring hyphae** sparse to abundant, hyaline, †2–3(–3.5) µm wide, walls 0.2 µm thick, forming a dense t. intricata. **SCBs** partially present in paraphyses, globose. **Exudate** over paraphyses, margin and flanks dark olive-brown, KOH-resistant, in young apothecia dark olive, turning greyish- or ochre-brown in KOH; 1–2 µm thick, broken in large clods or small granules, ± loosely attached. **— ANAMORPH**: unknown (but see under *O. pileosoma*, p. 469).

Habitat: collected on dry ground, decorticated, 35–40 mm thick projecting branch (or root?) of *Pinus contorta*, on wood, often in beetle galleries or hidden at the border of deep clefts, 0.3–0.5 mm deep very rotten, strongly greyed, with some green algae. **Associated**: '*Chlorosplenium*' *viridulum*, *Odontotrema oregonensis*, *Orbilia pileosoma*, various crustose lichens (*Amandinea*, *Lecanora*). **Desiccation tolerance**: fully viable for at least 13 months. **Altitude**: 2035 m a.s.l. **Geology**: Quaternary felsic volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia atrolentiformis* differs from the macroscopically similar *O. patellarioides* in narrower, subcylindrical ascospores lacking tails, also in the often strongly plug-shaped SBs. *O. purshiae* differs in much broader spores.

Ecology. *O. atrolentiformis* is only known from a single population of about 25 apothecia. It grew on rotten wood of a dead xeric branch (or root?) of *Pinus contorta* (lodgepole pine) in the boreal humid, upper montane lodgepole pine

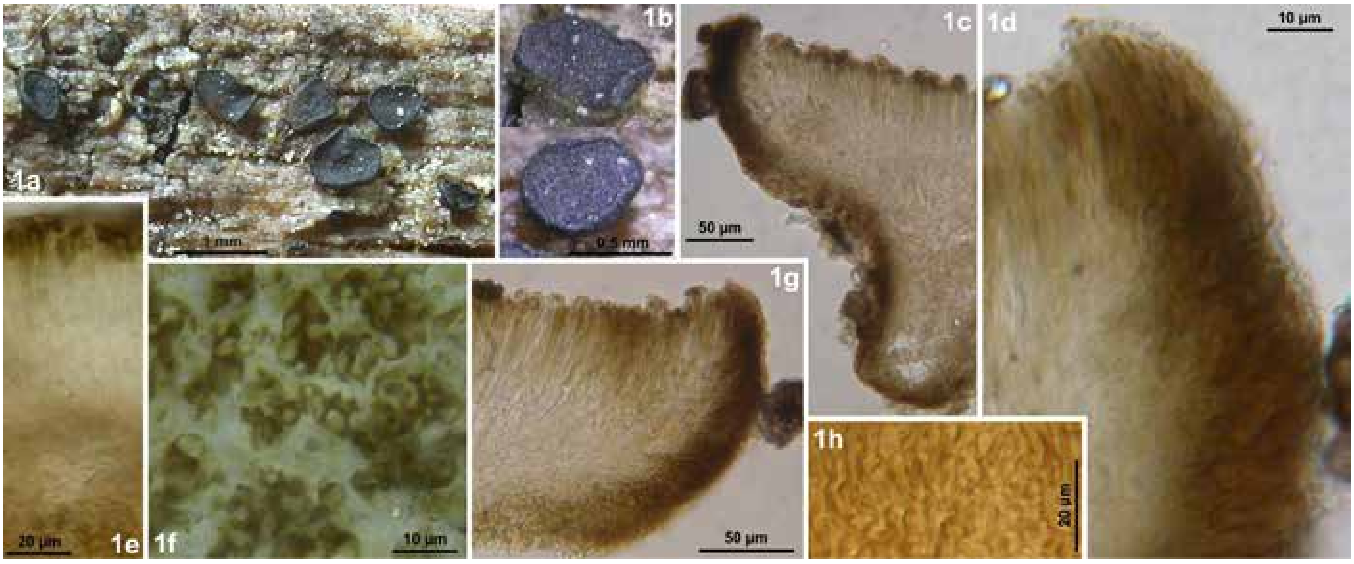

Plate 153. **1**: *Orbilia atrolentiformis*. – **1a–b**. apothecia in rehydrated state; **1c**. apothecium in median section; **1d**, **g**. id., near margin; **1h**. id., in external view; **1e**. hymenium and medullary excipulum in median section; **1f**. top view on hymenium. – Dead state (KOH, except for **1c**, **g**: H$_2$O). — **1a–h**. H.B. 5741a (holotype): USA, Montana, on *Pinus*.

forest at the northern end of the Middle Rocky Mountains in western North America. Black apothecia of an *Amandinea* sp. grew in association which much resemble the *Orbilia* but have more convex hymenia and are clearly connected to a thallus. The smaller-sized but otherwise macroscopically very similar apothecia of the associated *O. pileosoma* grew in a separate small population.

Specimens included. **USA**: **Montana**, Middle Rocky Mountains, SE of West Yellowstone, 2035 m, branch (?root) of *Pinus contorta*, on wood, 5.VI.1996, G. Marson (ex H.B. 5741a, M-0276437, **holotype**).

Orbilia purshiae Baral & G. Marson, **sp. nov.**, MB 814378 — Pls 154–155, Map 22

Etymology: named according to the predominant host plant, *Purshia stansburyana.*

Typification: USA, Arizona, Jacob Lake, branch of *Purshia stansburyana*, 17.V.1995, G. Marson (ex H.B. 5295a, M-0276573, holotype).

Latin diagnosis: *Similis* Orbiliae patellarioidi *sed corpuscula ascosporarum obturamentiformia, elongato-angulata, asci latiores, tunica apicali magis incrassata*. Habitat ad *lignum putridum ramorum siccorum* Purshiae *vel* Cercocarpi *in zona orotemperata subhumida ad semiarida Americae septentrionalis*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.7(–1) × 0.2–0.5(–0.7) mm, 0.13–0.18(–0.24) mm thick (receptacle 0.11–0.18 mm), black (rarely associated by some abnormal bright orange apothecia), round to often ± elongate in direction of the wood fibres, somewhat undulating when large, scattered or gregarious in small or larger groups; disc flat, finely rough, margin thin, not rising above disc, even; externally glabrous, sessile; margin dry not inrolled, more distinct, partially navicular like a *Hysteropatella*, ± immersed among wood fibres. **Asci** *55–75(–82) × 8.5–10 µm {3}, †(47–)60–80(–95) × (7.3–)7.8–8.8(–9.5) µm {3}, 8-spored, spores 3–4-seriate, (1–)3–5(–6) lower spores inversely oriented (not or partially mixed) {3}, pars sporifera *32–42(–45) µm long; **apex** (†) always hemispherical, dome †1.5–3.3 → 1–2 µm thick {3}, with very prominent apical chamber, exterior sometimes olivaceous by a thin layer of exudate; **base** with short to medium long, thick, flexuous stalk, T-, L-or Y-shaped. **Ascospores** *(8.3–)12–16(–17) × (2.8–)3–3.8(–4.2)((–5)) µm {3}, †10–14.3 × 2.7–3.2(–3.6) µm {2}, clavate to cylindric- or ellipsoid-clavate, apex rounded, base medium to often strongly attenuated, rarely tail-like (exceptionally with a short tail), straight or mostly slightly to strongly curved near base; **SBs** *(0.8–)1–1.6 × 1.2–1.8 µm {3}, plug-shaped with prominent inner edges, apically broadly attached; **LBs** sparse, minute. **Paraphyses** apically ± cylindrical to very slightly clavate or sublageniform, terminal cell */†8.5–15(–19) × 1.8–3 µm {2}, straight to ± flexuous, often with brownish-olivaceous, slightly roughened wall, lower cells *(4.5–)8–15 × 1.7–2.8 µm {2}; frequently branched near apex. **Medullary excipulum** ± hyaline, 30–50(–100) µm thick, of dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a hyaline to pale amber t. porrecta, dead cells with light yellow-ochre cytoplasm. **Ectal excipulum** ± hyaline, cortex black-brown-olivaceous, of (*) slightly to medium gelatinized, ± vertically oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 15–100 µm thick near base, cells *6–15 × 4.5–10 µm {3}; 15–25 µm thick near margin, of t. prismatica-angularis oriented at a 70–80° angle to the surface, or t. prismatica-porrecta at a 30° angle, marginal cortical cells */†6–15 × 2–4 µm {2}. **Anchoring hyphae** hyaline, †2–3.5 µm wide, wall 0.2–0.3(–0.7) µm thick {1}, forming a loose or dense, not or medium gelatinized t. intricata at the base. **SCBs** absent. **Exudate** dark olive-brownish, rough-cloddy, over paraphyses 2–4 µm thick, ± firmly attached, KOH-resistant (turning reversibly brass-amber-brown); over margin and flanks rough-cloddy, in KOH turning reddish-brown, near base fox-ochre. — **ANAMORPH**: vermispora-

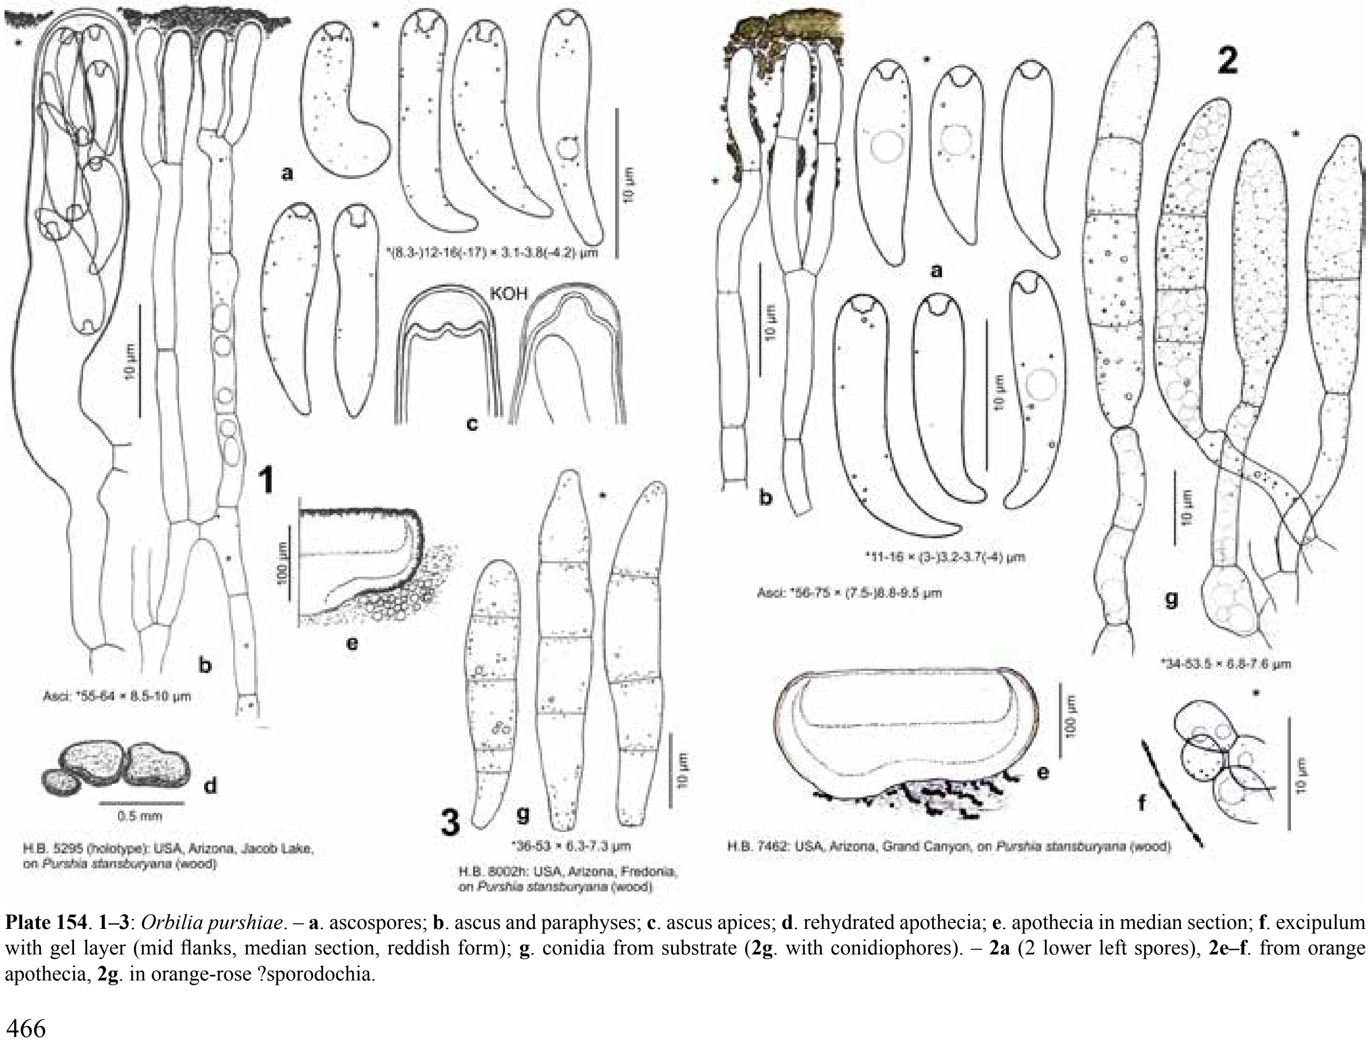

Plate 154. **1–3**: *Orbilia purshiae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. excipulum with gel layer (mid flanks, median section, reddish form); **g**. conidia from substrate (**2g**. with conidiophores). – **2a** (2 lower left spores), **2e–f**. from orange apothecia, **2g**. in orange-rose ?sporodochia.

like (presumed, from natural substrate {3}). (?)**Conidiomata** ~0.3–0.4 mm diam., ?sporodochial, bright orange-rose, inner tissue of textura angularis, thin-walled, small-celled, without a differentiated ectal layer {1}. **Conidiophores** short, sometimes branched. **Conidiogenous cells** *~12–25 × 3.3–4 µm. **Conidia** unbranched, almost straight to slightly (rarely medium) curved, narrowly fusoid, *(30–)35–45(–53.5) × 6.3–7.6 µm {2}, †33–43 × 5.3–6.3 µm {1}, (1–)3(–4)-septate.

Habitat: collected 0.5–2.5 m above the ground, on decorticated, (4–)6–16 mm thick twigs and branches of *Purshia stansburyana* {5}, *Cercocarpus ledifolius* {1}, on 0.3–1.5 mm deep strongly decayed wood {5}, slightly to strongly greyed, with a few or quite many green algae. **Associated**: *Caloplaca* sp. {1}, *Candelariella* sp. {1}, *Durella* sp. {1}, *Odontotrema oregonensis* {1}, *Orbilia arizonensis* {4}, *O. calyptrata* {1}, *O. delphinus* {1}, *O. euonymi* {1}, *O. flexisoma* {1/3}, *O.* ?*gambelii* {1}, *O.* ?*lentiformis* {3}, *O. macrodelphinus* {2}, *O. maeandrina* {4}, *O. multimaeandrina* {1}, *O. serpentina* {1}, *O. subovoidea* {1}, ?*Schizoxylon* sp. {1}, *Symbiotaphrina desertorum* {1}, foliose and crustose *Lecanorales*. **Desiccation tolerance**: fully viable for at least 7 months, after 28 months spores and some excipular cells still viable, conidia after 6 months. **Altitude**: 1880–2500 m a.s.l. **Geology**: Permian and Jurassic (red) sand- & limestone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia purshiae* differs from *O. patellarioides* in wider asci with a thicker apical dome, slightly larger ascospores which usually lack a tail, distinctly plug-shaped SBs, and in the substrate (*Rosaceae* vs. gymnosperms). The also conifericolous *O. atrolentiformis* has much narrower spores, but similar plug-shaped SBs.

A few bright orange-coloured apothecia in H.B. 7462a are microscopically indistinguishable (Pl. 154: 2a, lower left 2 spores, e–f) and appear to represent a colour variant of *O. purshiae*. Comparable rare cases of pigment loss were noted in *O. patellarioides* and *Amphosoma atroolivaceum*.

Anamorph. A few bright orange apothecioid fructifications (?sporodochia) without asci resembled the orange colour variant of *O. purshiae*, but were found in close association with the black apothecia in H.B. 7462a. The conidia formed in them (Pl. 154: 2g) coincide with those found on the natural substrate of another collection (Pl. 154: 3g). The wall surface of the conidiophores stained pale lilac with CRB, a character typical of *Orbiliomycetes*. The question remains open whether

Map 22. Known distribution of *O. purshiae* in North America.

these fructifications are host apothecia of another *Orbilia*, or conidiomata of *O. purshiae*.

Phylogeny. A sequence was taken in Feb. 2020 from apothecia on branches from Coconino Plateau (SSU V9, ITS, LSU D1 and part of D2). In our combined analysis of section *Lentiformes* (not shown) *O. purshiae* clustered unresolved among *O. patellarioides*, the core clade of section *Lentiformes*, *O. ovalis*, and series *Microspermae*. In the ITS it showed a distance of 22 % to *O. patellarioides*, while the lowest distance was 19.5 % to *O. lentiformis* s.l.

Ecology. *O. purshiae* was found on rotten wood of dead xeric branches of two genera of *Rosaceae* shrubs, *Purshia* (Stansbury's cliffrose) and *Cercocarpus* (mountain mahogany) in the Colorado Plateau (southwest of Northern America): in cold-temperate subhumid pinyon-juniper woodlands, partially adjacent to warm-continental semiarid or cold-temperate subhumid sagebrush desert scrubs, in the Grand Canyon section (Kaibab and Coconino Plateau) and at the foothills of Utah mountains.

Specimens included. **USA**: **Utah**, Utah Mts., 16 km SSW of Boulder, 1920 m, branch of *Purshia stansburyana*, on wood, 11.VI.2003, G. Marson (H.B. 8059a, anam. substr.). – 19 km ENE of Springdale, 11 km WNW of Mt. Carmel Junction, 1880 m, branch of *P. stansburyana*, on wood, 14.VI.2003, G. Marson (ø). – **Arizona**, Grand Canyon, Kaibab Plateau, 28 km ESE of Fredonia, 13 km NNW of Jacob Lake, 2115 m, branch of *P. stansburyana*, on wood, 17.V.1995, G. Marson (ex H.B. 5295a, M-0276573, **holotype**). – ibid., branch of *P. stansburyana*, on wood, 15.VI.2003, G. Marson (H.B. 8002h, anam. substr.). – 93 km SSE of Fredonia, S of North Rim, 2500 m, branch of *Cercocarpus ledifolius*, 17.V.1995, G. Marson (ø). – Coconino Plateau, 7.5 km ESE of Grand Canyon Village, close to South Rim, 2205 m, branch of *Purshia stansburyana*, on wood, 16.VI.2003, G. Marson (H.B. 7462a, G.M. 2003-06-16.1, anam. substr., sq.: MT356590).

Orbilia pileosoma Baral & G. Marson, **sp. nov.**,
MB 813484 — Pls 156–157

Etymology: referring to the extraordinarily thin, calotte-shaped spore bodies (resembling a pileolus).

Typification: USA, Utah, Panguitch, branch of *Abies concolor*, 20.VI.2000, G. Marson (ex H.B. 6998c, M-0276553, holotype).

Latin diagnosis: *Apothecia in statu rehydratata atroolivacea, 0.15–0.5 mm diam. Asci 16-spori, apice rotundati, in statu emortuo crassitunicati. Ascosporae *4.8–8 × 3.2–4.5 µm, late ellipsoideae vel obovoideae, intus prope apicem calotta refringente leniter incrassata. Paraphyses ad apicem haud inflatae, exsudato valido atroolivaceo tectae. Habitat ad lignum putridum ramorum siccorum arborum coniferarum in zona orotemperata ad boreali humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.4(–0.5) × 0.12–0.4 mm, 0.11 × 0.18 mm thick, black, round, sometimes broadly elliptical, scattered or subgregarious in small groups; disc flat,

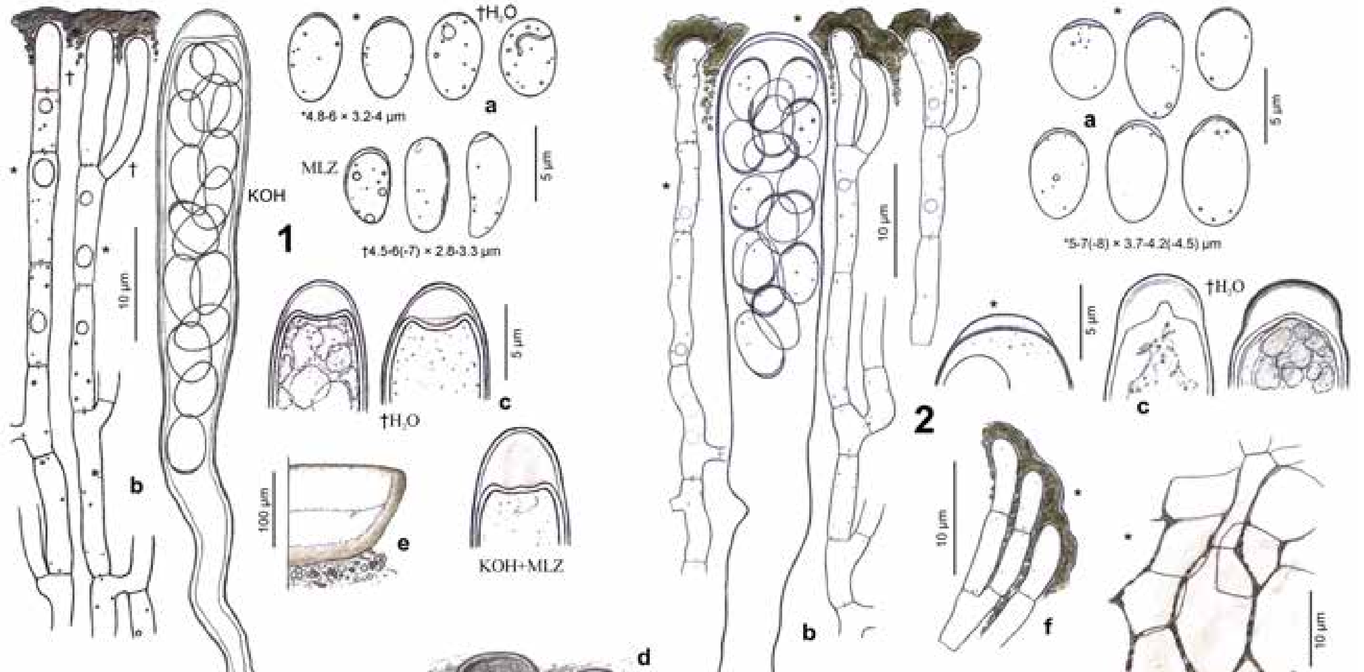

Plate 156. **1–2**: *Orbilia pileosoma*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apex (on **1c** dextrinoid in MLZ); **d**. rehydrated apothecia. **e**. apothecium in median section; **f**. ectal excipulum (margin, median section); **g**. id., near base.

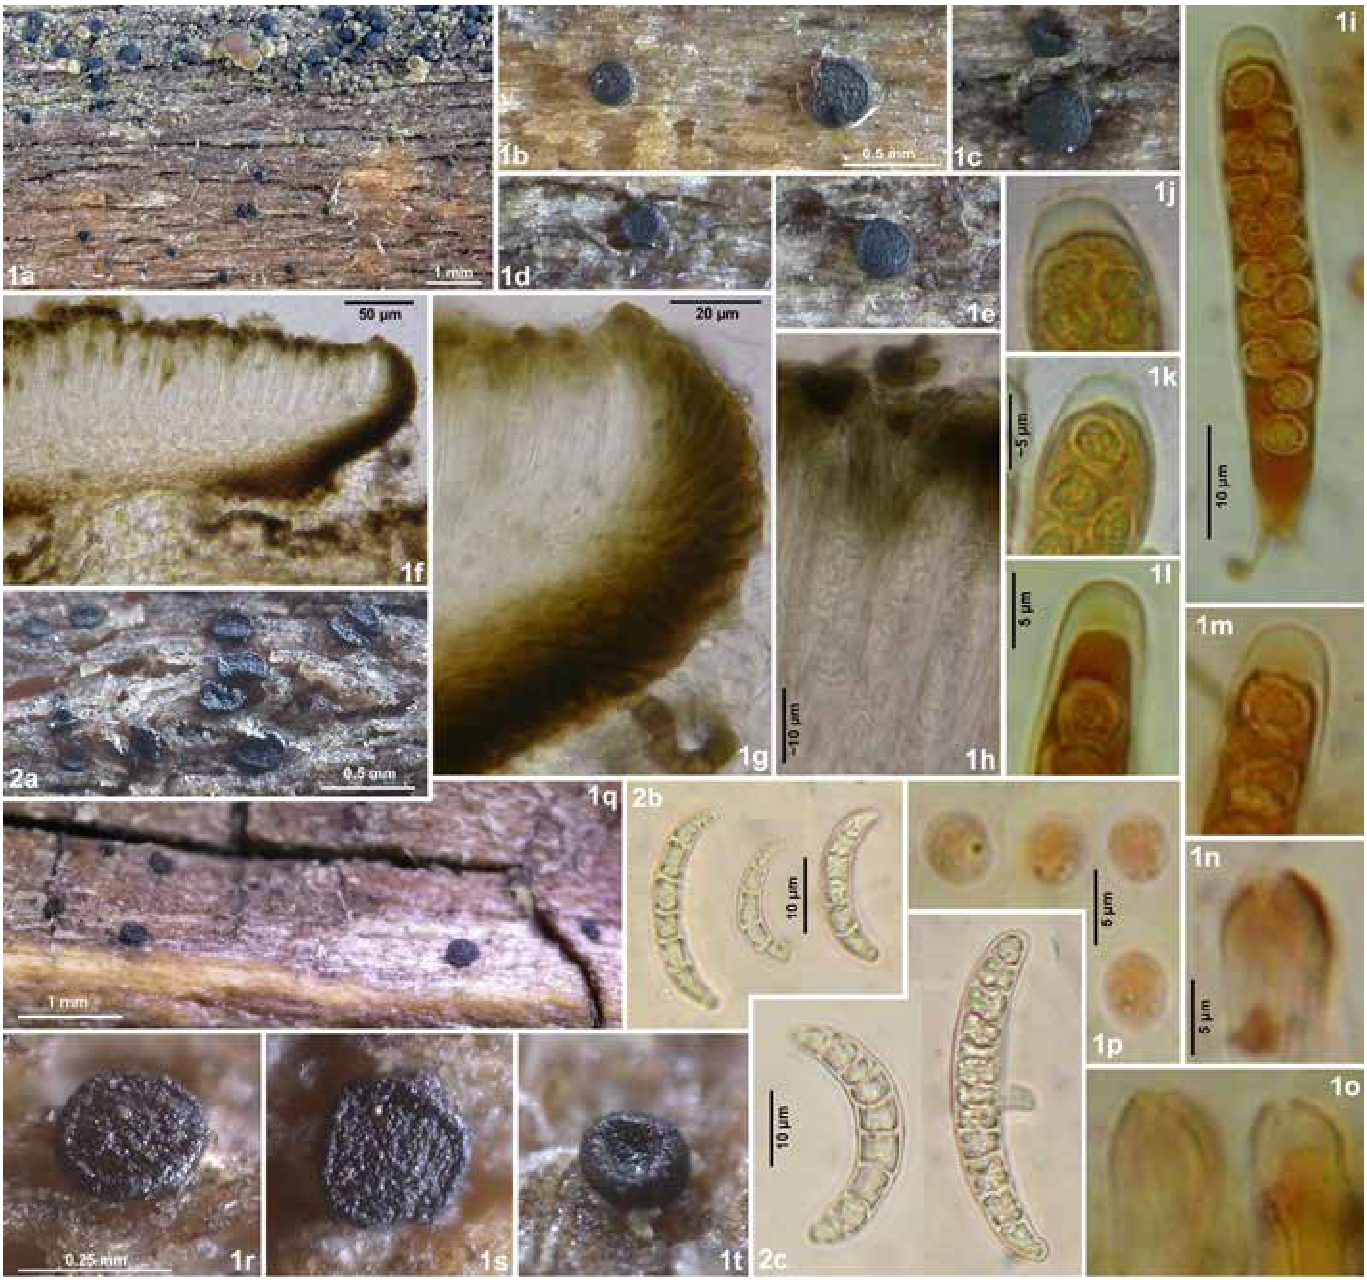

Plate 157. **1–2**: *Orbilia pileosoma*. – **1a–e**, **q–t**, **2a**. rehydrated apothecia (**1a**: crustose lichens in upper part); **1f**. apothecium in median section; **1g**. marginal region in median section; **1h**. detail of hymenium showing olive exudate; **1i**. ascus; **1j–o**. ascus apices (**n–o** emptied via apical slit); **1p**. ascospores (SBs located where plasma looks as being detached); **2b–c**. conidia from substrate. – All in dead state: **1f**, **h**, **2b–c** (in water); **1g** (in KOH); **1j–k** (in KOH+IKI); **1i**, **l–o** (in KOH+CR+IKI); **1p** (KOH+CR). — **1a–t**. H.B. 6998c (holotype): USA, Utah, on *Abies*; **2**. H.B. 5741b: USA, Montana, on *Pinus*.

eventually slightly convex, finely rough, margin ± thick, distinct, 0–10 µm protruding, shining; sessile, superficial or slightly immersed in detritus or wood fibres. **Asci** *(50–)55–69(–77) × 9–10.2(–13) µm {1}, †45–70 × (7–)7.5–9 µm {2}, 16-spored, spores 3–4-seriate, about half of the lower spores inversely oriented (strongly mixed, some horizontally oriented), pars sporifera *30–45 µm long, †24–46 µm; **apex** (†) hemispherical to distinctly subconical or subtruncate, dome immature †2–3(–4) µm thick, mature ~2–2.5 µm, sometimes with distinct apical chamber, dome in KOH+MLZ partially pale to light red (± ring-shaped) {2}, emptied asci especially in older apothecia often with bright olive-brown periascus; **base** with short to medium long, thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *4.8–7(–8) × (3.2–)3.5–4.5 µm {1}, †4.3–6(–7) {2} × 2.8–3.3 {1} or 3.8–4.2 {1} µm, broadly ellipsoid to obovoid, rarely clavate, straight; **SBs** 0.2–0.4 × 1.5–3 µm, forming a thin calotte-shaped layer very broadly attached to the apical wall. **Paraphyses** apically ± uninflated, terminal cell */†(6–)7–10(–13) × (1.6–)1.8–2.4(–3.3) µm {2}, lower cells *5–15 × 1.7–2.7(–4) µm {2}; quite frequently branched near apex. **Medullary excipulum** hyaline, 30–50 µm thick (50–70 µm in centre), of dense textura intricata with many inflated cells, (†) somewhat gelatinized, sharply or very indistinctly delimited. **Ectal excipulum** of (*) thin-walled, (†) strongly gelatinized, ± vertically oriented t. (globulosa-)angularis from base to mid flanks, 20–40 µm thick near base, cells *8–18 × 6–10.5 µm; near margin 15–20 µm thick, of t. porrecta oriented at 30–45°, cortical cells *5–9 × 2–2.2 µm {1}. **Anchoring hyphae** ± sparse, hyaline, †1.7–3 µm wide, walls †0.2–0.5 µm thick {1}. **SCBs** in paraphyses ± globose. **Exudate** over paraphyses cloddy (to granular), 1–3 µm thick, bright to deep olive-brown, in KOH turning light olive-amber-brown, ± firmly attached; over marginal excipulum cloddy(-granular), 1–2 µm thick, bright to dark olivaceous-brown (KOH more reddish-brown, acetic acid recovers the olive colour), also present between the cells, gradually paler towards medullary excipulum. — **ANAMORPH**: vermispora-like (presumed, from natural substrate {1}). **Conidiophores** not seen. **Conidia** unbranched, slightly to strongly curved, †16–27 × 3.8–4 µm, 4–5-septate, or 29–45 × 6.3–6.5 µm, 8–11-septate (observed in the same sample).

Habitat: collected ~0.2–2 m above the ground, decorticated, 15–35 mm thick branches (and roots?) of *Abies concolor* {1}, *Pinus contorta* {1}, close to or in old beetle galleries, on 0.2–1 mm deep very rotten wood {2}, strongly greyed, with some green algae. **Associated**: *Amandinea* sp. {2}, '*Chlorosplenium*' *viridulum* {1}, *Claussenomyces* sp. {1}, *Lachnellula* sp. {1}, *Lecanora* sp. {1}, *Melaspilea emergens* {1}, *Odontotrema oregonensis* {1}, *Orbilia atrolentiformis* {1}, *O. concoloris* {1}, *O. phanosoma* {1}. **Desiccation tolerance**: fully viable after min. 17 months. **Altitude**: 2035–2775 m. **Geology**: Upper Cretaceous calcareous sandstone, (Tertiary to) Quaternary volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pileosoma* is easily distinguished from the other species with black apothecia by 16-spored asci and extraordinary, very thin and wide, calotte-like SBs in the mature living ascospores. The SBs resemble the apical wall thickenings of living asci, but they stain light blue in CRB, and loose refractivity without getting inflated when adding KOH (Pl. 157: 1p).

Variation. In the sparse *Pinus* collection, the ascus apical dome reacted distinctly pale red in MLZ though it was negative in IKI or KOH+IKI. After KOH-treatment the MLZ-reaction was light red in all asci (Pl. 156: 1c, lower ascus). The abundant *Abies* collection was iodine-negative in either treatment (the stain in Pl. 157: 1l–m is probably due to presence of CR). This difference might be accidental, and further collections should be tested for the feature.

Anamorph. Two types of vermispora-like phragmoconidia were observed on the substrate of the *Pinus* collection (Pl. 157: 2b–c). Whether both of them belong to *O. pileosoma*, or perhaps one to the associated *O. atrolentiformis*, remains unclear.

Ecology. *O. pileosoma* grew on rotten wood of decorticated xeric branches of *Abies concolor* (white fir) in the boreal humid Douglas fir mixed forest at the southern end of Dixie Forest (Utah Mountains) and of *Pinus contorta* (lodgepole pine) in the boreal humid lodgepole pine forest at the northern end of Middle Rocky Mountains (Yellowstone). Black apothecia of an *Amandinea* grew in association in both collections; they much resemble those of the *Orbilia* but are generally larger, with more convex hymenia, and clearly connected to a thallus. The associated *O. atrolentiformis* differed macroscopically merely in larger apothecia.

Specimens included. **USA**: **Montana**, Middle Rocky Mountains, SE of West Yellowstone, 2035 m, branch (or root?) of *Pinus contorta*, on wood, 5.VI.1996, G. Marson (H.B. 5741b, anam. substr.). – **Utah**, Utah Mts., Bryce Canyon, 42 km SSE of Panguitch, Rainbow Point, 2775 m, branch of *Abies concolor*, on wood, 20.VI.2000, G. Marson (M-0276553, **holotype**; **isotype** in H.B. 6998c).

Species with reddish apothecia

Orbilia lentiformis Baral & G. Marson, **sp. nov.**, MB 814369 — Pls 158–162, Map 23

Etymology: named according to the lens-shaped spore bodies.

Typification: Australia, Northern Territories, Alice Springs, branches of *Atriplex nummularia*, 9.X.1998, G. Marson (ex H.B. 6569c, MEL 2389210, holotype; ex-type culture: CBS 140836; sq.: KT215225, MH878193).

Latin diagnosis: *Apothecia in statu rehydratata aurantiaca vel rosea, 0.1–0.7 mm diam. Asci 8-spori, apice in statu emortuo parum vel modice truncati, partim crassitunicati. Ascosporae *11–19 × 3–5.5 µm, clavatae, in statu vivo prope apicem corpusculum refringens lentiformem, perlate affixum continentes. Paraphyses ad apicem non vel modice inflatae, exsudato tenui hyalino tectae. Habitat ad lignum vel corticem putridum ramorum siccorum fruticum vel arborum angiospermarum, raro coniferarum, in locis borealis ad subtropicis, humidis ad aridis Europae, Asiae, Americae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.15–0.5(–0.7) mm diam., 0.12–0.23 mm high, pale to bright orange or rose, scarcely translucent, round, scattered to subgregarious; disc medium concave to slightly convex, margin indistinct to distinct, thin, 0–25 µm protruding, smooth; broadly sessile, superficial to deeply immersed, erumpent between fibres; dry bright to deep orange-red. **Asci** *((50–))61–90(–103)((–110)) {11} × (8–)8.5–9.7 {6} or 9–10.5(–11.5) µm {6}, †(50–)60–90(–105) × ((6–))(6.5–)7–10(–11)((–12)) µm {16}, 8-spored, spores *biseriate, (0–)1–6(–8) lower spores inverted {11} (not to strongly mixed), pars sporifera *32–52 µm long; **apex** (†) slightly to medium truncate, hemispherical in profile view, dome distinct, also nearly absent, †0.8–1.7(–2.7) → (0.3–)0.5–1(–1.5) µm thick {11}, some with distinct apical chamber; **base** with short to sometimes long, thick, flexuous stalk, unbranched or T-, L-, Y- to h-shaped. **Ascospores** *((8.3–))(10–)12–17(–19)((–21)) × (3–)3.3–4.5(–5.5) µm {22}, †((8–))(10–)11–15.5(–17) × (2.8–)3.2–4.2(–4.5) µm {11}, ellipsoid-clavate, often also cylindric-ellipsoid, apex rounded (to obtuse), base slightly to strongly attenuated, sometimes tail-like, straight to slightly, sometimes rather strongly curved; overmature up to 3-septate {1}; **SBs** *(0.3–)0.6–1.3(–1.6) × (1.5–)1.7–2.2(–2.5) µm {6}, lens- to sometimes plug-shaped, apically broadly attached; with some minute, scattered or grouped **LBs** in each half, 1–2 glycogen bodies 1–2 µm diam. per spore; very rarely a single spore 1-septate within the living ascus {1}, in dead asci 1-septate spores sometimes frequent {2}. **Paraphyses** apically uninflated to slightly or medium, sometimes strongly clavate-capitate, terminal cell *(3–)5–15(–20) × (2–)2.5–4.5(–5.5) µm {6}, †10–20 {1} × 2–4.5 µm {2}, lower cells *(3.5–)7–15(–23) × 1.4–2.5(–3.5) µm {4}, †1.3–1.7 µm wide {1}; rarely {2} or frequently {9} branched at upper septum, hymenium pale rose. **Medullary excipulum** pale rose, 30–60 µm thick, of dense textura intricata with some or many inflated cells, not sharply delimited. **Ectal excipulum** pale rose, of thin-walled to slightly gelatinized, irregularly or vertically oriented t. angularis from base to mid flanks or margin, 20–40 µm thick near base, cells *6–15 × 5–11 µm {4}, †4–8 × 4–6 µm {1}; 20–30(–40) µm thick near margin, of t. prismatica to t. porrecta oriented at a 0–30° angle to the surface, marginal cortical cells *6–13 × 3–5 µm {3}. **Anchoring hyphae** sparse to abundant, *2.5–3.5 µm wide, walls 0.2 µm {2} or 0.3–0.8 µm thick {1}, sometimes covering flanks and margin by an up to 25 µm thick layer. **SCBs** globose, in paraphyses (0.5–)1–2(–2.8) µm diam., in ectal excipulum (near margin) (1–)1.8–3.3 µm diam. **LBs** in basal ectal excipulum sometimes present, pale yellowish. **Exudate** over paraphyses 0.2–0.5(–1.5) µm thick, granular-cloddy or continuous, hyaline, loosely attached, rarely lacking; over margin and flanks ~0.2–0.5 µm thick, ± continuous. — **ANAMORPH**: vermispora-like {T/2} or trinacrium-like {1/4} (from ascospore isolate/natural substrate). **Conidiophores** not seen. Different strains produced different types of **conidia**: **(1)** phragmosporous, cylindric(-fusoid), mostly slightly curved at upper end, *18–25 × 5–6 µm {T}, †19–25 × 4–5 µm {2}, (1–)3(–4)-septate {3}; **(2)** Y-(or T-)shaped, total size *20–33 × (13–)18–21(–25) µm {3}, stipe *12–23 × 5.2–7.5 µm, 1–4-septate, arms *8–13 × 4–5.2 µm, 1–2-septate, straight or slightly curved downwards.

Habitat: collected 0.5–3 m above the ground, decorticated or corticated, 3.5–32 mm thick twigs and branches of *Abies lasiocarpa* {1}, *Amelanchier utahensis* {1}, *Artemisia tridentata* {1}, *A. filifolia* {1}, *Atriplex nummularia* {1}, *A.* cf. *polycarpa* {1}, ?*Chrysothamnus* sp. {1}, ?*C. viscidiflorus* {1}, *Ericameria nauseosa* {1}, *Fraxinus excelsior* {1}, ?*Glossopetalon spinescens* {1}, *Larrea tridentata* {2}, *Mahonia fremontii* {1}, *Picea abies* {1}, ?*Prunus* sp. {1}, *Pseudotsuga menziesii* {1}, *Purshia stansburyana* {1}, *Quercus robur* {1}, *Ribes cereum* {1}, *Salix* sp. {2}, *S. rhamnifolia* {1}, *Sarcobatus vermiculatus* {2}, *Thymelaea lythroides* {1}, indet. angiosperm {1}, on 0.3 mm deep strongly decayed wood {19} and bark {6} (bast, in clefts of periderm, bark partially detaching), strongly greyed, covered by green algae or not; inflorescence stems of *Yucca gloriosa* {1}, *Y. elata* {1}. **Associated**:

Taxonomic remarks. *Orbilia lentiformis* is characterized by 8-spored asci and comparatively large, cylindric-clavate ascospores with lens- to sometimes plug-shaped SBs. Among those 8-spored species of series *Lentiformes* with reddish apothecia, *O. lentiformis* forms together with *O. ocellata*, *O. subocellata*, and *O. foliicola* a difficult species complex. Our molecular analysis of the ITS rDNA show that the latter three species are rather similar and form a clade with high distance to *O. lentiformis*. Different conidial types (phragmo- vs. staurosporous) occur in both clades, however. This suggests that at least four species occur in this complex, while their recognition by features of asci and ascospores is hardly possible (see Tab. 63). Because sequence data were available only for a very small part of our collections, and anamorph data also only in about half of them, only premature taxonomic conclusions can be drawn at present. A number of collections are with hesitation referred to *O. lentiformis*. Specimens with both types of conidia are included in *O. lentiformis* here because of a low molecular distance between the North American strain with trinacrium-like conidia and the Australian type strain with vermispora-like conidia (Phyl. 8) and because characteristic morphological traits in the teleomorph could not be found.

Variation. A sharp delimitation between *O. lentiformis* and *O. ocellata* was impossible because of a rather high variation in both ascus and spore size as observed between or even within populations of both taxa. In three collections (Pls 158: 1; 159: 2 & 164: 2; 159: 3 & 164: 4) the two species grew in association apparently on the same branches, though in separate populations. In these cases, a differentiation was rather easily possible concerning every apothecium examined. The distinguishing features are mainly seen in the width of the living asci and the length of the living ascospores (see Tab. 63). Although in some of the collections the obtained values strongly overlap, many specimens could be assigned to one of the two taxa because usually either only ascus width or spore length overlapped, but not both. Extraordinarily long asci were observed in a collection from Morocco (Pl. 160) with consistently thin-walled ascus apices; also here spore size is intermediate to *O. ocellata*, despite the long asci.

Further variation within *O. lentiformis* concerns, e. g., the shape of SBs which are ± plug-shaped in some spores of some collections (Pls 158: 2, 4; 159: 2), and the thickness of the apical dome, being exceptionally thick in a collection on *Larrea* (Pl. 161: 5, KOH 2–2.7 → 1–1.5 µm). Those North American collections of *O. lentiformis* which tend to plug-shaped SBs may be confused with the reddish variant of the North American *O. purshiae*, which appears to be separable by strongly tapered and curved spore bases.

Not included collections. Three samples from western North America on *Purshia* (Pl. 162: 1–2, IVV: H.B. 8059b) are intermediate between *O. lentiformis* and *O. ocellata* because of their rather short spores (Tab. 63). Therefore, and because of deviating molecular data (see below), they are not included in either description. Their long asci appear to exclude *O. ocellata*, while spores and asci would fit *O. subocellata* rather well. The latter species is characterized by a vermispora-like anamorph (Pl. 166) and is likewise intermediate in spore length between *O. lentiformis* and *O. ocellata*.

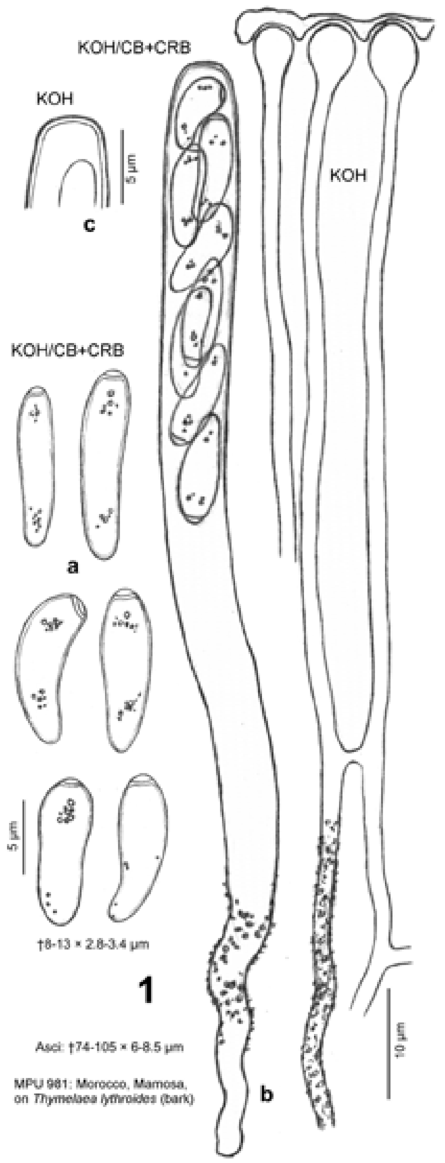

Plate 160. **1**: *Orbilia lentiformis*. – **a**. ascospores; **b**. ascus and paraphyses (septa invisible in KOH); **c**. ascus apex.

Anamorph. Striking differences in conidial morphology were noted among the collections tentatively referred here to *O. lentiformis*. In five collections we have observed conidia on the natural substrate, and in two further ones we obtained them in pure culture. In three of these seven samples the conidia were Y-shaped (staurosporous), with the two arms sometimes slightly bent downwards, resembling *Trinacrium incurvum*, Pls

Table 63. Tentative differences in ascus and ascospore size (in µm) within the *O. lentiformis* complex (taxa with 8-spored asci). The observed conidial types appear to be characteristic at the species level but differed between populations of *O. lentiformis* as circumscribed at present.

159: 3; 161: 2d, H.B. 7210), whereas in the other four they were unbranched (phragmosporous) and slightly curved (vermispora-like, Pl. 158: 2e, H.B. 5228a, 5705c, 8059b). These two types of conidia were also obtained in the two ascospore isolates: in one isolate (H.B. 6740d) stauro- and phragmoconidia were formed, while the other (H.B. 6569c) produced merely phragmoconidia.

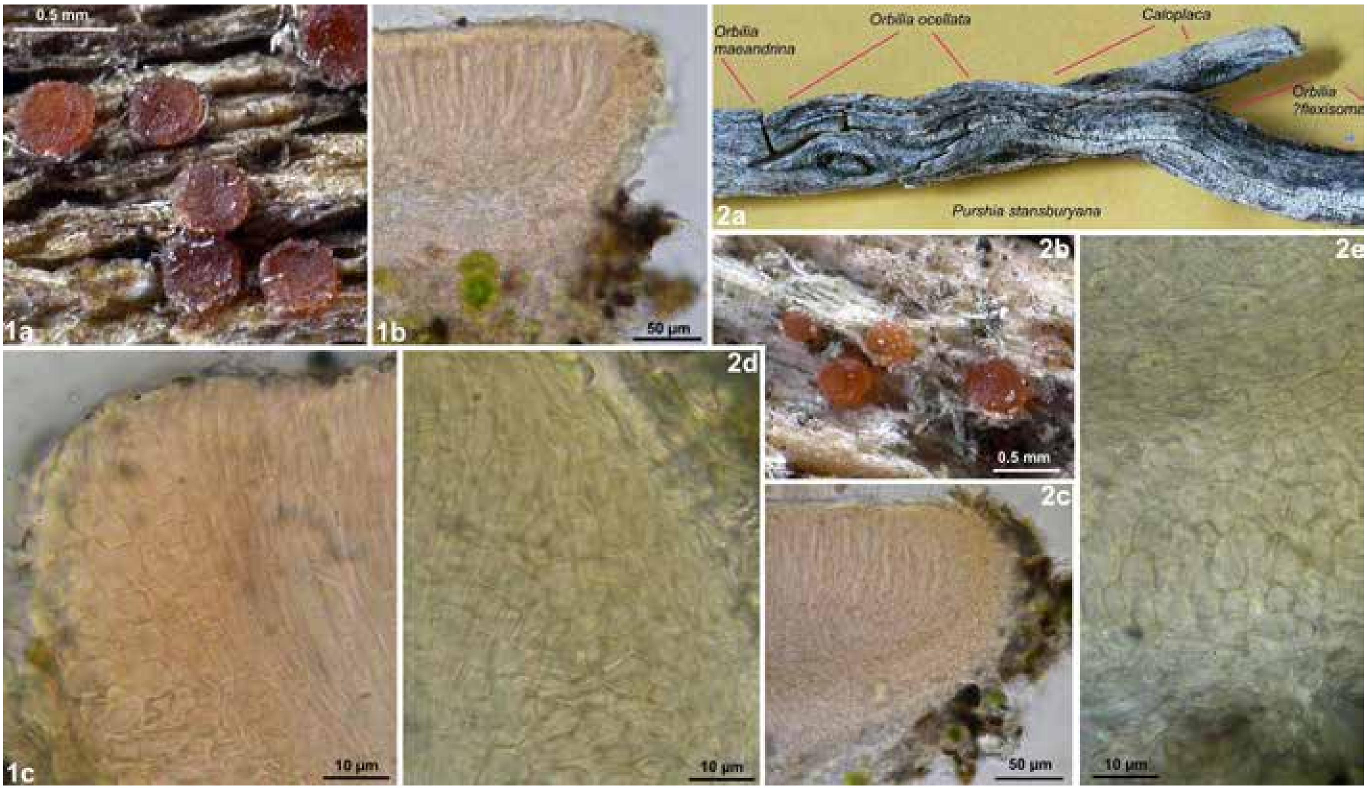

Plate 162. **1–2**: *Orbilia* aff. *lentiformis*. – **1a**, **2b**. rehydrated apothecia; **1b**, **2c**. apothecia in median section; **1c**, **2d**. id., ectal excipulum at margin; **2e**. id., at base. – Living state. — **1a–c**. H.B. 8002c: USA, Arizona, Fredonia, on *Purshia*; **2a–e**. H.B. 8061b: USA, Utah, Mt. Carmel, on *Purshia*.

In a not included collection (IVV: H.B. 8059b) the curved vermispora-like conidia were formed in abundance in the hymenium of a single apothecium which contained only empty asci. The associated mature apothecia are intermediate to *O. ocellata* in spore size (see above), suggesting a relation to the European *O. subocellata*, while the conidia were distinctly smaller (†14–17 × 4–4.3 µm).

Because anamorph data were not available in a majority of collections, and trinacrium-like anamorphs are generally known to produce also some unbranched conidia, these observations need further investigation. As the type of *O. lentiformis* we have selected an Australian collection which solely formed a vermispora-like anamorph in culture (Pl. 158: 2). A similar diversity in conidial morphology was observed between *O. ocellata*/*O. foliicola* and *O. subocellata* (Tab. 63).

Phylogeny. From two strains of *O. lentiformis* with different anamorphs, SSU+ITS+LSU sequences were taken from pure culture: holotype from Australia on *Atriplex*, vermispora-like (Pl. 158: 2); paratype from USA on *Artemisia*, trinacrium-like (Pl. 159: 3). From a further sample (*O.* aff. *lentiformis*), being intermediate to *O. ocellata*, an ITS sequence was taken from apothecia: from USA on *Purshia*, anamorph unknown (Pl. 162: 1). Our molecular analyses showed that the two typical strains always clustered in a strongly supported clade but with a 5 % distance in the ITS region (0.5 % in the LSU). This clade did not fall near *O. ocellata* as expected, but showed a high distance to any species of series *Lentiformes* and *Phanosomates* (10.5–15 % in the ITS and 3.5–5 % in the LSU). The lowest distance of 10.5–11 % was to *O. pluristomachia* (series *Phanosomates*), with which *O. lentiformis* formed a medium supported clade (Phyl. S9). The distance to *O.* aff. *lentiformis* ranged at 12–12.5 %, although the ascus size of that sample matched that of *O. lentiformis* (see Tab. 63). Only the intermediate collection nested in the *flavida-cucumispora* clade by showing a 6 % ITS distance to *O. ocellata*.

The above result indicates that pronounced molecular differences correlate with differently sized asci and ascospores, but less so with differently shaped conidia. The conidial types did not correlate with the observed clades (see also under *O. ocellata*/*O. subocellata*). We here distinguish *O. lentiformis* from *O. ocellata* based on ascus and spore size, supported by molecular data. Whether the observed 5 % distance between the trinacrium- and the vermispora-forming strain of *O. lentiformis* merits recognition at some taxonomic level should be investigated from sequences of further collections. Molecular data from one of the intermediate samples on *Purshia* (*O.* aff. *lentiformis*) points to a species of its own, although these samples did not markedly differ from *O. lentiformis* or *O. ocellata* in their hymenial features (see Tab. 63).

Ecology. *O. lentiformis* occurs on rotten wood and bark of dead xeric branches of various trees and shrubs of angiosperms (rarely gymnosperms). It was found to occur widespread in the southwest of Northern America in the subtropical to cold-temperate, arid to semiarid (to subhumid) creosotebush, sagebrush, salt bush, paloverde mixed cacti desert scrub, and mixed grass-scrubland in the Chihuahuan, Sonoran, and Mojave Desert, and in warm-continental semiarid pinyon-juniper woodlands of the Canyonlands section and boreal humid Engelmann spruce forests of the Mogollon Rim and Southern Rocky Mountains. Single collections are from subtropical semihumid (thermomediterranean) northwestern Africa (Morocco), mesosubmediterranean atlantic western Europe, supratemperate (almost suprasubmediterranean) Romania, hemiboreal to warm-continental (sub)humid eastern Europe (Russia), orotemperate (sub)humid (winter-dry), orotemperate (altimontane to subalpine) continental central Asia (Altay, western Mongolia), and subtropical arid central Australia (acacia open shrubland northeast of MacDonnell Ranges). The three not included North-American samples are from cold-temperate subhumid to warm-continental semiarid pinyon-juniper woodlands of the Colorado Plateau (Utah Mountains and Grand Canyon).

Orbilia ocellata Baral, G. Marson & E. Weber, **sp. nov.**, MB 813485 — Pls 163–165, Map 24

Etymology: referring to the lens-shaped spore body resembling a transect of an ocular lens.

Typification: Luxembourg, Esch-sur-Alzette, branch of *Quercus*, 12.VI.1994, G. Marson (ex H.B. 5104, M-0276540, holotype).

Latin diagnosis: Orbiliae lentiformi *persimilis sed asci leniter angustiores et ascosporae breviores.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.13–0.4(–0.5) mm diam., 0.11–0.13 mm high, pale to light (to bright) orange(-rose), slightly translucent, round, scattered to (sub)gregarious in small groups; disc slightly concave to flat, margin thin, 0–20 µm protruding, smooth or very finely crenulate; broadly sessile, slightly erumpent between fibres, immersed in detritus; dry bright orange-red(-apricot). **Asci** *(47–)54–68(–76)((–87)) × (6.5–)7–8.5(–9.2) µm {10}, †(37–)45–63(–68) × (5.2–)6–7(–7.5) µm {8}, 8-spored, spores *biseriate, (0–)1–4(–5) lower spores inverted {13} (± mixed or not), pars sporifera *(25–)28–40 µm long; **apex** (†) slightly to ± strongly (conico-)truncate, hemispherical in profile view, thin-walled {4} or with dome †0.3–1.4 → 0.3–0.6 µm thick {5}, sometimes variable

Map 23. Known distribution of *O. lentiformis* in North America and Eurasia (yellow = not included collections on *Purshia*).

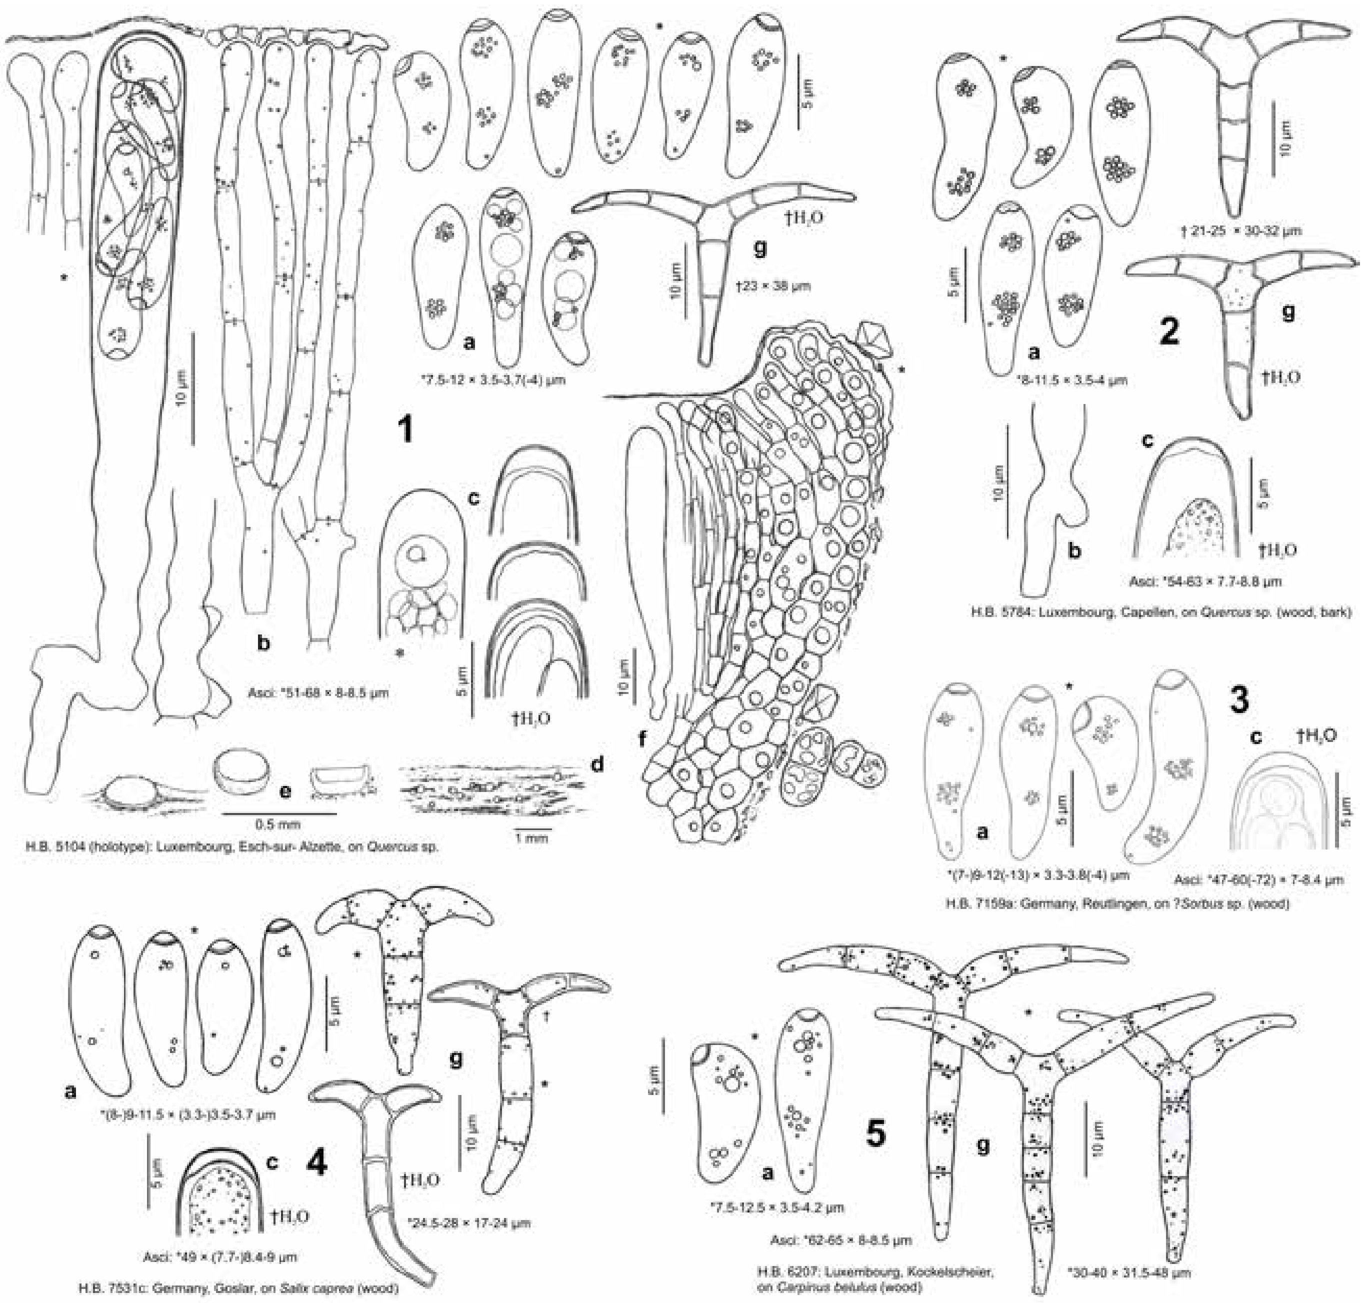

Plate 163. **1–5**: *Orbilia ocellata*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices (**1c** left: young ascus with large fusion nucleus); **d**. apothecia on substrate; **e**. apothecia (rehydrated, one in median section); **f**. ectal excipulum (margin and mid flanks, median section); **g**. conidia from substrate.

within a population, rarely with very slight apical chamber; **base** with very short to medium long, thick, ± flexuous stalk, unbranched or L-, H- or Y-shaped. **Ascospores** *(7–)8–12(–13)((–14)) × (2.8–)3.2–4(–4.5)((–5)) µm {15}, †(6–)7–11(–12.6) × 2.8–3.5 µm {4}, ellipsoid-clavate, sometimes subcylindrical or ellipsoid-fusoid, apex rounded to obtuse, slightly to strongly attenuated near base, straight to slightly curved (upper spores often strongly curved); **SBs** *0.4–1(–1.3) × 1.4–2 µm {6}, lens-shaped, apically broadly attached; often with some small **LBs** grouped in each half; overmature spores non-septate. **Paraphyses** apically uninflated or slightly (to medium) clavate-capitate, terminal cell *(4–)6–18(–23) × 1.8–3.5(–4.5) µm {2}, †1.5–3.8 µm wide {2}, lower cells *7–15.5 × 1.5–2.5(–3) µm {5}, †1–2 µm wide {1}; sometimes branched near apex. **Medullary excipulum** 30–40 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale to light rose, of thin-walled, vertically or indistinctly oriented t. angularis(-prismatica) from base to mid flanks, sometimes with pale yellowish LBs, 30–35 µm thick near base, cells *7–15 × 5–6 or 8–11 µm {2}; 20–30 µm thick near margin, of t. prismatica-angularis to prismatica-porrecta oriented at a 0–20(–80)° angle to the surface, marginal cortical cells *6.5–13 × (3–)4–5(–7) µm {2}, †10–14 × 2–3 µm {1}. **Anchoring hyphae** rather abundant, *1.8–2.7 or 2.5–4 µm wide, walls 0.2–0.6(–1) µm thick {2}, forming a rather dense hyaline t. intricata up to 40 µm thick, sometimes forming a thin layer up to the margin. **SCBs** globose, in paraphyses 1–2(–2.5) µm diam., sometimes absent, in ectal excipulum (1.5–)2–3(–4) µm diam. **Exudate** over paraphyses 0.4–1.5 µm thick, cloddy, hyaline, loosely attached; over margin and flanks 0.5–3 µm thick. **— ANAMORPH**: trinacrium-like (from ascospore isolate {1}, ascocarp on agar {1}, and natural substrate {7}). **Conidiophores** short. **Conidia** Y/T-shaped, the two arms often bent somewhat downwards, conidia from central Europe somewhat larger, total size */†21–30(–40) × (17–)25–52 µm, arms tapering */†(8–)15–25 × 3–4.5 µm, (1–)2–3-septate, stipe */†16–32 × 3.2–4.5(–5.5) µm, 2–4-septate; from southern Europe and USA: total size *22.5–32 × (10–)12–22.5 µm, arms *5–13 × 4.5–6.5 µm, 0–2(–3)-septate, stipe *15–2 4 × 5–7 µm, 2–4(–5)-septate, in pure culture (H.B. 6475b, 25.VIII.94) also unbranched, more or less straight phragmoconidia seen: *24–30 × 5.5–6.5 µm, 3–7-septate.

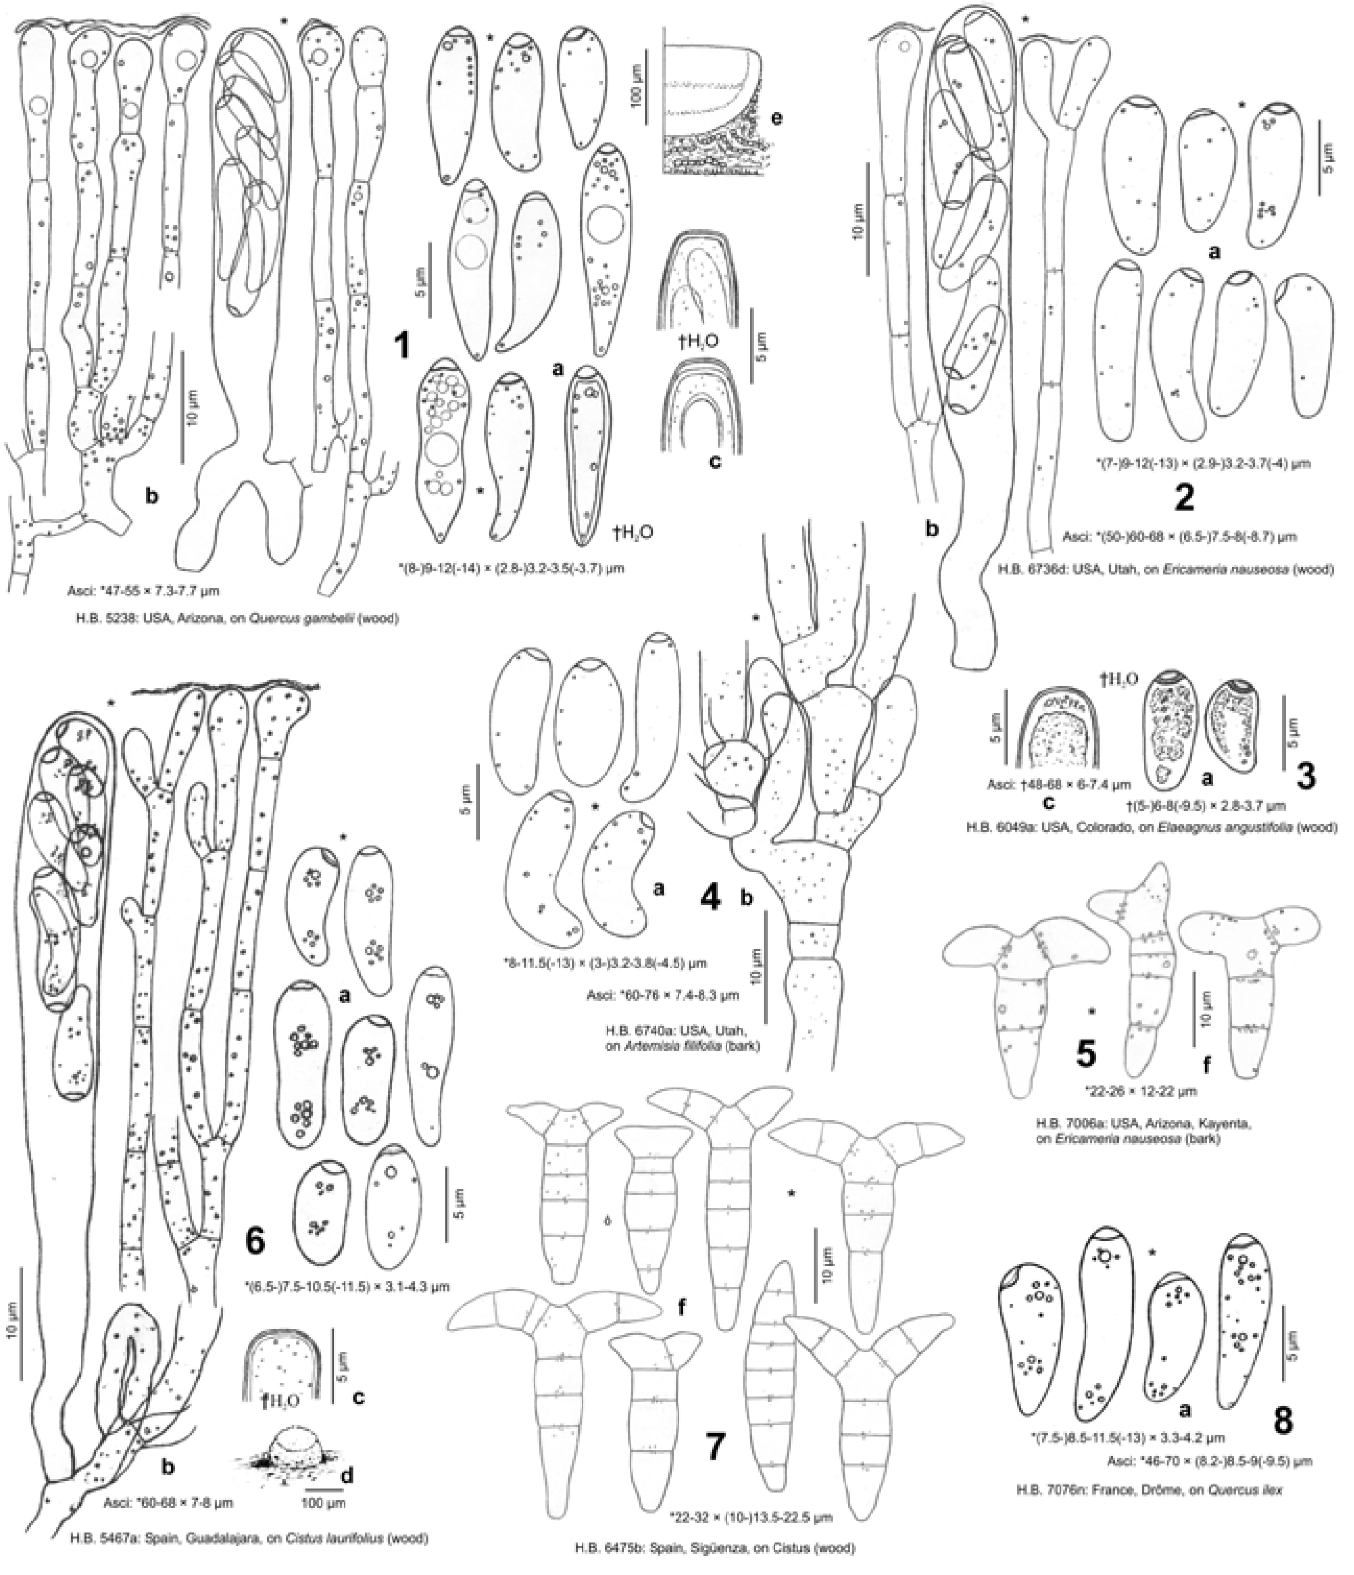

Plate 164. **1–8**: *Orbilia ocellata.* – **a**. ascospores (**3a**. refractive SBs in dead spores); **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium (rehydrated); **e**. apothecium in median section; **f**. conidia (**7f**. from culture, **5f**. from substrate).

Habitat: collected 0.1–3.5 m above the ground, ± corticated to decorticated, (2–)4–35(–60) mm thick twigs and branches (rarely ~15–20 cm thick trunk) of *Amelanchier utahensis* {1}, *Artemisia filifolia* {2}, *Baccharis salicifolia* {1}, *Carlina xeranthemoides* {1}, *Carpinus betulus* {1}, *Cercocarpus betuloides* {1}, *Chrysothamnus viscidiflorus* {1}, *Cistus* sp. {1}, *C. laurifolius* {1}, *Coleogyne ramosissima* {1}, *Elaeagnus angustifolia* {1}, *Ericameria nauseosa* {3}, *Fagus sylvatica* {1}, *Juglans major* {1}, *Lonicera altaica* {1}, *Malus domestica* {1}, *Pyrus communis* {1}, *Quercus* sp. {2}, *Q. gambelii* {1}, *Q. rotundifolia* {1}, *Rosa* sp. {3}, *Rhamnus myrtifolia* {1}, *Salix* sp. {2}, *S. caprea* {1}, *Sorbus* sp. {1}, on 0.1–0.5 mm deep medium to strongly decayed wood {22} and bark {12} (bast {6} or periderm {3}), rarely on leaves of *Yucca* sp. {2}, petioles of *Carlina xeranthemoides* {1}, often strongly greyed, with many green algae or not. **Associated**: ?*Calloria* spp. {2}, ?*Chaetoplea umbilicata* {1}, *Claussenomyces* sp. {1}, *Coniochaeta subcorticalis* {1}, *Durella* ?*atrocyanea* {1}, ?*Exarmidium* sp. (apothecioid) {1}, ?*Hypoxylon* sp. {1}, *Hysterium* ?*angustatum* {1}, ?*Laetinaevia* sp. {1}, *Melanelia glabratula* {1}, *Melanohalea*

Plate 165. **1–10**: *Orbilia ocellata*. – **1a**. clearing in beech forest with fallen trunk; **6a**. xeric branch of *Malus*; **2a–d**, **3**, **4a**, **5a**, **c**, **6b–e**, **7b–e**, **8a**. rehydrated apothecia; **5b**, **7a**, **f**, **8b**. dry apothecia; **2e**. apothecium in median section; **2f**. ectal excipulum in median section (flanks and margin); **4b**. globose SCBs in excipular cells; **1b**, **4e**. asci; **1c**, **4c–d**, **5d**. ascospores (inversely oriented spores with detached cytoplasm and SBs that remained refractive); **9**, **10**. conidia from substrate. – Living state, except for asci in **4d–e**, ascus and spores in **5d** (in IKI). – **1a–c**, **2c**, **6a–e**, **7a–f**, **8a–b**: phot. (western North America), 150 m a.s.l. (Alaska), 8–1250 m (Europe), 2161 m (Macaronesia), 2200 m (Mongolia). **Geology**: Lower Carboniferous sediment, Pennsylvanian-Permian sandstone, Triassic, Jurassic & Cretaceous sand-, marl-, mud- & limestone, Quaternary marine sand; rhyolite, dacite, trachytic basalt. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia ocellata* is characterized by 8-spored asci and medium-sized, cylindric-clavate ascospores with striking lens-shaped SBs. For the delimitation from *O. lentiformis* see p. 473. Without the anamorph, delimitation from *O. subocellata* is quite difficult (see p. 482), due to only gradual differences and rather high variation among the collections (Tab. 63). *O. ocellata* may also be confused with a rare reddish colour variant of the typically black-olivaceous conifer-inhabiting *O. patellarioides* (Pl. 150: 3). This variant seems to be separable from *O. ocellata* by consistently tapering, tail-like spore bases. *O. foliicola* concurs with *O. ocellata* in morphology of the teleomorph, but grows on coriaceous leaves and is separated for molecular reasons (see under *O. foliicola*, p. 483).

Variation. Specimens here assigned to *O. ocellata* vary in spore length, especially within a single ascus, also in ascus size and spore width. Further variation was noted in the apical domes which were entirely absent in some collections (Pl. 164: 1, 3, 6). For variation in the anamorph see below.

Not included collections. A Spanish sample on inflorescences of *Achillea millefolium* (see IVV: E.R.D. 7175) and another on undetermined *Asteraceae* deviate by distinctly narrower spores of *7.5–10.3 × 2.3–3 µm or *9.5-11.2 × 2.8-3.2 µm and asci †42–60 × 5–6 µm or *5.5–6 µm wide, respectively (E. Rubio pers. comm.).

Anamorph. In seven collections of *O. ocellata*, trinacrium-like conidia were observed on the natural substrate (Pls 164: 5; 165: 9–10). In two further samples, corresponding conidia were obtained on agar, one in pure culture from USA (IVV: 25.VIII.1994) and one from apothecia on agar from Spain (Pl. 164: 7). The latter culture was unintentionally obtained due to macroscopic confusion with associated apothecia of *O. subovoidea*. This culture is assumed to belong to *O. ocellata* because of the conidia that resemble those observed on the natural substrate in other collections. In the North American strain numerous unbranched straight conidia developed together with the short-armed trinacrium-like conidia, whereas such phragmoconidia were only rarely seen in the culture from Spain. There is a tendency to larger conidia (mainly longer-armed) in collections from temperate regions (Luxembourg, Germany), in comparison with those from warmer regions (southern Europe and western North America). The largest conidia were found in a collection from Luxembourg (H.B. 6207), with a total size of *30–40 × 31.5–48 µm (Pl. 163: 5).

Phylogeny. The single available sequence of *O. ocellata* (Arizona, on *Ericameria*, conidia trinacrium-like, IVV: H.B. 7006a) was gained from apothecia and comprises SSU, ITS, and LSU. It clustered in vicinity of *O. subocellata* (Phyl. 8) but with a minimum distance of 3.5 %, and with much higher distance to other members of series *Lentiformes* (see under *O. subocellata*, p. 482, and *O. foliicola*, p. 483). The *flavida-cucumispora* clade which comprises strains of seven species received medium (S11) or strong (Phyls 8, S9) support in our analyses.

Ecology. *O. ocellata* grows on rotten wood and bark of dead xeric branches of various angiosperm trees and shrubs (rarely herbaceous substrate) and shows also a high ecological amplitude regarding the climate. It is widespread in southwestern USA, being recorded in the Colorado Plateau (Uinta Basin, Utah Mountains, Grand Canyon, Canyonlands and Navajo section) and Chihuahuan desert in cold- to warm-temperate, subhumid to semiarid pinyon-juniper woodlands and sagebrush (and blackbrush) desert scrubs, also in a ponderosa pine forest adjacent to pinyon-juniper woodland (*Chrysothamnus*) and a riparian angiosperm woodland (*Juglans*). It was also recorded from boreal (or subarctic) Alaska, supramediterranean semihumid Macaronesia (*Spartocytisetum supranubiae*), and orotemperate (sub) humid (winter-dry), continental Mongolia (*Laricetum* with *Betula*, *Lonicera*, *Salix*). Various collections are from very diverse vegetation types in atlantic to subcontinental central, western, and southern Europe, including shady angiosperm forests, solitary trees and shrubs in open agricultural areas, and xerophytic shrublands in supra- (to oro-)temperate to suprasub- or mesosubmediterranean humid and supra- to thermomediterranean semihumid climates.

Specimens included. **POLAND**: **West Pomerania**, 20 km SE of Szczecin, ~2 km E of Dobropole Gryfiński, Osetno, ~70 m, trunk of *Fagus sylvatica*, on wood, 3.VIII.2008, G. Domian, vid. P. Perz (P.P. 20080803-GD-Osetno-1, doc. vid.). – **Lower Silesia**, Kłodzko, garden of Z. Perz, 400 m, branch of *Pyrus communis*, on wood, 11.VIII.2006, P. Perz (P.P. 20060811-1). – 3 km NNW of Polanica Zdrój, W of Wolany, ~400 m, branch of *Rosa*, on wood, 21.VI.2006, P. Perz (P.P. 20060621-1, doc. vid.). – Góry Bystrzyckie, 16 km W of Kłodzko, 1.5 km NW of Szczytna, Polna ulica, 480 m, branch of *Malus domestica*, on wood, 8.VIII.2006, P. Perz (P.P. 20060808-3). – ibid., branch of *Salix*, on wood, 8.VIII.2006, P. Perz (P.P. 20060808-4, H.B. 8309a). — **GERMANY**: **Niedersachsen**, Goslar, Oberharz, Goslar, Granestausee, 320 m, branch of *Salix caprea*, on wood, 2.VI.2004, H.O. Baral (H.B. 7531c, anam. substr.). – **Baden-Württemberg**, Schwäbische Alb, 5.3 km ESE of Eningen, 1.8 km NW of Würtingen, S of Mutschlenbühl, 705 m, branch of *Rosa*, on bark, 30.X.2001, H.O. Baral (ø). – 11 km SE of Reutlingen, 1.6 km ENE of Holzelfingen, Hohrot 785 m, branch of *Sorbus*, on wood, 28.VI.2002, G. Marson (H.B. 7159a, anam. substr.). — **LUXEMBOURG**: **Gutland**, **Capellen**, 4 km WNW of Capellen, 2 km E of Steinfort, Treisch, 325 m, branch of *Quercus*, on wood & bark, 8.V.1997, G. Marson (H.B. 5784, anam. substr.). – **Esch-sur-Alzette**, 3 km E of Esch-sur-Alzette, 2 km NW of Kayl, Brucherbierg, 380 m, branch of *Quercus*, on bark, 12.VI.1994, G. Marson (ex H.B. 5104, M-0276540, **holotype**; G.M. 5191 **isotype**: anam. substr.). – 5 km SSW of Luxembourg, 0.5 km W of Kockelscheier, Houbësch, 320 m, branches of *Carpinus betulus*, on wood, 11.VIII.1998, G. Marson (H.B. 6207, anam. substr.). — **FRANCE**: **Aquitaine**, **Gironde**, – 8 km SW of Royan, 6 km NE of Soulac-sur-Mer, 8 m, leaves (Wedel) of *Yucca*, 20.XI.2011, J.P. Priou (J.P.P. 11217, non vid.). – 20 km SW of Royan, 6 km SSW of Soulac-sur-Mer, l'Amélie, Arrière dune, 12 m, leaves of *Yucca*, 20.XI.2011, O. Priou (J.P.P. 11206, doc. vid.). — **SPAIN**: **Castilla-La Mancha**, **Guadalajara**, 18 km SW of Sigüenza, 2.5 km NE of Almadrones, NW of E-90, 1065 m, branch of *Cistus*, on wood, 24.IX.1999, H.O. Baral & G. Marson (H.B.

Map 24. Known distribution of *O. ocellata* in North America, Europe, and Macaronesia.

6475b, anam. apoth.). – 55 km NNW of Guadalajara, NW of Majaelrayo, Arroyo La Matilla, 1180 m, branch of *Salix*, on wood, 14.V.1996, H.O. Baral (H.B. 5472b). – ibid., branch of *Cistus laurifolius*, on wood, 14.V.1996, H.O. Baral (H.B. 5467a). – **Aragón**, **Teruel**, 21 km WSW of Montalbán, W of Pancrudo, 1250 m, branch of *Rhamnus myrtifolia* subsp. *myrtifolia*, on wood, 27.VIII.2011, R. Tena (R.T.L. 11082701, doc. vid.). – 25 km WNW of Teruel, 5 km ENE of Albarracín, 1090 m, branch of *Rosa*, on wood, 16.V.2015, J.P. Priou (J.P.P. 15141, doc. vid.). – **Com**. **Valenciana**, **Castellón**, 13.5 km NNW of Castellón, 3.2 km WSW of Vilafamés, Camí de Costur, 400 m, branch of *Quercus rotundifolia*, on wood, 27.IX.1999, H.O. Baral (ø). — **MACARONESIA**: **Canary Islands**, **Tenerife**, La Orotava, Las Cañadas del Teide, 7 km E of Teide, close to Montaña Mostaza, 2161 m, twigs & leaves (petioles) of *Carlina xeranthemoides*, on bark & wood, 13.II.2009, L. Quijada, J. Diaz Armas & E. Beltrán-Tejera (TFC Mic. 21491, H.B. 9224). — **MONGOLIA**: **Bayan Ölgii**, Altay Mts., 10 km SW of Tsengel, Khovd river valley, 2200 m, branch of *Lonicera altaica*, on bark, 9.VIII.2005, P. Karasch (H.B. 7893c ø). — **USA**: **Alaska**, Fairbanks, University Campus, 150 m, on indet. tree, VIII.2011, D.H. Pfister, vid. B. Liu (B.L., doc. vid.). – **Colorado**, Uinta Basin, 50 km ESE of Vernal, 6 km NE of Dinosaur, 2100 m, on *Cercocarpus betuloides*, 12.VI.1996, G. Marson (ø). – Canyonlands, ~31 km NW of Cortez, Pleasant View, 2110 m, branches of *Elaeagnus angustifolia*, on wood, 1.VI.1996, G. Marson (H.B. 6049a). – 15.5 km SSE of Cortez, Mesa Verde, 5 km NNW of Spruce Tree House, 2290 m, branch of *Artemisia filifolia*, on bark, 31.V.1996, G. Marson (H.B. 6276c ø). – **Utah**, Canyonlands, Capitol Reef, 40 km WSW of Hanksville, 23 km E of Torrey, 1557 m, branch of *Baccharis salicifolia*, on bark, 19.VI.2000, G. Marson (H.B. 6741f). – Natural Bridges, 41 km W of Blanding, 2090 m, branch of *Amelanchier utahensis*, on wood, 14.VI.2000, G. Marson (ø). – Arches, 20 km NNW of Moab, Salt Valley Wash, 1427 m, twigs & branches of *A. filifolia*, on bark, 18.VI.2000, G. Marson (H.B. 6740a). – near Valley of the Gods, 25 km NNW of Mexican Hat, 10 km N of Mokee Dugway, Cedar Mesa, 1990 m, branch of *Ericameria nauseosa*, on bark, 14.VI.2000, G. Marson (ø). – Canyonlands, 36 km S of Moab, 5 km WNW of Hatch Rock, 1813 m, branch of *E. nauseosa*, on bark & wood, 16.VI.2000, G. Marson (H.B. 6736d). – Utah Mts., Bryce Canyon, 30 km SE of Panguitch, 7.5 km WNW of Tropic, 2410 m, branch of ?*Chrysothamnus viscidiflorus*, on bark, 25.VIII.1994, G. Marson (ø, anam. cult.). – **Arizona**, Navajo, 85 km SW of Mexican Hat, 27 km SW of Kayenta, Rte. 160, Klethla Valley, 2015 m, branch of *Ericameria nauseosa*, on bark, 13.VI.2000, G. Marson (H.B. 7006a, anam. substr.; sq.: KT222414). – Canyonlands, 45 km SW of Page, 26 km SW of Marble Canyon, 1522 m, branch of *Coleogyne ramosissima*, on wood, 16.VI.2003, G. Marson (ø). – Grand Canyon, Coconino Plateau, 3 km N of Tusayan, 2068 m, branch of *Quercus gambelii*, on wood, 28.VIII.1994, G. Marson (H.B. 5238, anam. substr.). – **New Mexico**, Chihuahuan Desert, 30 km SW of Carlsbad, ?4 km NW of Whites City, ~3 km NE of Carlsbad Caverns, 1200 m, branch of *Juglans major*, on wood, 24.V.1996, G. Marson (H.B. 5673a).

Not included. **SPAIN**: **Asturias**, 12 km NW of Villablino, 1.7 km NW of Puerto de Leitariegos, ESE of Braña de Arriba, 1445 m, inflorescence of *Achillea millefolium*, 11.IX.2017, J. Linde, vid. E. Rubio (E.R.D. 7175). – id., on indet. *Asteraceae* (non vid.).

Orbilia subocellata Baral & E. Weber, **sp**. **nov**.,
MB 813486 — Pls 166–167

Etymology: named after the resemblance to *O. ocellata*.

Typification: Spain, Madrid, Alcalá de Henares, branch of *Cupressus sempervirens*, 23.IX.1999, G. Marson & H.O. Baral (ex H.B. 6474, M-0276596, holotype; ex-type culture: CBS 140816; sq.: KT215227, MH878186).

Latin diagnosis: Orbiliae ocellatae *persimilis, sed asci et ascosporae leniter latiores, conidia non ramosa, ab* O. lentiforme *in sequentia nucleotidium differt.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.15–0.3(–0.5) mm diam., 0.13–0.14 mm thick, light to deep (rose-)orange-red, round, subgregarious in small groups; disc slightly flat, margin finely crenulate; broadly sessile, slightly erumpent between fibres. **Asci** *57–67 {1} or 70–85(–91) {1} × (8.2–)8.5–9(–9.7) µm {2}, †(55–)62–82(–94) × 7–8.5 µm {2}, 8-spored, 1–2(–3) lower spores inverted {2} (rarely mixed), pars sporifera *35–39 µm long; **apex** (†) slightly to medium truncate, hemispherical in profile view, with dome †0.8–1 µm thick {1}; **base** T-shaped. **Ascospores** *((8–))(9–)10–13(–14)((–15.3)) × (3.3–)3.5–4.3(–5) µm {3}, †10–13 × 3–3.8 µm {1}, ellipsoid-clavate to subcylindrical, apex rounded to obtuse, slightly to medium attenuated near base, straight to slightly curved (upper spores often strongly curved); **SBs** *0.8–1 × 2–2.4 µm {2}, lens-shaped, apically broadly attached; mostly with some small **LBs** grouped in each half. **Paraphyses** apically uninflated to slightly, rarely medium clavate, sometimes curved at apex, terminal cell */†7–19 × 2–2.8 µm {1}, lower cells */†8–18 × 1–1.6 µm {1}; sometimes branched near apex. **Medullary excipulum** pale rose, 35–45 µm thick, of dense t. intricata-globulosa, indistinctly delimited. **Ectal excipulum** pale rose, 15–20 µm thick near base, of thin-walled t. globulosa(-prismatica), cells *7–13 × 5–8 µm {1}, 12 µm at flanks and margin, near margin of t. porrecta oriented at 0°, marginal cortical cells *7–9 × 2.5–3.5 µm. **Anchoring hyphae** medium abundant, *2–3.5 µm, wall 0.2 µm {1}. **SCBs** not observed. **Exudate** over paraphyses 1.5–3 µm thick, cloddy-continuous, loosely attached, at margin 0.5–1 µm thick. — **ANAMORPH**: vermispora-like (from ascospore isolate {2} and natural substrate {2}). **Conidiophores** short. **Conidia** phragmosporous, cylindric-fusoid, often apically or entirely slightly to medium, rarely strongly curved, *(17.7–)19–29(–35.5) × 5.5–6.5(–7.2) µm {2, culture}, *26.3–29.5 × ~5.5 µm {1, natural substrate}, (2–)3(–5)((–6))-septate, containing a few minute LBs and WBs, and numerous medium-sized non-refractive vacuoles, also many small, 1(–3)-septate conidia *11–16 × 4.2–4.5 µm observed in pure culture {1}.

Habitat: collected (0–)1–2 m above the ground, corticated to partially decorticated, 4–20 mm thick twigs and branches of *Cercis siliquastrum* {1}, *Cupressus sempervirens* {1}, *Rosa* sp. {2}, on 0.1 mm deep

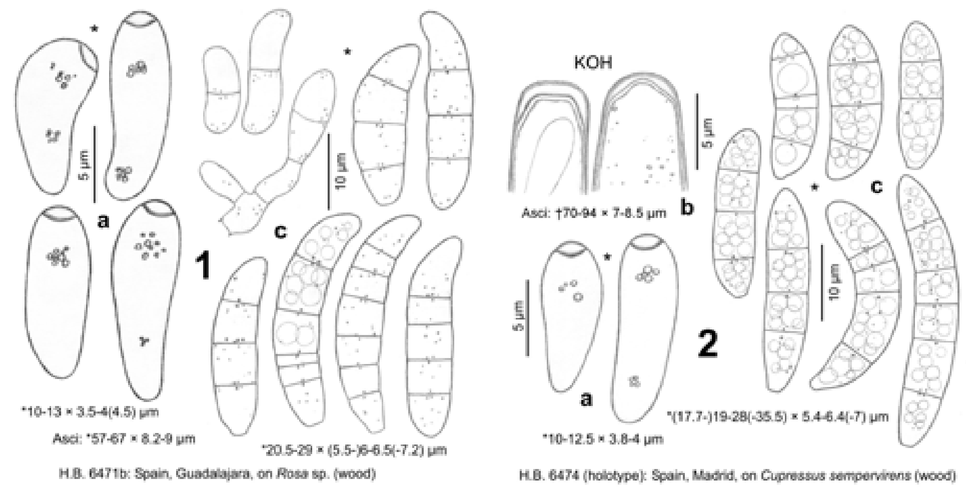

Plate 166. **1–2**: *Orbilia subocellata*. – **a**. ascospores; **b**. ascus apices; **c**. conidia (from culture).

medium to strongly decayed wood {4} and bark {2}, strongly greyed, wood splitted or with ± deep clefts. **Associated**: *Claussenomyces* sp. {1}, *Nitschkia broomeana* {1}, *Orbilia cercidicola* {1}, *O. flagellispora* {1}, *O. gambelii* {1}, *O. myriolentiformis* {1}, *O. myriosphaera* {1}, *O. subaristata* {2}, *O. subclavuliformis* {1}, *O. trapeziformis* {1}, *O. ?tremulae* {1}, *Unguiculariopsis ?rehmii* {1}, small lichen thalli. **Desiccation tolerance**: fully tolerant for at least 5 months, ascospores after 6.5 months. **Altitude**: 460–1060 m a.s.l. **Geology**: Cretaceous & Miocene calcareous clay, gravel & sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia subocellata* is somewhat intermediate between *O. ocellata*/*O. foliicola* and *O. lentiformis* in both spore length and ascus width (see Tab. 63). *O. ocellata* and *O. foliicola* differ in trinacrium-like conidia, the former also in narrower asci. *O. lentiformis* tends to larger asci and longer ascospores compared to *O. subocellata*, but there is actually no sharp difference, including conidial morphology. A collection on *Cercis* (Pl. 167) was without conidia but clustered with *O. subocellata*; also its asci and spores are too large to be included in *O. ocellata*.

Anamorph. We here segregate *O. subocellata* from *O. ocellata* mainly because of its vermispora-like conidia which were abundantly formed in pure culture in the holotype and a paratype. Because of the close microscopical similarity in the teleomorph, we assume that some of the specimens with insufficient morphological data and unavailable anamorph or sequence data, assigned by us to *O. lentiformis* or *O. ocellata*, might in fact belong to *O. subocellata*, especially those with an intermediate ascus and ascospore size. The conidia of *O. subocellata* closely concur with those of *O. lentiformis*, except for being slightly larger and more curved. In pure culture (Pl. 166: 1) also smaller conidia (possibly microconidia) were observed, which look as being immature but which were found detached from the conidiophores in abundance.

Not included collections. A Spanish sample on wood of *Quercus rotundifolia* with spores *11.5–14 × 3.7–4 µm and asci *57–80 × 9.2–9.4 µm (IVV: H.B. 5498) and a further collection on *Rosa* (J.P.P. 15124) might belong here, but any evidence is lacking

Phylogeny. Molecular data comprising SSU, ITS, and LSU were gained from the holotype of *O. subocellata* on *Cupressus* (from pure culture) and from a paratype on *Cercis* (from apothecia). The two strains differ by 0.5% in the ITS and 0% in the LSU. *O. subocellata* clustered in the *flavida-cucumispora* clade (Phyls 8, S9, S11) by showing to *O. ocellata* a distance of 3.5% in the ITS (1% in LSU), to *O. foliicola* 6.5/1.5–2%, and to *O. lentiformis* 15–16/4–5%.

Ecology. The four collections included in *O. subocellata* were found on wood and bark of xeric branches of *Cercis*, *Cupressus* and *Rosa*, in suprasub- to mesomediterranean, semihumid areas of central and northeastern Spain and southern France.

Specimens included. **SPAIN**: **Madrid**, 3.5 km NE of Alcalá de Henares, University Campus, 0.6 km NW of botany building, 610 m, branch of *Cupressus sempervirens*, on wood, 23.IX.1999, G. Orbilia foliicola Baral & E. Weber, **sp. nov.**, MB 813487 — Pls 168–169

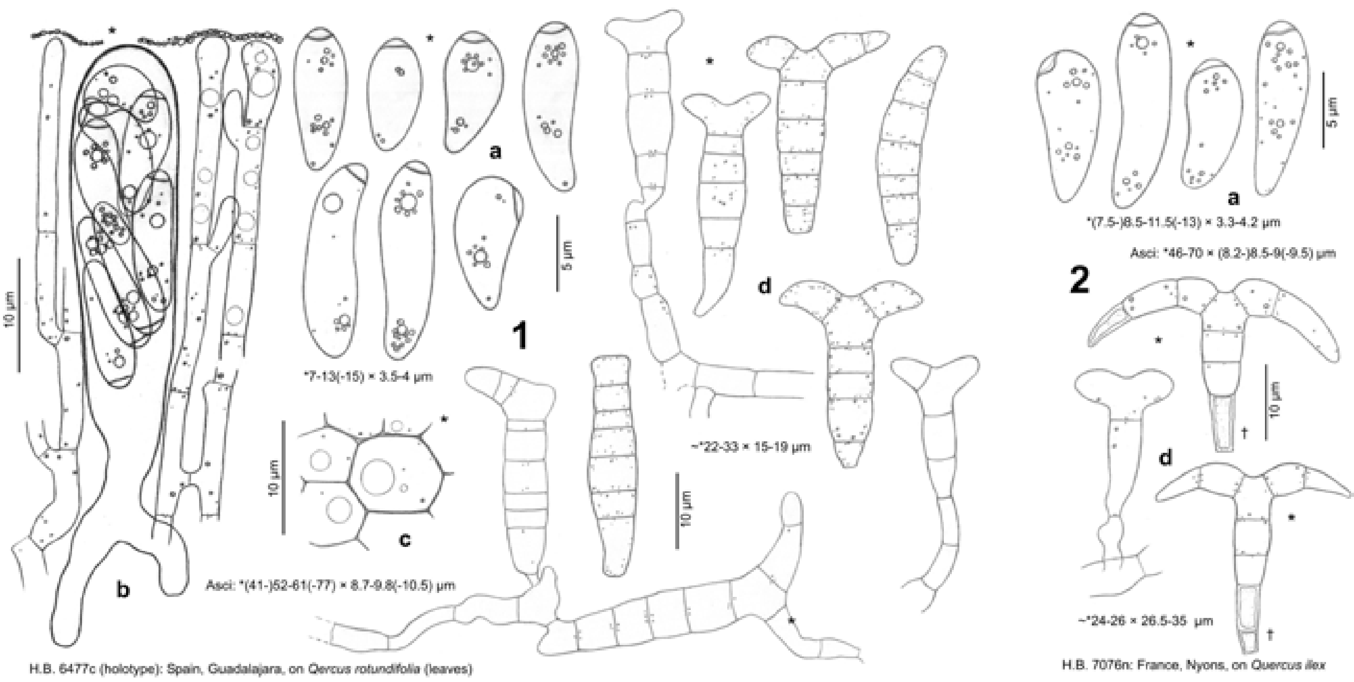
Etymology: named after the habitat, leaves of *Quercus*.

Typification: Spain, Guadalajara, Almadrones, leaves of *Quercus rotundifolia*, 24.IX.1999, H.O. Baral (ex H.B. 6477c, M-0276484, holotype, ex-type culture: CBS 140809; sq.: KT215229, MH878181).

Latin diagnosis: Orbiliae ocellatae *persimilis sed apothecia in foliis* Quercus ilicis *crescunt, etiam in sequentia nucleotidium differt.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.12–0.25 mm diam., 0.11–0.13 mm high,



H.B. 6477c (holotype): Spain, Guadalajara, on *Qercus rotundifolia* (leaves)

H.B. 7076n: France, Nyons, on *Quercus ilex*

Plate 168. **1–2**: *Orbilia foliicola*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ectal excipulum near margin in surface view, cells containing globose SCBs; **d**. conidia (**1d**. from culture, **2d**. from substrate).

pale to light orange-rose, slightly translucent, round, very scattered to subgregarious; disc flat, margin thin, 0–5 µm protruding, smooth; broadly sessile, superficial; dry bright apricot. **Asci** *(41–)46–70(–77) × (8.2–)8.5–9.5(–10.5) µm {2}, †48–65 × 7–8.5(–9.7) µm {2}, 8-spored, spores *3–4-seriate, 1–3(–5) lower spores inverted {2} (rarely mixed), pars sporifera *30 µm long; **apex** (†) slightly to rather strongly (conico-)truncate, hemispherical in profile view, varying within a population between thin-walled {2} or mostly with a †0.3–1.4 → 0.3–0.6 µm thick dome {2}, without apical chamber; **base** with very short to medium long, thick, ± flexuous stalk, L-, h- or Y-shaped. **Ascospores** *(7–)8–12.5(–15.5) × 3.3–4.2((–5)) µm {2}, †(7.5–)8.5–10(–12.5) × 3.1–3.4 µm {1}, ellipsoid-clavate, sometimes subcylindrical or ellipsoid-obovoid, apex rounded to obtuse, slightly to strongly attenuated near base, straight to slightly curved (upper spores often strongly so); **SBs** *0.5–1.2 × 1.8–2.1(–2.4) µm {2}, lens-shaped, apically broadly attached; often with some small **LBs** grouped in each half. **Paraphyses** apically uninflated to medium clavate, terminal cell *7.5–18.5 × 1.8–3.8 µm {2}, lower cells *5.5–12 × 1.5–3 µm {2}, rarely branched at upper septum. **Medullary excipulum** pale orange, 15–20 µm thick, of dense textura intricata-angularis, medium sharply delimited. **Ectal excipulum** subhyaline, of slightly gelatinized, indistinctly oriented t. angularis-prismatica from base to margin, 25–30 µm thick near base, cells †6–14 × 4–8.5 µm {1}; 15–20 µm thick near margin, oriented at a 20–30° angle to the surface, marginal cortical cells †6–10 × 3.5–4.7 µm {1}. **Anchoring hyphae** rather sparse, †2–3.5 µm wide, walls 0.2–0.5 µm thick {1}. **SCBs** globose, in paraphyses 1–2 µm diam., in ectal excipulum (1–)2–3 µm. **Exudate** over paraphyses 0.3–0.6 µm thick, cloddy-granular, hyaline, loosely attached; over margin and flanks 0.5–3 µm thick. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1} and natural substrate {1}). **Conidiophores** *~7–30 × 2–3.8 µm, 1–3-septate, usually branched, conidia formed terminally. **Conidia** branched, Y/T-shaped, the two arms always bent downwards, total size *22–33 {2} × 15–19 {1} or 26–33 {1} µm, stipe *14–25 × 4.5–6.5 µm, 2–5-septate, arms tapering, *(5–)6–13(–19) × 4–4.5 µm, 0–3-septate, some conidia unbranched, straight to slightly curved, */†~24–38 × 4–6 µm, 3–6-septate.

Habitat: collected 0.4–1.5 m above the ground, on lower surface of dead leaves of *Quercus ilex* {1}, *Q. rotundifolia* {1}, strongly greyed, green algae sparse. **Associated**: *Calycellina* aff. *albida* {2}, ?*Micraspis* sp. {1}, *Micropeziza mollisioides* {1}, *Mollisia nervicola* {1}, ?*Mycosphaerella* sp. {1}, *Orbilia quercus-ilicis* {1}, *Rutstroemia coracina* {1} etc. **Desiccation tolerance**: fully tolerant for at least 3 months. **Altitude**: 460–1065 [–1435] m a.s.l. **Geology**: Cretaceous & Miocene calcareous clay, marl, gravel & sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia foliicola* very closely concurs with the lignicolous *O. ocellata* and *O. subocellata* in apothecial characteristics (ascus and spore size, spores basally ± attenuated), and with *O. ocellata* also in the trinacrium-like conidia. It is separated here because of its peculiar ecology, coriaceous leaves of *Quercus ilex* agg., but mainly since our molecular data indicate that it is different from the all sequenced collections on ligneous substrate here assigned to *O. lentiformis* s.l., *O. ocellata*, and *O. subocellata*.

The only further *Orbilia* which we have found growing on coriaceous leaves of *Quercus* (*O. quercus-ilicis*, section *Habrostictis*) is macroscopically indistinguishable and even microscopically similar. It is mainly recognizable by a very different type of spore body and, therefore, difficult to segregate when dealing with dead material (only in *O. foliicola* the SBs remain indistinctly perceptible in dead spores).

Anamorph. The conidia of *O. foliicola* obtained in pure culture (Pl. 168: 1d) closely resemble those of *O. ocellata* from mediterranean regions (Pl. 164: 7), so that morphological distinction of the two taxa is impossible. Conidia found on the natural substrate differed in longer arms, but this might be a matter of maturity. Conidia of *O. quercus-ilicis* sharply differ in being tridentaria-like with straight arms.

Phylogeny. A sequence was gained from pure culture of the holotype of *O. foliicola*, comprising SSU, ITS, and LSU. A DNA isolate (partial 5.8S and entire ITS2) from *Pinus heldreichii* needles in Montenegro differs by only 1 nt in the ITS2. In our analyses *O. foliicola* clustered in the *flavida-cucumispora* clade (Phyls 8, S9, S11), with a 7% distance in the ITS region to *O. ocellata*, *O. subocellata*, and *O.* aff. *lentiformis*, and 11.5–12.5% to *O. lentiformis*.

Ecology. *O. foliicola* was collected on the greyed lower surface of dead, xeric, leathery leaves of *Quercus ilex* and *Q. rotundifolia* in the mesosub- to supramediterranean semihumid

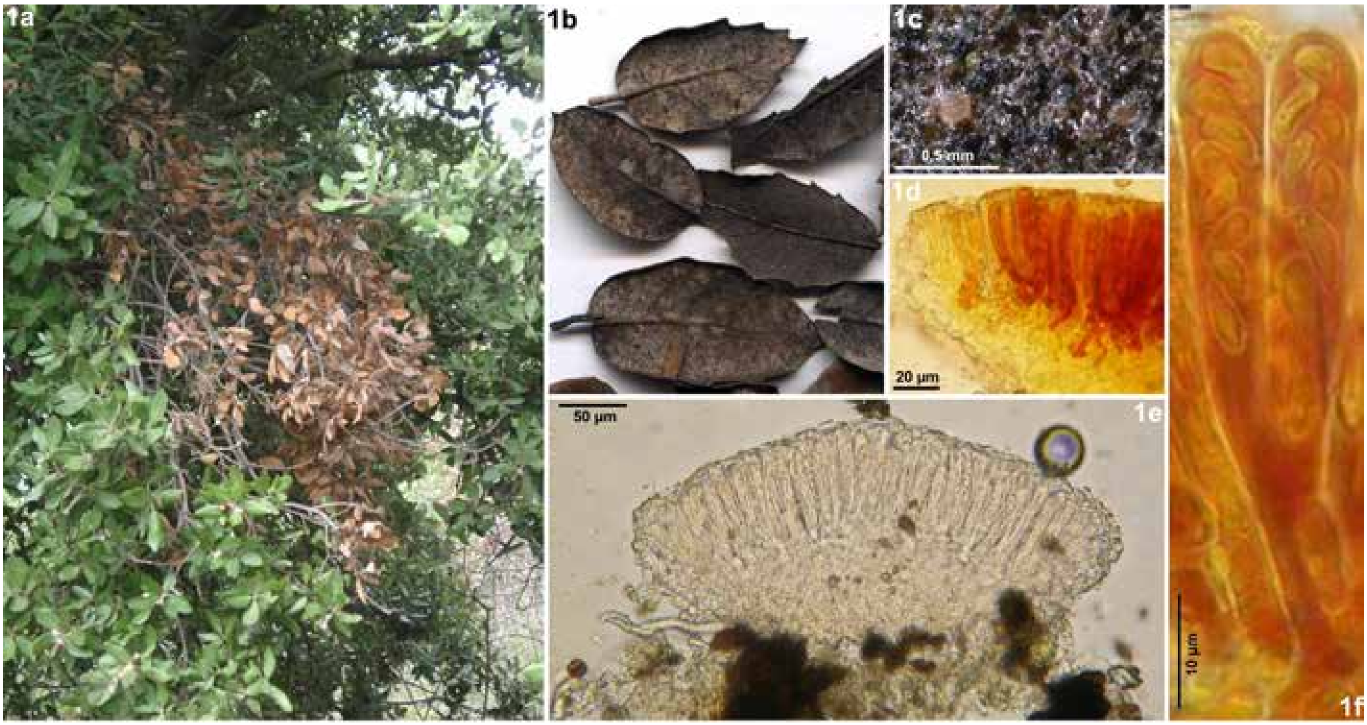


Plate 169. **1**: *Orbilia foliicola*. – **1a**. *Quercus ilex* shrub with partially dead twigs; **1b**. dead leaves of *Quercus ilex* (lower surface); **1c**. apothecia in rehydrated state; **1d–e**. apothecia in median section; **1f**. asci. – Dead state (KOH, KOH+IKI). — **1a–f**. paraphyses and many excipular cells alive. **Altitude**: 275–600 m a.s.l. (Europe), 1510–2600 m (western North America), 500 m (Australia). **Geology**: USA: Triassic-Jurassic-Cretaceous (red) sandstone, volcanic rock (basalt, andesite, rhyolite); France: Miocene sandstone, gravel & clay; Australia: Cenozoic regolith (sand). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiolentiformis* differs from *O. ocellata* and *O. lentiformis* only in spore number. In three collections, 8- and 16-spored populations grew together on the same branch, either intermingled or in separate groups at a distance of, e. g., 12 cm, which might suggest that the two spore numbers belong to one and the same population. In another collection of *O. pleiolentiformis*, however, *O. flavida* grew in association which has 32-spored asci and smaller spores, and which rarely shows a few 16-spored asci among the typical ones. On the other hand, apothecia of *O. pleiolentiformis* were never found to contain asci with a spore number higher than 16 (see also p. 56–57).

Variation. Considerable variation in ascus and spore dimensions was noted among the collections. Three of the four North American collections showed extraordinarily wide asci and ascospores. Whether this difference is more than accidental should be clarified from further collections. Specimens from herbaceous substrates but also those on *Allocasuarina* and *Ficus* showed rather short spores, whereas those on *Ericameria* and *Salicaceae* differed in rather long spores. One of the *Ericameria* samples (IVV: 24.VIII.1994) deviated in extraordinarily long asci (*112–128 × 8–9.5 µm) and spores (*13–15(–17) × 3.2–4(–4.4) µm). However, ascus and spore length also varied considerably within an apothecium, and measurements overlap too much, therefore, we preferred not to split our collections into different taxa.

Ecology. *O. pleiolentiformis* was found on ± rotten wood and bark of dead, xeric branches of angiosperm trees and shrubs, more rarely on herbaceous stems. The collections are from mesosub- and mesomediterranean semihumid southwestern Europe, e.g., ruderal places with *Foeniculum vulgare* and *Eryngium campestre*, and cold-temperate, almost suprasubmediterranean (sub)humid southeastern Europe. From the Sonoran Desert and Colorado Plateau (Canyonlands and Navajo section, Utah Mountains, Mogollon Rim) in western North America are samples in a warm-temperate semiarid mixed grass-scrubland, cold-temperate subhumid to almost semiarid sagebrush desert scrub and pinyon-juniper woodland, and cold-temperate humid Douglas fir forest, and from central Australia one from the Ayers Rock area in a subtropical arid acacia open shrubland.

Specimens included. **FRANCE**: **Rhône-Alpes**, **Drôme**, Préalpes du Dauphiné, 1 km N of Nyons, W of Col du Pontias, 415 m, branch of *Ficus carica*, on wood, 11.X.2002, G.   ≡ *Hyalinia uvispora* (Mouton) Boud., Hist. Class. Discom. Eur.: 104 (1907)

Etymology: *flavida*: from the yellowish colour of the apothecia in the holotype (though recent samples are consistently reddish); *paradoxa*: probably referring to the remarkable spore bodies; *uvispora*: indicating resemblance of the ascospores to seeds of *Vitis*.

Typification: Luxembourg, Brandenbourg, stem of *Seseli libanotis*, 7.VIII.1902, J. Feltgen (LUX 42552, holotype of ***Orbilia flavida***); Croatia, Dubrovnik-Neretva, Korčula island, Pupnat, stem of *Euphorbia wulfenii*, 11.VI.2000, H.O. Baral (ex H.B. 6716, M-0291761, epitype, designated here, MBT385111, ex-epitype culture: CBS 140807; sq.: KT215228). — Germany, Baden-Württemberg, Tauberbischofsheim, bracts of *Cichorium intybus*, 27.IX.1923, A. Ade (type of ***O. paradoxa***, not located). — Belgium, Wallonie, Liège, stem of *Angelica sylvestris*, undated, collector unknown (BR 090713-18, holotype of ***O. uvispora***).

Misapplied name: Feltgen (1901: 37, p.p.: on *Knautia*), as ‘*Orbilia* sp., aff. *O. rosella*’.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.4(–0.5) mm diam., 0.09–0.18 mm high, (pale to) light (to bright) rose to orange, very rarely with a shade of yellow (but pale yellow in the type, according to Feltgen), often translucent, round or sometimes broadly elliptical, very scattered to medium gregarious, hymenium slightly concave to flat; disc often finally slightly to medium convex, margin 0–5 µm protruding, irregularly finely crenulate, rarely smooth, thick in young apothecia, exterior glabrous; broadly sessile, erumpent between fibres, also seemingly superficial; dry apothecia light to deep orange. **Asci** *(54–)60–85(–109) × (6.7–)7–8.8(–9.3) µm {15}, †49–73(–82) × (5.7–)6–7(–7.5) µm {10}, 32-spored, very rarely some asci with only ~16 spores {2}, pars sporifera *(28–)33–49 µm long, †36–46 µm {type}, 10–16 lower spores inversely oriented {7}, usually mixed in the middle part only; **apex** (†) slightly to medium (to strongly) (conico-)truncate, hemispherical in profile view, dome †0.5–0.8(–1) → 0.3–0.4 µm thick {5}, with a low apical chamber; **base** with short or ± long undulating stalk, T-, L-, h- or rarely H-shaped. **Ascospores** *(3.8–)5–8(–9.7)((–10.5)) × (2–)2.2–2.8(–3)((–3.2)) µm {24}, †4–7 × 1.7–2.5 µm {5}, ellipsoid to often ellipsoid-clavate, also subcylindrical or fusoid, apex rounded to obtuse, rarely with a tail-like base, straight or quite often slightly to strongly curved near base (comma-shaped); **SBs** 0.4–0.7(–0.9) × 1.2–1.6 µm {7}, lens-shaped, apically broadly attached; with a few minute **LBs**. **Paraphyses** apically uninflated or often slightly to medium or even strongly clavate-capitate, often irregular in shape, terminal cell *(5–)7–17(–22) × (2–)2.5–5(–5.5) µm {13}, †1.5–3.5(–4.5) µm wide {4}, lower cells *8–14.5(–18) × 1.2–2(–3) µm {6}, †8–12 × 0.8–1.5 µm {2}, enlarged to *2–2.5(–2.8) µm near base and apex, quite often di(-tri)chotomously branched near apex. **Medullary excipulum** pale rose, 20–30 µm thick, of dense textura angularis, indistinctly delimited. **Ectal excipulum** very pale rose, of thin-walled t. globulosa-angularis from base to mid flanks or margin, 25–40(–55) µm thick near base, cells *5–15(–21) × 5–13(–18) µm {4}, oriented irregular or horizontal (though cells vertically elongate); 15–30 µm thick at flanks and margin, oriented at a 0–10° or up to 80° angle, cells *6–9 × 6–10 µm, slightly to strongly thick-walled (common walls †0.5–1(–1.5) µm thick), marginal cortical cells elongate, *5–15 × 3–4.5 µm {4}, cylindric-clavate. **Anchoring hyphae** especially near base, at flanks forming a thin appressed layer, */†2–3.5(–4) µm wide, walls 0.2–0.4(–0.8) µm thick {3}. **SCBs** globose, in terminal cells of paraphyses 1.5–3.5 µm diam., low-refractive, 1(–2) per cell; in marginal cortical cells 1.5–3(–4) µm diam. **Exudate** pale yellowish(-amber), over paraphyses 0.3–0.8 up to 1–2(–3) µm thick, continuous or ± cloddy, loosely attached; over margin thin. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1}). **Conidiophores** not observed. **Conidia** Y-shaped, total size *30–36 × 17.5–30.5 µm {1}, stipe *17.5–25 × 4.3–5.5 µm, 2–3-septate, arms tapering, *9–16.5 × 3–4.3 µm, 1–2-septate, a single unbranched phragmoconidium seen: *37 × 4.5 µm, 4-septate.

Habitat: collected on dry ground or 0.05–5 m above the ground, 1(?–2) years old, 6–35 mm thick herbaceous stems, rarely petioles of *Aeonium arboreum* {1}, *Agave americana* {1}, *Apiaceae* {2}, *Arecales* {1}, *Echinops sphaerocephalus* {4}, *Echium vulgare* {1/2}, *Epilobium* ?*angustifolium* {1}, *Euphorbia wulfenii* {1}, *Foeniculum vulgare* {3}, *Heracleum mantegazzianum* {1}, *H. sphondylium* {2}, *Knautia arvensis* {1}, *Melilotus* sp. {4}, *M. albus* {2}, *Rubus fruticosus* {1}, ?*Rumex* {1}, *Sambucus ebulus* {2}, *Seseli libanotis* {1}, *Tanacetum vulgare* {1/1}, *Urtica dioica* {1}, *Verbascum* sp. {1}, *V. densiflorum* {1}, *V. lychnitis* {1}, *Yucca* sp. {3}, *Y. gloriosa* {1}, on epidermis or often on areas devoid of epidermis; or on 5–40 mm thick, partially decorticated branches of *Acacia* sp. {1}, *Clematis vitalba* {1}, *Cytisus scoparius* {1}, *Ficus carica* {1}, *Mahonia dictyota* {1}, *Parthenocissus quinquefolia* {1}, *Salix* sp. {3}, *S.* (?)*caprea* {1}, also on textile {1}, on wood {9} or bark (bast) {5}, outer 0.1–0.3 mm slightly to strongly decayed, slightly to strongly greyed and covered with green algae, sometimes in old beetle galleries. **Associated**: *Bulbillomyces* sp. {1}, ?*Calloriopsis* sp. {1}, *Cistella grevillei* {4}, ?*Cucurbitaria* sp. {1}, *Cyathicula cacaliae* {1}, *C. cyathoidea* {1/1}, *C. nigrofusca* {1}, ‘*Dasyscyphus*’ *castaneus* {1}, *Diaporthe* sp. {1}, *D. arctii* {1}, *Eutypella*

?*scoparia* {1}, *Hydropisphaera arenula* {1}, *Karstenia rhopaloides* {1}, *Lachnella alboviolascens* {3}, *L. villosa* {7}, ?*Laetinaevia* sp. {1}, *Lecanora* sp. {1}, *Leptospora rubella* {1}, *Lewia scrophulariae* {1}, *Mollisia ligni* {1}, *Nectria* sp. {1/1}, *Neodasyscypha cerina* {1}, *Olla millepunctata* {1}, *O. scrupulosa* {1}, *Orbilia albovinosa* {1}, *O. aristata* {2}, *O. bicknellensis* {2}, *O. caulicola* {8}, *O. cylindrosoma* {5}, *O. eucalypti* {1}, *O. flavidorosella* {2}, *O. lentiformis* {1}, *O. ?obtusispora* {1}, *O. ocellata* {2}, *O. pleiolentiformis* {1}, *O. quaestiformis* {12}, *Orbilia serpentina* {1}, *O. subclavuliformis* {2}, *O. ungulata* {4}, *O. vibrioides* {1}, *O. ?vinosa* {1}, *O. vitalbae* {4/1}, *Patellaria atrata* {3}, ?*Phoma* sp. {3}, *Phyllactinia guttata* {1}, *Pseudolachnea hispidula* {1}, *Pyrenopeziza ?escharodes* {1}, *P. ?rubi* {1}, ?*Ramichloridium schulzeri* {1}, *Stictis ?stellata* {1}, *Trichopeziza* aff. *mollissima* {3}, *T. lizonii* {1}, *T. ?perrotioides* (immature) {1}, *T. sulphurea* {1}, *Unguiculariopsis ilicincola* {1}, *Urceolella crispula* {1}, *U. ?pani* {1}, *Xanthoria parietina* {1}. **Desiccation tolerance**: fully viable for at least 5 months. **Altitude**: 196–435 m a.s.l. (cold-temperate Europe), 1–1017 m (subatlantic to mediterranean Europe), 1195 m (Macaronesia). **Geology**: Devonian slate, Buntsandstein, Keuper (marl & sandstone, Minette), Lower to Upper Jurassic shale, sand- & limestone, Quaternary sand, loess; mica schist, basaltic flow. **Phenology**: (II–)IV–XI (long-lived).

Phenology of *O. flavida*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
0	2	1	2	4	8	11	7	7	4	6	0

Taxonomic remarks. *Orbilia flavida* is characterized by 32-spored asci and rather small, ellipsoid-clavate, partially curved ascospores. It differs from the similar North American *O. plurilentiformis* in smaller spores. Small-spored populations of *O. pleiolentiformis* differ from *O. flavida* mainly in 16-spored asci. *O. myriolentiformis* deviates in 64-spored asci, also in larger spores and, therefore, much larger asci.

The multispored asci of *O. flavida* and its characteristic SBs were overlooked by J. Feltgen who studied the species only in the dead state (see below). We here designate a Croatian specimen (Korčula, on *Euphorbia*, ex H.B. 6716, Pl. 172: 4), from which a sequence was gained, as **epitype** of *O. flavida*.

Variation. The examined collections of *O. flavida* showed little variation among each other. Even the two samples from North America match the European ones very well. However, as in the other species of series *Lentiformes*, spore length varies rather strongly within a single ascus. Only the collection from Asturias studied by E. Rubio (pers. comm.) showed unusually broad spores (7–8 × 2.8–3.2 µm, size evaluated from scale), appearing intermediate to the North American *O. plurilentiformis*.

Type studies. The holotype of ***O. flavida*** in LUX contained three apothecia when reexamined, contrary to Hein (1976) who suspected the material to be empty. Although the asci of the two tested apothecia were 32-spored (Fig. 172: 2), *O. flavida* was originally described as '8-spored, spores 1½–2-seriate'. Apart from this and the sporoplasm, which Feltgen figured and described with 'one oil drop in each end', protologue and Feltgen's drawing on the label (Fig. 152) fully concur with the present documentation regarding paraphysis and ascospore shape and size (see Tab. 64).

Sections of the two apothecia possessed asci with a spore number of at least 25–30. The lens-shaped SBs at the broader end of the spores were clearly visible as a slightly refractive region that is clearly separated from the detached cytoplasm, but only when adding ample MLZ or IKI to the KOH mount (Pl. 172: 2a–b).

Feltgen described the apothecia as 'pale yellow, yellow when dry'. Another collection from Luxembourg (on *Knautia*), being referable to *O. flavida* according to our reexamination, was identified by Feltgen (1901: 37) as '*Orbilia* sp., related to *O. rosella*' and described by him as 'pale yellowish-reddish' and again with 8-spored asci (IVV: H.B. 7305). We have almost never noticed a yellow tint in *O. flavida*, but instead a pale rose or orange colour. Possibly, the report of a yellowish component is due to examination under sunlight or a light source with a high yellow proportion.

We have never encountered 8-spored asci in *O. flavida* and only very exceptionally a few with 16 spores. Feltgen obviously overlooked polyspory in this species, perhaps as a consequence of his preparation method which killed the asci, with the result that spores were difficult to discern inside. On the other hand, we frequently found *O. flavida* growing in association with other species of *Orbilia*, mainly such with 8-spored asci, therefore, the possibility cannot be excluded that the holotype was a mixture, and Feltgen's description refers at least partially to an 8-spored taxon. Candidates which more or less fit his drawing are *O. ungulata*, *O. vitalbae*, *O. caulicola*, or *O. cylindrosoma*. However, when comparing measurements taken from the two collections studied by him (Tab. 64), it seems clear that he was dealing with the same fungus as now found in his voucher specimens.

Höhnel (1906: 1276) examined the type material of *O. flavida* and found only a single 'immature' pale reddish apothecium which he confirmed to belong to the genus *Orbilia*. Possibly, the asci he saw were mature and the spores inside masked by the refractive ascoplasma, in the case he did not apply staining agents. Based on Feltgen's description, Höhnel could not see major differences to *O. flavidorosella*, a species which is treated in the present study in section *Habrostictis*, and which seriously differs from *O. flavida* in truncate ascus apices and fusoid spores with subulate SBs.

Not included collections. Type material of ***O. paradoxa*** could not be located in S. In the protologue, Ade (1924) reported the apothecia to grow very sparsely at the base of dry rotten bracts of the flower heads of *Cichorium intybus*, 'am Apfelberg zwischen Hochhausen und Gamburg auf dem linken Tauberufer, 27. Sept. 1923'. Ade's description regrettably lacks any illustration, but strongly suggests identity with *O. flavida*. The main part of the description runs as follows: 'asci 16–24-spored, rounded above, 70–75 × 6–7 µm, spores comma-shaped, mostly curved, 7–9 × 3–4 µm, at the rounded and broader upper end

Table 64. *Orbilia flavida* in Feltgen's herbarium as described by Feltgen and reexamined in the present study.

Specimen	Element	Feltgen	Present study
holotype LUX 042552	Asci	†55–62 × 7–8 µm	†60–63 × 5.7–6.5 µm
	Ascospores	4–8 × 2.5–3 µm	†4–6.2 × 1.7–2.1 µm
	Spore number	8	32
'*Orbilia*. sp. aff. *rosella*' LUX 042439	Asci	†45 54 × 5–6 µm	†52–65 × 5.7–6.5 µm
	Ascospores	†5–6 × 2 µm	†4.5–6 × 2–2.4 µm
	Spore number	8	32

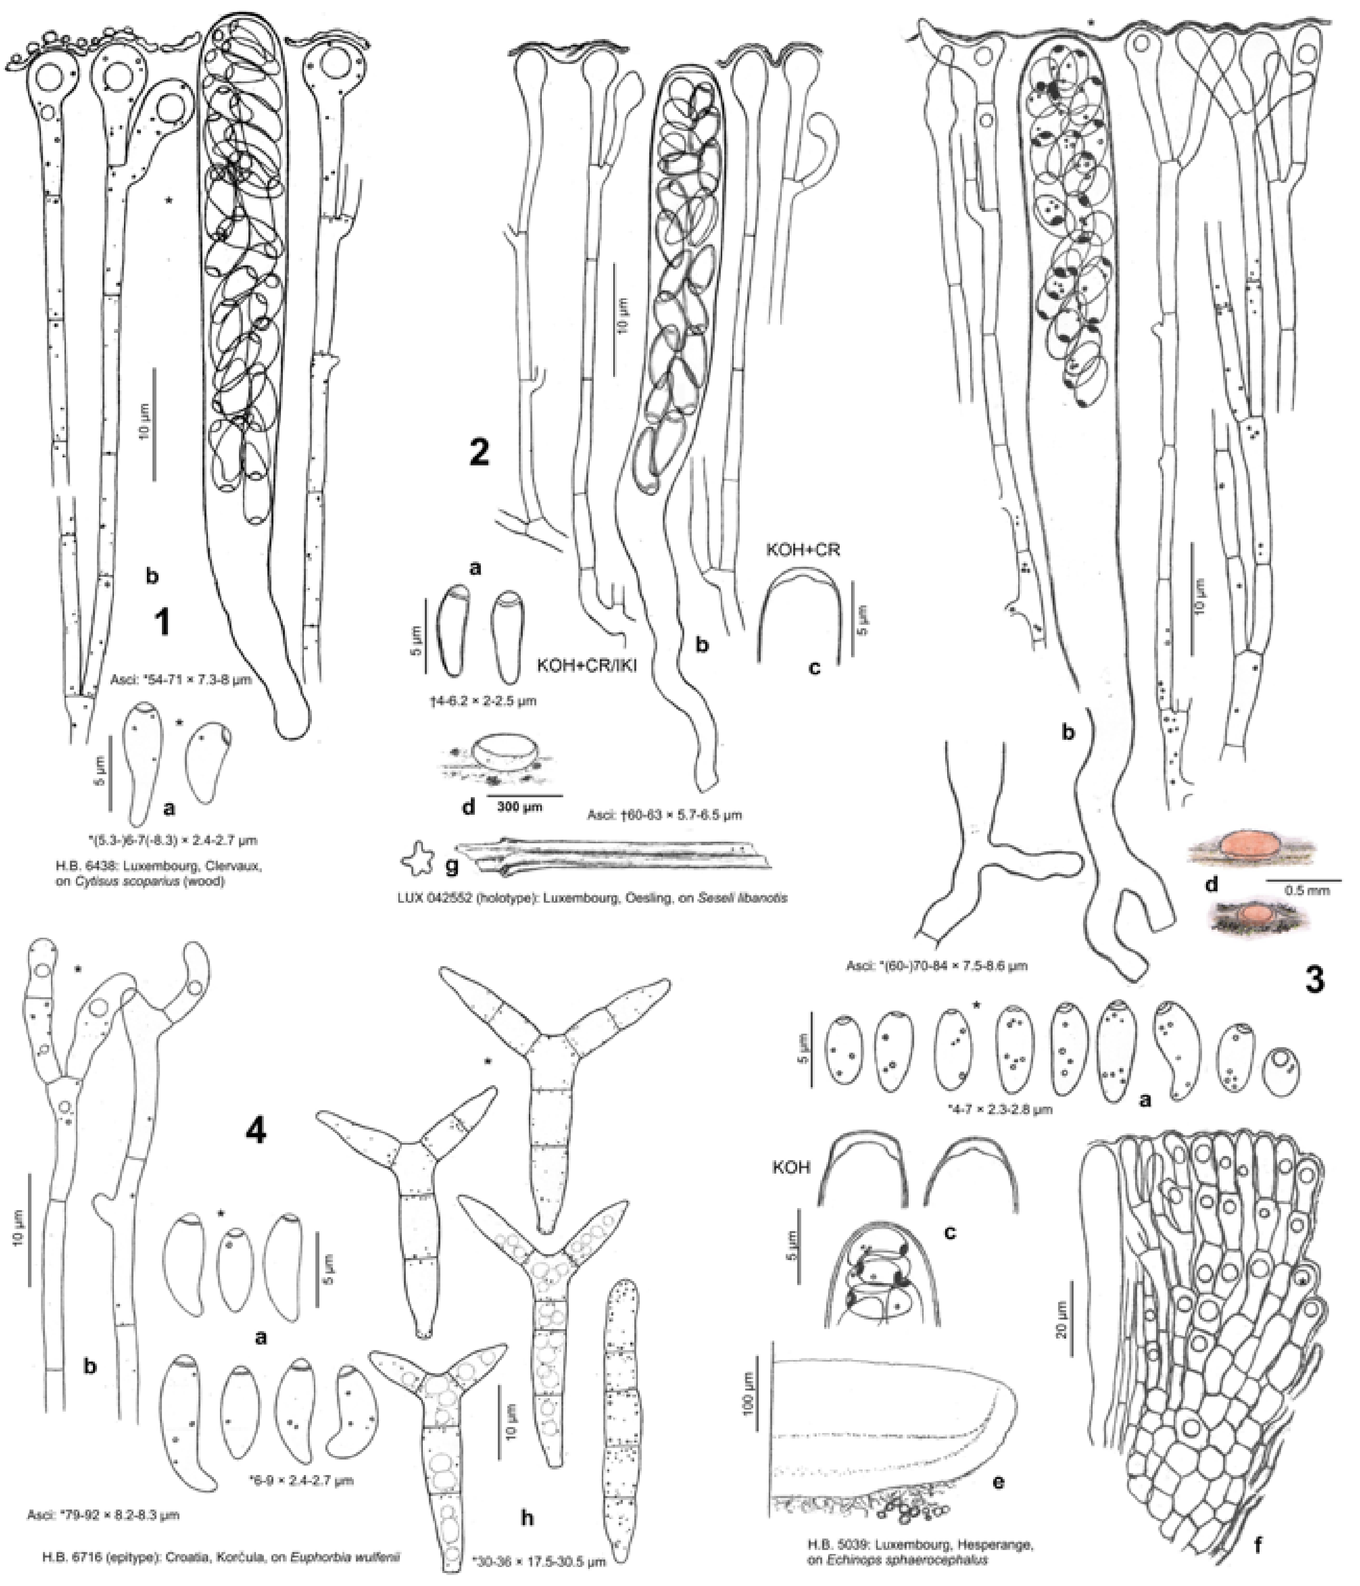

Plate 172. **1–4**: *Orbilia flavida*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., marginal ectal excipulum; **g**. dead herbaceous stem (on the left in cross section); **h**. conidia from culture.

always provided with a strongly refractive polar spot.' The report of a striking apical spore body indicates that Ade studied living material. The spore width is larger than in our description of *O. flavida*. It might either be erroneous, although the ascus size fits perfectly, or it is due to the formation of oversized spores combined with a reduced spore number.

The holotype of ***O. uvispora*** in BR (Belgium, Liège, on stems of *Angelica*, BR 090713-18) was reexamined by both Dennis and Spooner, and found to be devoid of apothecia that resemble an *Orbilia*, according to their revision labels. In the present examination, a single apothecium (rehydrated 0.15 mm diam) was found, which undoubtedly belongs to the described taxon, but only immature asci were seen (Pl. 173: 5). The observed microscopic features confirm Mouton's (1900) placement in *Orbilia*. The asci have a hemispherical (truncate-conical), distinctly thick-walled (0.7–0.8 µm) apex, hence the species

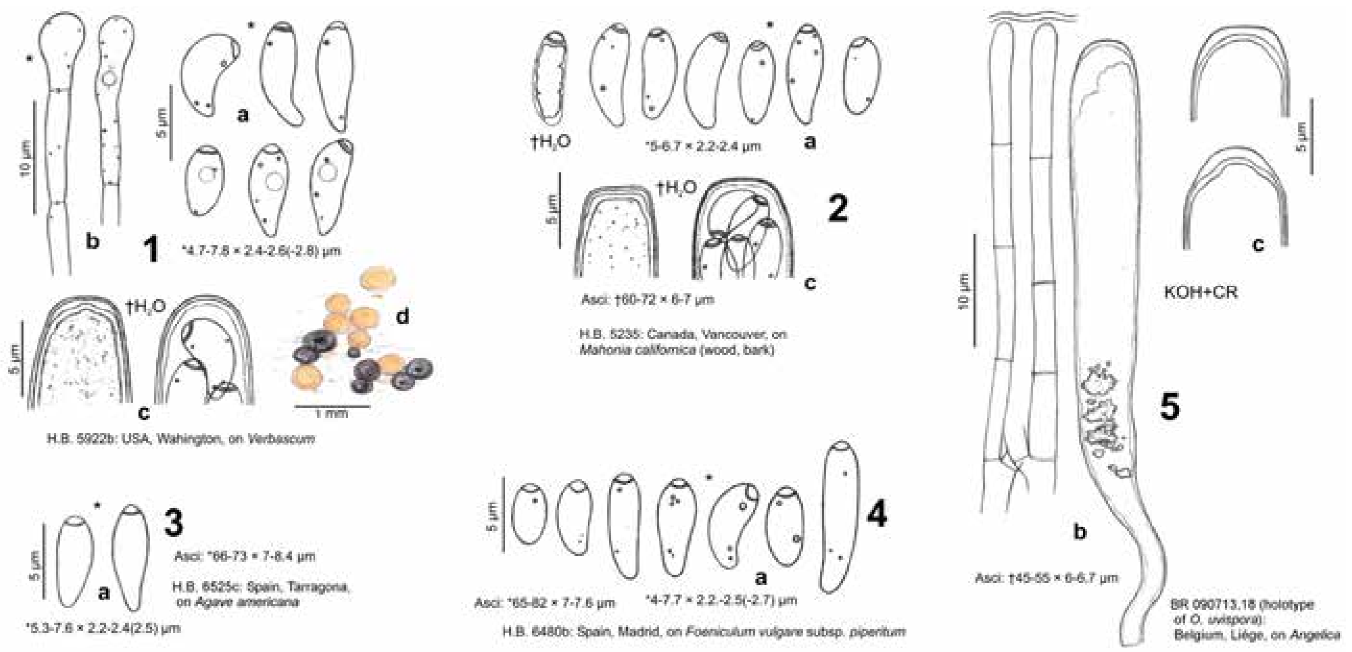

Plate 173. **1–4**: *Orbilia flavida*; **5**: *O.* cf. *flavida*. – **a**. ascospores; **b**. ascus (immature) and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia (**1d**. with ?*Phoma*).

belongs either in section *Lentiformes* or in sections *Hemiorbilia* or *Ovoideae*. The shape of the spores as drawn by Mouton might indicate that *O. uvispora* belongs in the neighbourhood of *O. vibrioides* (series *Vibrioides* of section *Hemiorbilia*). Regrettably, Mouton did not report spore bodies. In any case, the indicated spore size (6–7 × 2.5 µm) excludes the lignicolous *O. vibrioides* as well as the graminicolous *O. graminis* which both have smaller, more homopolar and more strongly curved spores, and also a much thicker apical ascus wall. Another member of section *Hemiorbilia*, *O. subcryptogena* (series *Hesperideae*), shows a similar spore shape and size but differs in 16-spored asci (*O. uvispora* is reported as 8-spored) and occurrence on woody substrate in North America. Within section *Ovoideae*, only extra-European taxa resemble *O. uvispora* to some extent.

Another possible relationship of *O. uvispora* points to series *Lentiformes*. Here the spores are often similarly curved and clavate as those reported for *O. uvispora*. Spore size as stated by Mouton, and also ascus apical thickening would fit *O. flavida*. A comparison of the size of here examined immature asci with the spore size as given by Mouton suggests that the asci contained more than 8 spores. If *O. uvispora* and *O. flavida* are in fact synonyms, then both Feltgen and Mouton neglected the lens-shaped spore bodies as well as ascus polyspory in their material. *O. uvispora* was described 4 years earlier, but its identity could not sufficiently be ascertained, therefore, we here adopt *O. flavida* as the oldest available name.

Anamorph. A few conidia were obtained in pure culture of one species (Pl. 172: 4), but only after flooding with water. They resemble *Trinacrium robustum* but have shorter arms. In a water agar plate of the same strain, mature apothecia developed in the presence of sterilized wood fragments after about 3 months, but here no conidia were seen.

Phylogeny. The single available sequence of *O. flavida* (Croatia, on *Euphorbia*, H.B. 6716, from pure culture, SSU+ITS+LSU) clustered in the *flavida-cucumispora* clade, though with a distance of 7–10.5 % in the ITS region to other species of this clade, with a minimum distance to *O. ocellata* (7 %, 0.5 % in LSU). Surprisingly, the similar *O. plurilentiformis* shows a 10 % ITS distance to *O. flavida* (1 % in LSU), though clustering also in the *flavida-cucumispora* clade.

Ecology. *O. flavida* preferably grows on rotten, xeric herbaceous stems, but also occurs on rotten wood and bark of xeric branches of different angiosperm trees and shrubs. To the present knowledge, the area of distribution includes supra- to mesotemperate (rarely orotemperate, Auvergne) humid or mesosub- to thermomediterranean semihumid, oceanic to subcontinental zones of Europe. The species also occurs in the thermomediterranean semihumid Canary pine forest (*Sideritido solutae-Pinetum canariensis cistetosum monspeliensis*), and in the mild-maritime humid lower pacific coastal region south of the Coast Mountains in the northwest of North America. *O. flavida* is not uncommon in central and southern Europe, yet no records from more northern and eastern areas came to our attention. The species appears to prefer thermophilous, sun-exposed sites in which the substrate rapidly dries out. In central Europe and North America these were usually sun-exposed, more or less ruderal places like quarries or railway tracks.

Specimens included. **LUXEMBOURG**: **L'Oesling**, **Diekirch**, 4.5 km SW of Diekirch, W of Ettelbruck, railway station, 196 m, branch of *Salix*, 6.VII.2002, G. Marson (ø). – ibid., stem of *Melilotus* (ø). – **Vianden**, ~5 km NNW of Diekirch, Brandenbourg, ?400 m, stem of *Seseli libanotis*, 7.VIII.1902, J. Feltgen (LUX 42552, **holotype** of *O. flavida*, H.B. 5358 ø). – **Clervaux**, 7.5 km NNW of Clervaux, Troisvierges, railway station, 422 m, stem of *Verbascum densiflorum*, 23.VII.1999, G. Marson (H.B. 6439a). – ibid., branch of *Cytisus scoparius*, on wood, 23.VII.1999, G. Marson (H.B. 6438). – **Gutland**, **Mersch**, 4.5 km S of Larochette, 1 km N of Koedange, Folkend, 293 m, on petioles of *Arecales* (deposited there since maybe a year), 23.VI.2005, G. Marson (H.B. 7820 ø). – **Grevenmacher**, 17 km NE of Luxembourg, 2.9 km NNE of Junglinster, Appelescht, 310 m, stem of *Sambucus ebulus*, 27.VIII.2004, G. Orbilia plurilentiformis Baral & G. Marson, **sp. nov.**, MB 813489 — Pls 175–176, Map 26

Etymology: named after the 32-spored asci and the lens-shaped spore bodies.

Typification: USA, Utah, Moab, branch of *Artemisia filifolia*, 18.VI.2000, G. Marson (ex H.B. 6740c, M-0276565, holotype; ex-type culture: CBS 140805; sq.: KT215230, MH878180).

Latin diagnosis: *Similis* Orbiliae flavidae *sed asci et ascosporae latiores, habitat ad lignum et corticem ramulorum siccorum fruticum in locis temperatis semiaridis ad borealis humidis Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.16–)0.22–0.55(–0.65) mm diam., 0.17–0.2 mm high, (light to) bright yellowish-) orange(-rose), round to slightly elliptical, scattered to subgregarious; disc flat, margin distinct, 0–10 µm rising above disc, even; externally somewhat whitish-rough, sessile, slightly or distinctly erumpent through small slits in the wood; dry deep orange. **Asci** *(60–)70–105(–120) × (8.4–)9–11(–12) µm {5}, †(55–)65–85(–93) × (7.3–)8–9.5 µm {4}, 32-spored, spores ± 4-seriate, lower spores inversely oriented (mixed), pars sporifera *45–70 µm long; **apex** (†) slightly to medium (rarely strongly) truncate, hemispherical in profile view, dome †1–1.4 → 0.7–1 µm thick {3}, with a narrow or wide, low apical chamber; **base** with short, thick, ± flexuous stalk, L-, T- or Y-shaped. **Ascospores** *((5.8–))7–10.5(–11.3) × (2.8–)3–3.6(–4)((–4.5)) µm {6}, †7–10 × 2.8–3.3 µm {3}, ellipsoid-clavate, also cylindric to ellipsoid-fusoid, apex rounded to obtuse, base slightly to strongly tapered, sometimes tail-like, straight or often slightly to strongly curved in the basal part; **SBs** *0.5–1 × 1.1–1.5 µm {4}, lens- to slightly plug-shaped, apically broadly attached; **LBs** ± sparse, small. **Paraphyses** apically slightly (to medium) clavate-capitate (to moniliform or lageniform), rarely cylindrical, terminal cell *(4–)6–17(–22) × 2.2–4(–4.5) µm {4}, lower cells *8–20 × 1.6–2.5 µm {4} (sometimes up to 3–4 µm wide near base or below terminal cell); medium to very frequently di(-tri) chotomously branched near apex {5}. **Medullary excipulum** hyaline, 40–70 µm thick, upper part of dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a 10–20 µm thick layer of t. porrecta. **Ectal excipulum** pale rose-orange, 25–40 µm thick near base, of thin-walled († slightly gelatinized), horizontal or vertical t. angularis(-prismatica), cells *7–12(–18) × 7–10 µm {1}; 15–30 µm thick at flanks and margin, at margin of t. angularis or t. prismatica-porrecta oriented at a 0–40° angle, marginal cortical cells *6–14 × 3.5–5 µm {2}. **Anchoring hyphae** sparse to abundant, *3–4 µm wide, †1.5–2.5 µm, walls 0.2 or 0.5–0.7 µm thick {2}, often extending up to margin as a 15–20 µm thick hyaline layer of ± gelatinized t. intricata-porrecta. **SCBs** globose, low-refractive, in paraphyses 1.2–2.5 µm diam.; in marginal excipular cells 1.5–2.8 µm. **Exudate** over paraphyses and margin 0.2–0.5(–1.5) µm thick, continuous or granular, loosely attached, hyaline. — **ANAMORPH**: unknown (no conidia developed in culture).

Habitat: collected 0.1–1 m above the ground, corticated to decorticated, 4–14 mm thick branches of *Artemisia filifolia* {2}, *A. tridentata* {1}, *Baccharis salicifolia* {1}, *Ericameria nauseosa* {1}, *Krascheninnikovia lanata* {2}, on 0.2 mm deep (medium to) strongly decayed wood {4} and bark {2}, medium to strongly greyed, with a few or many green algae. **Associated**: (?)*Coniochaeta* sp. {1}, *Orbilia bicknellensis* {2/1}, *O. delphinus* {1}, *O. dixiensis* {1}, *O. lentiformis* {2}, *O. macrodelphinus* {1}, *O. mesaverdiana* {2}, *O. multigambelii* {1}, *O. multimaeandrina* {3}, *O. multiphanosoma* {2}, *O. multitrapezoidea* {1}, *O. myriophanosoma* {1}, *O. ocellata* {4}, *O. serpentina* {1/1}, *O. subsiculispora* {1}, *Patellaria* ?*atrata* {1}, *Schizoxylon* sp. {1}, *Symbiotaphrina desertorum* {2}, *Teichospora* sp. {2}, *Teichosporella dura* {1}. **Desiccation tolerance**: fully viable for at least 6 months, after 24 months still some submature asci alive. **Altitude**: 1427–2450 m a.s.l. **Geology**: Triassic-Jurassic-Cretaceous (red) sand- and mudstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia plurilentiformis* is characterized by 32-spored asci and medium-sized, ellipsoid-clavate ascospores. The similar *O. flavida* is sharply delimited by distinctly narrower and slightly shorter asci and spores, and in a temperate to mediterranean distribution. The mediterranean *O. myriolentiformis* differs in larger, 64-spored asci and larger apothecia.

Variation. Little variation was noted among the collections, which mainly concerns spore width and shape.

Phylogeny. The single sequence of *O. plurilentiformis* (Utah, on *Artemisia*, from pure culture, SSU+ITS+LSU) clustered unexpectedly in vicinity of *O.* aff. *lentiformis* (H.B. 8002c) and *O. cucumispora*, with an ITS distance of 6.3 and 7% (LSU 0.5%), respectively, whereas the distance to *O. flavida* lies at 10% (LSU 1%).

Ecology. *O. plurilentiformis* inhabits rotten wood and bark of xeric branches of various angiosperm shrubs under a very diverse climate: in warm-temperate to boreal, mainly semiarid but also subhumid to humid sagebrush and winterfat desert scrubs and pinyon-juniper woodlands of the Colorado Plateau in the southwest of Northern America.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 15 km SSE of Torrey, 5.5 km S of Grover, Lion Mt., 2450 m, on wood of *Artemisia tridentata*,

Orbilia myriolentiformis Baral & G. Marson, **sp. nov.**, MB 813490 — Pls 177–178

Etymology: named after the 64-spored asci and the lens-shaped spore bodies.
Typification: France, Drôme, Nyons, branch of *Cercis siliquastrum*, 13.VIII.2009, G. Marson, H.O. Baral & B. Liu (ex H.B. 9151g, M-0276530, holotype).

Latin diagnosis: *Similis* Orbiliae plurilentiformi *sed asci 64-spori, majores. Habitat ad corticem* Cercidis *in loco mesosubmediterraneo semihumido Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1 mm diam., 0.27–0.29 mm high, bright dirty orange, round, scattered, sometimes in groups of two; disc flat, finally slightly convex, margin indistinct to distinct, not rising above disc, even or finely rough to denticulate, broadly sessile, superficial, sometimes immersed in clefts of bark; dry somewhat contracted, deep dirty orange-red. **Asci** *120–138 × 10.7–12.5(–13) µm, †100–118 × 10–11(–12.5) µm, 64-spored (58 counted), spores ± 4-seriate, lower spores inversely oriented (strongly mixed), pars sporifera *85–95 µm long; **apex** (†) slightly to strongly truncate, hemispherical in profile view, dome †1–1.5 → 0.3–1.5 µm thick (KOH up to 1.7 µm), with indistinct apical chamber; **base** with short to medium long, thick, ± flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(7–)8–11(–12) × (2.8–)3–3.5(–3.7) µm, †7.5–10.5 × 2.8–3.4 µm, ellipsoid-clavate, apex obtuse, base medium to strongly attenuated, with or without a thick tail, straight or basal part often slightly to strongly curved or geniculate; **SBs** *0.9–1.1 × 1.3–1.5 µm, lens- to slightly plug-shaped, apically broadly attached; **LBs** ± sparse, small. **Paraphyses** apically uninflated to medium (also strongly) clavate, sometimes lageniform, terminal cell *5–16 × (2.5–)3–4.5(–5.5) µm, lower cells *10–18 × 1.7–2.6 µm (up to 2.5–3.8 µm wide below terminal cell); unbranched or frequently dichotomously branched near apex. **Medullary excipulum** hyaline, 70–80 µm thick, of dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a 5–7 µm thick layer of t. porrecta. **Ectal excipulum** hyaline, 35–55 µm thick near base, of (†) ± distinctly gelatinized, indistinctly oriented t. globulosa-angularis, cells *8–25 × (5–)7–13 µm; 40 µm thick at mid flanks, of t. prismatica-angularis oriented at a 40–50° angle, 20–30 µm thick at margin, of t. porrecta oriented at 10–30°, marginal cortical cells *7–12 × 2.5–3 µm; covered by a ~10 µm thick hyaline layer of slightly gelatinized t. intricata-porrecta. **Anchoring hyphae** abundant, *2–2.5 µm wide (2.5–3.5 µm at insertion), walls 0.2 µm thick, sometimes forming a gelatinized, dense, up to 70 µm thick t. intricata. **SCBs** globose, in paraphyses 1.8–3 µm diam., in marginal excipular cells 1.7–2 µm. **Exudate** over paraphyses and margin 0.2–2(–3) µm thick, continuous to granular or cloddy, loosely attached, hyaline. **— ANAMORPH**: unknown.

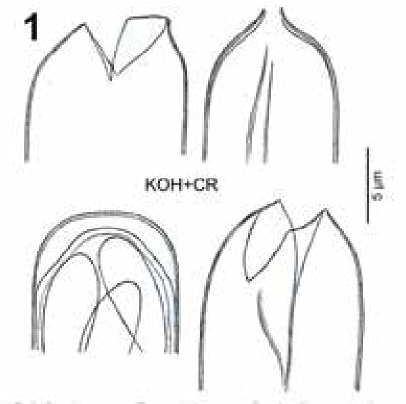

Plate 177. **1**: *Orbilia myriolentiformis* H.B. 9151g. – Ascus apices (3 emptied asci with a large split-like pore).

Habitat: collected ~1.5 m above the ground, corticated, 12 mm thick branch of *Cercis siliquastrum*, on medium decayed bark (bast), in cracks or holes of periderm, strongly greyed, with a few green algae. **Associated**: *Claussenomyces* sp., *Lecophagus vermicola*, *Nitschkia broomeana*, *Orbilia cercidicola*, *O. flagellispora*, *O. gambelii*, *O. myriosphaera*, *O. ocellata*, *O. subaristata*, *O. subclavuliformis*, *O. trapeziformis*. **Desiccation tolerance**: fully viable for at least 6 weeks. **Altitude**: 460 m a.s.l. **Geology**: Miocene sandstone near Cretaceous calcareous clay. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myriolentiformis* is characterized by very large, 64-spored asci and medium-sized, ellipsoid-clavate ascospores. The similar *O. plurilentiformis* and *O. flavida* consistently differ in smaller, 32-spored asci and smaller apothecia, *O. flavida* also in smaller spores.

Ecology. *O. myriolentiformis* is only known from a single sparse collection (four apothecia) on rotten bark of a xeric branch of *Cercis* in a mesosubmediterranean semihumid maquis at the foothills of the Southern French Alps in southern Europe.

Specimens included. **FRANCE**: **Rhône-Alpes**, **Drôme**, Préalpes du Dauphiné, 1 km N of Nyons, Col du Pontias, 460 m, branch of *Cercis siliquastrum*, on bark, 13.VIII.2009, G. Marson, H.O. Baral & B. Liu (ex H.B. 9151g, M-0276530, **holotype**).

Orbilia cucumispora Baral & G. Marson, **sp. nov.**, MB 813492 — Pls 179–180, Map 27

Etymology: referring to the shape of the spores resembling a cucumber.
Typification: USA, Arizona, Tusayan, branch of *Juniperus osteosperma*, 28.VIII.1994, G. Marson (ex H.B. 5178a, M-0276465, holotype).

Latin diagnosis: *Apothecia in statu rehydratata rosea, 0.25–0.5 mm diam. Asci 8-spori, apice in statu emortuo rotundati, modice crassitunicati. Ascosporae *11–22 × 4–5.7 µm, plus minusve curvatae, forma cucumeris, in statu vivo prope apicem corpusculum refringens obturamentiformem vel cylindricum continentes. †1.3–1.9 → 0.8–1.5 µm thick, with ± wide apical chamber; **base** with short to ± long, flexuous stalk with always T-shaped base. **Ascospores** *(11–)13–19(–22) × 4–5.2(–5.7) µm {5}, †13–19 × 4–4.7 µm {1}, slightly or medium clavate, rarely cylindrical, often slightly (to strongly) dumbbell-shaped, both ends rounded, straight to slightly (rarely strongly) curved near base; **SBs** *(1.5–)2–3(–3.5) × 0.6–1 µm {3}, plug- to rod-shaped, apically usually abruptly widened to 1–1.6 µm {3} (resembling a rivet), apically broadly attached; with several minute and sometimes a few large (0.8–1.5 µm) **LBs** grouped or scattered in each half. **Paraphyses** apically uninflated or usually slightly (to medium) clavate, terminal cell *(5–)8–17 × (2.3–)2.8–3.7(–4.2) µm {4}, †1.5–2.7 µm wide {2}, lower cells 9–18 × 1.7–2.6 µm {4}, †1.5–1.8 µm wide, at apex often di- or trichotomously branched {2} or always unbranched {1}. **Medullary excipulum** 40–70 µm thick, of ± dense textura intricata with rather few hyphae and many inflated cells suggesting a t. angularis, medium sharply delimited. **Ectal excipulum** of slightly gelatinous, vertically oriented t. angularis(-prismatica) from base to mid flanks, 35–40 µm thick at base, cells *7–16 × 6–11(–13) µm {2}; 25–30 µm thick at lower flanks, 15–30 µm at mid flanks, cells *9–16 × 7–14 µm, 15–25 µm thick at margin, of t. prismatica-angularis oriented at ~45–80°, cortical cells *7–10(–16) × 4–5 µm. **Anchoring hyphae** abundant, *2.5–4 µm wide, wall 0.2–0.8 µm thick {2}, covering the exterior up to mid flanks by a 5–15 µm thick dense layer. **SCBs** globose, low-refractive, in paraphyses 0.8–1.3 µm diam. {1}, partially absent {3}; in cortical cells of margin (and mid flanks) 1.5–2.8 µm. {2}.

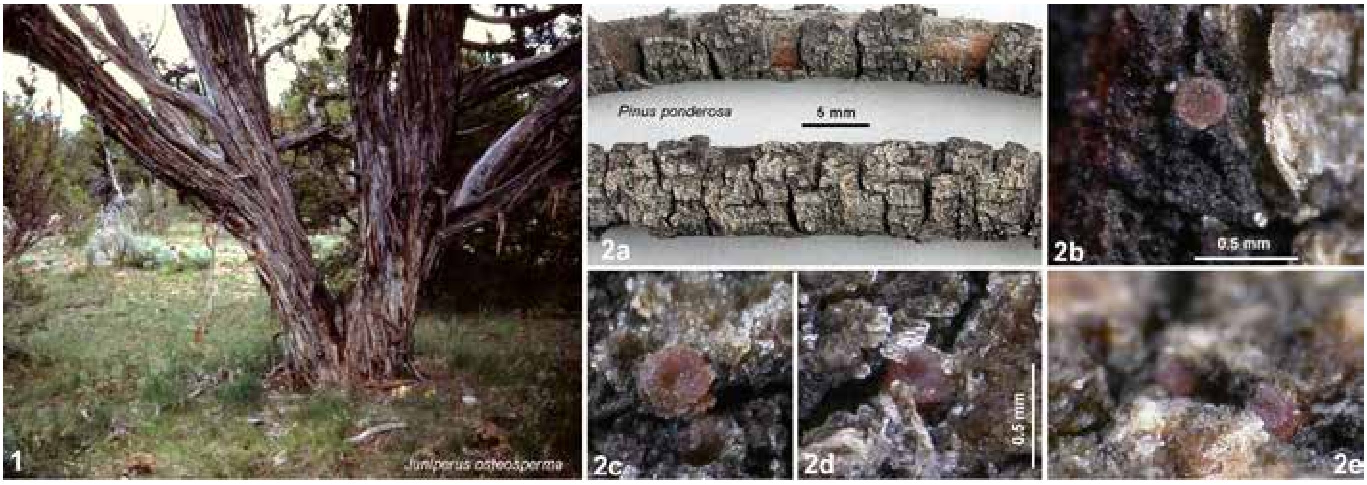

Plate 180. **1–2**: *Orbilia cucumispora*. – **1**. pinyon-juniper woodland in the Coconino Plateau, with *Juniperus osteosperma*, detached hanging bark; **2a**. corticated branches; **2b–e**. apothecia rehydrated after 6 years. — **1**. H.B. 5178a (holotype): USA, Arizona, Grand Canyon Village, on *Juniperus*; **2a–e**. H.B. 6762a: USA, Utah, Torrey, on *Pinus*.

Exudate over paraphyses and margin forming a continuous, thin, ± refractive line 0.2–1(–2) µm thick, loosely attached, hyaline; externally smooth {2} or covered by refractive, ± abundant crystals ~0.3–4 µm diam. (over paraphyses and/or excipulum) {3}, unstained in CRB. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1}). **Conidiophores** not observed. **Conidia** Y-shaped, total size *37–52(–56) × 37–58(–64) µm {1}, stipe *22–28 × (6–)6.5–8.5 µm, 2–3(–4)-septate, arms cylindrical to slightly tapering, with obtuse ends, *(23–)26–35(–38) × (6–)6.5–8(–8.5) µm, (2–)3–4-septate; a single phragmoconidium seen: *56 × 6.3 µm, 5-septate.

Habitat: collected 1–2 m above the ground, still-attached, corticated or partially, rarely entirely decorticated, 4–15 mm thick, dead branches of *Juniperus osteosperma* {3}, *Pinus ponderosa* {1}, indet. gymnosperm {1}, on (slightly to) medium decayed bark (bast and periderm) {4} or wood {1}, often in cracks, bark partially somewhat detached, nearly no green algae, distinctly greyed. **Associated**: closely associated with black pycnidia {2}, also with *Carestiella schizoxyloides* {1/2}, *Holmiella sabina* {1}, *Orbilia ?maeandrina* {1}, *O. multidelphinus* {1}, *O. multihamulata* {2}, *O. octosporoides* {1}, *O. ophiosoma* {1}, *O. osteospermae* {1}, *O. pisciculus* {1}. **Desiccation tolerance**: fully tolerant for at least 5 months, dead after 14 months (including ascospores). **Altitude**: 1225–2440 m a.s.l. **Geology**: Permian-Triassic-Jurassic-Cretaceous sand- & limestone. **Phenology**: long-lived.

Taxonomic remarks. The large, oblong, cucumber-like to dumbbell-shaped ascospores that contain broadly attached SBs with a remarkable inner prolongation (T-shaped) easily distinguish *O. cucumispora* from related taxa. The species is also characterized by a more or less striking pink colour. The inconsistent presence of CRB-unstainable small crystals over the exudate seems to be an exceptional feature within *Orbilia*. The broad attachment of the SBs to the spore apex suggests placement of *O. cucumispora* in series *Lentiformes*, which is supported by molecular data. *O. cercidicola* resembles *O. cucumispora* in spore size and shape, but has a very different type of SB which is narrowly attached to the spore apex by a ± thin filum, also it possesses striking orange crystalloid SCBs, for which reason it is placed in a series of its own.

Map 27. Known distribution of *O. cucumispora* in North America.

Variation. *O. cucumispora* varied somewhat in apothecial colour, also in the thickness of the apical dome, the apical branching of paraphyses, and in the presence of crystals on the exudate surface. Also the apical extension of SBs is not always well pronounced (Pl. 179: 1a).

Anamorph. *O. cucumispora* produces conidia that resemble *Trinacrium robustum* but differ in being larger-sized and with only slightly tapering arms. Conidia were obtained in abundance in culture, but only after flooding with water.

Phylogeny. Despite the deviating spore body type, our sequence of *O. cucumispora* (H.B. 6762a, from pure culture, SSU+ITS+LSU) clustered in the *flavida-cucumispora* clade, partially weakly supported with *O. plurilentiformis* (Phyls 8, S9, S11), with a 4.5 and 7 % ITS distance, respectively.

Ecology. *O. cucumispora* was found on slightly decayed bark (rarely wood) of dead xeric branches of different gymnosperm trees and shrubs in (warm- to) cold-temperate (to boreal), (semiarid to) subhumid (to humid) pinyon-juniper woodlands but also Douglas fir and Engelmann spruce forests in ravines, valleys, slopes or high plateaus of the Colorado Plateau of western North America.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 1.5 km ESE of Cedar City, 1815 m, branch of *Juniperus osteosperma*, on bark, 24.VIII.1994, G. Marson (ø). – 15 km SSE of Torrey, 5.5 km S of Grover, Lion Mt., 2440 m, branches of *Pinus ponderosa*, on bark, 19.VI.2000, G. Marson (H.B. 6762a, BBA 69342, anam. cult.; sq.: KT215231). – Bryce Canyon, Fairview Point, 2440 m, branch of indet. gymnosperm, on wood, 16.V.1995, G. Marson (ø). – **Arizona**, Canyonlands, ~35 km WNW of Page, Paria Canyon, ~1225 m, branch of *J. osteosperma*, on bark, 27.VIII.1994, G. Marson (H.B. 5224a). – Grand Canyon, Coconino Plateau, 3 km N of Tusayan, 2068 m, branch of *J. osteosperma*, on bark, 28.VIII.1994, G. Marson (M-0276465, **holotype**; **isotype** in H.B. 5178a).

Series *Ovales*

Orbilia subgenus ***Hemiorbilia*** section ***Lentiformes*** series ***Ovales*** Baral & E. Weber, **ser. nov.**, MB 815000 – Type species: *Orbilia ovalis* Baral & G. Marson

Latin diagnosis: *Apothecia rosea vel aurantiaca, margine laevi. Asci apice in statu emortuo valde truncato, tenuitunicato. Ascosporae ellipsoideo-ovoideae ad subglobosae, corpuscula refringentia bacilli-, pyri- vel ampulliformia. Paraphyses ad apicem leniter ad valde clavato-capitatae. Recognized species: *O. ovalis*.

Orbilia ovalis Baral & G. Marson, **sp. nov.**, MB 813494 — Pls 181–182, Map 28

Etymology: named after the frequently ovoid spore shape, also referring to the substrate of the type, *Amelanchier ovalis*.

Typification: Spain, Cuenca, Guadalaviar, branches of *Amelanchier ovalis*, 26.IX.1999, G. Marson (ex H.B. 6486b, M-0276546, holotype; ex-type culture: CBS 140883; sq.: KT215235).

Latin diagnosis: *Apothecia rosea vel aurantiaca, sessilia, superficialia, 0.2–1.3 mm diam. in statu rehydratata, disco plano, margine laevi. Asci 8-spori, apice in statu emortuo valde truncato, tenuitunicato. Ascosporae in statu vivo *(3–)3.7–7.5 × 2.2–3.3 µm, ellipsoideo-ovoideae ad fusoideo-clavatae vel subglobosae, prope apicem corpusculum refringens bacilli-, pyri- vel ampulliformem*, ad apicem *anguste* affixum continentes. *Paraphyses ad apicem leniter ad valde clavato-capitatae. Excipulum ectale textura globulosa-angulari, marginem versus cellulis vivis corpuscula globosa continentibus. Habitat ad corticem, raro lignum putridum ramorum siccorum* Aceris, Amelanchieris, Rosae, Pruni *vel* Juniperi *in zona orotemperata ad mediterranea Europae et Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.9(–1.3) mm diam., 0.1–0.21 mm high, light to bright rose-pink or rose-orange to apricot, round to slightly undulating, scattered to subgregarious; disc slightly concave to flat, margin thin, 0–10 µm protruding, very slightly inrolled, smooth; broadly sessile, also with an obconical stipe up to 150 × 350 µm, ± superficial, also erumpent through holes in periderm. **Asci** *(43–)50–65(–70) × (4.2–)4.7–5.7 µm {4}, †38–63 × (3.5–)4–4.7(–5) µm {4}, 8-spored, spores obliquely 1–2-seriate, (1–)2–4(–5) lower spores inverted {5} (sometimes mixed, very rarely upper spores inverted), pars sporifera *(24–)28–34 µm long; **apex** (†) medium to strongly truncate (not or very slightly indented, laterally not or slightly inflated), hemispherical in profile view, thin-walled; **base** with short to long, thick or thin, flexuous stalk, T- or h-shaped. **Ascospores** *3–3.7 {1} or (3.7–)4.3–6.5(–7.5) {6} × (2.2–)2.4–2.8(–3.3) µm {8}, †4–5.8 × 2–2.7 µm {1}, subglobose to ellipsoid-obovoid to fusoid-clavate, apex rounded to obtuse, sometimes subacute, rarely with a short tail-like base, straight to inequilateral or basally slightly curved; **SBs** *(1–)1.4–2.1(–2.4) × (0.4–)0.5–0.8(–0.9) µm {7}, rod-shaped, ampulliform, or tear- to narrowly pear-shaped, lower part mostly distinctly swollen, apically narrowed to a ± wide, more rarely to a small point, predominantly straight, sometimes slightly to very strongly geniculate. **Paraphyses** apically slightly to strongly clavate-capitate (rarely uninflated), terminal cell *(10–)13–28 × 2.5–5.8 µm {4}, lower cells *6–16 × 1.6–2.7 µm {3}; unbranched near apex, hymenium very pale orange-rose. **Medullary excipulum** pale rose, 25–60(–120) µm thick, of ± loose or dense textura intricata with many inflated cells (also of t. globulosa), usually sharply delimited. **Ectal excipulum** pale to light rose, of thin-walled, (†) slightly to medium gelatinized, (indistinctly) vertically oriented t. globulosa-angularis(-prismatica) from base to margin or mid flanks, 30–60(–100) µm thick near base, cells *8–23(–26) × 7–17(–20) µm {4}, common walls †0.5–1(–2) µm; 20–30 µm thick near margin, of t. globulosa to t. prismatica oriented at a 30–90° angle to the surface, marginal cortical cells *6–18 × 3–6(–8) µm {2}, †7–13 × 2.5–4.5 µm {2}, slightly thick-walled (†0.2–0.4 µm), sometimes with internal low-refractive wall thickening (1–2 µm) {1}. **Anchoring hyphae** mostly very abundant, *2–4 µm wide, walls */†0.2–0.7(–1.2) µm thick {4}, forming a dense hyaline t. intricata 20–60 µm thick, at flanks a 10 µm thick t. porrecta. **SCBs** in paraphyses and cortical cells globose (in the latter partially absent) {4}, glassy processes absent {4}. **Exudate** over paraphyses 0.1–0.3 µm thick, continuous to granular, firmly attached; over margin and mid flanks 1–8 µm thick, continuous, granular-cloddy, or cap-like, ± layered, partially firmly attached, pale yellow. **— ANAMORPH**: dicranidion-like (presumed, from natural substrate {6, 2 of them without associated apothecia}). **Conidiophores** not observed. **Conidia** tuning fork shaped, total size *30–48 × 10–13.5(–20) {4} or 51–67 × 13–14(–17.5) µm {*Juniperus*}, stipe *5–7(–9) × (2.3–)2.7–3.5(–4.2) µm, 1-celled, arms usually parallel, apically often slightly converging, rarely diverging (nearly Y-shaped), *21.5–41 or 42–55 × 4.5–6.8 µm, 5–10 {4} or 9–13-septate {*Juniperus*}.

Habitat: collected 0.2–2.5 m above the ground, ± corticated, 3–35 mm thick twigs and branches of *Acer* sp. {1}, *Amelanchier ovalis* {2}, *Betula* sp. {1}, *Fraxinus* sp. {1}, *Juniperus communis* {1}, *Prunus* sp. {1}, *P. domestica* {1}, *Rosa* sp. {1}, on medium to strongly decayed bast {8} (periderm rolled aside or removed, also on inner surface of detached bark), more rarely wood {3}, slightly greyed, sometimes blackened, green algae sparsely present. **Associated**: *Baggea* sp. {1}, *Caloplaca* sp. {1}, *Hysteropatella prostii* {1}, *Lachnella* sp. {1}, *Melanelia exasperata* {1}, *Mellitiosporiella pulchella* {1}, *Orbilia delphinus* {1}, *O. flexisoma* {1}, *O. gambelii* {2}, *O. pleioalbidorosea* {1}, *O. pleiogambelii* {1}, *O. subaristata* {1}, *O. subtrapeziformis* {3}, *O. trapeziformis* {1}, *Ostropa barbara* {1}, *Parmelia* sp. {1}, *Perrotia flammea* {1}, *Physcia stellaris* {1}, *Propolis farinosa* {1}, ?*Schizoxylon* sp. {1}, various crustose lichens. **Desiccation tolerance**: fully tolerant for at least 14 months, ascospores and inflated cells of medullary excipulum still viable after 33 months, conidia partially viable after 3 years. **Altitude**: 340–1605 m a.s.l. **Geology**: Europe: Lower Jurassic & Cretaceous limestone & dolomite; Canada: alluvial deposits from Proterozoic & Cambrian-Ordovician sedimentary rock. **Phenology**: II–III, VIII–XI (but long-lived).

Taxonomic remarks. *Orbilia ovalis* is characterized by rather small, ellipsoid-ovoid ascospores, and rod-shaped to ampulliform spore bodies that are attached by a ± wide point. *O. caudata*, a species here assigned to series *Piliferae* of section *Aurantiorubrae*, closely resembles *O. ovalis*. It differs in narrower spores with a mostly distinct tail, a presumed trinacrium-like anamorph, and a (sub)tropical distribution. Spores and SBs of *O. ovalis* match also those of *O. macroasca* (series *Phanosomates*), a species differing in polysporous asci, paraphyses with more equally long cells and non-capitate apices, and in distinctly thick-walled ascus apices.

Except for its spore body, *O. ovalis* strongly resembles *O. eucalypti* (series and subgenus *Orbilia*) in various features, including the presumed dicranidion-like anamorph. *O. ovalis* actually recalls series *Orbilia* with its thin-walled, truncate (shouldered) ascus apices and capitate paraphyses with the terminal cells usually distinctly longer than the lower cells. *O. ovalis* differs from that series in ± ampulliform to rod-shaped SBs which resemble those of *O. macroasca* or *O. myriophanosoma* in series *Phanosomates*.

O. ovalis is placed in section *Lentiformes* here based on rDNA data. Since the species seriously deviates from all the remaining members of this section, we place it in a series of its own, which stands somewhat isolated and with unclear affinities.

Variation. The Canadian collection on *Acer* fits well the European specimens, including the holotype. Two of the three collections from southern France (on *Prunus*, Pl. 181: 5; on *Betula*, IVV: 13.IX.2015) differ from the remaining ones on angiosperm hosts in somewhat shorter spores. That on *Prunus* shows also more tear-shaped SBs,

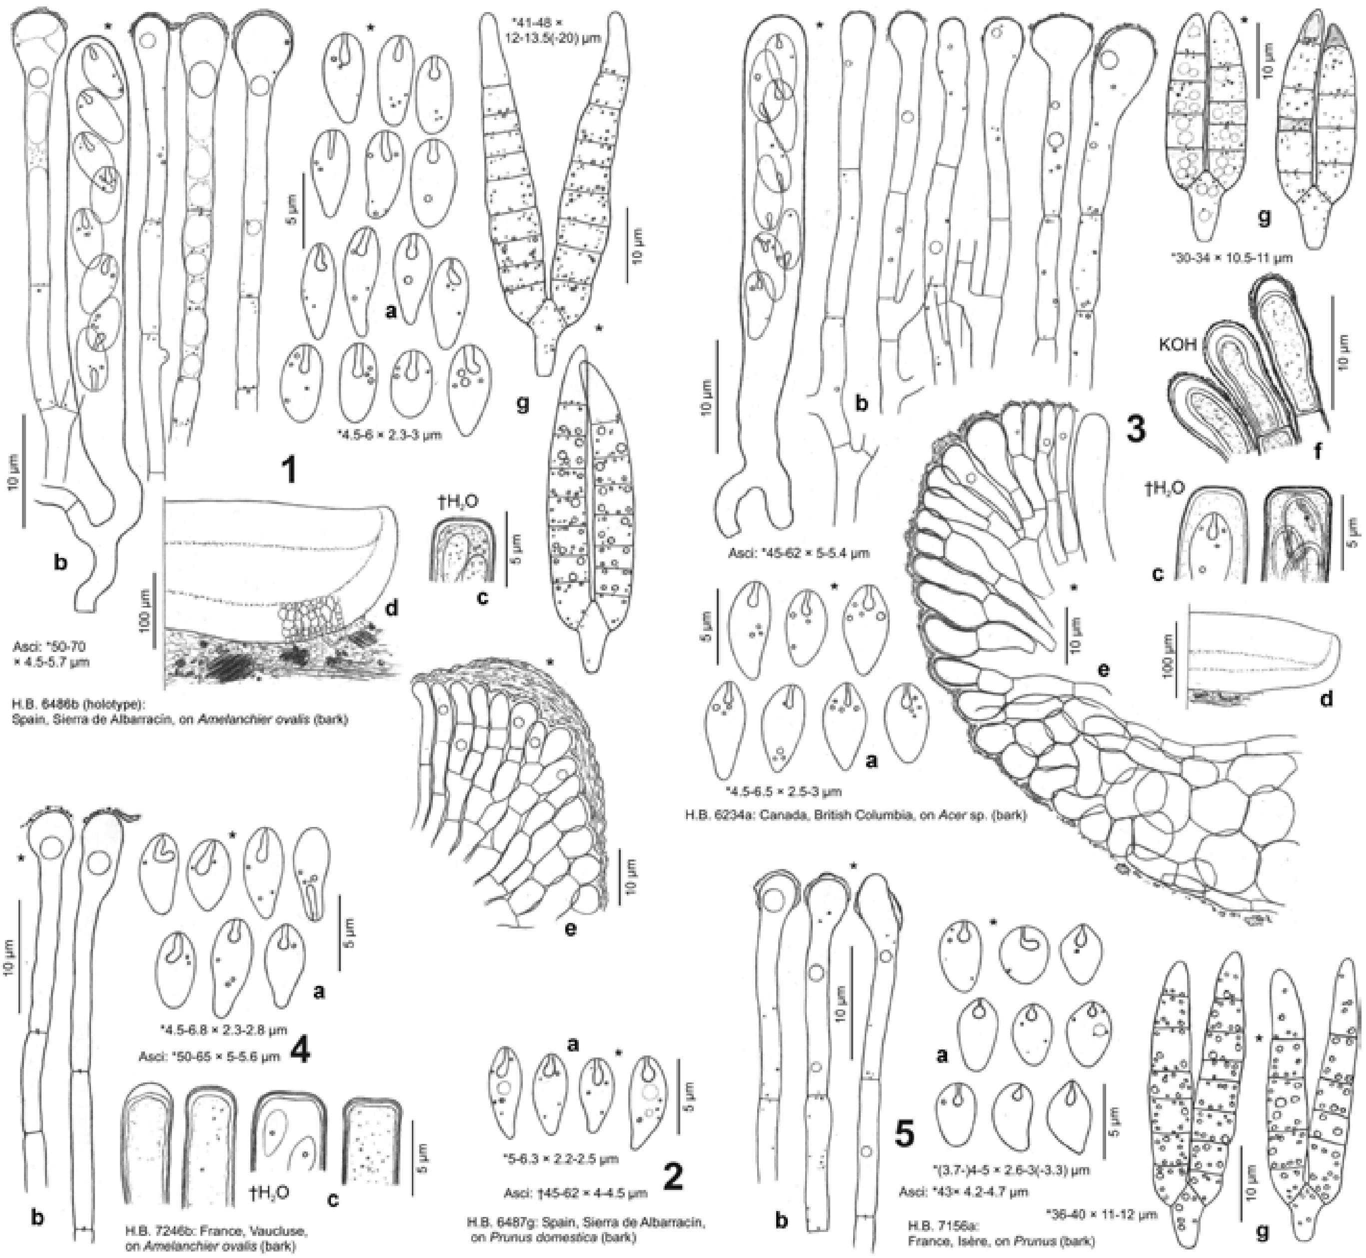

Plate 181. **1–5**: *Orbilia ovalis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. ectal excipulum (margin and mid flanks, median section); **f**. marginal cortical cells with internal wall thickening; **g**. conidia from substrate.

but the associated anamorph well concurs with that of the more typical collections. This specimen and the Austrian *Juniperus* sample, which shows extraordinarily short spores of *3–3.7 × 2.3–2.7 µm, somewhat resemble *O. dalmatica* (series *Orbilia*), a species that also grows on *Juniperus* but differs in smaller spores with much shorter SBs (0.8–1 µm) and in having glassy processes at the margin. Although the *Juniperus* sample of *O. ovalis* would fit *O. dalmatica* in spore size, its spore bodies are much more elongated (1.5–2.3 µm) and the asci distinctly wider (*5.5 µm, length not measured, Pl. 182: 3). In the collection from Canada, the dead marginal cortical cells show internal wall thickenings, which were not noticed in the European material.

Anamorph: In four of the seven records of teleomorphs of *O. ovalis*, dicranidion-like conidia were observed on the natural substrate. In two records (H.B. 6486b, 7246b) we obtained a pure culture in which, however, no conidia were formed. The presumed anamorph is similar in size to *Dicranidion parapalmicola*, from which it differs in more tapering arms. A dicranidion-like anamorph is so far extraordinary within section *Lentiformes*. The conidia in the *Juniperus* sample are distinctly longer than in those on angiosperm hosts, the arms having more septa.

Phylogeny. Sequences of four samples of *O. ovalis* were available: two from pure culture (France and Spain, on *Amelanchier*; both SSU+ITS+LSU), and two from apothecia (Austria, on *Juniperus*; France, on *Betula*; both ITS+LSU). The S1506 intron is absent in all of them. The two French samples differ by only 2 nt in the ITS and 1 nt in the LSU (D1–D2, pos. 631). The two on *Amelanchier* differ from each other by 3.9 % in the ITS (1.3 % in LSU), while that on *Juniperus* shows to the samples on angiosperms a distance of 2.9/0.3 % (Spain) and 3.8/0.8–0.9 % (France). It seems remarkable that in the D1–D2 domain the four sequences show deviations at 8 nucleotide positions, whereby the Austrian sample concurs with that from Spain at 5 positions

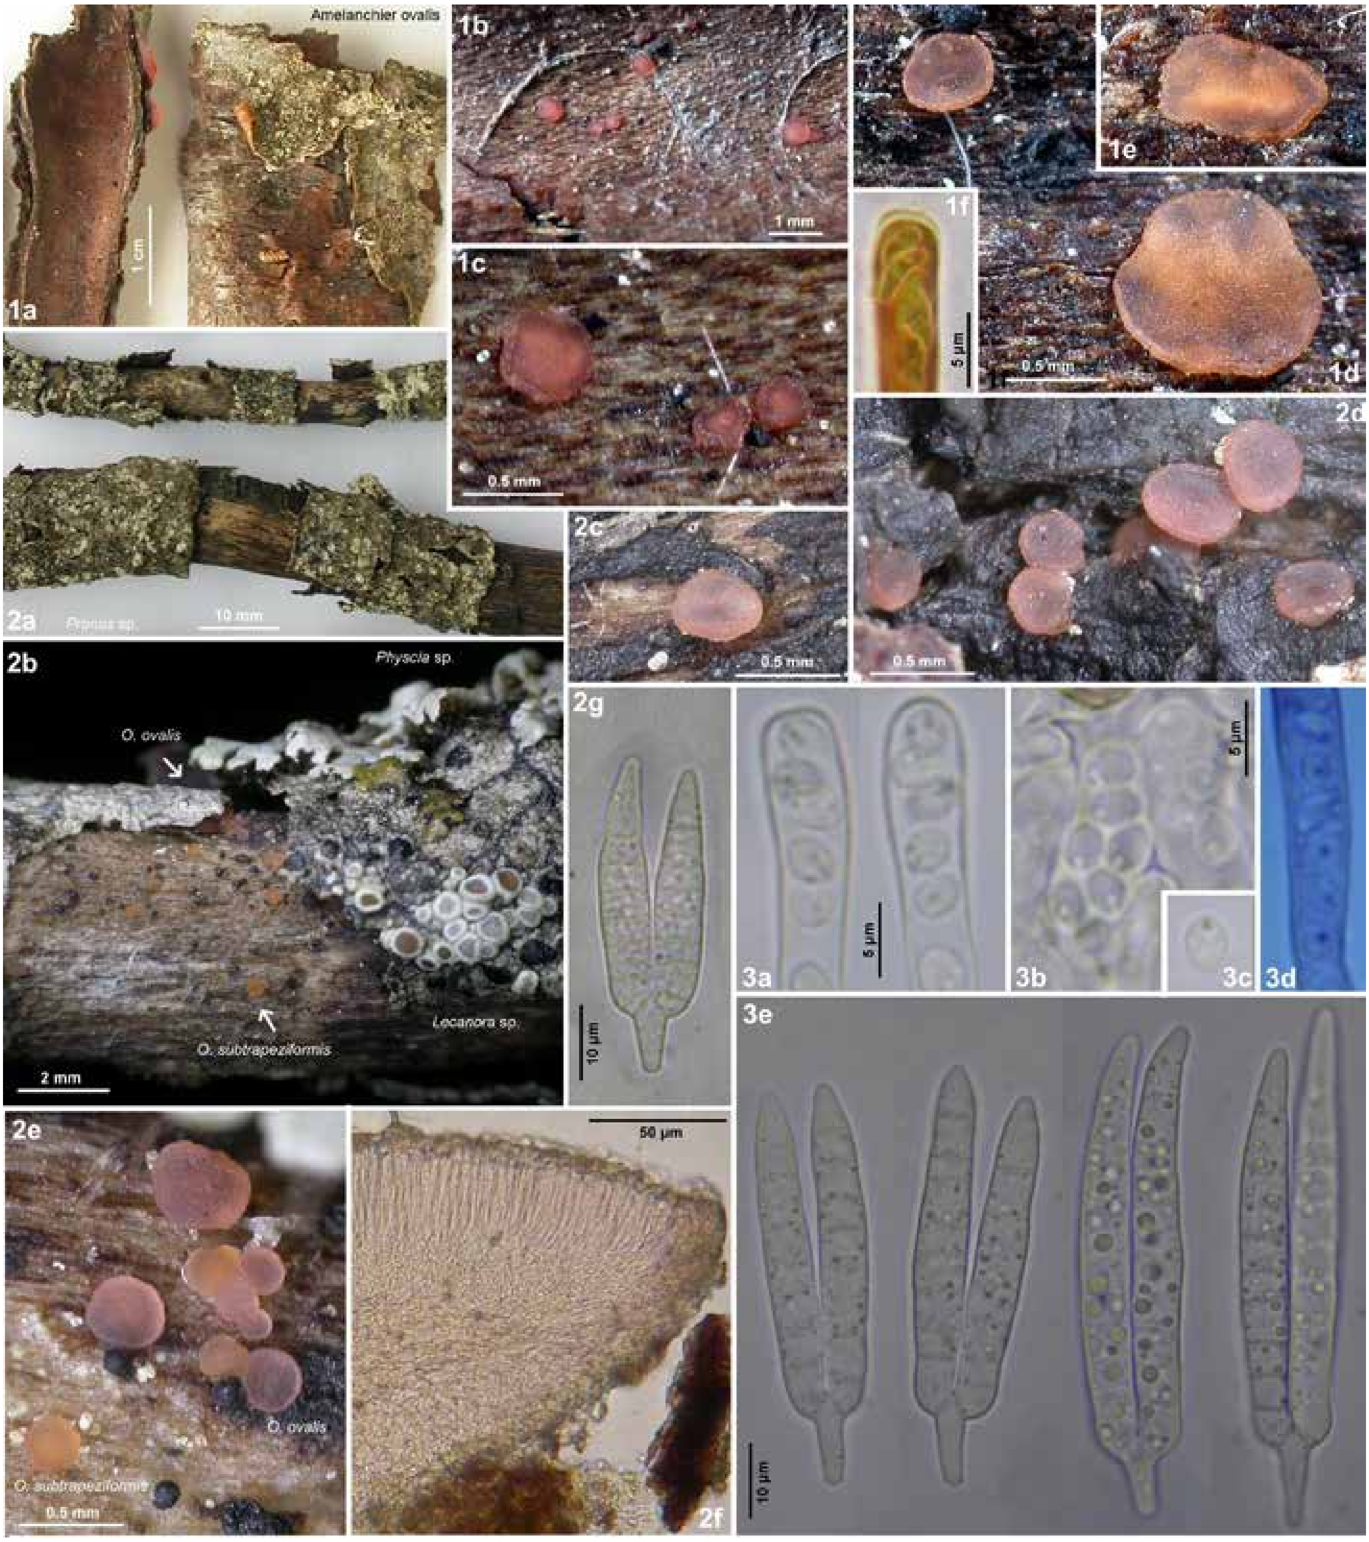

Plate 182. **1–3**: *Orbilia ovalis*. – **1a**. detached xeric bark of *Amelanchier ovalis*; **2a**. xeric branches of *Prunus*; **1b–e**, **2b–e**. rehydrated apothecia (**2b**, **e**. associated with orange *O. subtrapeziformis*); **1f**, **3a**. ascus apices; **2f**. apothecium in median section; **3a–d**. ascospores (**3a–b**, **d**. in asci); **2g**, **3e**. conidia from substrate. – Living state (**3d** in CRB), except for **1f** (KOH+IKI), asci in **3a–b**, **d**. — **1a–e**. H.B. 6486b (holotype): Spain, Sierra Albarracín, on *Amelanchier*; **2a–g**. H.B. 7156a: France, Isère, on *Prunus*; **3a–e**. G.F. 20160009: Austria, Steiermark, on *Juniperus*.

and with those from France at 2 positions, but there is no position where it deviates from both. Based on these findings and because of the similar morphology of the four samples, we consider them as conspecific.

In phylogenetic analyses of SSU+ITS+LSU (Baral et al. 2017b, Phyls 7–8), *O. ovalis* clustered strongly supported in section *Lentiformes*, though with a distance of ~20–25% in the ITS region to other members (3.5–7.5% in the LSU). In the 5.8S the distance is 0–2 nt (0–1.3%), with a full match with *O. patellarioides*. To members of series *Orbilia* the distance ranges at over 25% in the ITS (2–3.5% in the 5.8S) and 7.5–12.5% in the LSU.

Specific nucleotide positions. *O. ovalis* deviates from all other members of section *Lentiformes* in the SSU V8–V9 at pos. 60 and 252 (both A vs. G) and 269–270 (TT vs. CA), and in the LSU D1–D2 at pos. 138 (T vs. C), 432 (C vs. T), 446 (A vs. G or T), and 482/539/581 (T vs. C/A/G).

Ecology. *O. ovalis* was found on ± rotten bark but also wood of xeric twigs and branches of trees and shrubs of angiosperms (*Betulaceae*, *Rosaceae*, *Sapindaceae*), rarely gymnosperms (*Cupressaceae*). Collections are from mixed conifer forests of orotemperate and orosubmediterranean humid to suprasubmediterranean semihumid regions of southern Europe (Sistema Ibérico, Southern French Alps), from an orotemperate (altimontane) *Pinus-Picea*(-*Fagus*) forest with *Cypripedium* in the subcontinental humid eastern Austrian Alps, and from a boreal humid forest with *Populus tremuloides* and *Acer* adjacent to conifer forests in a valley of the Canadian Rocky Mountains. The sample without apothecia was from (?)supramediterranean semihumid western Anatolia. The soil at most collection sites was more or less strongly calcareous.

Specimens included. **AUSTRIA**: **Steiermark**, 20 km NNW of Bruck an der Mur, 3 km NNW of St. Ilgen, Karlschütt, 890 m, twig of *Juniperus communis*, on bark, 20.II.2016, G. SCBs in ± top view; **h**. anchoring hypha at insertion to excipulum; **i**. conidia (from substrate).

observed. **Conidia** *17–21 × 3.8–4 µm, C-shaped, 2–3-septate (only 3 conidia seen).

Habitat: collected 1–3 m above the ground, corticated, 8–13 mm thick branches of dead trees of *Cercis siliquastrum* {3}, *Ulmus minor* {2}, *U. pumila* {1}, on medium to strongly decayed bark (on bast, often in small cracks of periderm) {6}, greyed, with some to many green algae. **Associated**: *Baggea* sp. {1}, *Claussenomyces* sp. {1}, *Diplodia* sp. {1}, *Durella ?compressa* {1}, *Nitschkia broomeana* {2/1}, *Orbilia aurantiorubra* {1}, *O. carpoboloides* {2}, *O. flagellispora* {1}, *O. gambelii* {1}, *O. myriolentiformis* {1}, *O. myriosphaera* {3}, *O. pleiogambelii* {1}, *O. polyspora* {2}, *O. subaristata* {3}, *O. subclavuliformis* {2}, *O. subocellata* {1}, *O. trapeziformis* {2}, *Patellaria atrata* {2}, *Phragmiticola* sp. {1}. **Desiccation tolerance**: ascospores, submature asci, excipular cells and paraphyses still viable after 17 months. **Altitude**: -17–460 m a.s.l. **Geology**: France: Miocene sandstone near Cretaceous clayey limestone; Russia: Pleistocene sediments. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia cercidicola* is characterized by large, cucumber-like ascospores and rather large, bright orange apothecia. The species resembles *O. cucumispora* (series *Lentiformes*) in size and shape of spores and paraphyses. It sharply differs in shape and attachment of SBs (in *O. cucumispora* very broadly attached, in *O. cercidicola* ± narrowly attached), furthermore in having very large, orange, crystalloid SCBs in the living excipular cells (resulting in a bright orange apothecial colour), in lacking an apical endoascal thickening in most asci, and in a textura porrecta at the margin.

A similarity in SB shape between *O. cercidicola* and species such as *O. macroasca* and *O. phanosoma* appears to indicate a relationship to series *Phanosomates*. However, the presence of prominent crystalloid SCBs in *O. cercidicola* is so far unique within the entire section *Lentiformes*, in which otherwise

Plate 184. **1–2**: *Orbilia cercidicola*. – **2a**. mediterranean maquis with dead *Cercis*; **2b**. dead corticated xeric branch; **1a–c**, **2c–h**. rehydrated apothecia; **1d**, **2i–j**. apothecia in median section; **2k**. id., marginal region; **1e**, **2l**. Plate 185. **1**: *Orbilia cercidicola*. – **1a**. apothecia on bark (rehydrated); **1b**. median section of lower flanks, showing medullary (hyaline) and ectal (orange) excipulum, and hyaline anchoring hyphae with brown stray fungal cells below; **1c**., ascospores; **1d–e**. SCBs in excipular cells at mid flanks; **1f**. upper part of paraphyses and ascus (squash mount). – Living state, except for ascus in **1f**; phot. E.S. Popov (**1c** right, **d–f** DIC). — **1a–f**. LE 247090, 247091: Russia, Volgograd, Astrakhan, Baskunchak, on *Ulmus*.

exclusively globose SCBs were observed. Therefore, *O. cercidicola* is placed in a series of its own. Before molecular data was available, we were reluctant about the correct placement of this species, because similarities exist also with *O. cryptogena* of series *Hesperideae* of section *Hemiorbilia*.

Variation. In the holotype the paraphyses were frequently flexuous and branched near their tip, but in the two other collections on *Cercis* the tips were instead straight and unbranched. The specimens on *Ulmus* did not noticeably differ in any respect from those from France, with the paraphyses partially showing apical branching.

Type studies. The description of *Orbilia ulicis* (Chenant.) Trotter by Chenantais (1918, as *Hyalinia ulicis*) resembles the present species in its micromorphology, but the smaller spores and strongly lacerate apothecial margin rather suggest identity with *O. carpoboloides*. No type material appears to have survived, therefore, the identity of this taxon could not be settled (see p. 1033).

Anamorph. Only a few vermispora-like conidia were seen on the natural substrate (Pls.. 183: 1i; 184: 2p) which resemble those observed in some taxa of series *Lentiformes* and *Microspermae*.

Phylogeny. Molecular data gained from a pure culture of a topotype (SSU, ITS, LSU) place *O. cercidicola* in the core clade of section *Lentiformes*. When analysing SSU+ITS+LSU (Phyl. 8) or ITS (S9) it clustered weakly to medium supported with *O. myriosphaera* (series *Phanosomates*), but unresolved when analysing LSU (S11). Its distance in the ITS region is rather high, the minimum being 12.5% to *O. myriosphaera* and 14% to *O. ocellata*, but in the LSU the minimum is 2.5% to species around *O. ocellata*, while 3.5% to *O. myriosphaera*. The occurrence of crystalloid SCBs in *O. cercidicola*, being unique within section *Lentiformes*, remains unexplained in the present phylogenetic analyses, since a polyphyletic origin of these cell organelles is most unlikely.

Specific nucleotide positions. Series *Cercidicola* is unique within section *Lentiformes* in the ITS1 at pos. 1 having ATCATTA**T** instead of ATCATTA**C** (series *Microspermae*) or ATCATTA**A** (remaining taxa).

Ecology. *O. cercidicola* is so far only known from two very disjunct areas, where it occurred on medium rotten bark of dead xeric branches of two rather unrelated angiosperms (*Cercis* and *Ulmus*). At the type locality at the foothills of the Southern French Alps in southern Europe the species was collected three times on *Cercis siliquastrum* in a mesosubmediterranean semihumid maquis. Three collections were on *Ulmus* spp. from the warm-continental subhumid steppic zone of the Caspian lowland in southwestern Russia (easternmost part of Europe), either in the Volga floodplain forests with *Populus nigra*, *Fraxinus excelsior*, *Ulmus laevis*, *U. minor*, *Morus* sp., or nearby in the semidesert of the Bogdo-Baskunchak Reserve in the shelterbelt with *Ulmus pumila*.

Series *Phanosomates*

Orbilia subgenus ***Hemiorbilia*** section ***Lentiformes*** series ***Phanosomates*** Baral & E. Weber, **ser. nov.**, MB 815002 – Type species: *Orbilia phanosoma* Baral & G. Marson

Etymology: named after the spore body resembling a lantern.

Latin diagnosis: *Seriei* Lentiformium *similis, sed corpusculum refringens ascosporarum globosum ad lacrimiforme, bacilliforme vel angulare, filo tenui ad apicem affixum.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–0.5(–1.1) mm diam., pale to bright orange(-rose), sessile, ± smooth. **Asci** *(48–)60–120(–140) × (7–)8–14(–15.3) µm, 8- up to 128-spored, (0–)1/3–2/3 of lower spores inversely oriented or oriented in all directions; **apex** (†) hemispherical or slightly to medium, sometimes strongly truncate, never indented, rarely laterally slightly inflated, thin-walled or often with an (immature) †1–1.5(–2) µm thick dome with ± distinct apical chamber; **base** L-, T-, Y-, h-, never H-shaped. **Ascospores** *(3.7–)4.5–15(–17.3) × (2.4–)2.8–4.8(–6) µm, subglobose to obovoid, ellipsoid, clavate, or subcylindrical, straight or partially slightly curved near base; **SBs** *(1.5–)2–4(–5.5) × (0.2–)0.5–1.3(–1.5) µm, divided into a ± abruptly swollen, variously-shaped lower part and a fine filum of varying length, also rod-shaped with subapical constriction, apically narrowed to a small, rarely wide point. **Paraphyses** uninflated or slightly, sometimes strongly clavate(-capitate) at the apex, terminal cells (0.5–)0.7–1.5(–2)× longer than lower cells, sometimes branched near apex. **SCBs** always globose. **Exudate** 0.1–1.5(–3) µm thick, continuous to granular, smooth or ± rough, hyaline (to pale yellow), loosely attached. — **ANAMORPH**: trinacrium-like. **Conidiophores** short (~10 µm). **Conidia** Y/T-shaped, *15.5–35 × 14–31 µm, arms slightly to strongly bent downwards.

Habitat: on wood and bark of both gymno- and angiosperms, cold-temperate to subtropical, humid to semiarid, always desiccation-tolerant.

Recognized species: 11, plus 2 species with provisional name.

Taxonomic remarks. Members of series *Phanosomates* resemble those of series *Lentiformes* in many respects, but sharply differ in their peculiar type of spore bodies, which are divided into a thickened lower part and a very thin filiform upper part by which they are narrowly attached at the spore apex, thereby more or less resembling a lantern. Remarkable in some of the species is the stomach-shaped lower part of the SBs, after which some species are named, though this feature is apparently not consistent at the species level.

Variation in the ascus apex between hemispherical/thick-walled and truncate/thin-walled was noted in *O. magnifica*, *O. pleiostomachia*, *O. pluristomachia*, *O. phanosoma*, and *O. myriosphaera*. Species with rather strongly inflated paraphysis apices in combination with truncate, partially thin-walled and rarely shouldered asci (especially *O. myriosphaera*) resemble *O. ovalis* (series *Ovales*, asci often with shoulders), but also members of section *Ovoideae* (subgenus *Orbilia*, asci rarely with shoulders). *O. macroasca* and its 32-spored variant differ from the remaining species of series *Phanosomates* in their SBs having a short and rather wide upper part which is attached by a more or less wide point, similar as in *O. ovalis*.

Species delimitation. The limits between several of the included species are rather vague; moreover, only one or a few collections of some of them were available, their intraspecific variation being unexplored. For instance, *O. magnifica* is only tentatively separated from *O. lanternae*, and this in turn is only gradually different from *O. tremuloidis*, which again appears to be merely a long-spored variant of *O. phanosoma*, in which spore size and shape vary considerably. Sharp limits are also lacking between *O. multiphanosoma* and *O. pluristomachia*, in which spores and SBs also vary to some extent. The three collections included in *O. myriophanosoma* show rather different spore and SB shapes, nevertheless we assume that they belong to one species.

Anamorph. In only three of the twelve recognized species an anamorph was observed. In *O. pluristomachia* and *O. myriosphaera* trinacrium-like conidia were obtained in pure culture, while in *O. macroasca* only one such conidium was observed on the natural substrate. In all of them the conidial arms are bent downwards, either slightly or strongly. Conidia of *O. pluristomachia* closely resemble those of *O. lentiformis* (Pl. 159: 3), *O. ocellata* (Pl. 164: 7) and *O. foliicola* (Pl. 168: 1), which underlines the affiliation of this species in our phylogenetic analysis.

Phylogeny. The two sequences available at present (*O. pluristomachia*, *O. myriosphaera*) do not support a

Key to species of series *Phanosomates*

1. Inflated part of SBs rod-shaped, apically narrowed to a short and thick connecting part (~ 1/3–1/6 × the length and 1/4–3/4 × the width of the inflated part); spores *6.2–12.8 × 3.2–5.3 µm; on *Pinus*, temperate western North America 2
1. Inflated part of SBs rod- to tear-shaped or globose, apically abruptly narrowed to a long and thin connecting part ('filum', ~ 1/2–2 × the length and 1/10–1/20 × the width of the inflated part) 3

2. Asci 64-spored; bark of *Pinus edulis*, subhumid to semiarid .... ***O. macroasca***, p. 507
2. Asci 32-spored; ?bark of *Pinus ponderosa*, humid .... ***O. multimacroasca*** nom. prov. (mentioned under *O. macroasca*), p. 509

3. Asci 64- to 128–spored; spores *(2.5–)2.7–3.5(–4) µm wide 4
3. Asci 32-spored 7
3. Asci 8–16-spored 8

4. Inflated part of SBs globose, often laterally positioned, filum of equal length or often longer (sometimes almost invisible); asci *80–128 µm long, 64–128-spored; (sub)mediterranean Europe 5
4. Inflated part of SBs broadly tear-shaped to elongated, ± central, filum of equal length or shorter, exceptionally longer; asci *73–108 µm long, 64-spored; subhumid to arid North America and Australia 6

5. Asci 128-spored, *108–128 × 13.3–15 µm; spores *(6–)6.5–8(–8.5) µm long, clavate (pear-shaped); bark of *Berberis* .... ***O. pleistosphaera***, p. 526
5. Asci 64-spored, *80–105(–115) × (8.7–)9.5–10.5(–12) µm; spores *(3.8–)4.2–6(–6.8) µm long, ellipsoid-obovoid; wood and bark of *Cercis*, *Olea*, *Punica*, *Quercus* .... ***O. myriosphaera***, p. 523

6. Spores *4–4.6 × 2.9–3.4 µm, ovoid-subglobose; inflated part of SBs tear- to stomach-shaped, filum shorter than inflated part; asci †8.2–10 µm wide; wood of *Atriplex nummularia*, subtropical central Australia .... ***O. myriostomachia*** (mentioned under *O. pluristomachia*), p. 523
6. Spores *(4.5–)5.5–7.3(–8) × (2.5–)2.7–3.6(–4) µm, cylindric-ovoid; inflated part of SBs ovoid to filiform-allantoid, filum of equal length or shorter; asci †9.5–12 µm wide; bark of gymno- and angiosperms, temperate, subhumid to semiarid western North America .... ***O. myriophanosoma***, p. 517

7. Spores *(3.7–)4–6(–7.2) × (2.4–)2.8–3.5(–4) µm, ellipsoid-ovoid; SBs pyriform to stomach-shaped; wood & bark of angiosperms, semihumid to arid, mostly subtropical western North America, southern Africa, western & central Australia ***O. pluristomachia***, p. 520
7. Spores *(5.5–)6–8.5(–10) × (2.8–)3–4.2(–4.5) µm, ellipsoid-ovoid to cylindric-ellipsoid; SBs pyriform to ovoid-amygdaliform; bark of angiosperms, boreal to warm-temperate, humid to arid western North America .... ***O. multiphanosoma***, p. 515
8. Asci 16-spored; spores ovoid, *6.5–8.5 × 3.8–4.5 µm; wood of *Acacia*, tropical semiarid central Australia .... ***O. pleiostomachia***, p. 519
8. Asci 8-spored 9

9. SBs 1–2.2(–2.8) µm long, inflated part globose .... see ***O. clavipisca*** (p. 1283) **&** ***O. lilacina*** (p. 1265, **section *Ovoideae***)
9. SBs 2–5 µm long, inflated part only exceptionally globose 10

10. Spores cylindric-ellipsoid to obovoid or subglobose, mostly ± homopolar, *(6–)7–9(–11) × (3.2–)3.6–4.8(–5.2) µm, filum about as long as inflated part; wood and bark of gymno- and angiosperms, temperate to tropical, humid to arid western North America, central Asia, central Australia .... ***O. phanosoma***, p. 514
10. Spores ± clavate, slightly to strongly heteropolar, min. *(7.5–)8.5–12 µm long 11

11. Spores predominantly abruptly narrowed below in a thick tail, *(9–)12–15(–16) × (3.2–)3.4–4.2(–4.5) µm; SBs 2–3.8 × 0.8–1 µm, filum and globose to tear-shaped inflated part of ± equal length; bark of *Abies*, *Picea*, *Pseudotsuga*, boreal humid western North America .... ***O. magnifica***, p. 509
11. Spores slightly to moderately narrowed below but ± without tail-like base 12

12. SBs 3.8–5.2 × 1.3–1.5 µm, inflated part angular, ± isodiametric, filum often longer than inflated part; spores *11–17.3 × 3.6–3.8(–4.5) µm; immature asci with †1–1.3 µm thick apical thickening; wood of *Atriplex*, tropical arid central Australia .... ***O. lanternae***, p. 511
12. SBs 2.3–2.8 × 0.6–1 µm, inflated part elongate, not angular, filum shorter than inflated part; spores *(7.5–)8.5–12(–14.5) × 3.3–4 µm; immature dead asci without apical thickening; wood of *Populus tremuloides*, temperate humid western North America .... ***O. tremuloidis***, p. 512

monophyletic series *Phanosomates*, but are found within the series *Lentiformes* core clade in SSU+ITS+LSU analyses (Phyls 7–8, Baral et al. 2017b) or analyses restricted to either SSU or ITS (S8, S9). In the ITS analysis *O. myriosphaera* clustered with *O. cercidicola* and *O. pluristomachia* with *O. lentiformis* in 2 ± medium supported clades. Only when analysing LSU (D1–D2) *O. myriosphaera* formed a weakly supported clade with *O. pluristomachia*. A close molecular relationship between *O. pluristomachia* and *O. lentiformis* is also seen when analysing SSU or 5.8S alone (S8, S10).

Ecology. All 13 known species of series *Phanosomates* were exclusively recorded on ligneous substrate. Three of them were so far exclusively found on gymnosperm hosts (*O. magnifica*, *O. macroasca*, *O. multimacroasca* nom. prov.), though the latter two were only rarely collected. *O. phanosoma* and *O. myriophanosoma* occurred on both gymno- and angiosperm hosts. *O. myriosphaera* and *O. pleistosphaera* were exclusively found in Europe and here only in the (sub) mediterranean belt. Eight species were found in North America in the boreal humid to subtropical arid, ± continental Rocky Mountains, Colorado Plateau, and deserts in the south. Two of them (*O. phanosoma*, *O. pluristomachia*) were also collected in subtropical semihumid to arid Australia, the former also in cold-continental semiarid Asia and the latter in subtropical arid Africa. *O. lanternae* and *O. pleiostomachia* are only known from tropical arid Australia.

Orbilia macroasca Baral & G. Marson, **sp. nov.**, MB 813498 — Pls 186–187

Etymology: referring to the extraordinarily large size of the asci.

Typification: USA, Utah, Cedar City, branch of *Pinus edulis*, 24.VIII.1994, G. Marson (ex H.B. 5181a, M-0276502, holotype).

Latin diagnosis: Apothecia *in statu* rehydratata 0.3–0.7 mm diam. Asci 64-spori. Ascosporae *6.8–12.8 × 3.2–4.6 µm, ellipsoideo-clavatae, *in statu vivo* corpusculum refringens bacilliformem *absque filo* continentes. Paraphyses ad apicem non vel leniter inflatae. *Habitat ad corticem putridum ramorum siccorum* Pini edulis*, in zona temperata subhumida ad semiarida montana America septentrionali.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.7 mm diam., 0.2–0.24 mm high, light to bright orange, round, rarely somewhat lobate, scattered to ± gregarious in small groups; disc slightly concave to flat; margin distinct, thin, whitish-powdered, somewhat crenulate to hairy, protruding 10–30 µm, half to entirely immersed; dry rather closed and retracted. **Asci** *85–140 × (12–)13–15.3 µm {2}, †80–135 × (9–)11–12(–13) µm {2}, 64-spored (50–54 counted), spores multiseriate, partially inversely oriented (especially the lower spores), pars sporifera *65–80 µm long; **apex** (†) slightly to medium (to strongly) truncate, hemispherical in profile view, dome †1.5–2 → 0.3–1.5 µm thick {2}, with distinct, finally broad and low apical chamber; **base** with or without short to medium long stalk, L- to h-shaped. **Ascospores** *(6.8–)8–11(–12.8) × 3.2–4(–4.6) µm {2}, †5.5–10.3 × 3–3.7 µm {2}, (cylindric-)ellipsoid to clavate, apex rounded, straight to slightly curved towards base; **SBs** *2.5–3.5(–4.7) × (0.5–)0.6–0.8(–1) µm {2}, rod-shaped, base sometimes tapered, also inflated (ampulliform), apically narrowed to a ± wide, rarely small point, subapically partially distinctly constricted, straight or ± flexuous; **LBs** sparse, minute. **Paraphyses** apically uninflated, also slightly clavate or sublageniform, terminal cell *(5–)7–17(–23) × (2–)2.5–3.5(–3.8) µm {2}, lower cells *(8–)11–18(–21) × 1.8–2.8 µm {2} (near base or apex 3–3.8 µm); very rarely or quite frequently branched near apex. **Medullary excipulum** hyaline, 50–60 µm thick, of dense textura intricata with some inflated cells, sharply delimited. **Ectal excipulum** hyaline, pale orange at flanks and margin, of thin-walled († slightly to medium gelatinized), irregularly or vertically oriented t. angularis from base to submargin, 30–40 µm thick at base and flanks, cells */†8–15 × 7–10(–12) µm {2}; 20–30 µm thick near margin, of t. porrecta oriented at a 0–10° angle to the surface, forming paraphysis-like, somewhat free hairs with rough surface, terminal cells *12–15 × 3–4 µm {1}. **Anchoring hyphae** sparse to rather abundant, †1.7–3.3 µm wide, walls 0.2–0.3(–0.8) µm thick {1}, forming at flanks and margin a hyaline t. porrecta-intricata that projects beyond the hymenium. **SCBs** in paraphyses absent or present, globose, small, scarcely visible. **Exudate** over paraphyses visible as a 0.2 µm thick refractive line, lying over thick gel, partially also 1–2(–3) µm thick, cloddy, pale yellow(-orange), loosely attached. **— ANAMORPH**: trinacrium-like (presumed, from natural substrate {1}). **Conidiophores** unknown. **Conidia**: T-shaped, 2-armed, total size *32 × 31 µm, stipe *25 × 6 µm, 2-septate, arms tapering, somewhat bent downwards, *13–14.5 × 5–5.3 µm, 1-septate (only 1 conidium seen).

Habitat: collected 0.5–2 m above the ground, on corticated (upper side partially somewhat decorticated), 8–16 mm thick branches

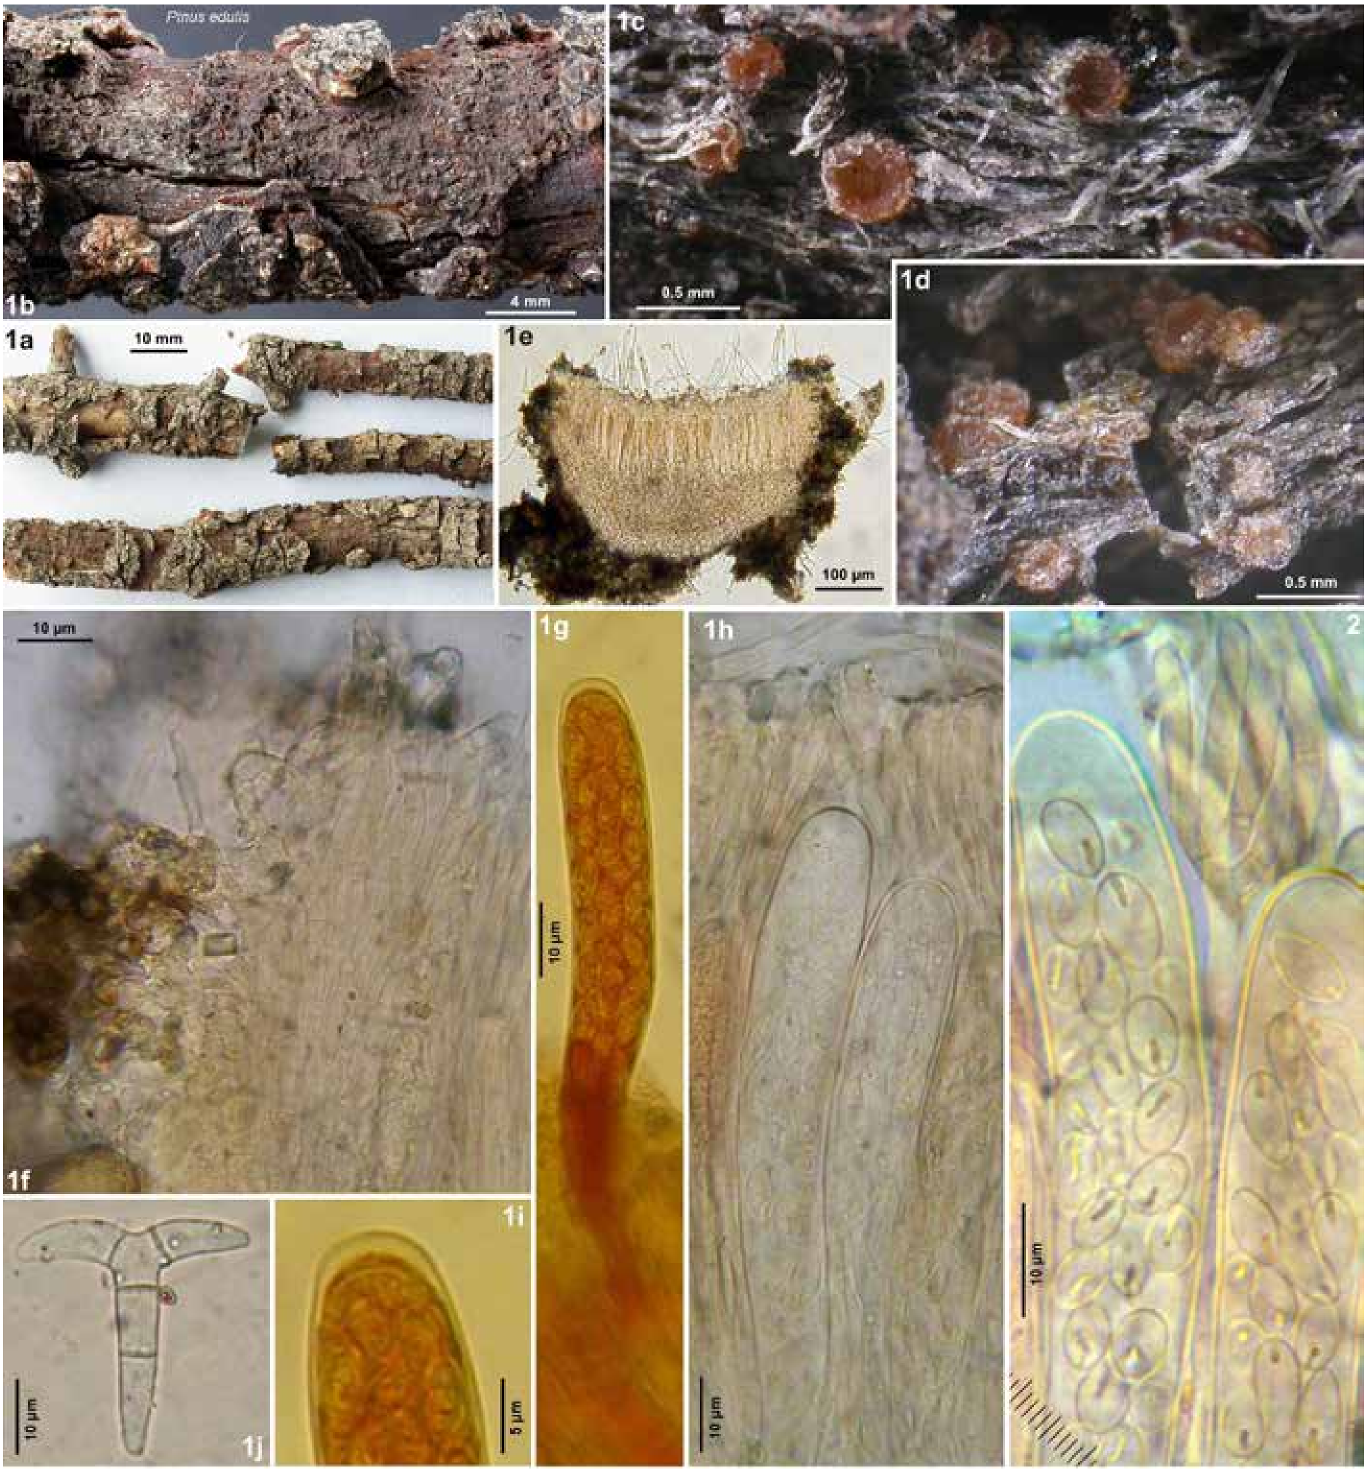

Plate 187. **1**: *Orbilia macroasca*; **2**: *O. multimacroasca* nom. prov. – **1a–b**. branches of *Pinus edulis*; **1c–d**. rehydrated apothecia; 1e. apothecium in median section; **1f**. marginal ectal excipulum in median section; **1g–h**, **2**. asci and paraphyses; **1i**. ascus apex; 1j. conidium from substrate. – Living state, except for **1g**, **i** (in KOH+IKI). — **1a–j**. of *Pinus edulis* {2}, in small cross-cracks or larger periderm-free areas on medium to strongly decayed bark (bast) {2}, with scattered resin, greyed and with some green algae. **Associated**: *Acremonium limoniforme* (parasitic in *O. macroasca*) {1}, *Amphosoma macrosporum* {1}, *Dothideales* {1}, *Encoelioideae* {1}, crustose lichen. **Desiccation tolerance**: fully viable for at least 33 months. **Altitude**: 1815–1920 m a.s.l. **Geology**: Triassic & Upper Cretaceous (calcareous) sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia macroasca* is characterized by 64-spored asci and ellipsoid-clavate ascospores with ± rod-shaped SBs. The species differs from the similar *O. myriophanosoma* in longer and wider spores, thicker asci, larger apothecia, and especially in the SBs that lack a fine filum but are, instead, more broadly inserted to the apical spore wall by a distinctly thicker, very short connecting part. Due to the absence of a filum the species might instead belong to section *Hemiorbilia*, but the SBs resemble those occasionally seen in *O. magnifica* (Pl. 188: 2a upper row).

Not included collection. A sparse, unpreserved sample on *Pinus ponderosa* differs mainly in 32-spored asci and was not studied in detail. Only a microphoto exists (Pl. 187: 2): asci *13.2–13.7 µm wide, pars sporifera *42 µm long; ascospores

*6.2–8.3(–9) × 3.5–4.7(–5.3) µm, SBs 2.7–4 × 0.6–0.8 µm; paraphyses apically uninflated, terminal cell *18.5–21 × 2.6–3.1 µm (all data evaluated from photo). This might well represent a different species due to the deviating spore number, and is provisionally called ***O*. *multimacroasca*** G. Marson & Baral nom. prov.

Anamorph. Only one conidium was found on the substrate which resembles those trinacrium-like conidia of some other members of section *Lentiformes*.

Ecology. *O. macroasca* is so far only known from two records from pinyon-juniper woodlands in western North America: on rotten bark of dead xeric branches of *Pinus edulis* from a warm-continental semiarid high plateau in the Canyonlands section of the Colorado Plateau (paratype) and from a cold-temperate subhumid dry riverbed in the Utah Mountains (holotype). The 32-spored population (*O. multimacroasca*) occurred in a cold-temperate humid pure ponderosa pine forest at higher altitude in the Mogollon Rim in association with *Orbilia spermoides*.

Specimens included. **USA**: **Utah**, Utah Mts. adjacent to Great Basin, 1.5 km ESE of Cedar City, Dixie Forest, 1815 m, branch of *Pinus edulis*, on bark, 24.VIII.1994, G. Marson (ex H.B. 5181a, M-0276502, **holotype**). – Canyonlands, 35 km SSW of Moab, 1.3 km E of Needles Overlook, Hatch Point, 1920 m, branch of *Pinus edulis*, on bark, 7.VI.2003, G. Marson (H.B. 8080a, anam. substr.).

O*. *multimacroasca nom. prov.: **USA**: **Arizona**, Mogollon Rim, 16 km NW of Flagstaff, San Francisco Peaks, 6 km WSW of Humphreys Peak, 2550 m, branch of *Pinus ponderosa*, 17.VI.2003, G. Marson (ø).

Orbilia magnifica Baral & G. Marson, **sp**. **nov**., MB 813499 — Pls 188–189, Map 29

Etymology: at first named '*magnificae*' after the type host, originally misidentified as *Abies magnifica*, then changed to *magnifica* (= magnificent).

Typification: USA, Arizona, Jacob Lake, branches of (?)*Pseudotsuga menziesii*, 17.V.1995, G. Marson (ex H.B. 5404b, M-0276507, holotype).

Latin diagnosis: *Differt ab* Orbilia phanosomate *et* O. lanternae *ascosporis ad basim valde attenuatis et caudatis. Habitat ad corticem putridum ramorum siccorum arborum coniferarum in zona boreali ad temperata humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5(–0.7) mm diam., 0.16–0.23 mm high (receptacle 0.15 mm), pale to bright (rose-)orange(-ochraceous), round, gregarious in ± small groups; disc slightly concave (to flat), margin ± thick, even, protruding 0–10 µm; sessile or with a hidden stipe 0.05 × 0.2 mm, ± erumpent (partially hidden in cracks); dry bright orange-red. **Asci** *(53–)65–86(–92) × 7–8 {2} or 8.5–9.3(–10) µm {3}, †(50–)60–85(–94) × (6–)6.5–8(–9.5) µm {5}, 8-spored, spores *2–3-seriate, 0–4(–6) lower spores inversely oriented {4} (not or sometimes mixed), pars sporifera *33–43 → 26 µm long; **apex** (†) hemispherical or slightly to medium truncate, dome present {5}, †1–1.3 → 0.3–0.8 µm thick {4}, with ± distinct apical chamber; also partially absent (immature, wall †0.3–0.5 µm thick) {2}; **base** with short to long, ± thin or thick, flexuous stalk, T- to L- or Y-shaped. **Ascospores** *(9–)12–15(–16) × (3.2–)3.4–4.2(–4.5)((–5)) µm {4}, † (8–)9–11(–11.5) {1} or (10–)12–15(–16.7)((–18.5)) {2} × (3–)3.2–3.8(–4) µm {3}, (slightly to) strongly clavate or mostly ± ellipsoid, with a thick tail *(2–)3–5(–7) × 1.3–2(–2.4) µm, apex rounded, tail sometimes with inflated base, straight to slightly (or medium) curved in lower part; **SBs** *(1.5–)2–3.8(–4.5) × 0.8–1(–1.2) µm, divided into a very abruptly swollen, tear- to pear- or rod-shaped or ellipsoid to globose lower part and a fine filum of ± equal or shorter length, filum either thin up to the apex {3}, or distinctly widened at point

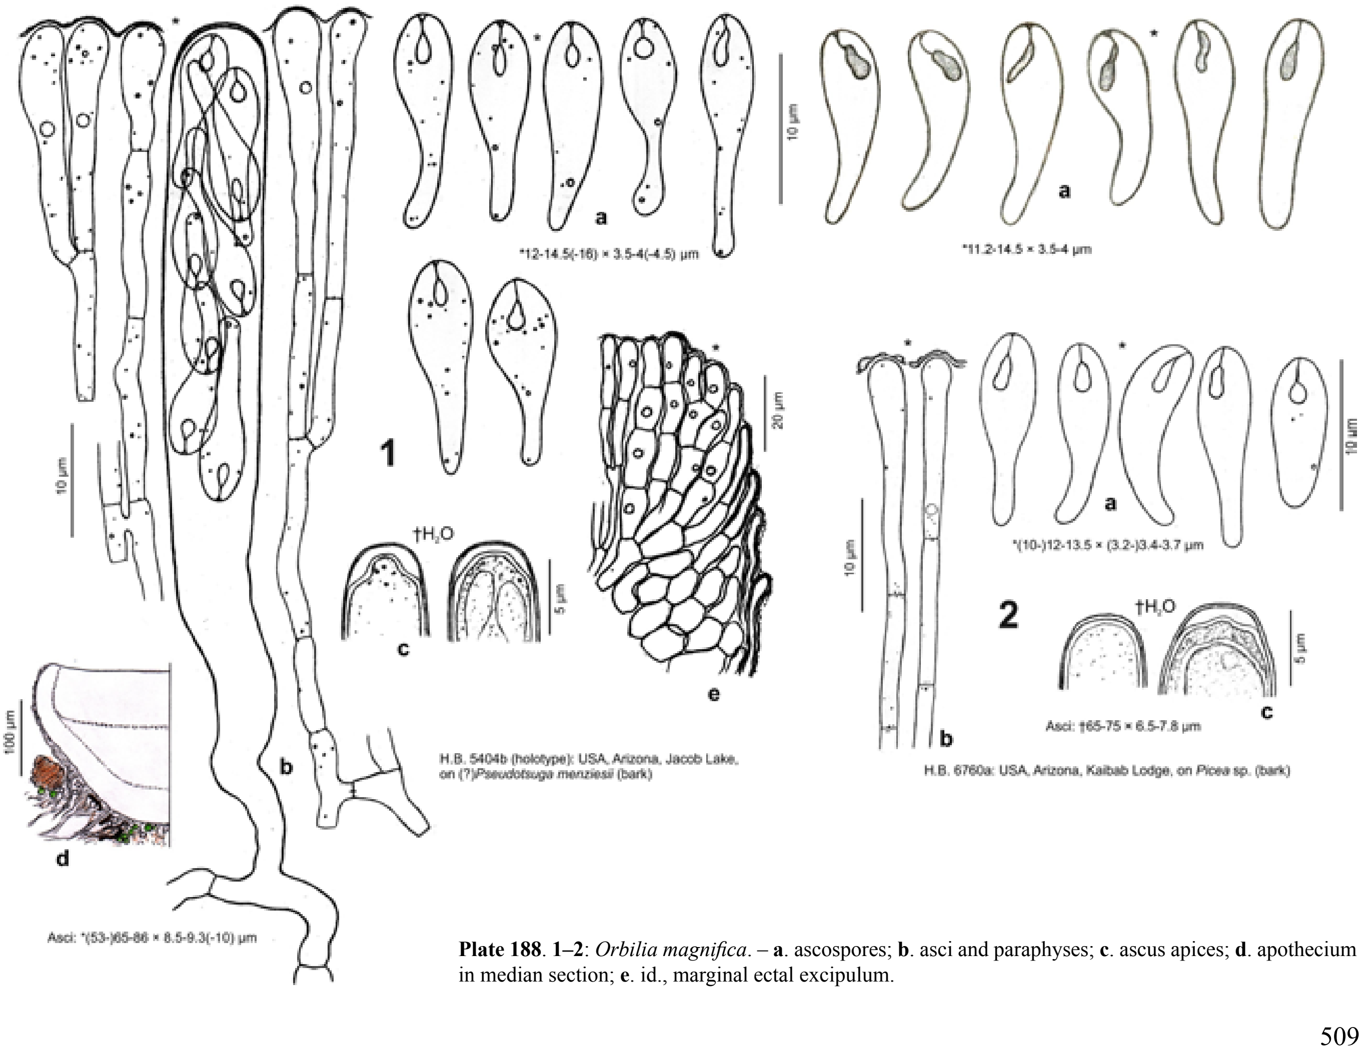

Plate 188. **1–2**: *Orbilia magnifica*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

of attachment {T}, straight, rarely curved or bent. **Paraphyses** apically slightly to medium (sometimes strongly) clavate(-capitate), terminal cell *(8–)13–21(–26) × 2–4.7 µm {2}, †2.5–5 µm wide {1}, lower cells *9–18 × 1.7–2.3 µm {1}; sometimes branched near apex. **Medullary excipulum** pale rose, 40–70 µm thick, of ± dense textura intricata with a few or many inflated cells, sharply delimited. **Ectal excipulum** pale rose, from base to mid flanks of (†) thick-walled (common cells 1–2 µm {1}), vertically oriented t. angularis(-prismatica), 30–60 µm thick near base, cells */†8–21 × 7–14(–18) µm {2}; 15–25 µm thick at flanks, cells *6–12 × 5–8 µm, 15–20 µm thick at margin, of t. angularis(-prismatica) oriented at 80° at submargin, at margin of t. porrecta oriented at 0–45°, cortical cells elongate, *7–14 × 2–3.5 µm {1}. **Anchoring hyphae** abundant, */†2–3.5 µm wide, walls 0.2–0.4(–0.8) µm thick {2}, forming thin, long hyphal strands, covering flanks and submargin by a 3–15 µm thick ± gelatinized layer. **SCBs** globose, in terminal cells of paraphyses 1–1.3 µm diam., 1 per cell, very slightly refractive, partially absent; in cortical cells 1.3–1.5 µm diam. **LBs** in basal ectal excipulum small and sparse {1} or large {1}. **Exudate** over paraphyses 0.1–1.5 µm thick {2}, continuous, ± rough; over margin and flanks 0.5–1 µm thick. — **ANAMORPH**: unknown (but 1 vermispora-like conidium seen emerging from hymenium).

Habitat: collected 1.2–3 m above the ground, corticated, 4–14 mm thick branches of ?*Abies* sp. {1}, *A. lasiocarpa* {1}, *Picea* sp. {1}, *P. sitchensis* {1}, *Pseudotsuga menziesii* {1/1}, on loosely attached, medium decayed bark {5} (bast, often in cracks of periderm) or wood {1}, greyed, slightly covered by green algae. **Associated**: *Helicogonium orbiliarum* (parasitic in *O. magnifica*) {1}, *Lachnellula* sp. {1}, *Lecanora caesiorubella* {1}, *Melanohalea subolivacea* {2}, *Orbilia aristata* {1}, *O.* ?*carpoboloides* {1}, *O. coniferarum* {1}, *O. lentiformis* {2}, *O. macrodelphinus* {1}, *O. maeandrina* {2}, ?*Physcia* sp. {1}, *Stictis* sp. {1}, *Teichospora* sp. {1}, *Xanthoria* sp. {1}. **Desiccation tolerance**: fully viable for at least 1 year, a few spores and many paraphyses still viable after 5 ⅓ years. **Altitude**: 2000–2800 m a.s.l. **Geology**: Mississippian-Permian, Triassic-Jurassic and Cretaceous sand- and limestone; basalt breccia with andesite & rhyolite. **Phenology**: long-lived.

Taxonomic remarks. *O. magnifica* is characterized by clavate ascospores with often distinct thick tails, also by rather large apothecia. Despite a strong heteropolarity in spore shape, inversely oriented spores are entirely lacking in some of the asci. In spore shape *O. magnifica* resembles *O. patellarioides*, a species differing in lens-shaped SBs and black apothecia, but also *O. clavuliformis* in which the SBs have no filum. *O. magnifica* is obviously closely related to *O. lanternae* (see p. 512).

Variation. Although *O. magnifica* appears to be a rather constant species, some variation was noted among the collections. From the other three samples that were studied in the living state, the holotype differed in the SB filum being apically often abruptly widened (funnel-shaped). In the two collections on *Picea* the ascus apical thickening was sometimes or often absent, whereas in the those on *Abies* and (?)*Pseudotsuga* examined for this feature it was always present.

Phylogeny: A sequence taken in Feb. 2020 from apothecia on *Pseudotsuga* clustered in our ITS+LSU ML analysis (not shown) supported sister to the *flavida-cucumispora* clade. The minimum ITS distance was 10.5% to *O.* aff. *lentiformis* (H.B. 8002c) and 11.5% to *O. cucumispora*.

Ecology. *O. magnifica* was collected on rotten bark of dead xeric branches of *Abies* and *Picea* in a cold-temperate humid ponderosa pine forest (holotype) and in cold-temperate to boreal humid Douglas fir and Engelmann spruce forests of the Middle Rocky Mountains and Colorado Plateau (Utah Mountains, Kaibab Plateau, Mogollon Rim) in western North America.

Map 29. Known distribution of *O. magnifica* in North America.

Specimens included. **USA**: **Wyoming**, Middle Rocky Mountains, Grand Teton, N of Jackson, ~2000 m, on branch of ?*Abies*, 6.VI.1996, G. Marson (ø). – **Utah**, Utah Mts., Dixie Forest, 22 km SSE of Torrey, 13 km S of Grover, 1 km N of Pleasant Creek Campground, 2650 m, branches of *Picea sitchensis*, on bark & wood, 19.VI.2000, G. Marson (H.B. 8545a). – ibid., NW of Pleasant Creek Campground, 2664 m, branches of *Pseudotsuga menziesii*, on bark, 11.VI.2003, G. Marson (G.M. 2003-06-03.1, sq.: MT356589). – **Arizona**, Grand Canyon, Kaibab Plateau, 37 km SE of Fredonia, S of Jacob Lake, 2415 m, branches of (?)*Pseudotsuga menziesii*, on bark, 17.V.1995, G. Marson (M-0276507, **holotype**; **isotypes** in M & H.B. 5404b). – 3 km N of Kaibab Lodge, 2680 m, branch of *Picea*, on bark, 17.V.1995, G. Marson (H.B. 6760a). – Mogollon Rim, 83 km SSE of Vernon, 9.5 km SSW of Hannagan Meadow, Rte. 191 (Coronado Trail), 2800 m, branches of *Abies lasiocarpa*, on bark, 2.VI.2003, G. Marson (H.B. 9578b).

Orbilia lanternae Baral & G. Marson, **sp. nov.**, MB 813500 — Pl. 190

Etymology: named after the spore body resembling a lantern.

Typification: Australia, Northern Territories, Wilora, branch of *Atriplex*, 8.X.1998, G. Marson (ex H.B. 6262f, MEL 2389197, holotype).

Latin diagnosis: *Differt ab* Orbilia magnifica *ascosporis ad basim minus attenuatis neque caudatis*, *corpusculis refringentibus angularibus*; O. lentiformis *differt ab* O. lanternae *corpusculis refringentibus lentiformibus. Habitat ad lignum putridum ramorum siccorum* Atriplicis *in zona tropica arida Australiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.5 mm diam., 0.14 mm high, light (dirty) orange-rose, ± round, scattered to gregarious; disc slightly concave, margin thin, scarcely protruding, smooth; sessile, slightly erumpent between fibres. **Asci** *70–80 × 9.5–10.5 µm, 8-spored, spores *2–3-seriate, 3–5 lower spores inverted (slightly mixed), pars sporifera *44 µm long; **apex** (†) hemispherical to slightly truncate, dome immature †1–1.3 µm thick, with slight apical chamber; **base** with short, thick, flexuous stalk, L-shaped. **Ascospores** *11–17.3 × 3.6–3.8(–4.5) µm, (ellipsoid-)clavate, apex rounded, base medium to strongly attenuated, sometimes thick and tail-like, straight to slightly inequilateral or curved at base; **SBs** *3.8–5.2 × 1.3–1.5 µm, divided into an abruptly swollen, angular or sometimes tear-shaped lower part and a filum of equal or often double length. **Paraphyses** apically uninflated to very slightly clavate, terminal cell *5–14 × 2.5–3.7 µm, lower cells *9–16 × 1.8–2.5(–2.8) µm; sometimes branched at upper septum. **Medullary excipulum** pale rose, 20 µm thick, of dense textura globulosa(-intricata), horizontally oriented, ± sharply delimited. **Ectal excipulum** of thin-walled, irregularly oriented t. angularis(-prismatica) from base to mid flanks, 40 µm thick near base, cells *10–

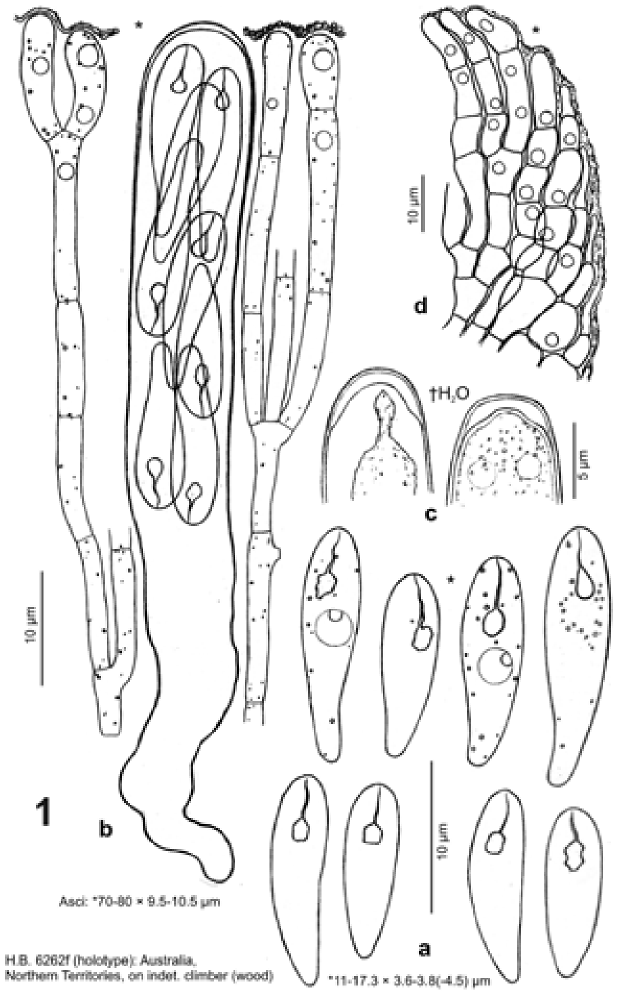

Plate 190. **1**: *Orbilia lanternae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum (median section).

15 × 7–10 µm; 20 µm thick near margin, of t. prismatica oriented at a 10–20° angle to the surface, marginal cortical cells *(6–)9–11 × 4–5 µm. **Anchoring hyphae** not examined. **SCBs** globose, in paraphyses 1.3–2 µm diam., in ectal excipulum (near margin) 2–2.5 µm. **Exudate** over paraphyses and margin 0.5–2 µm thick, granular-continuous, loosely attached. **— ANAMORPH**: unknown.

Habitat: collected 0.2–2 m above the ground, decorticated, 9–10 mm thick branches of *Atriplex* sp., on 0.2 mm deep very decayed wood, strongly greyed, no algae. **Associated**: *Dothideales*, *Orbilia barrowensis*, *O. livistonae*, *O. multiaustrocylindrica*, *O. multigambelii*, *O. octocercocarpi*, *O. pleioaustraliensis*. **Altitude**: 480 m a.s.l. **Desiccation tolerance**: fully tolerant for at least 3 weeks. **Geology**: Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia lanternae* differs from the conifericolous North American *O. magnifica* in slightly to medium tapered spore bases without distinct tails, also in mostly angular inflated parts of the SBs. Moreover, the paraphyses have shorter terminal cells and the marginal cortical cells of the excipulum are wider. *O. lanternae* closely resembles *O. lentiformis* (series *Lentiformes*) in spore shape. However, the two species can easily be distinguished by the very different type of spore body. The lens-shaped SBs in *O. lentiformis* can even be seen in dead spores whereas those in species of series *Phanosomates* become invisible.

Ecology. *O. lanternae* is only known from a single sparse collection which is now without apothecia. The species grew on rotten wood of dead xeric twigs of *Atriplex* sp. climbing up trees of *Acacia* sp. in an acacia open shrubland north of MacDonnell Ranges in tropical arid central Australia.

Specimens included. **AUSTRALIA**: **Northern Territories**, Burt Plain, 31 km SW of Barrow-Creek Hotel, 3.7 km WSW of Wilora, Stuart Hwy, 480 m, branch of *Atriplex*, on wood, 8.X.1998, G. Marson (ex H.B. 6262f, MEL 2389197, **holotype**).

Orbilia tremuloidis Baral & E. Weber, **sp. nov.**,

MB 813501 — Pl. 191

Etymology: named after the substrate of the type, *Populus tremuloides*.

Typification: USA, Arizona, Flagstaff, branch of *Populus tremuloides*, 12.VI.2000, G. Marson (ex H.B. 7086d, M-0276603, holotype).

Latin diagnosis: *Differt ab* Orbilia phanosomate *ascosporis longioribus*, *ad basim magis attenuatis*, *corpusculis refringentibus filis multo brevioribus. Habitat ad lignum putridum ramorum siccorum* Populi tremuloidis *in zona temperata humida altimontana Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.3 mm diam., 0.15 mm high, light orange(-rose), hardly translucent, round to elliptical, subgregarious in a small group; disc slightly concave, margin thin, not protruding, smooth; broadly sessile, superficial to erumpent. **Asci** †60–80 × 7–8.5 µm, 8-spored, spores (†) obliquely biseriate, 1–4 lower spores inverted (partially strongly mixed); **apex** (†) hemispherical to very slightly truncate, rarely conico-truncate, thin-walled (†0.2–0.3 µm thick); **base** with short to medium long,

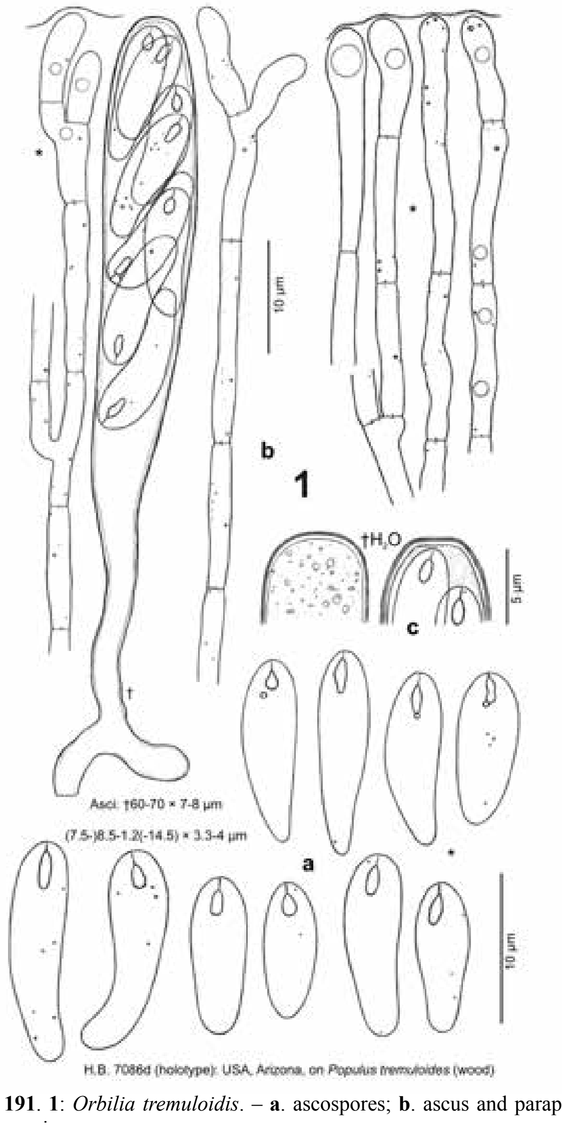

Plate 191. **1**: *Orbilia tremuloidis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices.

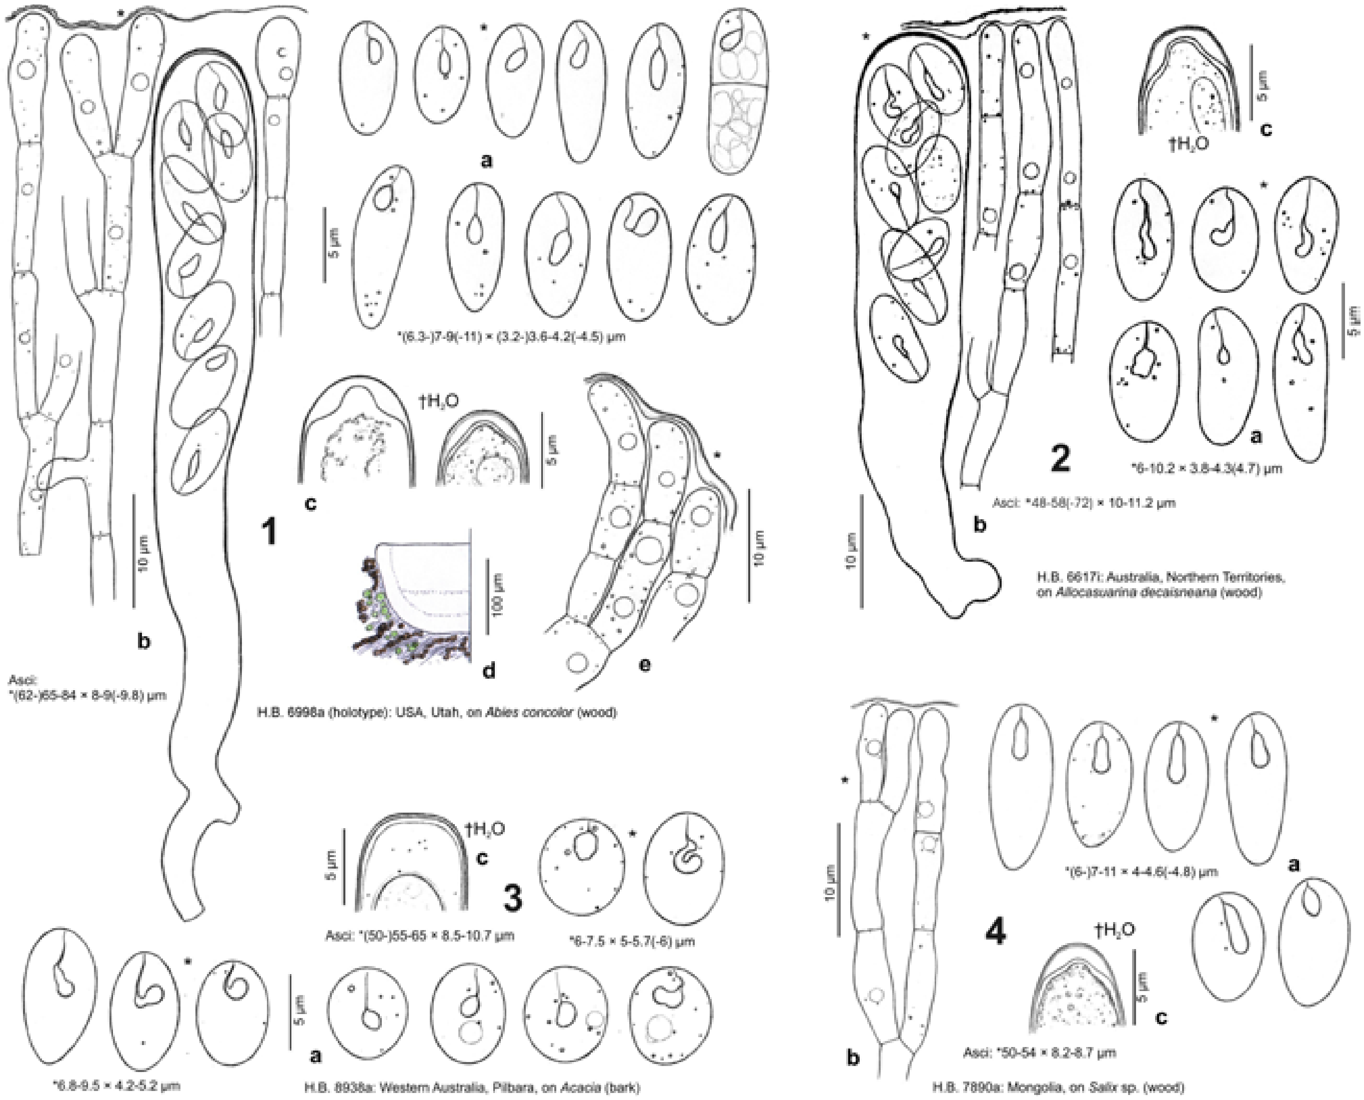

H.B. 6998a (holotype): USA, Utah, on *Abies concolor* (wood)

H.B. 6617i: Australia, Northern Territories, on *Allocasuarina decaisneana* (wood)

H.B. 8938a: Western Australia, Pilbara, on *Acacia* (bark)

H.B. 7890a: Mongolia, on *Salix* sp. (wood)

Plate 192. **1–4**: *Orbilia phanosoma*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

thick, flexuous stalk, Y- to L-shaped. **Ascospores** *(7.5–)8.5–12(–14.5) × 3.3–4 µm, †9–12.5 × 3.3–3.7 µm, subcylindric-ellipsoid to ellipsoid-clavate, apex rounded, towards base slightly or strongly attenuated and straight to slightly (to medium) curved; **SBs** *(2–)2.3–2.8(–3.2) × 0.6–1 µm, lower part cylindrical to ellipsoid-fusoid or pyriform, rarely constricted, apically narrowed to a short filum (½ to ¼ of length of inflated part), ± straight. **Paraphyses** apically uninflated or slightly (to medium) clavate, terminal cell *8–23 × 2–3(–4) µm, lower cells *9.5–18 × 1.8–2.5(–3.3) µm; sometimes branched at upper septum. **Medullary excipulum** hyaline, 50 µm thick, of ± dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale orange, of ± thin-walled, irregularly (to horizontally) oriented t. angularis(-prismatica) from base to mid flanks, 20 µm thick near base, cells †6–11 × 5–8 µm; 15–20 µm thick near margin, of t. prismatica oriented at a 0–10° angle to the surface, marginal cortical cells †9–15 × 3–4 µm. **Anchoring hyphae** medium abundant, †1.5–3 µm wide, walls 0.2–0.3 µm thick, extending to the margin as a thin layer. **SCBs** in paraphyses globose, 1.2–2.7 µm diam. **Exudate** over paraphyses 0.1 µm thick, continuous, smooth, loosely attached, over margin and flanks 0.2–0.3 µm thick. — **ANAMORPH**: unknown.

Habitat: collected 3 m above the ground, partially to entirely decorticated, 18–24 mm thick branches of *Populus tremuloides*, on 1 mm deep very decayed wood, slightly to strongly greyed, a few to many green algae. **Associated**: *Hysterium* spp. {2}, *Hysteropatella* sp., *Mellitiosporiella pulchella*, *Odontotrema oregonensis*, *Orbilia delphinus*, *O. gambelii*, *O. microsoma*, *O. navajoana*, *Phragmiticola* sp. **Desiccation tolerance**: paraphyses and spores still viable after 1.5 years. **Altitude**: 2450 m a.s.l. **Geology**: basaltic lava and cinders with andesite, dacite & rhyolite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia tremuloidis* is tentatively segregated from *O. phanosoma* based on its longer, more clavate ascospores and by spore bodies with a shorter filum. *O. tremuloidis* resembles *O. lanternae* in spore shape, but the latter species differs in the SBs having a much longer filum and broader, angular inflated parts. *O. tremuloidis* differs from both species in the absence of an apical thickening of the asci. However, also in *O. phanosoma* thin-walled asci rarely occur, and *O. tremuloidis* might vary in a similar way if more collections will be available for study.

Ecology. *O. tremuloidis* is only known from a single collection on rotten wood of dead xeric branches of *Populus tremuloides* from the cold-temperate humid ponderosa pine forest on a high plateau at the northwest-end of the Mogollon Rim in the southwest of Northern America.

Specimens included. **USA**: **Arizona**, Mogollon Rim, 23 km NW of Flagstaff, 10.5 km WNW of Humphreys Peak, Rte. 180, 2450 m, branch of *Populus tremuloides*, on wood, 12.VI.2000, G. Marson (ex H.B. 7086d, M-0276603, **holotype**).

H.B. 8938a: Western Australia, Pilbara, on *Acacia*; **2**. H.B. 5227b: USA, Arizona; **3**. H.B. 8879d: Western Australia, Pilbara, on *Acacia*; **4a–b**. H.B. 6998a (holotype): USA, Utah, on *Abies*.

Orbilia phanosoma Baral & Marson, **sp. nov.**, MB 813502 — Pls 192–193

Etymology: named after the shape of the spore body resembling a lantern.

Typification: USA, Utah, Panguitch, branch of *Abies concolor*, 20.VI.2000, G. Marson (ex H.B. 6998a, M-0276553, holotype).

Latin diagnosis: *Apothecia* in statu *rehydratata 0.2–0.6 mm diam. Asci 8-spori. Ascosporae *6–11 × 3.2–5.2 µm, ellipsoideae, interdum subclavatae, in statu vivo corpusculum refringens ellipsoideum ad pyriformem, partim curvatum, continentes*, *filo longo et tenui ad apicem affixum. Paraphyses ad apicem non vel leniter inflatae. Habitat ad lignum vel corticem putridum ramorum siccorum arborum coniferarum vel angiospermarum*, *in zona temperata ad tropica humida ad arida Americae septentrionalis, Asiae et Australiae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.5(–0.6) mm diam., (0.09–)0.12–0.15(–0.2) mm high, light to bright orange(-rose), round, scattered to subgregarious; disc slightly concave to flat, margin medium thick, even, protruding 0–10 µm; broadly sessile, slightly to strongly erumpent. **Asci** *(48–)55–72(–82) × 8–10(–11.2) {4} µm, †43–70 × 7.5–9(–10.5) µm {4}, 8-spored, spores (1–)2(–3)-seriate, (2–)3–5 lower spores inversely oriented (often mixed) {6}, pars sporifera *30–44 µm long; **apex** (†) hemispherical to slightly or medium truncate, dome absent {1}or †1–1.4 → 0.5–1 µm thick {3}, with ± distinct apical chamber; **base** with short to medium long stalk, L- to h-shaped. **Ascospores** *(6–)7–9(–11)((–12)) × (3.2–)3.6–4.8(–5.2) µm {5}, (cylindric-)ellipsoid(-obovoid), sometimes slightly clavate, rarely subglobose, *6–7.5 × 5–5.7(–6) µm {1}, ends rounded, straight, rarely slightly inequilateral; **SBs** *(2.5–)3–5(–5.5) × 0.8–1.3(–1.5) µm {5}, divided into an abruptly swollen, ellipsoid, tear-shaped or cylindric-pyriform to angular, often stomach-shaped lower part and a fine filum of about ½–2 × the length of the lower part, straight to strongly flexuous; germinating spores 1-septate. **Paraphyses** apically uninflated to slightly clavate or sublageniform, terminal cell *5–16.5 × (2–)2.3–3.3(–3.7) µm {4}, lower cells *(5.5–)7.5–15(–17) × 2–3 µm {4}; rarely to frequently branched near apex. **Medullary excipulum** 20–70 µm thick, of dense textura intricata with many inflated cells (resembling t. angularis), indistinctly delimited, towards margin more sharply. **Ectal excipulum** from base to mid flanks of (†) thin-walled to medium gelatinized, irregularly oriented t. (globulosa-)angularis(-prismatica), near base 20–50 µm thick, cells *7–16(–20) × 6–12(–16) µm {2}, common walls (†) up to 1 µm thick, gel hyaline to pale yellowish-amber, near margin of 20–30 µm thick t. angularis-prismatica-porrecta oriented at 10–45°, marginal cortical cells *6–13 × 3.3–4.5(–5) µm {2}, †7–11 × 2–4 µm {2}, embedded in some gel, no glassy caps. **Anchoring hyphae** sparse to medium abundant, hyphae †1.8–3.5 µm wide, walls 0.2–0.8 µm thick {2}. **SCBs** globose {4}, in paraphyses 1–1.5 µm diam., in marginal excipulum 1.5–3.3 µm. **Exudate** continuous to granular, over paraphyses 0.2–1.8 µm thick, loosely attached, over excipulum 0.2–1.3(–3) µm thick. — **ANAMORPH**: unknown.

Habitat: collected 1–4 m above the ground, decorticated, 7–22 mm thick branches of *Abies concolor* {1}, *Acacia aneura* {1}, *Acacia* sp. {3}, *Allocasuarina decaisneana* {1}, *Pinus edulis* {2}, *Salix* sp. {1}, on 0.1–0.5 mm deep (medium to) strongly decayed wood {4} and bark (periderm & bast) {4}, sometimes in old beetle galleries, strongly greyed, with a few or quite many green algae. **Associated**: *Amandinea* sp. {1}, *Claussenomyces* sp. {1}, *Durella atrocyanea* {1}, *Lachnellula* sp. {1}, *Melanohalea subolivacea* {1}, *Orbilia concoloris* {1}, *O. macrotrapeziformis* {1}, *O. ?multitrapezoidea* {1}, *O. multivinosa* {1}, *O. myrioaustraliensis* {1}, *O. myriomuscula* {2}, *O. phragmotricha* {1}, *O. pileosoma* {1}, *O. pleiolentiformis* {1}, *O. pleioobtusispora* {1}, *O. pleioserpens* {2}, *O. pleiovitalbae* {1}, *O.*

pluristomachia {2}, *O. serpentina* {2}, *O. spermoides* {1}, *Parmelia* sp. {1}, *Patinella abietina* {1}, *Propolis farinosa* {1}, *Sclerococcum* sp. {1}, *Symbiotaphrina desertorum* {1}, *Teichosporella dura* {1}, *Usnea* sp. {1}. **Desiccation tolerance**: desiccation-tolerant for at least 20 months, some spores, excipular cells and paraphyses still viable after 3.5 years. **Altitude**: 2033–2778 m a.s.l. (USA, Mongolia), 500–690 m (Australia). **Geology**: USA: Permian and Upper Cretaceous sand- & limestone; Australia: Archean to Paleoproterozoic sedimentary rock, Cenozoic regolith (red-brown sand & gravel). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia phanosoma* is characterized by 8-spored asci and ± (cylindric-)ellipsoid ascospores. From *O. pleiostomachia* and *O. multiphanosoma* it differs mainly in spore number. The 8-spored *O. lanternae* and *O. tremuloidis* are also very similar, but their spores are longer and more or less clearly clavate (for further differences see under these species).

Variation. Usually, the lower parts of SBs are partially or predominantly curved (stomach-shaped). However, in two collections (on *Abies* and *Salix*) the lower parts were apparently always straight. The SBs in the *Salix* sample had an exceptionally short filum (Pl. 192: 4), and the Australian one on *Allocasuarina* (Pl. 192: 2) differs from the remaining in rather wide asci. In one of the specimens on *Acacia* the spores were consistently subglobose in some of the apothecia, i. e., shorter and wider than typical, but ellipsoid-ovoid in others (3a). In this collection the ascus apices were unexpectedly medium truncate and thin-walled, irrespective of the spore type which the asci contained. For the time being all these differences are thought to lie within the scope of variation of a single species.

Ecology. *O. phanosoma* grew on rotten wood and bark of xeric branches of different gymno- and angiosperms. The few known records indicate that the species shows a worldwide distribution. It was found in western North America in a cold-temperate subhumid pinyon-juniper woodland and boreal humid Douglas fir mixed forest in the Colorado Plateau (Utah Mountains and Grand Canyon), in a continental, orotemperate (sub)humid (winter-dry), subalpine steppe of central Asia (western Mongolia), and in (sub)tropical arid acacia open wood- and shrublands (mulga) in western and central Australia (Pilbara and Ayers Rock area).

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, Bryce Canyon, 42 km SSE of Panguitch, Rainbow Point, 2778 m, branch of *Abies concolor*, on wood, 20.VI.2000, G. Marson (M-0276553, **holotype**; **isotype** in H.B. 6998a). – **Arizona**, Grand Canyon, Coconino Plateau, 3 km N of Tusayan, 2068 m, branch of *Pinus edulis*, on bark, 28.VIII.1994, G. Marson (H.B. 5227b ø). – 3 km S of Tusayan, 2033 m, twig of *P. edulis*, 28.VIII.1994, G. Marson (ø). — **MONGOLIA**: **Bayan Ölgii**, Sagsai, Altay Mts., Tavan Bogd, 25 km SSE of Dayan lake, Songino Gol, 2400 m, branch of *Salix*, on wood, 15.VIII.2005, P. Karasch (H.B. 7890a ø). — **AUSTRALIA**: **Western Australia**, centre of Pilbara, 49 km NW of Newman, Great Northern Hwy, northern border of Ophthalmia Range, 690 m, branch of *Acacia*, on bark, 28.X.2007, G. Marson (H.B. 8938a). – ibid., branch of *Acacia*, on bark, 28.X.2007, G. Marson (H.B. 8940c ø). – ibid., branch of *Acacia*, on bark, 28.X.2007, G. Marson (H.B. 8879d ø). – **Northern Territories**, Great Sandy Desert, 12 km SE of Yulara, 0.7 km N of Ayers Rock (Uluru), 515 m, branch of *Acacia aneura*, on wood, 11.X.1998, G. Marson (H.B. 7129b). – 11.5 km ENE of Yulara, 14 km NNE of Ayers Rock, Lasseter Hwy, 500 m, branch of *Allocasuarina decaisneana*, on wood, 12.X.1998, G. Marson (H.B. 6617i ø).

Orbilia multiphanosoma Baral & G. Marson, **sp. nov.**, MB 813503 — Pls 194–195, Map 30

Etymology: named according to the 32-spored asci and lantern-like spore bodies.
Typification: USA, Arizona, Tusayan, branch of *Quercus gambelii*, 28.VIII.1994, G. Marson (ex H.B. 5287a, M-0276524, holotype).

Latin diagnosis: *Differt ab* Orbilia phanosomate *ascis 32-sporis*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.35(–0.5) mm diam., 0.11–0.23 mm high, light (to bright) orange(-rose), non-translucent, round, scattered to subgregarious; disc flat, margin distinct, 0–5 µm protruding, finely rough; broadly sessile, superficial or ± immersed among fibres or detritus. **Asci** *(60–)70–96(–105) × 9.2–11.8(–12.5) µm {4}, †(53–)60–80(–90) × 7–10.5 µm {3}, 32-spored (28–32 spores counted), spores *3–5-seriate, partially inverted (strongly mixed, some spores ± horizontal), pars sporifera *44–52 µm long; **apex** (†) slightly to medium (or strongly) truncate, hemispherical in profile view, dome †0.5–1.5 → 0.3–1 µm thick {4}, often with ± distinct, broad apical chamber; **base** with or without short, thick, flexuous stalk, L- to Y- or h-shaped. **Ascospores** *(5.5–)6–8.5(–10)((–11)) × (2.8–)3–4.2(–4.5) µm {9}, †5–7(–8.5) × (2.5–)3–3.5(–4) µm {2}, cylindric-ellipsoid to obovoid(-clavate), apex rounded, base sometimes slightly to medium (to strongly) tapered, ± straight, sometimes slightly curved, rarely medium geniculate at base; **SBs** *(2.3–)2.7–3.8(–4.5)((–5)) × (0.6–)0.8–1.1 µm {5}, divided into an abruptly swollen, tear-shaped to pyriform, also ellipsoid to ovoid, rarely rod-shaped lower part and a fine filum of varying length, both parts ± straight, rarely slightly curved. **Paraphyses** apically uninflated to slightly (rarely medium) clavate-capitate, terminal cell *5.5–19(–23) × 2.3–3.7(–4.4) µm {5}, lower cells *(7–)9–15(–20) × 1.7–3 µm {4}; rarely or often branched at upper septum. **Medullary excipulum** 30–70 µm thick, of loose to dense textura intricata with some or many inflated cells, sharply delimited from ectal excipulum at flanks by a parallel 10 µm thick layer of t. porrecta. **Ectal excipulum** pale rose-orange (with yellow-orange LBs), of thin-walled, (†) distinctly gelatinized, vertically or horizontally oriented t. angularis(-globulosa) from base to mid flanks or margin, 15–40 µm thick near base, cells *7–20 × 6–16 µm {2}, †8–10 × 5–7 µm {1}; 15–25 µm thick near margin, of t. angularis or t. prismatica-porrecta oriented at a 30–60° angle to the surface, marginal cortical cells *6–11 × 3–5.5 µm, uppermost cells *9–14 × 3 µm {1}. **Anchoring hyphae** medium abundant, †2.2–3.5(–4) µm wide, walls 0.2–0.7 µm thick {1}, partially extending to the margin as a 5–15 µm thick layer. **SCBs** in paraphyses and ectal excipulum (near margin) globose {5}, 1–2.2 µm diam. **Exudate** over paraphyses and excipulum 0.2–0.5(–0.8) µm thick, granular to continuous, loosely attached, sometimes as thin caps being firmly attached to the paraphysis tips. — **ANAMORPH**: unknown.

Habitat: collected ~0.2–1.5 m above the ground, corticated to somewhat decorticated, 8–15 mm thick, sometimes still-living branches of *Artemisia tridentata* {2}, *Ericameria nauseosa* {3}, *Quercus gambelii* {1}, *Salix ?bebbiana* {1}, indet. angiosperm {1}, on (medium to) strongly decayed bark (bast) {5}, more rarely wood {2}, not or often strongly greyed or blackened, no or a few green algae. **Associated**: *Carestiella schizoxyloides* {1/1}, *Corticiaceae* {1}, *Dothideales* {1}, *Hysteropatella* sp. {1}, *Melanohalea subolivacea* {1}, *Mellitiosporiella* sp. {1}, *Orbilia bicknellensis* {1}, *O. delphinus* {3}, *O. dixiensis* {1}, *O. flexisoma* {1}, *O. gambelii* {1} *O. lentiformis* {2}, *O. macroserpens* {1}, *O. mesaverdiana* {1}, *O. multimaeandrina* {2}, *O. multitrapezoidea* {2}, *O. myriophanosoma* {1}, *O. ocellata* {4}, *O. pleiolentiformis* {1}, *O. plurilentiformis* {2}, *O. serpentina* {1/1}, *O. subtrapeziformis* {1}, *Perrotia flammea* {1}, *Stictis* sp. {1}, *Teichospora* sp. {1}. **Desiccation tolerance**: fully viable for at least 9 months, immature asci still viable after 14 months. **Altitude**: 1315–2600 m a.s.l. **Geology**: Proterozoic-Cambrian & Eocene sedimentary rock, Pennsylvanian-Permian to Triassic-Jurassic red carbonate sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multiphanosoma* differs from the very similar *O. pluristomachia* in longer and also wider ascospores, and in never strongly curved (stomach-shaped) SBs. *O. multiphanosoma* appears to be a close relative of the 8-spored *O. phanosoma* and the 64-spored *O. myriophanosoma*. The latter was two times found in association with *O. multiphanosoma*.

Variation. *O. multiphanosoma* varies somewhat in shape and size of spores and SBs, even within a collection. The holotype (on *Quercus*, Pl. 194: 5) deviates in consistently obovoid spores from those on desert shrubs, but also from

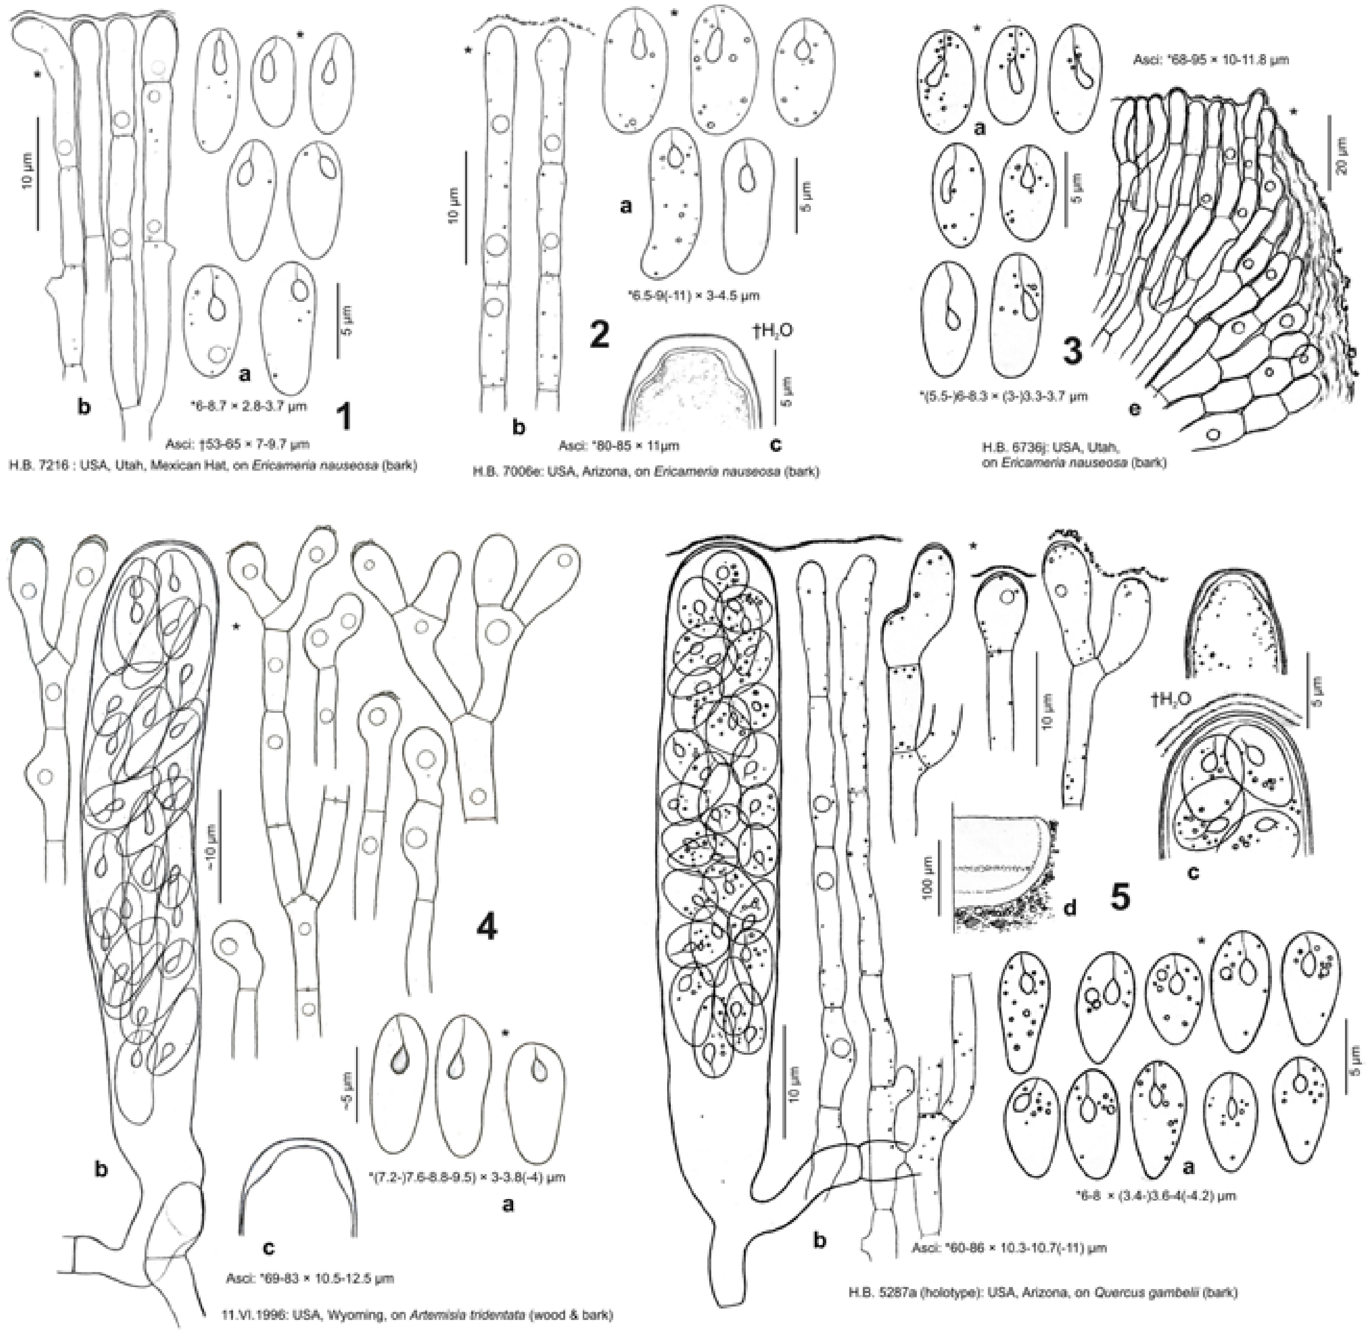

Plate 194. **1–5**: *Orbilia multiphanosoma*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

one on *Salix* (IVV: 15.V.1995), in all of which the spores are (sub)cylindrical. In some of these finds, however, the spore shape varies from cylindrical to clavate. In some collections, including the holotype, the inflated part of SBs is rather regularly short and ellipsoid-ovoid, whereas in others it varies from ellipsoid-ovoid to pyriform (exceptionally reniform). Those spores in the holotype, being distinctly over 7 µm long were probably formed in asci with a reduced spore number, while in the other samples spores of ~8–9 µm length were apparently formed in 32-spored asci.

Ecology. *O. multiphanosoma* was recorded on rotten bark (rarely wood) of xeric branches of desert shrubs such as *Artemisia* and *Ericameria*, but also on angiosperm trees. It is known from boreal to cold-temperate, humid to subhumid Douglas fir forests (with *Salix*) and pinyon-juniper woodlands, and from cold- to warm-temperate subhumid to arid sagebrush and saltbush desert scrubs in the Wyoming Basin (south of Wind River Range), Colorado Plateau, and Mojave Desert in western North America.

Specimens included. **USA**: **Wyoming**, Wyoming Basin, 24 km SE of Pinedale, 7 km S of Boulder, 2140 m, branch of *Artemisia tridentata*, on bark & wood, 11.VI.1996, G. Marson (ø). – **Utah**, Utah Mts., Dixie Forest, 15 km SSE of Torrey, 5.5 km S of Grover, Lion Mt., 2450 m, branch of *A. tridentata*, 15.V.1995, G. Marson (ø). – 14 km S of Grover, N of Pleasant Creek Campground, 2600 m, branch of *Salix ?bebbiana*, 15.V.1995, G. Marson (ø). – Canyonlands, near Valley of the Gods, 25 km NNW of Mexican Hat, 10 km N of Mokee Dugway, Cedar Mesa, 1990 m, branch of *Ericameria nauseosa*, on bark, 14.VI.2000, G. Marson (H.B. 7216). – Canyonlands, 36 km S of Moab, 5 km WNW of Hatch Rock, 1813 m, branch of *E. nauseosa*, on bark, 16.VI.2000, G. Marson (H.B. 6736j). – **Arizona**, Navajo, 85 km SW of Mexican Hat, 27 km SW of Kayenta, Klethla Valley, 2015 m, branch of *E. nauseosa*, on bark, 13.VI.2000, G. Marson (H.B. 7006e ø). – Grand Canyon, Coconino Plateau, 3 km N of Tusayan, 2068 m, branch of *Quercus gambelii*, on bark, 28.VIII.1994, G. Marson (ex H.B. 5287a, M-0276524, **holotype**). – **California** (border to Nevada), Mojave Desert, 20 km SW of Beatty, 16 km SW of Rhyolite, Daylight Pass E of Death Valley, 1315 m, branch of indet. angiosperm, on wood, 2.V.1995, G. Marson (H.B. 8528a).

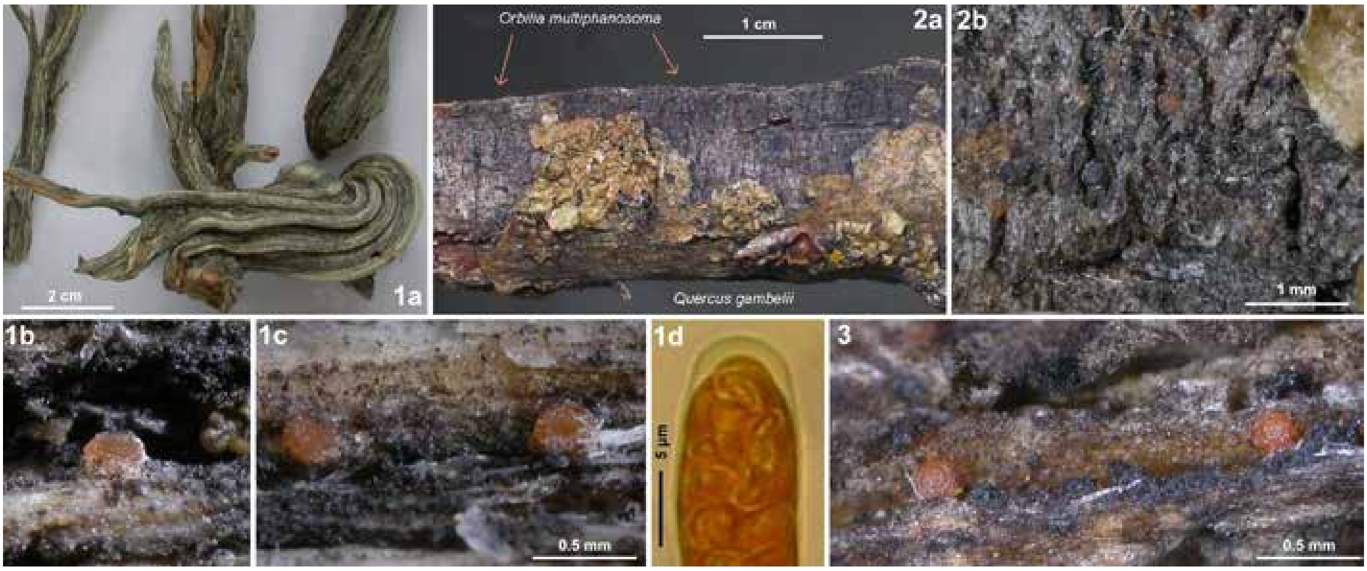

Plate 195. **1–3**: *Orbilia multiphanosoma*. – **1a**, **2a**. inhabited dead xeric branches; **1b–c**, **2b**, **3**. rehydrated apothecia; **1d**. ascus apex (dead state, in IKI). — **1a–d**. Orbilia myriophanosoma Baral & G. Marson, **sp. nov.**, MB 813504 — Pls 196–197, Map 31

Etymology: referring to the 64-spored asci and the spore body resembling a stomach.

Typification: USA, Utah, Hatch Rock, branch of *Ericameria nauseosa*, 16.VI.2000, G. Marson (ex H.B. 6736f, M-0276532, holotype).

Latin diagnosis: *Differt ab* Orbilia multiphanosomate *ascis 64-sporis*, *ab* O. myriosphaera *ascosporis cylindricis vel ellipsoideo-ovoideo-clavatis*, *corpusculis refringentibus lacrimi- vel bacilliformibus. Habitat ad corticem putridum*, *raro lignum*, *ramorum siccorum arborum vel fruticum in zona temperata subhumida ad semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.35 mm diam., 0.12–0.2 mm high, pale to light greyish-orange-ochraceous, round, ± scattered to gregarious in small groups; disc slightly concave to flat, margin ± distinct, scarcely protruding, smooth or finely rough; sessile, slightly erumpent. **Asci** *73–108 × (11–)11.3–12.5(–13.4) µm {2}, †(58–)63–96(–118) × (9.5–)10–11.5(–12) µm {3}, 64-spored (55–62 spores counted), spores ± 4–6-seriate, lower spores inversely oriented (strongly mixed), pars sporifera *47–68 µm long; **apex** (†) hemispherical or slightly, rarely strongly truncate, dome †1–1.7 → 0.5–1.2 µm thick {3}, some with broad apical chamber; **base** unstalked or with short to long, thick stalk, T-, L-, Y- to h-shaped. **Ascospores** *(4.5–)5.5–7.3(–8) × (2.5–)2.7–3.6(–4) µm {3}, †(4.5–)6–7(–9) × 2.8–3.5 µm {2}, subcylindrical to ellipsoid or often obovoid to ± clavate, apex rounded, straight to slightly curved; **SBs** *(2–)2.6–3.7(–4.5) × 0.2–0.7 or 0.8–1 µm {2}, divided into an ovoid to tear-shaped or narrowly pyriform, also rod-shaped to vermiform lower part (1–)1.3–2.5(–3.5) µm long, and a filum of varying length, straight to strongly curved or geniculate. **Paraphyses** apically uninflated to medium clavate-capitate, terminal cell *6–18(–23) × 2–3–4.5 µm {2}, lower cells *10–18 × 1.7–2 µm {1}; sometimes branched near apex. **Medullary excipulum** hyaline, 20–50 µm thick, of dense textura intricata-angularis, sharply delimited. **Ectal excipulum** very pale (cream-)rose, of (†) thin-walled to slightly gelatinized, vertically oriented t. angularis(-prismatica) from base to submargin, 20–30 µm thick near base, cells †5–9 × 3.5–6 µm {2}; 15–20 µm near margin, oriented at a 30–40° angle to the surface, submarginal cortical cells †5–7 × 3–4 µm {1}, at uppermost margin of t. porrecta, cells 8–14 × 2.5–3 µm. **Anchoring hyphae** sparse to medium abundant, †(1.8–)2.5–3.5 µm wide, walls 0.2–0.5(–1) µm thick {2}, sometimes also covering flanks and margin. **SCBs** in paraphyses globose, 1–2 µm diam. **Exudate** over paraphyses ~0.2–0.6 µm thick, continuous, ± rough, loosely attached. **— ANAMORPH**: unknown.

Map 30. Known distribution of *O. multiphanosoma* in North America.

Habitat: collected 0.1–0.5 m above the ground, corticated to decorticated, 6–20 mm thick branches of *Ericameria nauseosa* {1}, *Pinus* sp. {1}, *Quercus gambelii* {2}, on medium to strongly decayed bark {4} (periderm & bast), strongly greyed, no algae, on *Pinus* sometimes near resinous patches. **Associated**: *Orbilia delphinus* {2}, *O. dixiensis* {1}, *O. lentiformis* {1}, *O. mesaverdiana* {1}, *O. multimaeandrina* {1}, *O. multiphanosoma* {1}, *O. multitrapezoidea* {1}, *O. ocellata* {1}, *O. plurilentiformis* {1}, ?*Teichospora* sp. {1}. **Desiccation tolerance**: fully viable for at least 17 months. **Altitude**: 1813–2500 m a.s.l. **Geology**: Triassic-Jurassic-Cretaceous and Oligo- & Miocene calcareous sandstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myriophanosoma* is characterized by 64-spored asci and ± ellipsoid-clavate ascospores. It differs from European *O. myriosphaera* in longer spores and in elongate inflated parts of SBs, also in wider asci. *O. multiphanosoma* differs mainly in 32-spored asci. In the holotype collection (on *Ericameria*) both species occur on the same branches: 17 out of roughly 60 apothecia have been examined and found to have 64-spored asci, but only three with 32-spored asci were detected (Pl. 194: 3). Also on *Quercus gambelii* both species occur as a mixture. A single apothecium in an Australian collection on *Atriplex* (Pl. 200: 7) differs from

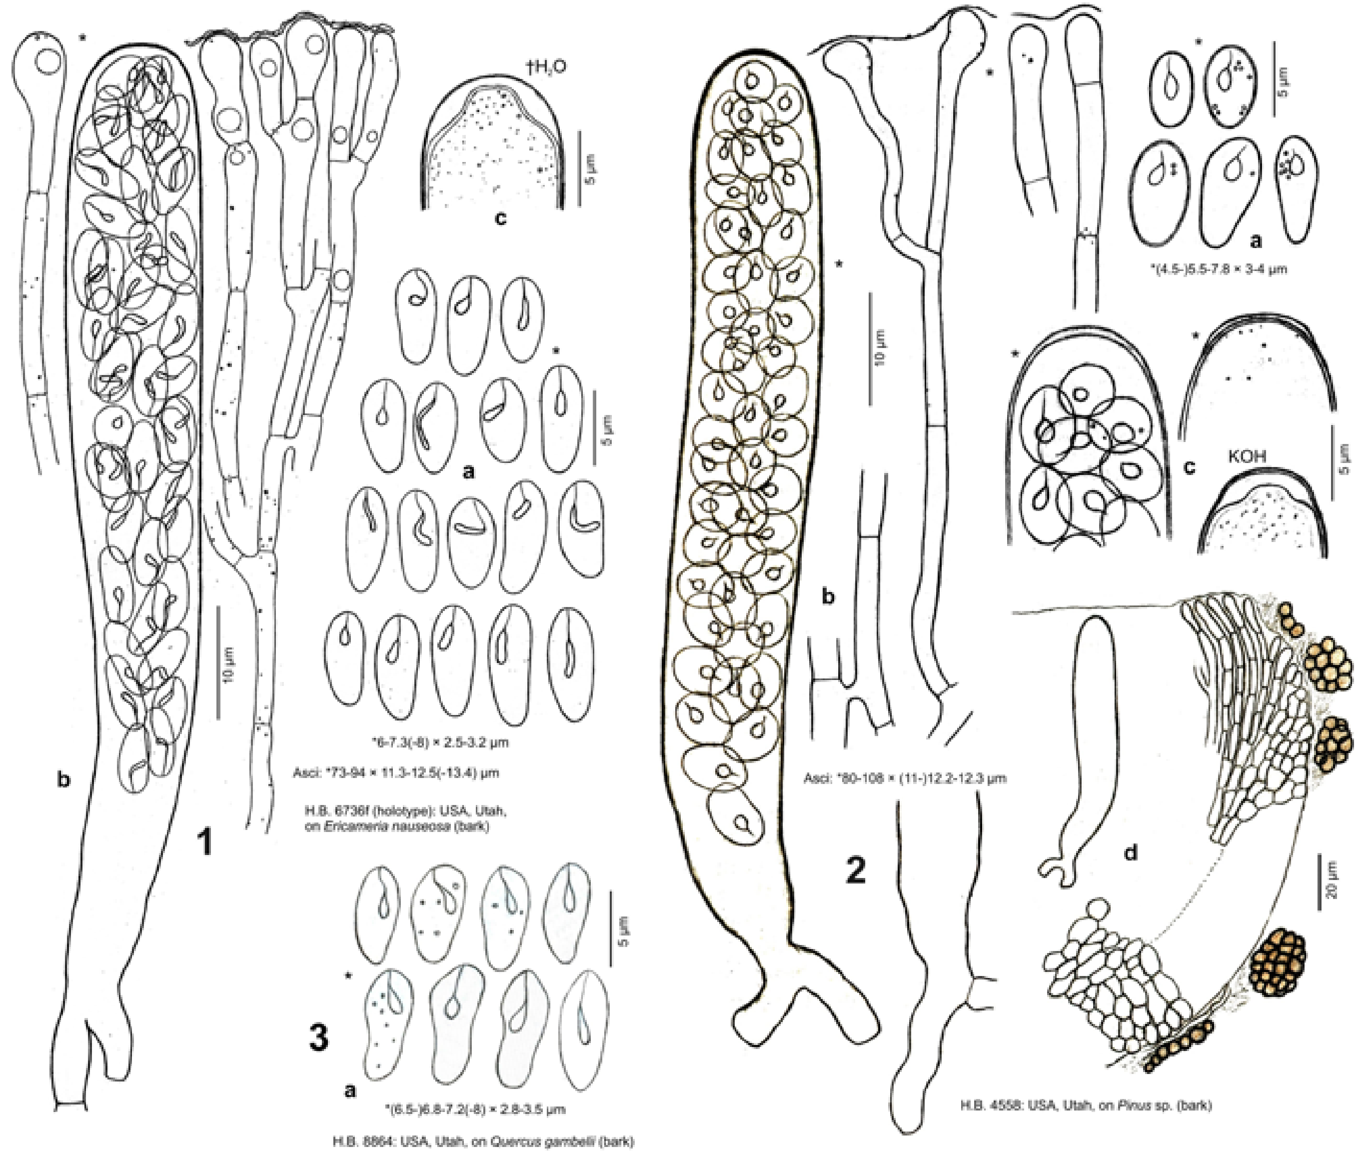

Plate 196. **1–3**: *Orbilia myriophanosoma*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium near margin in median section.

O. myriophanosoma in shorter spores with a somewhat different spore body shape. It might be a 64-spored derivative of *O. pluristomachia* with which it grew in association.

Variation. The holotype of *O. myriophanosoma* has rather narrow, often cylindrical spores with quite variable SBs (mostly ± rod-shaped, often curved). In the collection on *Pinus* the spores are more ellipsoid-clavate and the inflated parts of the SBs consistently ovoid. Those shorter, broadly ellipsoid spores observed here concur very well with the typical spores of *O. pluristomachia*, a species to which this collection actually might belong instead. The one on *Quercus* is somewhat intermediate, with a spore shape similar as in the *Pinus* collection but with the lower parts of SBs sometimes cylindrical and slightly curved.

Ecology. The few records of *O. myriophanosoma* were from rotten bark (rarely wood) of dead xeric branches of different coniferous and angiosperm trees and shrubs. The species was found in a cold-temperate subhumid pinyon-juniper woodland and ponderosa pine forest and in a boreal humid Douglas fir mixed forest in the Utah Mts., also in a warm-continental semiarid sagebrush desert scrub in the Canyonlands section of the Colorado Plateau in the southwest of Northern America.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 1.5 km ESE of Cedar City, 1815 m, branch of *Quercus gambelii*, on bark, 24.VIII.1994, G. Marson (H.B. 8865a). – Bryce Canyon, 30 km SE of Panguitch, 7.5 km WNW of Tropic, near Visitor Center, 2410 m, branch of *Pinus*, on bark, 25.IX.1991, G. Marson (H.B. 4558). – 32 m SE of Panguitch, 13 km WSW of Tropic, near Trough

Orbilia pleiostomachia Baral, **sp. nov.**,

MB 813505 **—** Pls 198–199

Etymology: referring to spore number and shape of spore body resembling a stomach.

Typification: Australia, Northern Territories, Wilora, branch of *Acacia*, 8.X.1998, G. Marson (ex H.B. 6260f, MEL 2389194, holotype).

Latin diagnosis: *Differt ab* Orbilia pluristomachia *ascis 16-sporis*, *ascosporis corpusculis refringentibus partim curvatis. Habitat ad lignum putridum rami sicci* Acaciae *in zona tropica arida Australiae centralis*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.15–0.22 mm diam., 0.12 µm thick, light orange, round, subgregarious; disc slightly concave to flat, margin ± distinct, 10 µm protruding, smooth; sessile, half immersed. **Asci** *80–90 × 10.4–11(–11.5) µm, †65–78 × 9–10 µm, 16-spored, spores 3–4-seriate, 6–12 lower spores inversely oriented (often mixed), pars sporifera *40–55 µm long; **apex** (†) slightly to medium truncate (hemispherical in profile view), with or without distinct dome †1.8–2 → 0.6–1 µm thick, with indistinct apical chamber; **base** with short to medium long, thick, flexuous stalk, L-(to Y-)shaped. **Ascospores** *6.5–8.5 × 3.8–4.5 µm, obovoid(-clavate), apex rounded, straight; **SBs** *3.3–4 × 1–1.2 µm, divided into a ± abruptly swollen, tear- to stomach-shaped lower part and a filum of ± equal length, mostly strongly geniculate; with some minute **LBs**. **Paraphyses** apically uninflated (to slightly clavate), terminal cell *7–12 × 2.8–3 µm, lower cells *12–20 × 2.2–3.5 µm; branched only near base. **Medullary excipulum** hyaline, 20 µm thick, medium sharply delimited. **Ectal excipulum** pale orange, of non- to slightly gelatinized, indistinctly horizontally oriented textura angularis from base to mid flanks, 20–25 µm thick near base, cells *9–12 × 8–10 µm, 20 µm thick at margin, of t. prismatica oriented at a 10° angle, marginal cortical cells †8–11 × 3–5 µm, firm-walled. **Anchoring hyphae** medium abundant, †1.8–2.5(–3) µm wide, walls 0.2–0.4 µm thick. **SCBs** absent. **Exudate** scattered, 0.1–0.3 µ thick, granular, lying over abundant gel, over margin more abundant, 0.2–1 µm thick, pale yellowish. **— ANAMORPH**: unknown.

Habitat: collected on the ground, decorticated, 20 mm thick branch of *Acacia* sp., on ¼ mm deep strongly decayed and greyed wood, no algae. **Associated**: closely intermingled with a dothidealean pyrenomycete, also with *Acanthostigma ellisii*, *Capronia* sp., *Orbilia barrowensis*, *O. maeandrina*, *O. pleioungulata*, *O. pluristomachia*. **Desiccation tolerance**: fully viable for at least 3 weeks. **Altitude**: 480 m a.s.l. **Geology**: Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiostomachia* is characterized by 16-spored asci and obovoid ascospores. In its stomach-shaped SBs it resembles *O. pluristomachia* which differs in 32-spored asci and distinctly smaller spores. The two taxa grew on the same branch in separate but closely associated populations, each consisting of about 10 apothecia.

Variation. The dead ascus apices were thin-walled in that apothecium, on which the drawing of the living elements was based (Pl. 198: 1c below), whereas in another apothecium examined 10 years later, the likewise 16-spored asci possessed distinct apical domes (Pl. 198: 1c, the two above).

Ecology. *O. pleiostomachia* is only known from a single sparse collection on rotten wood of a dead xeric branch of

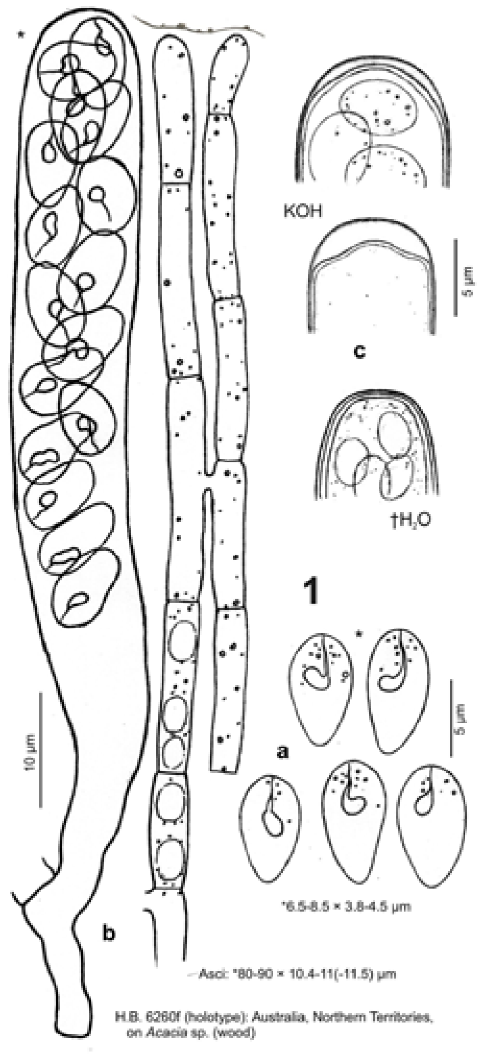

Plate 198. **1**: *Orbilia pleiostomachia*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices (mature, immature, and half mature).

Acacia in an acacia open shrubland at the north of MacDonnell Range in tropical arid central Australia.

Specimens included. **AUSTRALIA**: **Northern Territories**, Burt Plain, 31 km SW of Barrow-Creek Hotel, 3.7 km WSW of Wilora, Stuart Hwy, 480 m, branch of *Acacia*, on wood, 8.X.1998, G. Marson (ex H.B. 6260f, MEL 2389194, **holotype**).

Orbilia pluristomachia Baral & G. Marson, **sp. nov.**, MB 813506 — Pls 200–201, Map 32

Etymology: referring to the 32-spored asci and the spore body resembling a stomach.

Typification: Western Australia, Yulara, branch of *Allocasuarina decaisneana*, 12.X.1998, G. Marson (ex H.B. 6617a, MEL 2389212, holotype; ex-type culture: CBS 116235; sq.: KT215232).

Latin diagnosis: *Differt ab* Orbilia multiphanosomate *ascosporis brevioribus, corpusculis refringentibus partim valde curvatis. Habitat ad lignum vel corticem putridum ramorum siccorum arborum vel fruticum in zona subtropica semihumida ad arida Americae septentrionalis, Africae et Australiae.*

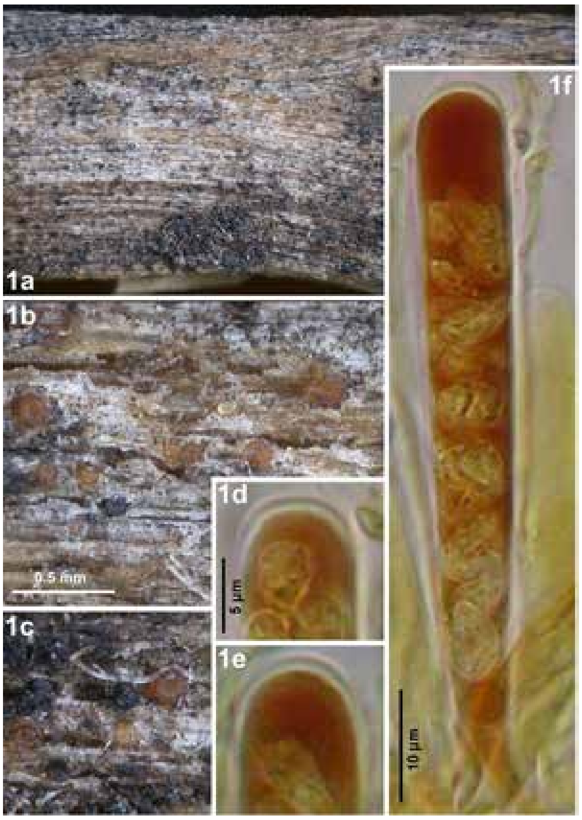

Plate 199. **1**: *Orbilia pleiostomachia*. – **1a**. xeric branch of *Acacia*; **1b–c**. rehydrated apothecia; **1d–e**. ascus apices; **1f**. ascus. – Dead state (in KOH+IKI). — **1a–f**. H.B. 6260f (holotype): Australia, Northern Territories, Wilora, on *Acacia*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.1–0.32 mm diam., 0.095–0.13 mm high, light to bright orange(-rose), round, scattered to ± gregarious; disc flat, margin thin or thick, also indistinct, 0–15 µm protruding, smooth or rough; broadly sessile, nearly superficial to almost completely immersed between fibres. **Asci** *(50–)60–80(–89) {7} × 8.3–8.8 {2} or 9–10.5 {6} µm, †(45–)54–70(–75) {5} × 6.8–7.5 {1} or 7.5–9.5 µm {4}, 32-spored, spores 3–4-seriate, lower spores indistinctly inversely oriented (strongly mixed), pars sporifera */†38–54 µm long; **apex** (†) slightly to medium truncate, hemispherical in profile view, dome †1–1.2 → 0.4–1 µm thick {5}, with ± broad apical chamber, rarely absent in some apothecia {1}; **base** with ± short, thick stalk, L- to Y-shaped. **Ascospores** *(3.7–)4–6(–7.2) × (2.4–)2.8–3.5(–4) µm {10}, †(3.8–)4.5–5.5(–6) × 3–3.3(–3.5) µm {2}, ellipsoid to ovoid or obovoid, sometimes subglobose, apex rounded or obtuse, straight, rarely very slightly curved; **SBs** *(2–)2.5–3(–3.6) × (0.4–)0.7–1.1 µm {8}, divided into an abruptly swollen, tear- to pear- or often stomach-shaped lower part and a filum of ± equal (or shorter) length, thickened part straight to often ± strongly curved (geniculate). **Paraphyses** apically uninflated to slightly (or medium) clavate-capitate, terminal cell *6.5–20 × (2–)2.3–4.3(–5) µm {7}, lower cells *(6.5–)9–17 × 1.7–3(–4.5) µm {6}, near base sometimes 4.5–7.5 µm wide; sometimes branched near apex, hymenium pale orange-rose. **Medullary excipulum** pale rose-orange, 15–30 µm thick, of dense textura intricata with many inflated cells, very indistinctly to medium sharply delimited. **Ectal excipulum** subhyaline to pale rose, of thin-walled to medium gelatinized, ± horizontally oriented t. angularis-globulosa from base to flanks, 15–25 µm thick near base, cells */†7–15(–20) × 6–10(–13) µm {3}; 10–30 µm thick near margin, of t. prismatica-porrecta oriented at a 0–40° angle to the surface, marginal cortical cells with †0.5–1 µm thick glassy walls, *(5.5–)7–13 × 4–7 µm {3}, towards hymenium up to 20 × 3 µm; **SCBs** globose, in paraphyses 1–2.5 µm diam., in marginal excipulum 1.5–3 µm. **Exudate** over paraphyses and margin 0.3–0.5(–1.2) µm thick, continuous, smooth or granular, loosely attached. **Anchoring hyphae** ± sparse, †1.6–3 µm wide, walls 0.2–0.5 µm thick {3}. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1} and natural substrate {1}). **Conidiophores** *~10 × 4 µm. **Conidia** Y/T-shaped, 2-armed, total size *24–30(–35) × 14–20(–25) µm {1}, stipe *19–22 × 5.5–6.3 µm, 2–3(–5)-septate, arms tapering, somewhat bent downwards, *7–12 × 4–4.5(–5) µm, 1(–2)-septate.

Habitat: collected 0–4 m above the ground, partially to entirely decorticated, 4–30 mm thick branches of *Atriplex nummularia* {1}, *Acacia* sp. {2}, *A. aneura* {1}, *Allocasuarina decaisneana* {1}, *Fraxinus velutina* {1}, ?*Glossopetalon spinescens* {1}, *Larrea tridentata* {3},

Parkinsonia microphylla {1}, *Vachellia* {1}, indet. angiosperm {1}, on 0.1–1 mm deep (medium to) strongly decayed wood {8} and bark (bast) {2}, sometimes in old beetle galleries or along clefts, (slightly to) strongly greyed, no or a few green algae. **Associated**: *Acanthostigma ellisii* {1}, *Baggea* sp. {1}, *Capronia* sp. {1}, *Carestiella* ?*schizoxyloides* {1}, *Coniochaeta* sp. {1}, *Hypoxylon* sp. {1}, *Hysterobrevium mori* {1}, ?*Hysteropatella* sp. {1}, ?*Muellerella* sp. {1}, *M. lichenicola* {1}, *Orbilia atriplicis* {1}, *O. barrowensis* {1}, *O. bicknellensis* {1}, *O. breviclava* {1}, *O. commarosa* {1}, *O. cryptogena* {3}, *O. lentiformis* {2}, *O. macrotrapeziformis* {2}, *O. maeandrina* {3}, *O. microserpens* {1}, *O. multicercocarpi* {1}, *O.* ?*multitrapezoidea* {1}, *O. multiurosperma* {3}, *O. multivinosa* {1}, *O. myrioflexa* {1}, *O. myriofusiclava* {1}, *O. myriostomachia* {1}, *O. myriourosperma* {1}, *O. namibica* {1}, *O.* ?*navajoana* {1}, *O. phanosoma* {2}, *O. pleiolentiformis* {1}, *O. pleionavajoana* {1}, *O. pleioobtusispora* {1}, *O. pleioquaestiformis* {1}, *O. pleiostomachia* {1}, *O. pleioungulata* {1}, *O. pleiourosperma* {1}, *O. pleiovitalbae* {1}, *O. sedonensis* {1}, *O. serpentina* {2/1}, *O. sonorensis* {1}, *O. wannerooensis* {1}, *Patellaria atrata* {1}, ?*Peniophora* sp. {1}, *Schizoxylon* sp. {2}, *Symbiotaphrina desertorum* {1}, *S. larreae* {1}, *Teichospora* ?*obducens* {1}, *Teichosporella dura* {2}, 3 different indet. coelomycetes. **Desiccation tolerance**: fully viable for at least 17 months, some mature asci and spores still viable after 3.5 years. **Altitude**: 500–1700 m a.s.l. (USA), 1560 m (Africa), 40–586 m (Australia). **Geology**: Neoproterozoic to Ordovician sedimentary rock, Triassic-Jurassic-Cretaceous or Cenozoic (whitish or red-brown) sand-, lime- and mudstone; granite, felsic volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pluristomachia* is characterized by 32-spored asci and ± ellipsoid ascospores. The very similar *O. multiphanosoma* differs in longer, partially more cylindrical

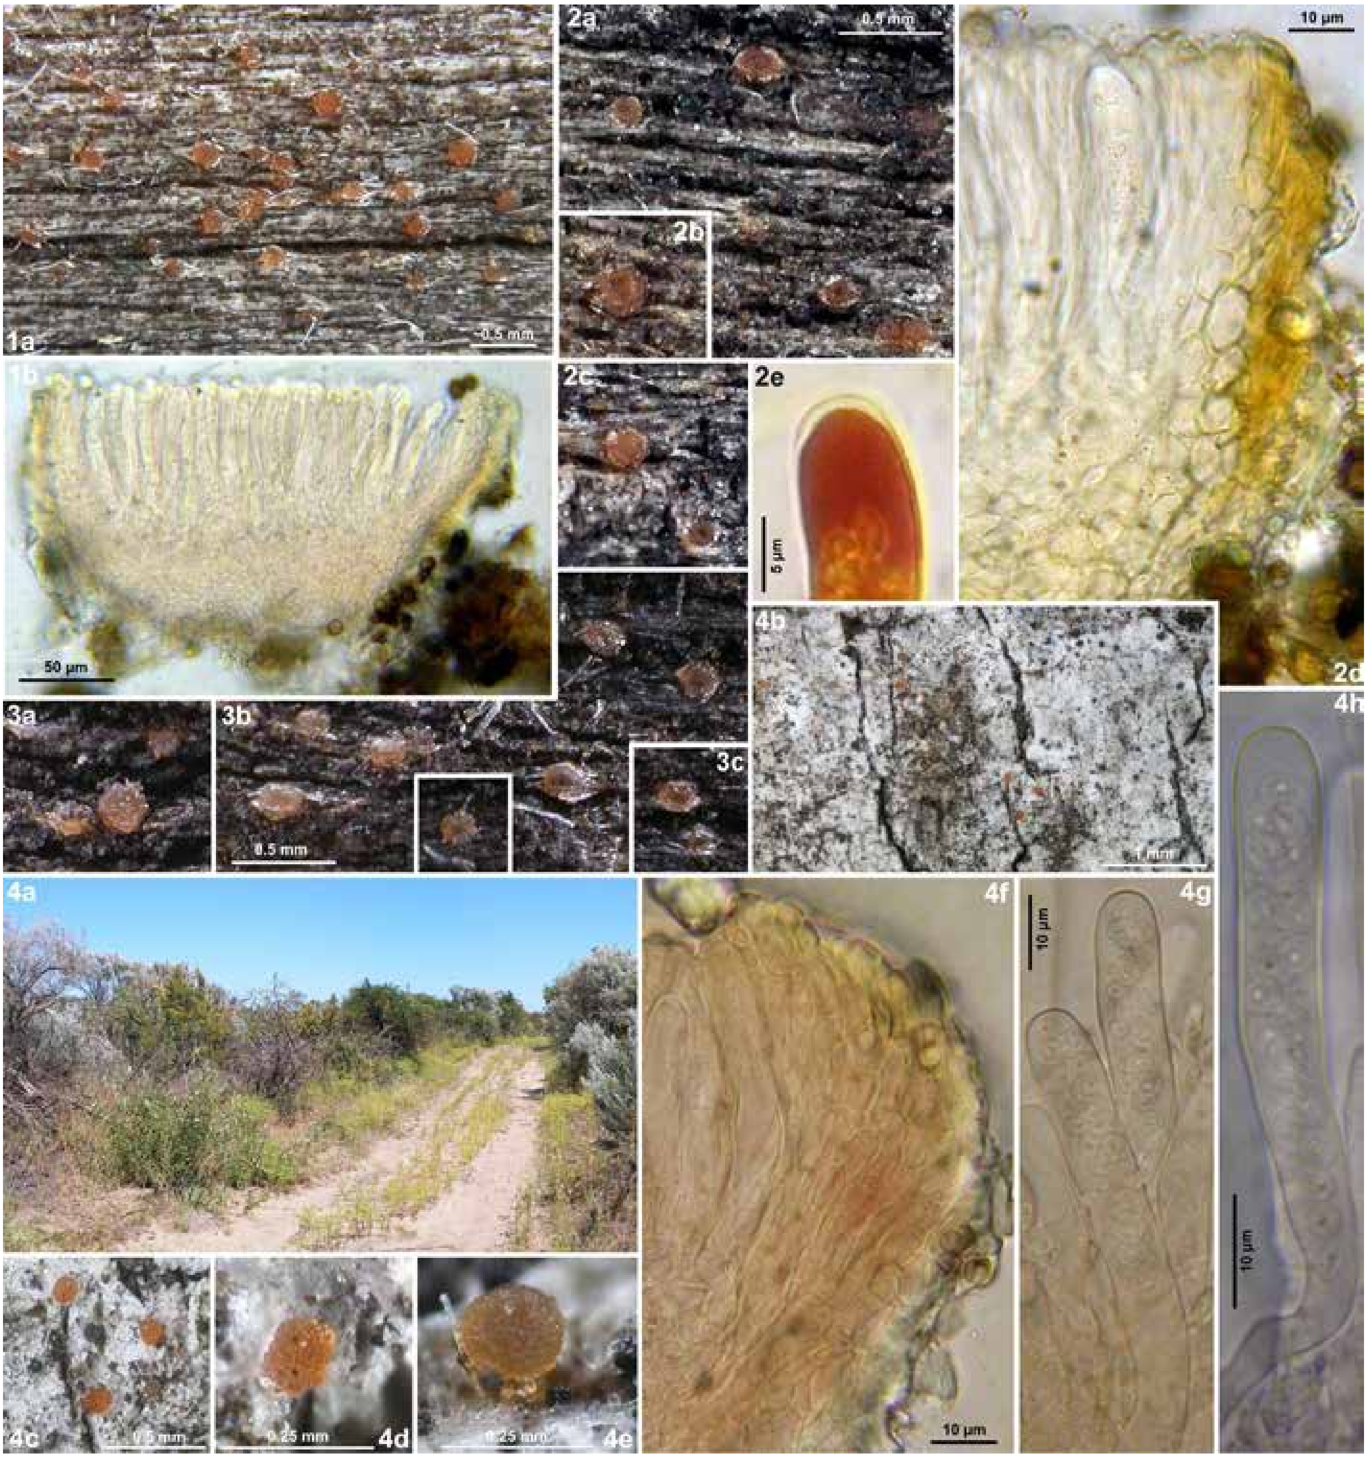

Plate 201. **1–4**: *Orbilia pluristomachia*. – **4a**. semihumid sandy acacia shrubland NNW of Perth; **1a**, **2a–c**, **3a–c**, **4b–e**. rehydrated apothecia; **1b**. apothecium in median section; **2d**, **4f**. id., marginal ectal excipulum; **2e**. ascus apex; **4g–h**. asci. – Living state, except for **2e** (in IKI). — **1a–b**. H.B. 7397d: USA, Arizona, on *Larrea*; **2a–e**. H.B. 6617a (holotype): Australia, Ayers Rock, on *Allocasuarina*; **3a–c**. H.B. 7129a: ibid., on *Acacia*; **4a–h**. H.B. 8745a: Western Australia, Perth, on *Acacia*.

spores and a less pronounced tendency to curved SBs, but is not sharply delimited. *O. myriophanosoma* differs in 64-spored asci and distinctly longer spores. In two of the examined collections of *O. pluristomachia* (Pl. 200: 4–5) very similar taxa with deviating spore numbers were detected. In one on *Acacia* the similar *O. pleiostomachia* occurred, which has 16-spored asci and distinctly larger spores.

Variation. Typically, the ascospores are ellipsoid to almost subglobose and 4–5(–6) µm long. Ovoid spores were seen in four collections (Pl. 200: 1, 3–4). In two of them (Pl. 200: 3; IVV: H.B. 5658f, *5.6–7.2 × 3–3.4 µm) some of the spores exceeded 6 µm in length, and thus formed a transition to *O. multiphanosoma*. In a collection on *Parkinsonia* (IVV: 7.V.1995) the spores were partially medium curved, for which reason we excluded it from the description.

Not included collection. In the collection from Northern Territories on *Atriplex* only two apothecia of series *Phanosomates* were found, besides apothecia of four *Orbilia* spp. from other series: one apothecium was *O. pluristomachia*, while the other deviated in 64-spored asci and slightly smaller spores with narrower SBs (Pl. 200: 7). This appears to represent a taxon of its own which differs from European *O. myriosphaera* in SB

Map 32. Known distribution of *O. pluristomachia* in North America and Australia.

shape and from *O. myriophanosoma* in much shorter spores. It is provisionally called ***O. myriostomachia*** Baral nom. prov., but not described due to the sparse microscopic data.

Anamorph. The anamorph of *O. pluristomachia* (Pl. 200: 2h) resembles *Trinacrium incurvum*; however, the arms are only slightly bent by pointing upwards or laterally, whereas in *T. incurvum* they are more strongly curved and consistently point downwards.

Phylogeny. A sequence gained from the ex-type culture of *O. pluristomachia* (SSU+ITS+LSU, S1506 intron absent) clustered weakly to strongly supported with *O. lentiformis* in a clade in the combined analyses in Baral et al. (2017b) and Phyl. 7, or in our ITS analysis (S9). However, it clustered unresolved in the combined analysis of Phyl. 8, and when analysing LSU (S11) it formed a weakly supported clade with the morphologically similar *O. myriosphaera*, to which it shows a 12% distance in the ITS region (4% in LSU, D1–D2).

Ecology. *O. pluristomachia* grew on dead xeric branches of very different woody substrates of angiosperm trees and shrubs, predominantly on decorticated rotten wood. The known records indicate that the species shows a worldwide distribution in desert regions. It was so far recorded in the southwest of Northern America in subtropical semiarid (to arid) paloverde-mixed cacti or creosotebush-bursage desert scrubs of the Sonoran Desert and a warm-continental subhumid manzanita chaparral scrubland in the Chihuahuan Desert, in southwestern Africa in the hot, subtropical arid (winter-dry) Kalahari highland thornbush savannah about 150 km away from the Namib Desert, and within Australia in subtropical arid acacia open shrublands in central Australia and in a subtropical semihumid acacia mixed shrubland in southwestern Australia. *O. myriostomachia* on wood of *Atriplex* was from subtropical arid central Australia on Neoproterozoic sedimentary rock.

Specimens included. **NAMIBIA**: **Khomas**, 60 km S of Windhoek, 25 km N of Rehoboth, Central Plateau, Auas Mts., 1560 m, branch of ?*Vachellia*, on wood, 25.VIII.1995, R. Taxonomic remarks. *Orbilia myriosphaera* is easily recognized by its 64-spored asci and ellipsoid-obovoid ascospores containing a globose spore body attached apically by a rather long, hardly visible filum. The globose part of the SB is often positioned close to the lateral wall. *O. myriostomachia* from Australia (Pl. 200: 7) differs hereof in more consistently subglobose spores with pear- to stomach-shaped SBs. The North American *O. myriophanosoma* is very similar to *O. myriosphaera*: especially the collection on *Pinus* differ only in slightly larger spores and more ovoid SBs (Pl. 196: 2).

Taxa with lower spore numbers that resemble *O. myriosphaera* in the globose SBs could so far not be found. However, a striking similarity with the 8-spored *O. clavipisca* is obvious, which is tentatively placed in section *Ovoideae* but could as well belong to section *Lentiformes*. Even the hyphoid marginal cortical cells of *O. myriosphaera*, being thick-walled in the dead state, resemble those of typical representatives of section *Ovoideae*. Nevertheless, in our phylogenetic analysis section *Ovoideae* is very distant from section *Lentiformes* in which *O. myriosphaera* clusters.

Variation. The apical dome of dead asci varies in thickness within a population, being usually thick-walled with a slight apical chamber, but in some asci rather thin-walled and the ascus apex then often more truncate.

Anamorph. The conidia of *O. myriosphaera* differ from *Trinacrium incurvum* in the arms pointing much more downwards at their base, and particularly in being slightly curved up- instead of downwards (Pl. 202: 3f). The observed conidia developed only when the culture was flooded by water.

Phylogeny. Sequences of two samples were gained, one from pure culture of the holotype on *Olea*, the other (not shown in phylograms) from a sample on *Cercis* (G.M. 2018-09-12.10a), comprising SSU (with S1506 intron), ITS, and LSU. They differ in the ITS by 3 nt, in the intron by 3 nt, and in the LSU D1–D3 by 1 nt (D1), while the SSU V8–V9 fully concurs. A further sequence from another group of apothecia of the *Cercis* sample (G.M. 2018-09-12.10b) lacks the intron and further differs by 2–4 nt in the ITS and 2–3 nt in the LSU (D1–D2).

The species clustered unresolved in the strongly supported core clade of section *Lentiformes* (Phyl. 8). Surprisingly, it clustered in a weakly to medium supported clade with *O. cercidicola* (Phyls 8, S9), though with a distance of 12.5%, while the distance to the morphologically much closer *O. pluristomachia* lies also at 12%. Likewise, in the LSU region it shows a 4% distance to *O. pluristomachia*, with which it formed a weakly supported clade (Phyl. S11), and a similar distance (3–5%) to members of section *Lentiformes*. The intron is so far rather exceptional in the whole section *Lentiformes*, being otherwise only observed in series *Microspermae*.

Map 33. Known distribution of *O. myriosphaera* in southern Europe.

Ecology. *O. myriosphaera* is known from a few collection sites in Provence, Dalmatia, and Peloponnese, but is expected to occur throughout the mediterranean belt. It grew on rotten wood and bark of dead xeric branches of *Cercis*, *Olea*, *Punica* and *Quercus* in the suprasub- to thermomediterranean but mainly mesosubmediterranean semihumid maquis.

Specimens included. **FRANCE**: **Rhône-Alpes**, **Drôme**, Préalpes du Dauphiné, 1 km N of Nyons, Col du Pontias, 460 m, branches of *Cercis siliquastrum*, on wood, 22.VIII.1996, G. Marson (H.B. 5613a). – ibid., on wood & bark, 18.VIII.2001, G. Marson (H.B. 7077a). – ibid., 11.X.2002, (H.B. 7272e). – ibid., 13.VIII.2009, G. Marson, H.O. Baral & B. Liu (H.B. 9151b). – ibid., on bark, 12.IX.2018, G. Marson (G.M. 2018-09-12.10; sq.: MK473392, MK473424). – 10 km ENE of Nyons, 1 km N of Curnier, 383 m, branch of *C. siliquastrum*, on bark, 12.VIII.2009, G. Marson (H.B. 9182c ø). — **CROATIA**: **Dubrovnik-Neretva**, **Korčula**, 11.5 km W of Korčula, 2 km W of Račišće, below Samograd cave, 40 m, branch of *Olea europaea*, on bark, 4.VI.2000, H.O. Baral (ex H.B. 6679a, M-0276533, **holotype**, anam. cult., CBS 140830; sq.: KT215233, MH878190). – ibid., Samograd bay, 2 m, twig of *Punica granatum*, on wood, 4.VI.2000, H.O. Baral & N. Matočec (H.B. 6687b ø). — **GREECE**: **Peloponnese**, 25 km E of Sparta, 4 km SW of Kosmas, chapel between Geraki and Kosmas, 855 m, twig of *Quercus ilex*, on wood, 8.VI.2009, S. Helleman (H.B. 9097). – 8.5 km SE of Korinthos, 2 km SSE of Isthmia, Kalamaki beach, 1 m, twig of *Quercus coccifera*, on bark, 1.VI.2009, S. Helleman (H.B. 9096).

Orbilia pleistosphaera S. Tello & Baral, **sp. nov.**, MB 825629 — Pl. 204

Etymology: named after the 128-spored asci and the globose spore bodies.
Typification: Spain, Andalucía, Jaén, twig of *Berberis hispanica*, 13.VIII.2017, S. Tello (ex S.T. 13081701, AH 48635, holotype).

Latin diagnosis: *Similis* Orbiliae myriosphaerae *sed asci 128-spori, longiores et latiores, ascosporae longiores, clavatae. Habitat ad corticem putridum ramuli in aere prominentis* Berberidis hispanicae *in zona supramediterranea Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.35 mm diam., pale greyish-orange, round, scattered; disc flat, margin distinct, ~10–15 µm protruding, ± uneven; broadly sessile, superficial. **Asci** *108–128 × 13.3–15 µm, †~95 × 11.5–12.8 µm, 128-spored (min. 74 spores counted on photo), spores ± 4-seriate, orientation irregular, pars sporifera *92–103 µm long; **apex** (†) slightly truncate, hemispherical in profile view, with †~0.5–1 µm thick dome; **base** unstalked or with short, thick, Y-shaped. **Ascospores** *(6–)6.5–8(–8.5) × (2.8–)3–3.3(–3.5) µm, broadly clavate (pyriform), apex rounded to obtuse, base always medium to strongly attenuated, straight to slightly inequilateral; **SBs** *3–3.7 × 0.9–1.1 µm, divided into a very abruptly swollen, globose lower part and a very fine, 2–3 µm long filum, ± straight, globose part often laterally positioned. **Paraphyses** apically slightly to strongly clavate-capitate, terminal cell *16–37 × (3–)4–5.5 µm, lower cells *12–17 × 1.7–2.3(–3) µm; sometimes branched near apex. **Medullary**

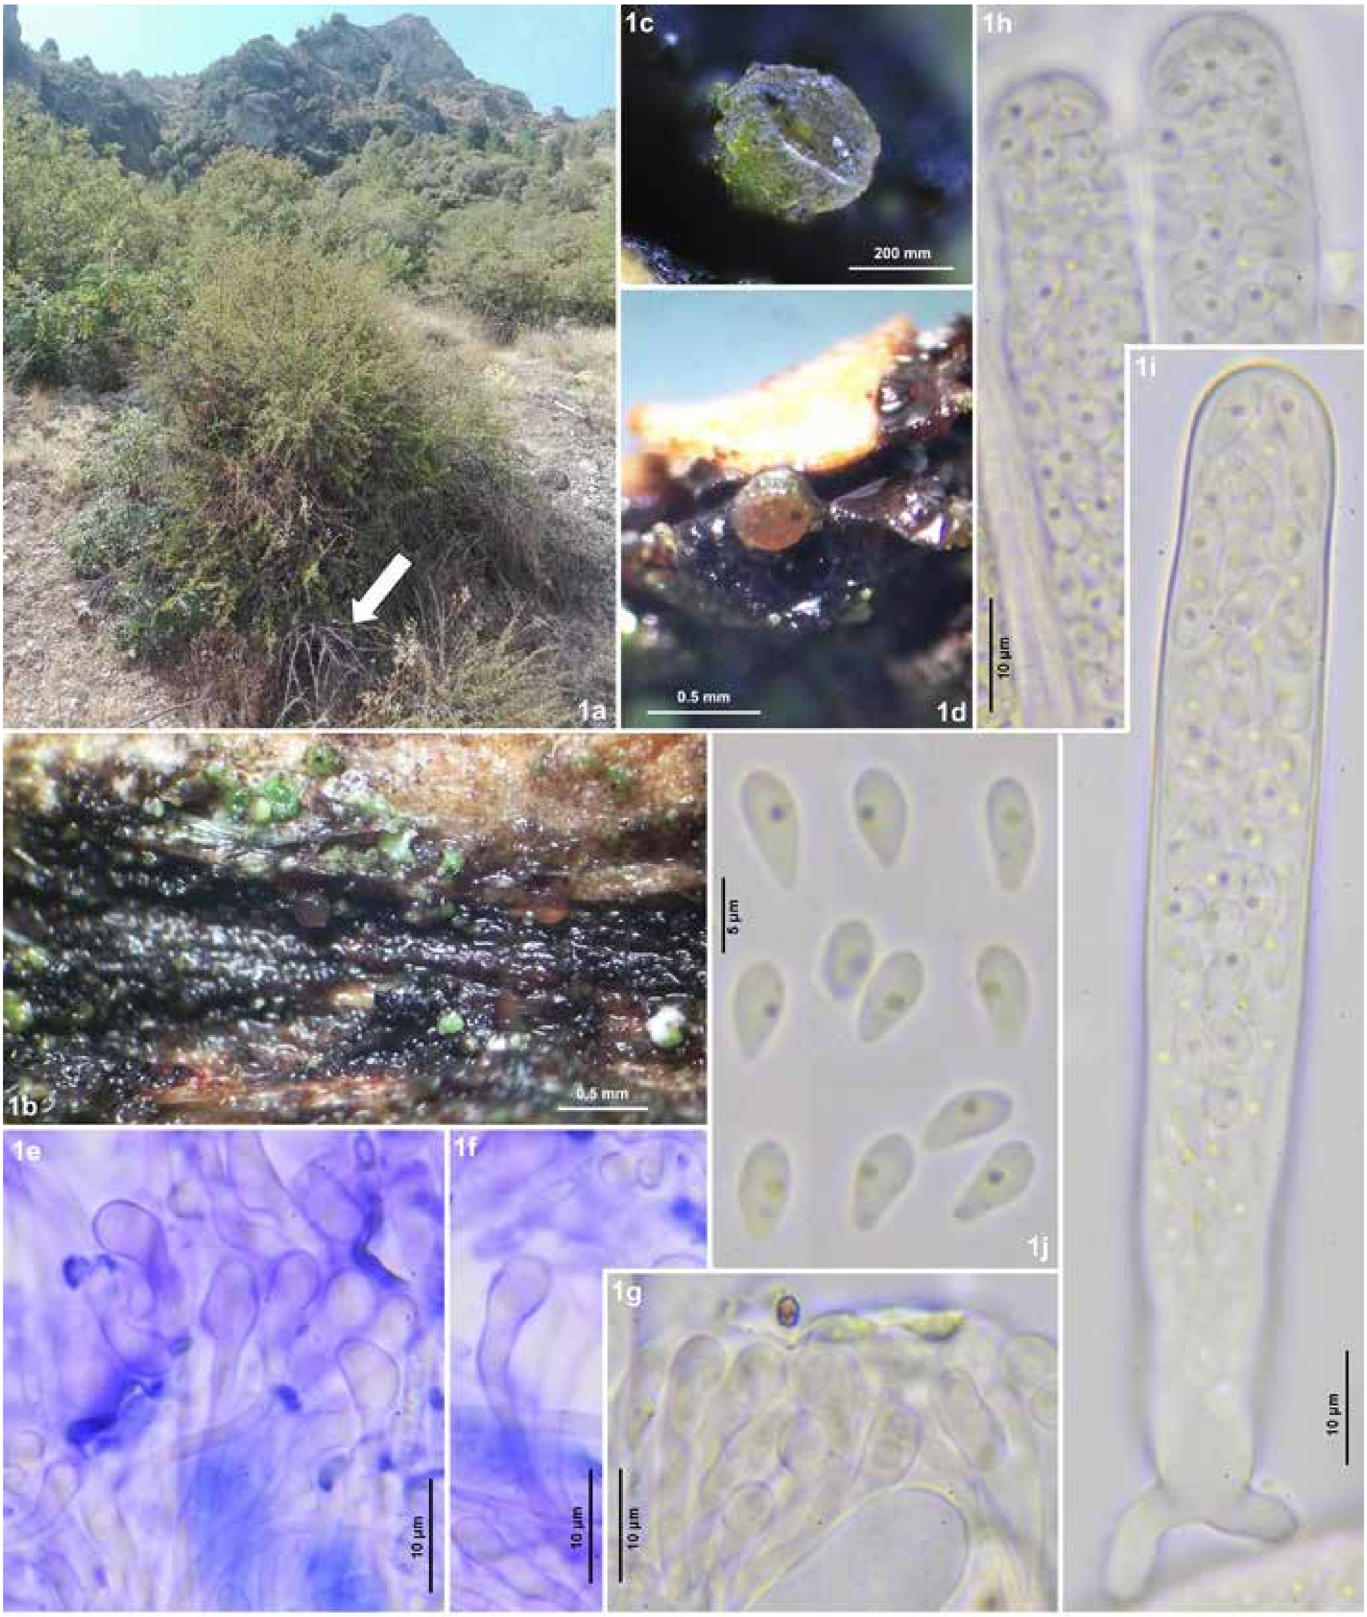

Plate 204. **1**: *Orbilia pleistosphaera*. – **1a**. open supramediterranean shrubland on a north-exposed scree slope in the Sierra de Ventisqueros of Andalucía; **1b**. twig of *Berberis hispanica*; **1b–d**. rehydrated apothecia; **1e–g**. paraphyses (**1e–f** in CRB); **1h–i**. asci; **1j**. ascospores. – Living state, except for left ascus in **1h**. — **1a–j**: phot. S. Tello; AH 48635: Spain, Valdepeñas de Jaén, on *Berberis*.

excipulum not studied. **Ectal excipulum** of t. angularis(-prismatica) from base to mid flanks, cells at flanks *6–12 × 4–7 µm, at margin of firmly agglutinated t. porrecta, marginal cortical cells *~13–15 × 3–4 µm, sometimes somewhat flexuous. **Anchoring hyphae** not studied. **SCBs** globose, in paraphyses 1.7–2.7 µm diam., in marginal cortical cells 1.7–2 µm. **Exudate** over paraphyses 0.5–1.7 µm thick, continuous to cloddy, loosely attached. — **ANAMORPH**: unknown.

Habitat: collected 0.4 m above the ground, 5 mm thick, dead corticated twig of *Berberis hispanica*, on very decayed bark (bast). **Associated**: *Thyronectria lamyi*. **Desiccation tolerance**: fully viable for at least 2 months. **Altitude**: 1200 m a.s.l. **Geology**: Cretaceous marly limestone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleistosphaera* differs from *O. myriosphaera* in larger asci which contain many more spores than 64, and in clavate, pear-shaped, basally usually strongly narrowed ascospores (Pl. 204). The protologue is entirely based on the description and photos of the finder, S. Tello (pers. comm.).

Ecology. *O. pleistosphaera* is only known from the single sparse holotype collection. It grew on rotten bark of a dead xeric twig of *Berberis* in a supramediterranean semihumid open shrubland in a north-exposed scree slope in the Sierra de Ventisqueros of Andalucía. The vegetation includes *Quercus rotundifolia*, *Crataegus monogyna*, *Pistacia terebinthus*, *Juniperus oxycedrus*, *Acer monspessulanum*, *Pinus nigra*, and *Prunus mahaleb*.

Specimens included. **SPAIN**: **Andalucía**, **Jaén**, Sierra de Ventisqueros, 18.5 km SSE of Jaén, 7 km ENE of Valdepeñas de Jaén, 2 km S of El Parrizoso, 1200 m, twig of *Berberis hispanica*, on bark, 13.VIII.2017, S. Tello (ex S.T. 13081701, AH 48635, **holotype**).

Series *Microspermae*

Orbilia subgenus ***Hemiorbilia*** section ***Lentiformes*** series ***Microspermae*** Baral & E. Weber, **ser. nov.**, MB 815003 – Type species: *Orbilia euonymi* Velen.

Etymology: named after the minute ascospores.

Latin diagnosis*: Asci 16- ad 128-spori, apice in statu emortuo hemisphaerico, crassitunicato. Ascosporae *2.2–5.5 × 1.5–2.8 µm, subglobosae, ovoideae, cylindrico-ellipsoideae vel fusoideo-clavatae, apice rotundatae vel obtusae, in statu vivo corpusculum refringens minutum lacrimiformem, filo breve ad apicem affixum continentes.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.08–)0.12–0.6(–0.9) mm diam., pale to bright yellowish-orange(-rose), margin smooth, sessile. **Asci** *(26–)30–70(–86) × (6–)7–9(–10) µm, 16- up to 128-spored, orientation in all directions; **apex** (†) hemispherical (to slightly truncate), dome immature 1.2–2(–2.5) µm thick, with apical chamber; **base** L-, T-, Y- or h-, but never H-shaped. **Ascospores** *(2.2–)2.5–4(–5.5) × 1.5–2.5(–3) µm, subglobose, ovoid, ellipsoid, subcylindrical, or fusoid-clavate, apex rounded to obtuse, straight or slightly (rarely medium) curved; **SBs** *(0.8–)1–1.8(–2) × 0.2–0.6(–0.8) µm, divided into a ± abruptly swollen, tear-shaped (also pear-shaped or subglobose) lower part and a filum of ± equal length. **Paraphyses** uninflated or only slightly clavate at the apex, terminal cells (0.5–)0.8–1.5(–2)× longer than lower cells, sometimes branched near apex. **SCBs** always globose. **Exudate** 0.5–2(–4) µm thick, continuous to cloddy, ± rough, loosely attached, hyaline or pale yellowish. **— ANAMORPH**: vermispora-like. **Conidiophores** short (10–35 µm), unbranched, simple or with swollen cells. **Conidiogenous cells** monoblastic or sympodial, with denticles. **Conidia** *(12–)20–62 × 2.8–5.5 µm (in situ and actual length), (1–)3–10(–12)-septate, slightly to strongly curved.

Habitat: wood and bark of gymno- and angiosperms (sometimes resinicolous), rarely on petioles of a palm, temperate to subtropical, humid to semiarid, always desiccation-tolerant.

Recognized species: *O. euonymi*, *O. myrioeuonymi*, *O. pleioeuonymi*, *O. pleistoeuonymi*.

Taxonomic remarks. Members of series *Microspermae* form a small homogeneous group. They resemble series *Phanosomates* in shape of ascospores and SBs, the latter being divided into a tear-shaped lower and a short filiform upper part. Series *Microspermae* differs in distinctly smaller spores and SBs, and consequently in smaller asci when comparing taxa with corresponding spore numbers, with always thick-walled apices which are never truncate.

Species delimitation. The four taxa included in this series are very similar. They mainly differ in spore number, therefore, they might as well be recognized as varieties of a single species. However, some differences are noted in the associated anamorphs, and molecular data support distinction at the species level.

Spore size and shape is hardly different among the included taxa, except for *O. pleioeuonymi* which has wider, more subglobose spores. In addition, these features show a certain variation within each species, therefore, the spores alone cannot be used for identification of species with a spore number higher than 16. Size and shape of the SBs are quite similar in the four species.

Anamorph. The conidia of series *Microspermae* are phragmosporous, mostly slightly curved (like in *Vermispora*), formed on denticles on short conidiophores. None of the observed anamorphs could by identified with a described species. The conidia of *O. euonymi* and *O. myrioeuonymi* were only found on the natural substrate, but in *O. pleioeuonymi* and *O. pleistoeuonymi* we obtained them in pure culture. The conidiophores of *O. pleistoeuonymi* are remarkable by their swollen conidiogenous cells with abundant prominent denticles. In this respect the anamorph somewhat resembles *Sigmoidea aurantiaca* Descals which, however, differs in distinctly longer conidia. Similar conidiogenous cells were observed in pure culture of *O. carpoboloides* (subgen. *Habrostictis*, Pl. 568: 3j).

Conidial morphology as observed within series *Microspermae* is rather similar, differing between *O. euonymi* and *O. pleistoeuonymi* mainly in size and number of septa. The conidia of *O. pleioeuonymi* are distinctly narrower than in the other three species, while those of *O. pleistoeuonymi* are comparatively short and with fewer septa (Pl. 205: 4).

Phylogeny. Sequences were available for three species, which formed a strongly supported clade of their own within the rather strongly supported monophyletic clade of section *Lentiformes* (Baral 2017b, Phyl. 7). Irrespective of whether analysing ITS, LSU, or combinations with SSU, *O. pleistoeuonymi* consistently clustered sister to the other two taxa of the series. Which spore number was the ancestral character state within series *Microspermae* is unclear since spore numbers appear to have frequently changed within a series, which is obvious from our phylogenetic analyses of series *Lentiformes* and *Phanosomates*.

Despite its morphological similarity to series *Phanosomates*, series *Microspermae* is genetically not closely associated herewith. The distance in the ITS region to other series of section *Lentiformes* is very high (18.5–25 %). Also in the SSU (V8–V9, 362 nt) a distance of 4–6 % is observed, which is extraordinary within section *Lentiformes*, compared to merely 3.3–4 % to members of section *Hemiorbilia*. In the LSU D1–D2 domain the distance to the other series of section *Lentiformes* is 4–8 %, compared to 6–11 % to section *Hemiorbilia*. In the 5.8S region series *Microspermae* fully concurs with series *Phanosomates* and most species of series *Lentiformes*, but differs from section *Hemiorbilia* by 2–5 nt.

Contrary to the other series of section *Lentiformes*, species of series *Microsomates* possess the S1506 intron, with so far two exceptions: the single sequence of *O. myriosphaera* also has this intron, and one out of five sequences of *O. euonymi* appeared to lack it.

Specific nucleotide positions. Series *Microsomates* deviates from all other members of section *Lentiformes* in the ITS1 at pos. 1 by ATCATTA**C** vs. ATCATTA**A** (or ATCATTA**T** in *O.*

Table 65. Comparison of ascus, ascospore, and conidial data among the four species of series *Microspermae*.

Spore number	*Asci [µm]	†Asci [µm]	*Spores [µm]	*Conidia [µm]	Conidial septa
16 (*pleioeuonymi*)	(26–)30–40(–45) × 6–7.5(–8)	25–38 × (5–)5.5–6(–6.5)	(2.5–)2.8–3.5(–3.8) × (2–)2.2–2.8(–3)	(38–)42–54(–62) × 2.8–3.6	(4–)5–6(–8)
32 (*euonymi*)	(30–)34–55(–68) × 6.3–8.5(–9)	(29–)31–50(–54) × (5–)5.5–7(–7.5)	(2.2–)2.6–4.3(–5.5) × (1.5–)1.6–2.1(–2.3)	(21–)28–49(–58.5) × (3.5–)4–5(–5.5)	(1–)5–9(–12)
64 (*myrioeuonymi*)	37–48 × 7.5–10	29–46(–67) × (5–)6–7.5(–8.5)	(2.8–)3–4.3(–4.8) × 1.5–1.8(–2)	~52 × 4	8
128 (*pleistoeuonymi*)	(45–)55–75(–86) × (8.5–)9–10	(38–)45–70(–80) × (7–)7.5–9(–10)	(2.2–)2.5–3.5(–4.5) × (1.5–)1.7–2.2(–2.4)	(12–)18–31(–34) × (3.5–)4–4.5(–5)	(1–)3–5(–6)

cercidicola), in the ITS2 at pos. 9 by C vs. A, and in the middle of ITS2 by GC**T**GGTGA vs. GC**G**GGTGA, besides some other characteristic motifs. It also deviates in the LSU D1–D2 at pos. 176 by **A**TAG or **A**TGG vs. **C**CGG or **C**TGG, at 189 by TTC**T**TT vs. TTC**C**TT, at 205 by GTC**A** vs. GTC**G**, at 235 & 238 by A**T**GG**T** vs. G**C**GG**C** or A**C**GG**C**, and at 600–601 by **AA**GCTAGG vs. **TT**GCTAGG or **TC**GCTAGG. Some further positions in the D1–D2 (142, 162, 228, 252, 254, 442, 560) are only unique for this series when excluding *O. pleistoeuonymi* which shows the character of the remaining section *Lentiformes*.

Ecology. Among the four recognized taxa, *O. euonymi* is by far the most frequently encountered species, which seems to occur ubiquitous throughout Europe from cold-temperate humid to subtropical semihumid regions, except for the northern, (hemi)boreal parts. *O. pleioeuonymi* is much less frequent, and the other two were only rarely encountered. The four species have almost never been observed to grow in association on the same branch. The 64-spored species is so far geographically restricted to southeastern Asia and Australia, whereas the other three were mainly recorded in Europe. *O. euonymi* also occurs in the humid Rocky Mountains of North America, the dry summit broom scrubs in Macaronesia, and in semiarid cold-continental central Asia. The four species inhabit exclusively ligneous substrate, with a single exception of a palm petiole.

Orbilia pleioeuonymi Baral, G. Marson & Priou, **sp. nov.**, MB 813508 — Pls 205–206, Map 34

Etymology: named after the 16-spored asci and the close relation to *O. euonymi*. **Typification**: Luxembourg, Dudelange, branch of *Robinia pseudoacacia*, 29.X.1993, G. Marson (ex H.B. 4984a, M-0276557, holotype).

Latin diagnosis: *Differt ab* Orbilia euonymi *ascis 16-sporis, ascosporis subglobosis vel late ellipsoideo-ovatis. Habitat ad lignum vel corticem putridum ramorum in aere prominentium arboris vel fruticis variis, in silvis supra- ad mesotemperatis humidis, plerumque thermophilis Europae centralis et occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.08–0.25(–0.3) mm diam., 0.08–0.11 mm high (receptacle 0.06–0.07 mm), subhyaline or pale to light yellowish-amber-orange, translucent, round, very scattered to medium gregarious; disc flat, sometimes slightly convex, margin thin, not protruding, smooth; sessile or with distinct stipe 0.02–0.05 × 0.06–0.1 mm, superficial to slightly immersed; dry pale yellowish-cream or light orange. **Asci** *(26–)30–40(–45) × 6–7.5(–8) µm {5}, †25–38 × (5–)5.5–6(–6.5) µm {3}, 16-spored, spores *± 4-seriate, orientation irregular, pars sporifera *13–15(–19.5) µm long; **apex** (†) hemispherical to slightly truncate, with dome †1.2–1.6 → 1 µm thick {2}, with apical chamber; **base** with or without short to long, flexuous stalk, L- or Y-shaped. **Ascospores** *(2.5–)2.8–3.5(–3.8) × (2–)2.2–2.8(–3) µm {11}, subglobose to broadly ellipsoid-ovoid or -obovoid, also broadly fusoid, ends rounded (to obtuse); **SBs** *(1–)1.2–1.8 × 0.3–0.8 µm {5}, divided into a ± abruptly swollen, tear-shaped to subglobose lower part and a filum of ± equal length, straight or slightly curved. **Paraphyses** apically uninflated to slightly clavate-capitate, rarely sublageniform, straight or ± flexuous, terminal cell *(4–)5–12(–14) × (1.3–)1.7–2.5(–3.2) µm {5}, lower cells *3.5–9 × (1.6–)1.8–2.4(–3.2) µm {5}; frequently branched in middle and basal part, never at upper septum. **Medullary excipulum** 20–40 µm thick, of ± loose to dense textura intricata-angularis with many inflated cells, sharply delimited. **Ectal excipulum** of thin-walled, ± vertically oriented t. angularis from base to lower flanks, 15–50 µm thick near base, cells *5–13 × 5–11 µm {2}; at flanks of t. prismatica oriented at a 30–40° angle to the surface, at margin at 10–30°, marginal cortical cells *(4–)5–8(–12) × (1.6–)2–3(–3.7) µm {2}. **Anchoring hyphae** sparse, */†1.8–2.7 µm wide, walls 0.2(–0.3) µm thick {3}. **SCBs** in paraphyses and ectal excipulum (near margin) globose to ellipsoid, low-refractive, (1–)1.5–2.3 µm diam. **Exudate** over paraphyses, margin and flanks (0.2–)0.5–1.5(–2) µm thick, cloddy, hyaline to pale amber-coloured, loosely attached. **— ANAMORPH**: vermispora-like (from ascospore isolate {1}). **Conidiophores** *~11–30 × 3.2–4 µm, unbranched, irregularly bent and ± moniliform. **Conidiogenous cells** monoblastic, partially with a short, *1.6–1.8 µm wide apical denticle. **Conidia** unbranched, narrowly cylindric-fusoid, tapered towards both ends, ± straight but slightly to medium curved near each end, *(38–)42–54(–62) × 2.8–3.6 µm, (4–)5–6(–8)-septate {1}, containing a few minute LBs in each cell.

Habitat: collected 0.1–2.2 m above the ground, corticated to ± decorticated, 7–26 mm thick branches (rarely cones) of *Acer campestre* {1}, *Clematis vitalba* {3}, *Fagus sylvatica* {2}, *Ilex aquifolium* {1},

Taxonomic remarks. *Orbilia pleioeuonymi* differs from the other taxa of series *Microspermae* in (max.) 16-spored asci, also in distinctly wider, more ovoid-subglobose ascospores, and in longer and particularly narrower conidia. In at least one of the collections, the similar 32-spored *O. euonymi* grew in association, the two species being macroscopically hardly distinguishable. Based on micromorphological and molecular data we separate *O. pleioeuonymi* from *O. euonymi* at the species level.

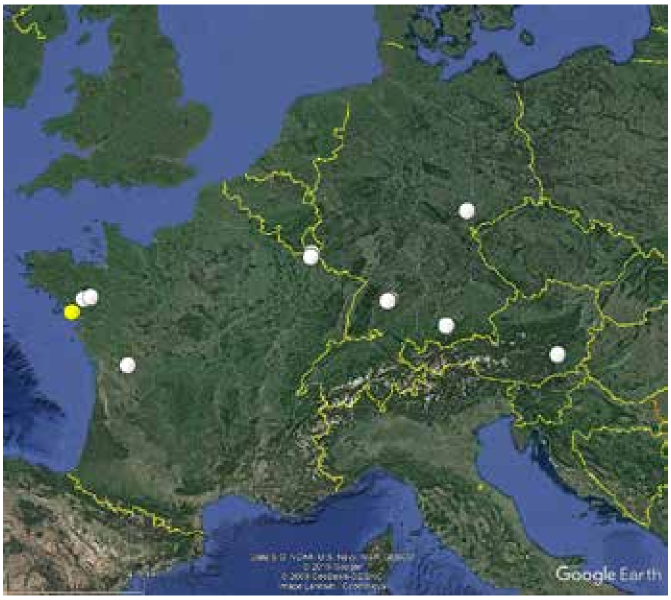
Variation. We sometimes observed in *O. pleioeuonymi* a few asci with reduced spore numbers, e.g., 13–14-spored, which contained some oversized spores measuring *4–4.7 × 3.5–4 µm among the normal ones. However, the asci never contained more than 16 spores in all apothecia which we have examined. Likewise, some collections of *O. euonymi* showed a few asci with reduced spore numbers of 16–22, with some or all of the spores corresponding very well in size and shape to those of *O. pleioeuonymi*. However, G. Friebes (pers. comm.) observed in the sparse Austrian sample besides 16-spored asci also more spores in several asci, but the spores were always subglobose (IVV: 9.XII.2017). Slight variation was noted in spore length, and in width and curvature of the terminal cells of paraphyses.

Not included collection. An unpreserved sample from Bretagne (one apothecium on *Ulex*) differs in extraordinarily long asci (†45–60 × 7–7.5 µm) and a spore size at the upper end of the range (*3.5–4 × 3 µm, IVV: J.P.P. 28219).

Anamorph. The conidia of *O. pleioeuonymi* were obtained in pure culture of a single collection (Pl. 206: 6). They resemble those of the other species of series *Microspermae* except for being longer and especially narrower. The conidiophores are unbranched and the conidiogenesis is always terminal, in contrast to *O. pleistoeuonymi* in which often many denticles were found on a single conidiophore.

Phylogeny. A sequence comprising S1506 intron, ITS, and LSU was taken from a pure culture of *O. pleioeuonymi* from Luxembourg (16.XI.2013, on *Clematis*). In the ITS region the distance to *O. euonymi* is 6.3–6.5% and to *O. pleistoeuonymi* 15%, in the intron it lies at 7.5–8.5% and 18.5%, and in the LSU at 2.2% and 5.2% (overlapping 633 nt), respectively. These distances confirm the values of spore numbers and that *O. pleioeuonymi* is a species of its own. For its phylogeny see under *O. euonymi*, p. 535.

Ecology. *O. pleioeuonymi* occurs on a wide range of substrates: rotten wood and bark of dead xeric branches of angiosperm trees, shrubs and climbers, two times also on conifers (*Picea* wood, *Larix* cone). The first record of



Map 34. Known distribution of *O. pleioeuonymi* in Europe (yellow = not included collection).

this species was rather abundant, but later collections often contained only a few apothecia. The species is mainly known from supratemperate humid, rarely mesotemperate and mesomediterranean humid or almost semihumid atlantic western and subcontinental central Europe. It occurs in ± thermophilous, usually deciduous forests on both alkaline and acidic soils, often at sun-exposed borders of forests or on free-standing trees and shrubs, also in old vineyards and gardens.

Specimens included. **LUXEMBOURG**: **Gutland**, **Esch-sur-Alzette**, 4.5 km S of Luxembourg, 1 km W of Hesperange, Biersak, 300 m, ?*Sambucus nigra*, on wood, 20.XII.1997, G. 5	6	14	3	22	16	8	15	13	7	7	6

Taxonomic remarks. *Orbilia euonymi* is characterized by 32-spored asci and small, cylindric-ellipsoid to clavate ascospores with small, ± tear-shaped SBs with a short filum.

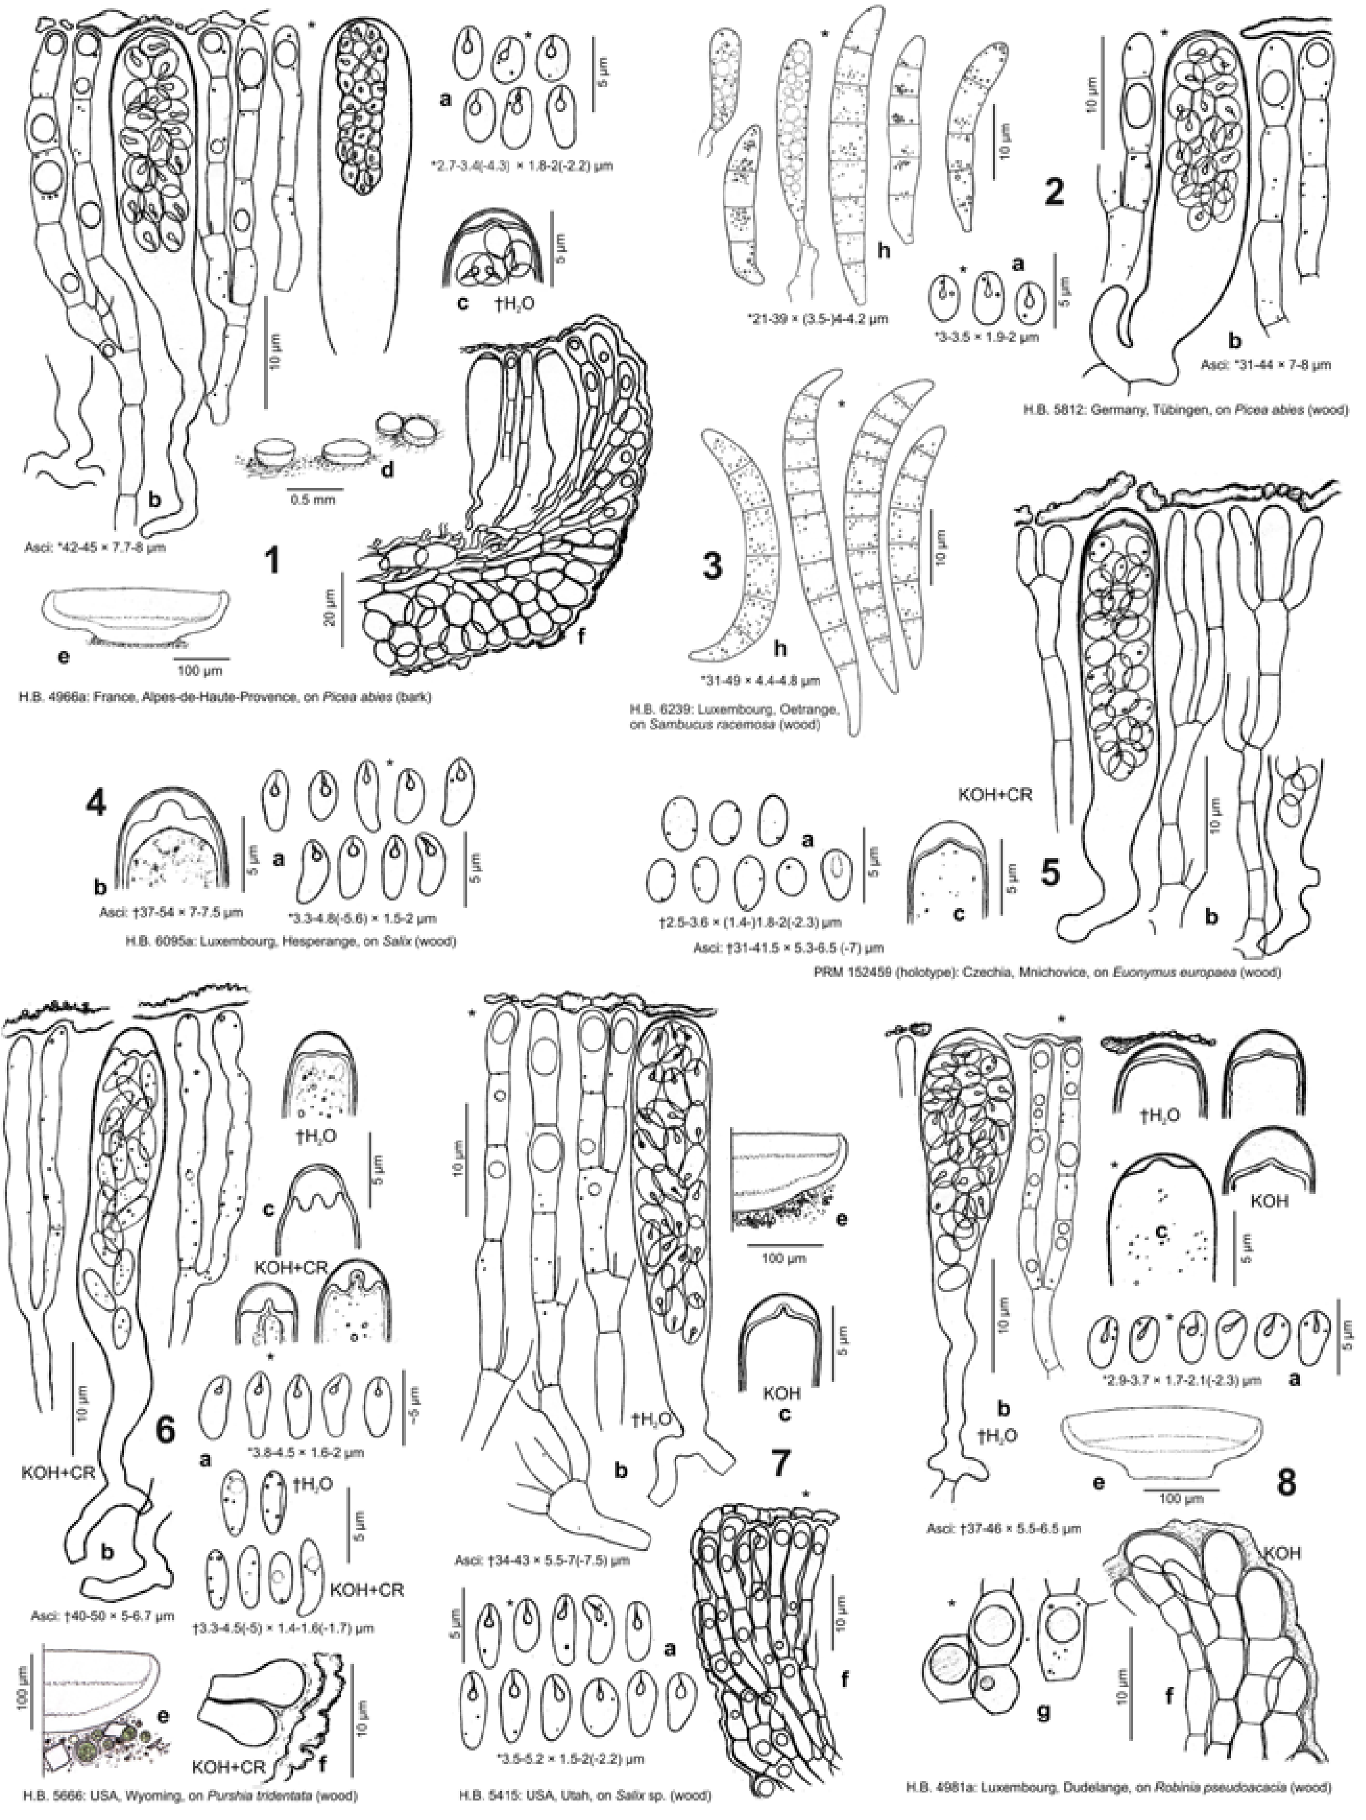

Plate 207. **1–8**: *Orbilia euonymi*. – **a**. ascospores; **b**. asci and paraphyses (**1b** right ascus fully turgescent); **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. id., ectal excipulum at margin and flanks; **g**. marginal excipular cells in external view; **h**. conidia and conidiophore tips (from substrate).

O. myrioeuonymi and *O. pleistoeuonymi* differ in higher spore numbers and larger asci, whereas spore size and SBs are more or less the same. Confusion with 8-spored taxa around *O. eucalypti* (subgen. *Orbilia*) seems possible due to a similar spore size and shape, especially when studying dead herbarium material in which polyspory is easily overlooked and the characteristic SBs are invisible. Yet, the much wider asci of *O. euonymi* and their hemispherical, thick-walled apices are very different from those of section *Orbilia*.

Variation. Spore number in some of the asci was rarely reduced to (8–)16–22 spores (H.B. 5174, 6001; also in two collections from Poland, P. Perz pers. comm.). In asci with spore numbers between 16 and 32, some of the spores are wider than the others. This variation illustrates the difficulty to separate the closely related 16-spored *O. pleioeuonymi* (see p. 530). Oversized spores from asci with a reduced spore number measured *3.2–4.2 × 2.3–2.7(–3) μm {2} and their SBs ~2–2.2 × 0.5–0.8 μm.

Pronounced variation in spore shape and length (but hardly in width) among the collections can be noted, ranging from rarely subglobose-ovoid (2.2–3 μm long) over mostly cylindric-ellipsoid (3–4 μm) to rarely elongate-cylindrical (4.5–5.5 μm). Longer spores appear to be correlated with longer asci and were mainly observed in mediterranean and semiarid areas of southern Europe and North America. Longer spores were sometimes found to be correlated with thicker apical domes, but in other cases no such correlation was noted. Collections on gymnosperms concurred in all respects with those on angiosperms. The observed variation in colour is probably due to the rate of insolation during growth: whitish apothecia occurred at more shady sites, whereas reddish ones at more open thermophilous places.

One of the North American collections (Pl. 207: 6) slightly deviates in asci with rather thick apical domes (KOH 2–2.8 → 1.3–2.5 μm) with deep apical chamber, and wider marginal cortical cells (†6–10 × 4–5 μm), also in rather long and narrow spores. Similar spores were observed in two samples from Tenerife (*3.5–)4.2–5.2 × 1.6–1.8 μm, see Quijada (2016: fig. 2).

Type studies. Both Svrček (1954: 14) and Hawksworth & Sivanesan (l.c.) could not find any apothecia on the small twig fragment in the holotype of *O. euonymi*. In the present study four pale cream-amber apothecia of 0.2–0.3 mm diam. were detected after rehydration. One was examined and the asci found to be polysporous (28 spores seen, Pl. 207: 5b), contrary to Velenovský's (1934) protologue and drawing which shows 8-spored asci. The ascospores were found to be ellipsoid-ovoid unlike Velenovský's report ('2–3 μm, globose, eguttulate'). However, the sketch in Velenovský's original manuscript (see Fig. 156) shows more distinctly subglobose spores which better match our observation. There is no doubt that the examined apothecium represents the taxon described by Velenovský, especially because ascus size and the uninflated paraphyses with their exudate fit well.

A specimen from Luxembourg (Waldhaff, on *Pseudotsuga*, IVV: H.B. 9152), from which a sequence was gained, is designated here as **epitype** of *O. euonymi*.

Misapplications. In the type collection of *O. euonymi*, Velenovský (1934) reported the spores as globose and overlooked polyspory of the asci (see below). Therefore, Hawksworth & Sivanesan (1975) referred a British collection with 8-spored asci and 'globose' spores to this taxon, after a suggestion by W.D. Graddon. Reexamination of this specimen (Pl. 126: 3) showed that it represents a *Hyalorbilia*, probably *H. erythrostigma*. An unpublished collection on *Euonymus europaeus* identified by Velenovský as '*O. evonymi*' (PRM 147968) was studied by Svrček (l.c.) and found to be *O. curvatispora* (= *O. auricolor*). This material was not examined in the present study.

A Chinese report under the name '*O. evonymi*' (HMAS 75874) was so named by Liu (2006) according to drawings of *O. euonymi* distributed on DVD (Baral & Marson 2005). This record concerns an intrahymenial parasite, *Helicogonium orbiliarum*, that produces ascoconidia in abundance from subglobose ascospores inside the asci. Two large (2 mm), sterile apothecia of *O. luteorubella* were infected by this parasite and grew in mixture with mature, uninfected apothecia of that *Orbilia*. Liu gave the spore number as 'up to 32', but on his photos about 40 ascoconidia can be seen, moreover, some of the 8 much larger ascospores are visible.

Anamorph. We observed the vermispora-like anamorph of *O. euonymi* only on the natural substrate. In one collection (on *Ginkgo*, Tübingen) the conidiophores emerged from the margin of a mature apothecium and were undoubtedly connected to the marginal excipular cells.

Phylogeny. Five sequences comprising ITS and LSU were taken from apothecia of *O. euonymi*: three on *Pseudotsuga* from Luxembourg, one on *Cedrus* from Turkey, and one on *Buxus* from southern France. All of them possess the S1506 intron, except for one from Luxembourg (Waldhaff, H.B. 9152) which appears to lack it (but the 3'-end of SSU was not unequivocally evaluated here). Therefore, the absence of the intron remains uncertain. This sequence and that from southern France include also SSU. In the LSU the five strains are identical in the overlapping 572–920 nt, whereas a difference of 2–4 nt (0.4–0.7%) and a few gaps is found in the ITS, mainly in the ITS1.

Although *O. pleistoeuonymi* is very similar in morphology, its molecular distance to *O. euonymi* is considerably high (in the ITS region 15.5–16%, in the LSU 5.8% in the overlapping 633 nt), whereas *O. pleioeuonymi* with its much broader spores is less distant from *O. euonymi* (6.3–6.5% and 2.2%, respectively).

The intron region is almost identical in the two *O. euonymi* sequences on *Pseudotsuga* (0.6% distance in overlapping 353 nt), whereas the *Cedrus* strain shows some more deviations to them (2.5–2.7%), and the one on *Buxus* 2% to *Cedrus* and 4.2–4.5% to *Pseudotsuga*. The distance to *O. pleioeuonymi* ranges at 7.5–8.5% and to *O. pleistoeuonymi* at 18.5%. The five strains clustered in a medium to strongly supported sister clade to *O. pleioeuonymi* (Phyls 8, S9, S11).

Ecology. *O. euonymi* belongs to the most frequently collected species within this study, although no material referable to it was found in the consulted herbaria, except for the holotype. The species has obviously been overlooked due to its minute apothecia and xeric habitat. At the present state of knowledge it is only known from the northern hemisphere. *O. euonymi* occurs on rotten wood (more rarely bark) of dead xeric twigs

and branches of a broad range of gymno- and angiosperm trees and shrubs. Records from Europe include atlantic (see Priou 2005) to subcontinental, cold- to warm-temperate as well as orotemperate to orosubmediterranean humid, but also suprasub- to supramediterranean or rarely mesosub- to mesomediterranean semihumid regions, from planar to subalpine altitude and on mainly calcareous or neutral but also acidic soils. The species prefers thermophilous forests, particularly their sun-exposed borders, or free-standing trees and shrubs, but it occurs sometimes also in shady forests. It was repeatedly collected in the mediterranean maquis (*Juniperetum thuriferae*) of the Iberian Peninsula, and in submediterranean forests of western Anatolia it belongs to the most often detected species, according to an unpublished study by T. Askun (pers. comm.). In the European boreal zone it is so far not found.

Within Macaronesia *O. euonymi* was recorded in Tenerife around the Teide in the supramediterranean semihumid summit broom scrub (*Spartocytisetum supranubii*) near to vegetationless lava areas, or in the adjacent upper mesomediterranean *Erysimo scoparii-Pterocephaletum lasiospermi* near to the pine forest. Records were also made in the west of Northern America in cold-temperate to boreal (sub)humid pinyon-juniper woodland, ponderosa pine, Douglas fir, and Engelmann spruce forests of Middle and Southern Rocky Mountains and Colorado Plateau, and in the south in a subtropical subhumid broad-leaved woodland of Texas. In central Asia it occurred in continental, orotemperate (sub)humid (winter-dry) western Mongolia (*Larix-Picea* taiga with *Betula rotundifolia*). The species can be expected to occur also in (hemi)boreal regions of Europe, but it appears to avoid warm-temperate to subtropical (semi)arid regions because it was never found in our many collections from the North American semideserts.

Specimens included. **GREAT BRITAIN**: **Yorkshire**, **South Yorkshire**, 4 km SW of Barnsley, 0.2 km W of Wentworth Castle, Stainborough Park, 185 m, branch of *Ilex aquifolium*, on wood, 14.V.2011, H.O. Baral (H.B. 9508b, J.H.P. 11.100). – **East England**, **Suffolk**, 4 km ESE of Halesworth, NNW of Wenhaston, Bicker's Heath, 15 m, branch of *Ulex europaeus*, on wood, 20.IX.2004, E. Batten (ø). — **DENMARK**: **Sjælland**, 8 km NNW of Ringsted, 1 km S of Allindelille, Fredskov, 65 m, branch of *Fagus sylvatica*, on wood and *Peniophora*, 26.V.2007, H.O. Baral (H.B. 8516a ø). — **NETHERLANDS**: **Flevoland**, 17 km SE of Lelystad, 5 km N of Harderwijk, Broekbos, 2 m, branch of *Sambucus nigra*, on wood, 20.III.2005, H.O. Baral (ø). – 6 km SW of Kampen, 9 km E of Dronten, Reve Abbert, Revebos, 9 m, branch of *Fraxinus excelsior*, on bark, 20.III.2005, H.O. Baral (ø). – **Noord-Brabant**, 10 km WSW of Boxmeer, 3.3 km WSW of Oploo, St. Anthonisbos 30 m, branches of *Thuja occidentalis*, on wood, 19. III.2011, S. Helleman (ø, doc. vid.). – ibid., branch of *Pinus strobus*, on wood, 19.III.2011, S. Helleman (ø, non vid.). – ibid., twig of *Abies balsamea*, on wood, 19.III.2011, S. Helleman (ø, non vid.). – **Limburg**, 38 km ENE of Eindhoven, 2.7 km NE of Venray, 22 m, branch of *Juniperus communis*, on wood, 13.V.2012, S. Helleman (ø, non vid.). — **LUXEMBOURG**: **L'Oesling**, **Wiltz**, 11 km WSW of Wiltz, NE of Harlange, 440 m, twig of *Pseudotsuga menziesii*, on bark & wood, 19.VI.2004, G. Marson (H.B. 7553). – **Gutland**, **Mersch**, 8 km NW of Mersch, 1.6 km E of Schrondweiler, Bakes, 305 m, branch of *Robinia pseudoacacia*, on wood, 6.XI.1993, G. Marson (ø). – 14 km N of Luxembourg, 4 km SE of Mersch, Schoos, 417 m, twigs of *P. menziesii*, on wood, 4.V.2014, G. Marson (G.M. 2014-05-04.2; sq.: KT222390). – **Echternach**, 2.5 km SSW of Echternach, Haard (north-part), 355 m, twigs of *P. menziesii*, on wood & bark, 17.VII.2004, G. Marson (ø). – **Grevenmacher**, 4.5 km W of Grevenmacher, 1 km SW of Potaschberg, Buchholzerwiss, 270 m, twig of *P. menziesii*, 10.VI.2008, G. Marson (ø). – 3.5 km NNE of Grevenmacher, 1.5 km ENE of Manternach, WNW of Fielsmillen, 185 m, branches of *R. pseudoacacia*, on wood, 16. XI.1993, G. Marson (H.B. 5006). – **Remich**, 7.5 km SW of Remich, SE of Mondorf-les-Bains, 210 m, branches of *Cryptomeria japonica*, on wood, 4. II.2004, G. Marson (ø). – **Capellen**, 4.5 km NW of Luxembourg, S of Bridel, 370 m, twigs of *P. menziesii*, on wood, 4.V.2014, G. Marson (G.M. 2014-05-04.1; sq.: KT380071). – **Luxembourg**, 6 km NE of Luxembourg, SE of Waldhaff (Waldhof), Gréngewald (Grünewald), Arboretum, 410 m, twigs of *P. menziesii*, on wood, 20.VIII.2009, G. Marson (ex H.B. 9152, M-0291775, **epitype**; sq.: KT222444). – 2 km NW of Luxembourg, Limpertsberg, Park Neumann, 320 m, twigs of *Sequoiadendron giganteum*, on bark & wood, 3.VII.2004, G. Marson (H.B. 7554). – 1 km N of Waldhaff, Schetzelklaus, 410 m, branches of *P. menziesii*, on wood, 23.V.2004, G. Marson (H.B. 7529, anam. substr.). – 11 km ESE of Luxembourg, 2 km E of Oetrange, Draf, 268 m, branch of *Sambucus racemosa*, on wood, 4.IX.1998, G. Marson (H.B. 6239, anam. substr.). – 5 km SSW of Luxembourg, 0.7 km N of Kockelscheier, Weier, 300 m, branch of *Picea abies*, on wood, 10.I.2000, G. Marson (ø, anam. substr.). – 4.5 km S of Luxembourg, 1 km W of Hesperange, Biersak/Géisselbierg, 290 m, branch of *Salix*, on wood, ?9.XII.1997, G. Marson (ø). – ibid., branch of *Sambucus nigra*, 22.V.2002, G. Marson (ø, anam. substr.). – ibid., branch of *Picea abies*, on wood, 3.I.2004, G. Orbilia myrioeuonymi Baral & G. Marson, **sp. nov.**, MB 813509 — Pls 209–210

Etymology: named after the 64-spored asci and a close relationship to *O. euonymi*.

Typification: Western Australia, Upper Swan, branches of *Jacksonia*, 2.IX.2006, G. Marson (ex H.B. 8611h, MEL 2389244, holotype).

Latin diagnosis: *Differt ab* Orbilia euonymi *ascis 64-sporis. Habitat ad lignum putridum ramorum in aere prominentium arborum angiospermarum vel petiolos palmae, in zona temperata ad subtropica semihumida ad humida Australiae meridio-occidentalis vel -orientalis et Asiae orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.16–0.24 mm diam., 0.075–0.11 mm high, pale to light cream-reddish to orange, ± round, ± scattered; disc flat, margin indistinct or distinct, ~0–10 µm protruding, smooth; sessile to subsessile, superficial; dry bright orange. **Asci** *37–48 {3} × 7.4–8.4 {2} or 8.5–10 µm {1}, †29–46(–67) × (5–)6–7.5(–8.5) {3}, 64-spored (40–52 spores counted), spores multiseriate, pars sporifera *21–29 µm long; **apex** (†) hemispherical to slightly truncate, dome †1.5–2 → (0.7–)1–1.3(–1.7) µm thick {3}, some with very distinct apical chamber; **base** with short to medium long, thin or thick, flexuous stalk, L-shaped. **Ascospores** *(2.8–)3–4.3(–4.8) × 1.5–1.8(–2) µm {3}, †2.7–4(–4.8) × 1.5–1.7 µm {2}, cylindric-ellipsoid to slightly clavate, ends rounded to obtuse, straight (to slightly inequilateral); **SBs** *1.1–1.9 × 0.3–0.5(–0.6) µm {3}, divided into an abruptly swollen tear-shaped lower part and a filum of ± equal or shorter length. **Paraphyses** apically uninflated to slightly capitate, terminal cell *6–15 × (1.5–)2–2.5(–3) µm {2}, lower cells *5–11 × 1.5–2.7 µm {2}; rarely branched near apex. **Medullary excipulum** pale orange, 15–30 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** pale rose, of thin-walled, irregularly oriented t. angularis from base to mid flanks, 15–35 µm thick near base, cells *6–10 × 5–7(–8) µm {1}; 5–15 µm near margin, of t. porrecta oriented at a 10–30° angle to the surface, marginal cortical cells †5–10 × 2–2.5 µm. **Anchoring hyphae** medium abundant, *2–3 µm wide (†1.5–2 µm), walls 0.2 µm thick {1}, at lower flanks forming a gelatinized layer 20–30 µm thick, towards base sometimes with 3.5–5 µm wide angular cells near cortex of excipulum. **SCBs** in paraphyses globose to short elongate, 1.2–2 µm diam. **Exudate** over paraphyses 0.3–1 µm thick, ± continuous, or 1–2.5 µm thick, cloddy, slightly rough, loosely attached; over margin rough-cloddy, pale yellowish, 1–3 µm thick. — **ANAMORPH**: vermispora-like (presumed, from natural substrate {1}). **Conidiophores** not observed. A single **conidium** seen, unbranched, slightly curved, *52 × 4 µm, 8-septate, with pointed ends.

Habitat: collected 0.2–2 m above the ground or on the moist ground, on 11–18 mm thick, ± decorticated branches of *Jacksonia* sp. {1}, *Melaleuca* sp. {1}, indet. angiosperm {2}, on 0.1 mm deep strongly decayed, partially eroded wood {3}, petiole of *Livistona nitida* {1}, greyed, green algae absent or scattered. **Associated**: *Claussenomyces* sp. {1}, *Gloniopsis* sp. {1}, *G. praelonga* {1}, *Mellitiosporiella* sp. {1}, *Orbilia acaciae* {1}, *O. australiensis* {1/1}, *O. ?commarosa* {1}, *O. coronohesperidea* {1}, *O. curvativitalbae* {1}, *O. ?dixiensis* {1}, *O. eucalypti* {1}, *O. livistonae* {1}, *O. multiserpens* {1}, *O. myriofusiclava* {1}, *O. myrioobliqua* {1}, *O. palmicola* {1}, *O. parviclava* {1}, *O. pleiohesperidea* {1}, *Patellaria atrata* {1}. **Desiccation tolerance**: fully viable for at least 9 months. **Altitude**: 76–875 m a.s.l. (Australia), 1890 m (southern China). **Geology**: Triassic and Jurassic sedimentary rock; granite. **Phenology**: VI (N-hemisphere), IX–X (southern hemisphere).

Taxonomic remarks. *Orbilia myrioeuonymi* deviates from *O. euonymi* and *O. pleistoeuonymi* merely in 64-spored asci, whereas ascospore size and shape is about the same. It could well be a rare molecular variant which was, however, so far not observed to grow in association with any other taxon of this series, and not even on the same continent. However, a European collection was first thought to be 64-spored, but differs in larger asci and might therefore belong to *O. pleistoeuonymi* (see Pl. 211: 3).

Variation. Ascus size but also spore length varies somewhat within *O. myrioeuonymi*. Asci were largest in the collection from China (but see below), while its spores fit quite well the Australian records.

Literature report. A Chinese report by Zhang et al. (2009b, as *O.* cf. *euonymi*) obviously refers to *O. myrioeuonymi* (Pl. 210: 2), although collected on the moist ground. The reported spore number of 64 was evaluated from the volume of the pars sporifera on the photographed living asci. Ascus and spore size were undoubtedly given too small by the authors. We assume that the scale in a previous version of the plate (Y. Zhang pers. comm.) was correct. According to that scale the here figured ascus has a size of 39 × 9 µm, whereas it has 30 × 6.8 µm in the published version. A comparable error of 130% affects the spore scale, therefore, we here reproduce all these images with a corrected scale. Apothecia where described as pale yellow to watery-whitish, 0.15–0.8 mm diam., but such large range in size is not confirmed by the illustrations: the sectioned apothecium has a diameter of 0.16 mm, and those on the macrophoto appear to lie in the range of 0.15–0.2 mm.

Ecology. The few Australian samples of *O. myrioeuonymi* have been collected on rotten wood of dead xeric branches of different angiosperm trees and on dead dry leaves of a palm in a subtropical semihumid eucalypt open woodland in southwestern

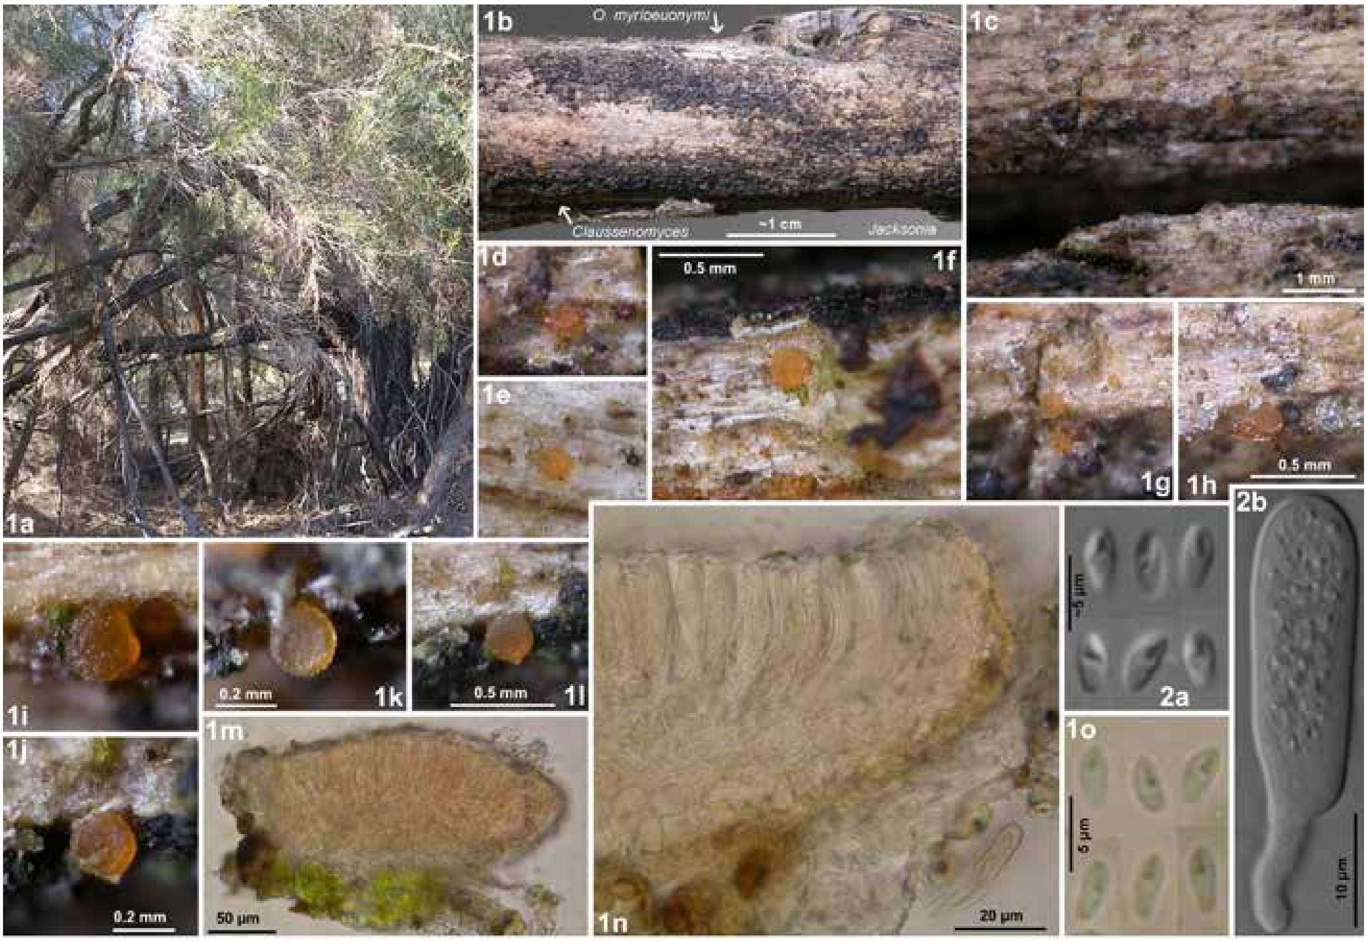

Plate 210. **1–2**: *Orbilia myrioeuonymi*. – **1a**. semihumid Eucalypt open forest with *Jacksonia*; **1b**. decorticated branch of *Jacksonia*; **1c–l**. rehydrated apothecia; **1m**. apothecium in median section; **1n**. ectal excipulum in median section (margin and flanks); **2b**. ascus; **1o**, **2a**. ascospores. – Living state. – **2a–b**: phot. Zhang et al. 2009b. — **1a–o**. H.B. 8611h (holotype): Western Australia, Swan Valley; **2a–b**. YMFT004: China, Yimen, on indet. angiosperm.

Australia and in subtropical subhumid to warm-temperate humid eucalypt woodland and open forest in eastern and southeastern Australia (eastern side of Great Dividing Range). The specimen from southern China was on hygric wood ('bark' in the description in Zhang et al. is probably erroneous) of an unidentified angiosperm in a subtropical humid (winterdry), monsoon-dominated evergreen forest. Only one apothecium was detected in the collection on *Livistona* and ~15 on *Jacksonia*; that on *Melaleuca* was more abundant but could only be studied in the dead state.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 30 km NE of Perth, 4 km NE of Upper Swan, 76 m, branches of *Jacksonia*, on wood, 2.IX.2006, G. Marson (ex H.B. 8611h, MEL 2389244, **holotype**). – **Queensland**, Brigalow Belt South, 69 km SSW of Theodore, 15 km N of Taroom, Palm-Tree Creek, Roy Staines Bridge, 200 m, petiole of *Livistona nitida*, 22.X.1998, G. Marson (H.B. 6424h). – **New South Wales**, Sydney Basin, 84 km W of Sydney, 2 km S of Katoomba, Blue Mountains, Echo Point, Spooner Outlook, 875 m, branch of *Melaleuca*, on wood, 26.X.1998, G. Marson (H.B. 6822, anam. substr.). — **CHINA**: **Yunnan**, **Yuxi**, Yimen, 75 km SW of Kunming, 53 km NW of Yuxi, Longkou Forest Park, 1890 m, on wood of indet. angiosperm, 27.VI.2006, Y. Zhang (YMFT004, doc. vid.).

Orbilia pleistoeuonymi Baral & P. Perz, **sp. nov.**, MB 814371 — Pls 211–212, Map 36

Etymology: referring to the 128-spored asci and the close relation to *O. euonymi*.
Typification: Spain, Cataluña, Cambrils, branch of *Robinia pseudoacacia*, 27.IX.1999, H.O. Baral & G. Marson (ex H.B. 6494a, M-0276564, holotype; ex-type culture: CBS 116274; sq.: KT215234).

Latin diagnosis: *Differt ab* Orbilia euonymi *ascis 128-sporis. Habitat ad lignum putridum ramorum in aere prominentium arborum deciduarum, plerumque* Quercus*, in zona supratemperata humida (sub)continentale ad thermomediterranea semihumida Europae centralis, orientalis et meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.12–)0.15–0.4(–0.5) mm diam., (0.08–)0.1–0.18(–0.23) mm high, light to bright (rose-)orange(-ochraceous), also pale yellow, round, scattered to often densely gregarious; disc flat, margin distinct, thin, 0–10 µm protruding, smooth; sessile or with a very short and thick, ill-defined stipe, superficial; dry bright orange. **Asci** *(45–)55–75(–86) × (8.5–)9–10(–10.7) µm {5}, †(38–)45–70(–80) × (6.8–)7.5–9(–10) µm {6}, 128-spored (min. 70–100 spores counted), spores multiseriate, irregularly oriented, pars sporifera *(27–)30–44 µm long, †(28–)33–44(–50) µm; **apex** (†) hemispherical, dome †1.5–2.2(–2.5) → 0.7–1.7 µm thick {3}, with apical chamber; **base** with short to long, thick, flexuous stalk, L-, T- or often Y-shaped with sometimes very long legs. **Ascospores** *(2.2–)2.5–3.5(–4.5) × (1.5–)1.6–2.2(–2.4) µm {5}, †(1.8–)2.2–3(–4) × 1.4–2(–2.2) {3} µm, cylindric-ellipsoid to somewhat clavate or obovoid, ends rounded, straight or rarely slightly to medium curved; **SBs** *(0.8–)1–1.5(–1.7) × (0.2–)0.3–0.4(–0.5) µm {5}, divided into an abruptly swollen, tear-shaped to subglobose, rarely fusoid lower part and a filum of ± equal length. **Paraphyses** apically uninflated or slightly clavate-capitate, terminal cell *6–12(–14) × (1.7–)2–3(–4) µm {3}, lower cells *(3.5–)5–9(–10) × 1.5–2.5(–3.3) µm {3}; rarely branched at upper septum. **Medullary excipulum** hyaline, 20–40 µm thick, of dense textura intricata-angularis, medium sharply delimited. **Ectal excipulum** pale rose, of (†) thin-walled (cortical part distinctly gelatinized), indistinctly oriented t. angularis(-prismatica) from base to mid flanks, 20–80 µm thick near base, cells *(5–)8–15(–20) × (3–)5–11(–13) µm {3}; 20–35 µm thick at lower flanks, 10–20 µm thick near margin, of t. prismatica-porrecta oriented at a 10–30° angle to the surface, marginal cortical cells */†(6–)7–9(–10) × 2.2–3(–4) µm {3}. **Anchoring hyphae** very sparse to medium abundant, hyphae †1.5–2.8

µm wide, wall 0.2(–0.3) µm thick {3}. **SCBs** globose, in paraphyses 0.9–1.5(–2.5) µm diam., in marginal excipulum 1.2–2 µm. **Exudate** over paraphyses (0.3–)0.5–2(–4) µm thick, ± continuous to cloddy, very rough, loosely attached, over margin (0.5–)1–3(–5) µm thick, hyaline to pale yellowish-chlorinaceous. **— ANAMORPH**: vermispora-like (from ascospore isolate {1} and natural substrate {3}). **Conidiophores** *~10–35 µm long {3}, 0–5-septate, often irregularly bent, sterile basal cells *2.5–3.8 µm wide. **Conidiogenous cells** often broader than basal cells, either simple with a single apical denticle, *6–12 × 2.2–4.4 µm, or mostly in a row, *4–8 × 2.8–5.5 µm, each with 1–4 cylindrical denticles *1–2.5(–3) × 0.9–1.3 µm. **Conidia** unbranched, slightly (rarely strongly) curved, *(12–)18–31(–34) × (3.5–)4–4.7(–5) µm {3}, (1–)3–5(–6)-septate {4}, containing some minute LBs.

Habitat: collected (0–)0.5–3 m above the ground, partially to entirely decorticated, 15–100 mm thick branches and logs of *Carpinus betulus* {1}, *Quercus* sp. {3}, *Q. pubescens* {1}, *Q. robur* {4}, *Robinia pseudoacacia* {1}, on 0.1–2 mm deep or entirely strongly decayed wood {10}, ± weathered and bleached, slightly to medium greyed, green algae absent or sparse to abundant. **Associated**: *Chaetosphaeria myriocarpa* {1}, *Durella atrocyanea* {1}, *D. connivens* {1}, *Hyalorbilia helicospora* {1}, *Mollisia ligni* {1}, *Orbilia aprilis* {4}, *O. bicknellensis* {1}, *O. montigena* {1}, *O. pleiomicrosoma* {1}, *O. tremulae* {1}, *O. ungulata* {1}, *O. vinosa* {1}, *Patellaria atrata* {1}, *Phellinus* (?) *contiguus* {1}. **Desiccation tolerance**: fully viable for at least 1 month, many ascospores and basal ectal excipular cells still viable after almost 5 years. **Altitude**: 15–445 m a.s.l. **Geology**: Keuper (Knollenmergel), Upper Cretaceous calcareous clay- & marlstone, Quaternary fluviatile sand & gravel; granite & granodiorite, gneiss & migmatite. **Phenology**: III–IV, VI, IX, XII (throughout the year, long-lived).

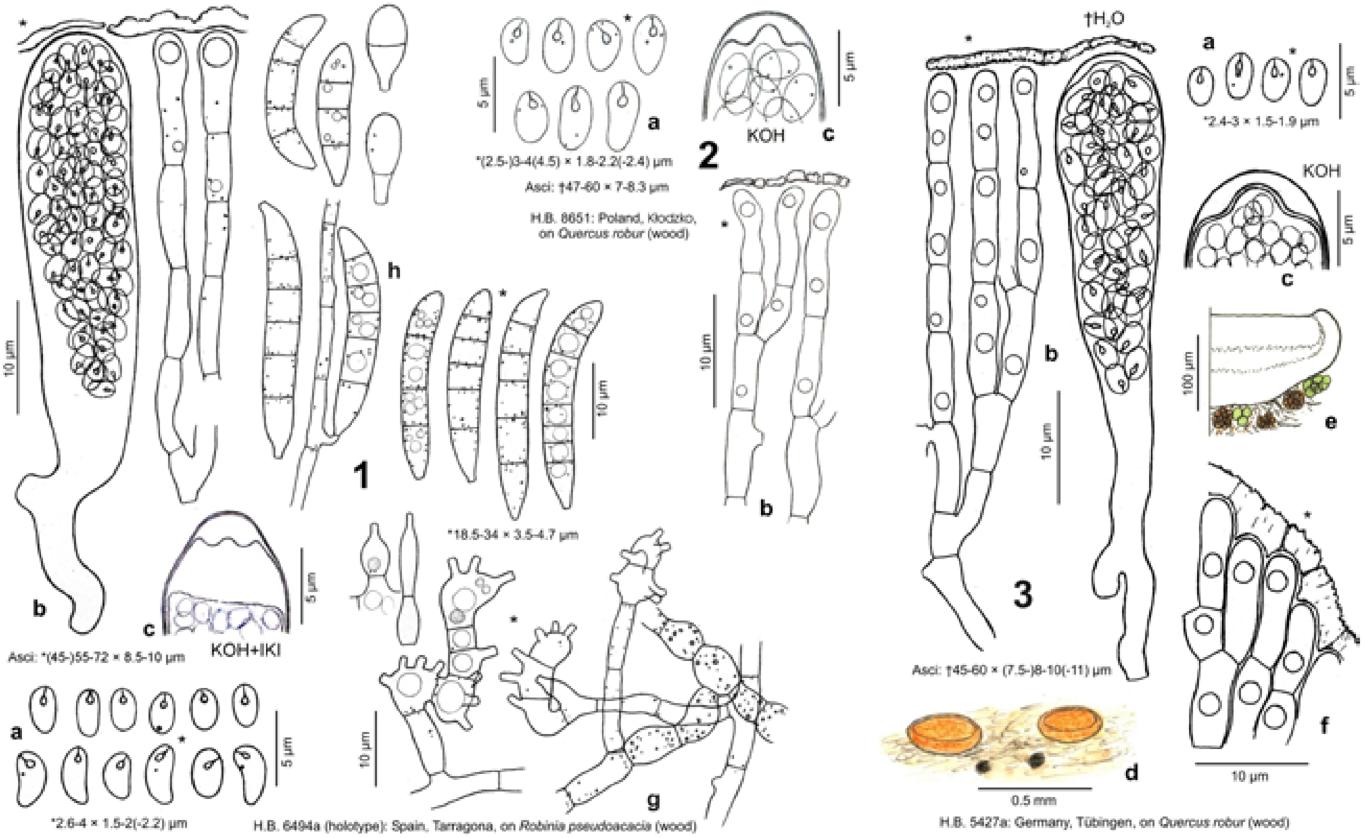
Taxonomic remarks. *Orbilia pleistoeuonymi* differs from *O. euonymi* and *O. myrioeuonymi* in larger, 128-spored asci. Although the number of such small ascospores is difficult to count, the asci were found to be at least 100-spored in most of the specimens examined. The spores are scarcely shorter than in *O. euonymi* and *O. myrioeuonymi*. Also spore width corresponds well and lies even slightly above that of *O. myrioeuonymi*. Due to the high spore number the asci of *O. pleistoeuonymi* tend to be distinctly larger than in the other three species of the series.

Variation. Spore size in *O. pleistoeuonymi* was quite variable, ranging among the collections from *2.4–2.8 to 3–4 µm in length and *1.5–1.8 to 2–2.3 µm in width. However, this variation was also noted among apothecia of a single sample (e. g., Pls 211: 1–2, 212: 4).

In a collection from Tübingen (Pl. 211: 3) the asci were originally thought to be 64-spored and to belong to *O. myrioeuonymi*. Over a third of the ~50 apothecia have been examined. In most of these apothecia the asci were found to contain many more spores than 32, and it is well possible that they contained more than 64 spores, especially because the ascus size fits better *O. pleistoeuonymi*. Its extraordinarily large ascus width in the dead state is perhaps due to artificial flattening. In the rather short spores this specimen fits the smaller spores illustrated in Pl. 211: 1a (upper row). Also in a specimen from Russia studied by E.S. Popov (pers. comm.) the spore number possibly exceeds 64, considering the rather large asci (†63–65 × 8–9 µm) and the short, 5-septate conidia.

Anamorph. The vermispora-like anamorph obtained in pure culture differs from that of *O. euonymi* in slightly smaller conidia. Whether the swollen conidiogenous cells with prominent denticles are typical of this species needs to be clarified from further cultures, particularly in comparison with *O. euonymi*.

Phylogeny. A sequence comprising SSU, ITS, and LSU was taken from pure culture of the holotype of *O. pleistoeuonymi*. The distance to *O. euonymi* is unexpectedly high (see p. 535).



H.B. 6494a (holotype): Spain, Tarragona, on *Robinia pseudoacacia* (wood)

H.B. 8651: Poland, Klodzko, on *Quercus robur* (wood)

H.B. 5427a: Germany, Tübingen, on *Quercus robur* (wood)

P. Perz. — **1a–n**. H.B. 8651: Poland, Kłodzko, on *Quercus*; **2a–c**. H.B. 6494a (holotype): Spain, Tarragona, on *Robinia*; **3a–b**. H.B. 9237a: Poland, Domaszków, on *Quercus*; **4a–d**. H.B. 5427a: Germany, Tübingen, on *Quercus*.

The S1506 intron is here much larger (1555 vs. 444 nt in *O. euonymi*) than in most other species of *Orbiliomycetes* (see Tab. 24). When comparing the ~350 overlapping nucleotides, it shows 18.5% distance to *O. pleioeuonymi*, 20–20.5% to *O. euonymi*, and 18.5% to *O. myriosphaera*, the only further member of section *Lentiformes* in which we found this intron.

Ecology. The few records of *O. pleistoeuonymi* were on rotten wood of dead xeric branches of mainly *Quercus*, but also *Carpinus* and *Robinia*. In central Europe (Poland, Czechia, Slovakia, Germany) it was found in cold-temperate humid, ± thermophilous *Querco-Carpinetum* forests, especially near the border to open woodland and pastures or agriculture. In southern Europe it grew in a mesosubmediterranean semihumid *Quercetum pubescentis* (Drôme) and in the thermomediterranean coastal zone at a rivulet with *Phragmites* and planted *Robinia* (Tarragona, holotype). The collection from the Caspian lowland

Map 36. Known distribution of *O. pleistoeuonymi* in Europe.

(Astrakhan) was from a warm-continental steppic subhumid grassland area near a salt lake, with scattered *Quercus* and *Ulmus*.

Several collections of *O. pleistoeuonymi* were quite sparse (1–10 apothecia), whereas others, including the holotype, were abundant, comprising ca. 50–100 apothecia. The holotype, however, grew in close association with the holotype of *O. pleiomicrosoma*, sometimes even intermingled, and since these two species are macroscopically indistinguishable, their relative abundance in this collection remained unclear. In four other samples *O. aprilis* grew close to or sometimes intermingled with *O. pleistoeuonymi*.

Section *Hemiorblia*

Orbilia subgenus ***Hemiorbilia*** section ***Hemiorbilia*** –
Type species: *Calloria occulta* Rehm [≡ *Orbilia occulta* (Rehm) Sacc.]

Description: — **TELEOMORPH**: **Apothecia** rehydrated ((0.07–)) (0.1–)0.15–1(–1.5) mm diam., pale to bright orange, ochraceous-orange, brick-red, or rose(-lilaceous), disc smooth or pruinose, margin smooth to rough, whitish pubescent to long-haired, or with small to large whitish teeth. **Asci** *(27–)35–100(–130) × (4–)5–12(–15) µm, 8- up to 128-spored, some of the lower spores inverted (~1/8–3/4 of spores, strongly mixed if polysporous); **apex** (†) hemispherical to slightly (rarely medium) truncate, with (0.4–)0.7–4(–6) µm thick apical dome (but thin-walled in *O. concoloris*), often with distinct apical chamber; **base** L-, T-, Y- or h-shaped. **Ascospores** *(3.4–)5–20(–30) × (1–)1.5–4(–6) µm, cylindrical, clavate, ellipsoid, fusoid, obovoid, subglobose, cashew-shaped, heart-shaped, triangular, sperm-shaped, apex rounded to subacute, rarely acute to acuminate, straight to strongly curved (C- to L-shaped or helicoid); **SBs** affixed to apical, subapical or lateral spore wall, (1–)1.5–5(–6.5) × (0.2–)0.4–1.5(–2.5) µm, cylindrical to subulate or tear-shaped to ampulliform, sometimes globose, apically narrowed to a small or wide point, filum absent or exceptionally very short, straight or sometimes curved. **Paraphyses** not or often slightly, rarely strongly inflated at the apex, clavate-capitate, exceptionally sublageniform, terminal cells (0.5–)1–2(–2.5)× longer than lower cells, unbranched or sometimes branched near apex. Cortical cells of **ectal excipulum** at flanks of textura (globulosa-)angularis(-prismatica), cells isodiametric or vertically elongated, near base */†(5–)7–20(–30) × (4–)6–15(–20) µm, (†) thin-walled to slightly, sometimes medium to strongly gelatinized, common walls †(0.3–)0.5–1.5(–3) µm thick, near margin of t. angularis to t. porrecta, oriented at a high to low angle, with or without 1–10 µm up to 30–100(–200) µm long **glassy processes**, rarely with septate, 60–210(–300) µm long **hairs**. **SCBs** globose, or mixed with crystalloid ones; **VBs** consistently absent; **carotenoids** in **LBs** present in some taxa. **Exudate** (0.1–)0.5–3(–10) µm thick, continuous, cloddy, or granular, loosely or firmly attached, hyaline to bright yellow, rarely absent. — **ANAMORPH**: trinacrium-like*,* descalsia-like, dwayaangam-like, sometimes vermispora-like. **Conidiophores** ~1.5–30 µm long. **Conidiogenous cells** monoblastic or sympodial. **Conidia** staurosporous, rarely phragmosporous.

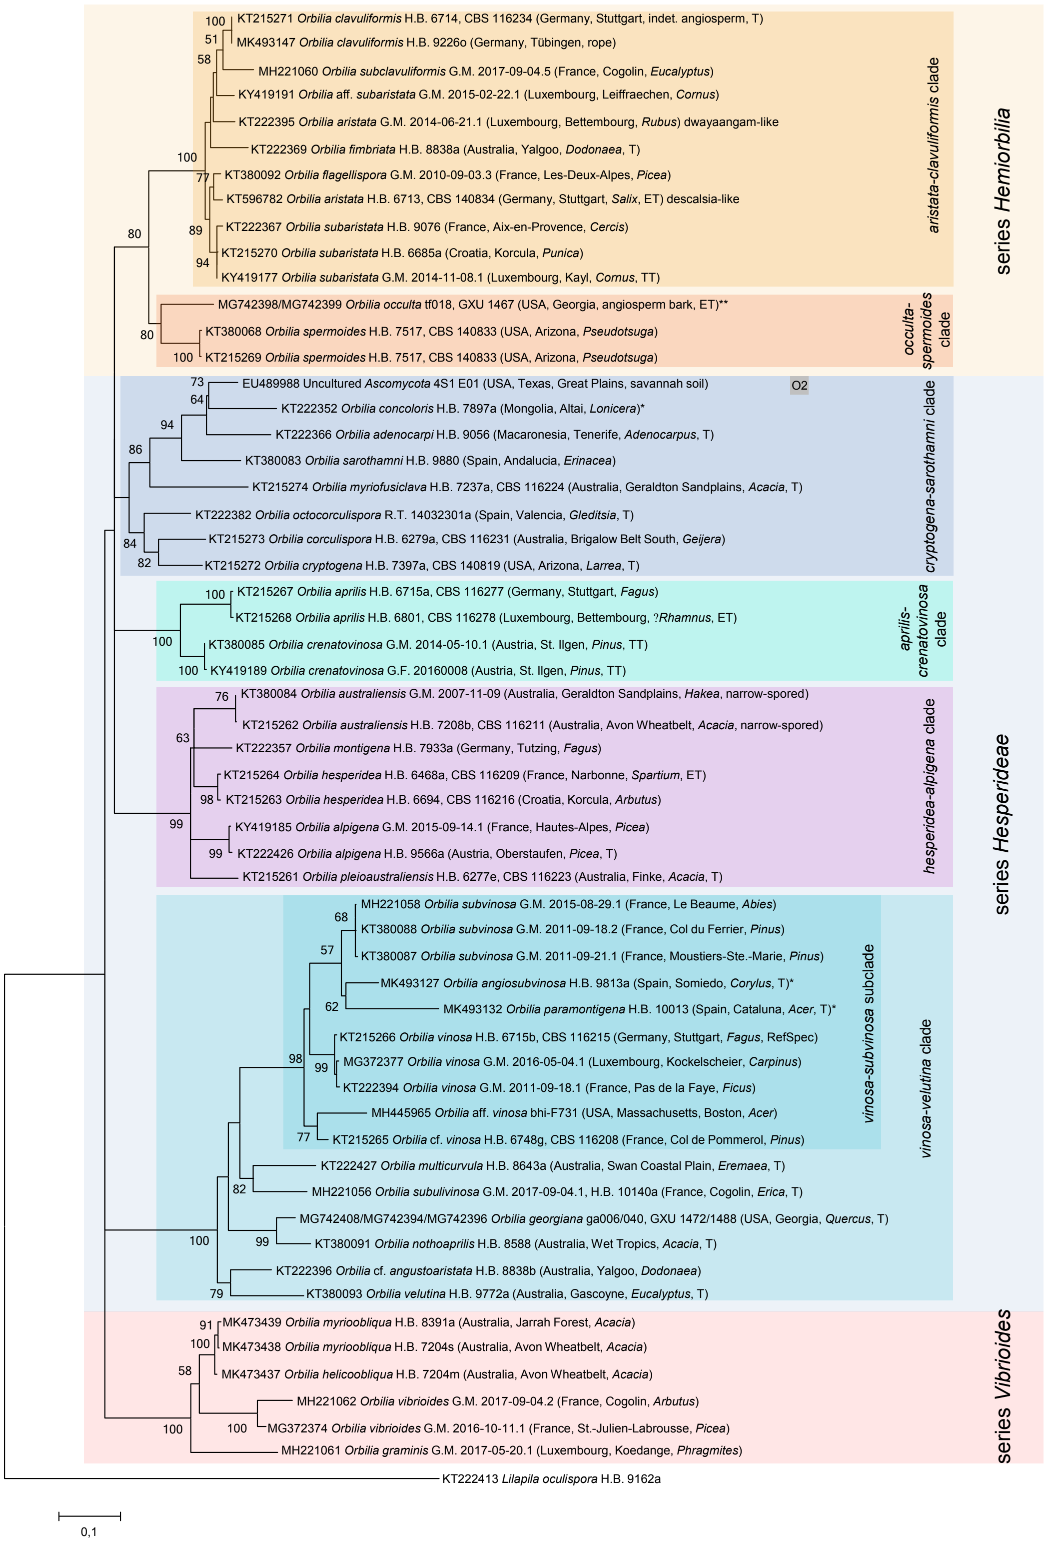
Habitat: on wood and bark of gymno- & angiosperms, also caulicolous, foliicolous, acicolous, or bryicolous, in boreal to tropical, humid to arid climates, always desiccation-tolerant.

Recognized series: *Hemiorbilia*, *Hesperideae*, *Vibrioides*, with 81 recognized species plus 15 unnamed ('affinis') and 1 of uncertain affinity.

Taxonomic remarks. Members of section *Hemiorbilia* are characterized by asci with a more or less hemispherical apex (dead state) with distinct apical wall thickening and often also with apical chamber. The apical thickening is usually congophilous by staining rose-red in CR_{SDS}, while a pale red (dextrinoid) reaction in IKI or MLZ was observed only in those species with an extraordinarily thick apical wall (*O. nothovinosa*, *O. vibrioides*). In some species the apex is partially medium truncate (e. g., *O. myrioauris*) and/or the apical thickening rather thin (e. g., *O. octocorculispora*) or even absent (*O. concoloris*). The spore bodies are mostly ± elongate, rod-shaped to subulate or tear-shaped to ampulliform, usually straight and rather thick, apically attached to a narrow or wide point, but never with a filum.

Section *Hemiorbilia* is morphologically rather sharply delimited, e. g., against species with thin-walled truncate ascus apices (subgenera *Habrostictis* and *Orbilia*). However, exceptions occur. Particularly some species included in section *Ovoideae* of subgenus *Orbilia* are morphologically hardly separable from section *Hemiorbilia* because of an inconsistent or even predominant (*O. clavipisca*) presence of ascus apical thickenings. Also section *Lentiformes* comprises taxa with a similar ascus apex structure, but differs in SB morphology, being either ± lens-shaped and very broadly attached, or ± lantern-shaped and narrowly attached, mostly with a short to long filum.

Series delimitation. Section *Hemiorbilia* includes three series, *Hesperideae*, *Hemiorbilia*, and *Vibrioides*, which are mainly separated by ascospore morphology and the thickness of the apical ascus wall, although spore shape is rather diverse within each series. Polyspory characterizes various members of series *Hesperideae* and *Vibrioides*, but is entirely absent in series *Hemiorbilia*. In series *Hemiorbilia* only a few of the lower



Phylogenetic analysis 9. Phylogram of section *Hemiorbilia* inferred from ML analysis of combined ITS1-5.8S-ITS2+LSU (D1–D2) rDNA dataset (57 sequences, 1309 positions, aligned with MUSCLE) using the GTR+G+I model in MEGA6 (500 replicates). An environmental strain from GenBank represents an unidentified species (O2). The tree is rooted with *Lilapila oculispora*. RefSpec = reference specimen, T = type, ET = epitype, TT = topotype. * = without LSU, ** = only partial LSU (D1).

spores are inverted in the asci, while in the other two series the proportion of inverted and not inverted spores is more equal. Glassy processes inconsistently occur in many species but are absent in series *Vibrioides*. Cashew-shaped or falcate ascospores occur in about 20 % of the species of series *Hesperideae* and in > 50 % of series *Vibrioides*, but are absent in series *Hemiorbilia*. The main characteristic of series *Hemiorbilia* is the basal tail of the spores which, however, also occurs in some multispored taxa of series *Hesperideae*. A pruinose disc and margin is characteristic of 64–128-spored species of series *Vibrioides* but not observed in 8–16-spored species of that group.

Anamorph. Members of section *Hemiorbilia* are characterized by anamorphs with staurosporous, sometimes 3-dimensional conidia formed on short conidiophores. These include different conidial types that are defined by the number and orientation of arms and by different branching types. Trinacrium-like conidia with one stipe and two arms are the prevalent case, but higher branching types (descalsia- and dwayaangam-like) also occur in two series (for series *Vibrioides* no certain connections to anamorphs are known), whereby descalsia-like conidia are so far only known in series *Hemiorbilia*. Rarely vermispora-like phragmoconidia are formed in series *Hesperideae* (*O. myriofusiclava*, *O. georgiana*).

Phylogeny. In our phylogenetic analysis of SSU+ITS+LSU in Baral et al. (2017b), section *Hemiorbilia* formed a monophyletic clade though without support and partially high distance among the clades. When analysing ITS+LSU, ITS, or LSU (Phyls 9–12, S13) seven main clades can be recognized. Except for the unsupported *cryptogena-sarothamni* clade, which received strong support in the ITS tree (Phyl. 10), and the medium supported *occulta-spermoides* clade, all received very strong support in the combined analysis (Phyl. 9). These seven clades clustered unresolved within section *Hemiorbilia*, with two exceptions: (1) the two clades which constitute series *Hemiorbilia* clustered with medium support in a clade when analysing ITS+LSU; (2) the *hesperidea-alpigena* clade and the *aprilis-crenatovinosa* clade clustered in a medium supported clade in the analysis of ITS (Phyl. 10, in some not shown analyses under the same conditions even strongly supported).

Morphologically these clades differ from each other only to some extent. For instance, series *Hemiorbilia* includes species with distinct, more or less thin ascospore tails and consistently 8-spored asci. However, an 8-spored sample with long and thin spore tails (*O.* cf. *angustoaristata*) is found in the *vinosa-velutina* clade, in which otherwise only species with very indistinct spore tails occur. *O. occulta*, the type species of series *Hemiorbilia*, and *O. spermoides* clustered distant from the bulk of series *Hemiorbilia* though having long and thin spore tails. Despite these discrepancies we included all these taxa in series *Hemiorbilia* because of their high morphological similarity.

In the overlapping 362 nt of available SSU sequences (V8–V9) the observed variation was 1–1.5% as a maximum, (see Phyl. S11). Many species of section *Hemiorbilia* are identical in this region, for instance, *O. aprilis*, *O. hesperidea*, and *O. aristata*, although belonging to different relationships. Also to other sections of *Orbilia* the differences in this gene region are few or even absent regarding some taxa of section *Lentiformes*. Therefore, the V8–V9 region is of little use in phylogenetic analyses of the genus *Orbilia*.

The rDNA gene regions which are available at present do not permit any conclusion about where section *Hemiorbilia* might be positioned within the genus *Orbilia* and which of its clades comprises a majority of taxa with plesiomorphic characters. From a morphological point of view it would seem logical that long and thin spore tails represent an apomorphic character. With this hypothesis it can be concluded that polyspory, which occurs in many members of section *Hemiorbilia* but so far in none of series *Hemiorbilia*, was an ancestral character state within the group.

Specific nucleotide positions. Molecular motifs in the SSU V8–V9, ITS, or LSU D1–D3 specific to the entire section *Hemiorbilia* have not been found. Two positions in the LSU D1–D2 (292: AGCTC**A**AA, 591: GAGG**T**CCGCG) are consistent within section *Hemiorbilia* and concur with most remaining *Orbilia* spp., except for section *Lentiformes* which here agrees with almost all basal genera (292: AGCTC**T**AAA, 591: GAGG**A**CCGCG, see also under section *Lentiformes*, p. 549).

A rare deviation near the 5'-end of LSU is unique for section *Hemiorbilia* (pos. 70: CAAC**C**GGGA), but occurs there only in some of its members: *O. vinosa* (including H.B. 6748g), *O.* aff. *vinosa* (bhi-F731), *O. multicurvula*, *O. nothoaprilis*, *O. georgiana*, *O. crenatovinosa*, *O. spermoides*, *O. occulta*, *O.* cf. *angustoaristata*, series *Vibrioides*, and *O. gemma*. All other orbiliaceous LSU sequences have instead CAAC**A**GGGA, including most members of series *Hemiorbilia* and *Hesperideae*, even *O. subvinosa* and *O. aprilis* which are closely related to *O. vinosa* and *O. crenatovinosa*, respectively.

Ecology. All members of section *Hemiorbilia* are desiccation-tolerant and occur worldwide, ranging from boreal to tropical and from humid to arid areas. They mainly inhabit woody but also herbaceous substrates including leaves, rarely hepatics.

Key to species of section *Hemiorbilia*

1. Asci 32- up to 128-spored 2
1. Asci 8- or 16-spored .... **key C**

2. Ascus apical wall immature †0.5–2.5(–3.5) µm thick; exudate never forming warts on the hymenium; crystalloid SCBs present or absent .... **key A**
2. Ascus apical wall immature †(2–)3–4(–6) µm thick; rough yellowish exudate often provoking a warted hymenium and radial ribs at the margin; crystalloid SCBs absent; all species from western Australia .... **key B**

Key A (series *Hesperideae* p.p., asci 32–128-spored)

1. SBs narrowly rod-shaped, spores *6.8–12.8 × 3.2–4.6 µm .... see ***O. macroasca*** (section *Lentiformes*), p. 507
1. SBs elongate tear-shaped to ± globose, if rod-shaped then spores narrower 2

2. SBs (sub)globose, often laterally inserted (somewhat below the middle) but also apically; spores clavate-oblong, with obtuse apex and slightly tapered, ± curved base, *6.8–11.5 × 2.2–3 µm; asci 64-spored; bark of *Acacia*, subtropical arid .... ***O. myrioauris***, p. 670
2. SBs strictly apical 3

3. Spores predominantly distinctly curved 4
3. Spores straight or only slightly (exceptionally strongly) curved 8

4. Spores *6.8–9.5(–10) × 1.3–1.5(–1.6) µm, quite consistently strongly falcate; SBs vermiform to subulate; asci 32-spored; apothecia with prominent teeth made up of long glassy processes; bark of *Eremaea* & *Hibbertia*, subtropical semihumid western Australia .... ***O. multicurvula***, p. 636

4. Spores min. *2–2.5 µm wide; apothecia without teeth 5

5. Spores *2–2.7 µm wide, fusoid-clavate, slightly to strongly curved near base; asci 64-spored 6
5. Spores *3–4.5 µm wide, ± cashew-shaped, or ± lunate with a thin tail; asci 32–64-spored 7

6. Spores †9–12 × 2.3(–2.4) µm, slightly to medium curved, with obtuse apex and distinct thick tail; bark of *Acacia*, subtropical semiarid western Australia .... ***O. myriohesperidea***, p. 589
6. Spores *(5–)6–8.5(–10.5) × (2–)2.2–2.5(–2.7) µm, slightly to very strongly curved, with obtuse to acute apex and ± attenuated base; bark of *Acacia*, *Jacksonia*, subtropical semihumid to semiarid western Australia .... ***O. myriofusiclava***, p. 653

7. Spores *(8–)9.5–13(–16) × (3–)3.5–4.5 µm, ± cashew-shaped, without tail; SBs tear-shaped; asci 32-spored; wood of *Larrea*, subtropical (semi)arid western North America .... ***O. cryptogena***, p. 662
7. Spores *(5.7–)6.3–7(–8) × (3–)3.3–3.6 µm, with ellipsoid-lunate head and an abrupt, thin, strongly bent tail; SBs almost globose; asci 64-spored; bark of *Acacia*, (sub)tropical (semi)arid western Australia .... ***O. myriomuscula***, p. 666

8. Spores *1.3–2.5 µm wide 9
8. Spores *2.7–4.5 µm wide 11

9. Spores *5.5–8 × 1.7–2.5 µm, ellipsoid-fusoid, without tail-like base; asci (64–)128-spored; apothecia ± hairy; wood of *Eucalyptus*, subtropical semiarid western Australia .... ***O. velutina***, p. 638
9. Spores *9–14.5 µm long, often with a tail-like base or tail; asci 32–64-spored; apothecia smooth 10

10. Asci 32-spored; spores *12–14.5 × 1.8–2 µm; wood of *Allocasuarina*, subtropical arid central Australia .... ***O. multivinosa***, p. 633
10. Asci 64-spored; spores †9–12 × 2.3(–2.4) µm; bark of *Acacia*, subtropical semiarid western Australia .... ***O. myriohesperidea***, p. 589

11. Asci 64-spored, †(9.5–)10–11.5(–12.5) µm wide; spores *(9–)10–12.5(–15) × 3.5–4(–4.5) µm, straight, with ellipsoid head and abrupt, thick tail; bark of *Acacia*, (sub)tropical (semi)arid western Australia .... ***O. myrioaustraliensis***, p. 564
11. Asci 32-spored, †(6.5–)7–9(–9.5) µm wide; spores *(2.7–)2.9–3.5(–3.8) µm wide 12

12. Spores †13–16 µm long, consistently with a distinct tail ~4.5–6.5 × 0.9–1.4 µm; bark of *Acacia*, subtropical semiarid western Australia .... ***O.* aff. *macrocarpa***, p. 570
12. Spores max. *12.5 µm long 13

13. Apothecia 0.4–1 mm diam., 0.2–0.4 mm high, often laterally compressed, with a 20–50 µm protruding margin; spores †8–12 µm long, with or without a short tail; bark of *Acacia*, subtropical (semi)arid western Australia .... ***O. macrocarpa***, p. 568
13. Apothecia 0.2–0.5 mm diam., 0.1–0.2 mm high, ± round, margin 0–10 µm protruding 14

14. Spores not attenuated in a tail-like base, *5–8(–8.5) µm long; with only globose SCBs; bark & wood of *Cytisus*, supra(sub)mediterranean semihumid southern Europe .... ***O. sarothamni***, p. 668
14. Spores often attenuated in a tail-like base or a distinct tail, usually longer than 7 µm; with crystalloid SCBs 15

15. Spores *(5.7–)7–8.7(–10.5) µm long, rarely with a distinct tail; SBs 1.5–2 µm long; petioles of *Livistona*, subtropical subhumid eastern Australia .... ***O. palmicola***, p. 567
15. Spores *(8.3–)9–11.5(–12.5) µm long, often with a distinct, rather narrow tail; SBs (2–)2.5–3 µm long; wood of *Acacia*, subtropical (semi)arid western & central Australia .... ***O. multiaustraliensis***, p. 564

Key B (series *Vibrioides* p.p., asci 32–128-spored)

1. Most of the spores slightly to strongly curved; asci (32–)64-spored 2
1. Spores ± straight, exceptionally slightly bent below, max. 7(–9) µm long; asci (32–)64–128-spored 6

2. Spores *(10–)11–16(–17) × (1.4–)1.5–1.7 µm, slightly to strongly falcate to geniculate; SBs apically attached, 2.8–4(–4.5) µm long; bark of *Acacia*, subtropical semiarid .... ***O. angustoobliqua***, p. 764
2. Spores max. 12 µm long, min. 1.7 µm wide 3

3. Spores *(4–)4.5–5.5 × 1.7–1.9(–2.1) µm, strongly curved (falcate to helicoid); SBs apically attached, 2.2–2.8 µm long; asci *9.7–10.7 µm wide [†8.5–9.5(–10) µm]; bark of *Acacia*, subtropical semiarid .... ***O. curvatiobliqua***, p. 761
3. Spores *6–12 µm long; asci *11–12 µm wide [†(8–)9–11(–11.5) µm] 4

4. Spores predominantly distinctly helicoid, *(6–)6.5–10.5(–12.8) × (1.8–)2–2.3(–2.5) µm; SBs apically attached, 3–4(–4.3) µm long; bark & wood of *Acacia*, subtropical semiarid .... ***O. helicoobliqua***, p. 760
4. Spores not or only indistinctly or exceptionally helicoid 5

5. Spores *6–8(–9.5) × (1.7–)1.8–2.1(–2.4) µm, ± L-shaped, often constricted in middle part (dumbbell-shaped); SBs predominantly subapically attached, 2–3.2 µm long; asci *(55–)60–80(–88) µm long (†45–58 µm), pars sporifera *30–57 µm long; bark & wood of *Acacia*, subtropical semiarid .... ***O. anguliobliqua***, p. 758
5. Spores *(6.5–)7.5–10(–11.7) × (1.8–)2–2.5(–2.6) µm, falcate (C- to L-shaped), also ± straight, never constricted; SBs apically attached, 3–4 µm long asci *78–105 µm long (†73–85 µm), pars sporifera *52–70 µm long; wood of *Eucalyptus*, subtropical arid .... ***O. allantoobliqua***, p. 762

6. SBs consistently apically attached 7
6. SBs consistently subapically attached 8

7. Asci 128-spored; spores *(5–)5.5–7(–8) × (1.6–)1.7–1.9(–2.2) µm; SBs 1.7–2.5(–3) µm long; bark of *Acacia*, subtropical semiarid .... ***O. paraobliqua***, p. 757
7. Asci 64-spored; spores *(5.8–)6.5–8(–9) × 2.2–2.4 µm; SBs (2.3–)2.6–3.8 µm long; bark of *Acacia*, subtropical semiarid (compare also *O. allantoobliqua*).. ***O.* cf. *paraobliqua***, p. 757

8. Asci 128-spored, *12.5–15.7 µm wide; spores *4.3–5.8 × 2–2.3 µm, cylindrical; bark of *Acacia*, subtropical arid.... ***O. pleistoobliqua***, p. 755
8. Asci (32–)64-spored, *8.5–12(–12.5) µm wide; spores *(4.3–)4.5–6.5(–7) × (1.8–)2–2.7(–3.2) µm, cylindrical to ± clavate; bark & wood of various angiosperms, leaves of *Cycadales*, (sub)tropical semihumid to arid.. ***O. myrioobliqua***, p. 753

Key C (section *Hemiorbilia*, asci 8- or 16-spored)

1. SBs laterally attached (at the ± protruding central part).. 2
1. SBs apically or subapically attached 5

2. Apothecial margin ± smooth; spores heart-shaped to triangular; asci 8–16-spored (series *Hesperideae*)..3
2. Apothecial margin dentate by long glassy processes; spores ± triangular or like a bird's head; asci 8-spored; subtropical semihumid western Australia (series *Hemiorbilia*) 4

3. Asci 16-spored; crystalloid SCBs present; spores heart- to kidney-shaped, *(5–)6–8(–9.5) × 3–4.2(–4.5) µm; bark or rarely wood of predominantly *Fabales*, temperate to tropical, humid to arid atlantic and southern Europe, eastern Asia, Australia, Africa, Macaronesia .... ***O. corculispora***, p. 656
3. Asci 8-spored; crystalloid SCBs absent; spores ± triangular to almost heart-shaped, *(6–)7–9(–10.5) × 4.2–5.5 µm; wood of *Pinus*, *Gleditsia*, *Ulex*, mediterranean semihumid southern Europe .... ***O. octocorculispora***, p. 660

4. Spores *(3.5–)4–6(–7) × (3.3–)3.5–4 µm, basal end short tapered, without a tail; bark & wood of *Chamelaucium* & *Verreauxia* .... ***O. triangulispora***, p. 744
4. Spores *(6–)7–8(–9) × 2.8–3.3(–3.8) µm, basal end attenuated in a very short tail (max. half as long as head); bark of *Banksia*. .... ***O. aviceps***, p. 742

5. Spores with a rather abrupt, thin or thick tail, i. e., a cylindrical or constricted basal end which is at least 3 × longer than wide, base of tail sometimes swollen; asci always 8-spored .... **key D (series *Hemiorbilia*)**
5. Spores without an abrupt tail but often with a gradually attenuated, tail-like base, if with distinct tail then asci 16-spored ... . **key E (series *Hesperideae* & *Vibrioides* p.p.)**

Key D (series *Hemiorbilia*, asci 8-spored)

1. Spore tail 2/3 up to 3 × the length of head, predominantly < *0.8 µm wide at its narrowest part, basal end sometimes swollen to 1–2 µm; apothecial margin nearly always with short to long glassy processes 2
1. Spore tail max. 2/3 the length of head, predominantly > *0.7 µm wide at its narrowest part, basal end swollen or not; glassy processes absent or present 19

2. Spore head predominantly < *2.6 µm wide, symmetrical, tail usually shorter than head 3
2. Spore head predominantly > *2.6 µm wide, symmetrical or asymmetrical 10

3. Spores *5–9 µm long, head broadly ellipsoid or fusoid..4
3. Spores *12–21 µm long, head elongate, narrowly ellipsoid.. 5

4. Apothecia with very prominent teeth; spores *5.5–7 × 1.6–1.7(–1.9) µm, head broadly ellipsoid, tail *2–3.2 × 0.2–0.3 µm; bark of *Eucalyptus*, subtropical semihumid western Australia .... ***O. nanosperma***, p. 737
4. Apothecia ± smooth; spore tail †~ 1–2 × 0.5 µm..***O. aprilis***, p. 645 (key H)

5. Spores †12.3–14 × 1.8–2.1 µm, tail 2.5–3.5 µm long; leaves of *Dryas*, (sub)alpine humid Europe .... ***O.* cf. *angustoaristata***, p. 701
5. Spore tail 3.5–8 µm long 6

6. SBs mainly rod-shaped to subulate, (2–)2.5–3.5 × 0.4–0.5 µm; spores *12–15(–17) × 1.6–2.4 µm, tail never inflated at base; crystalloid SCBs present; glassy processes 0–20 µm long; bark & wood of *Acacia* & *Pittosporum*, temperate subhumid eastern and subtropical arid central Australia .... ***O. angustoaristata***, p. 700
6. SBs cylindrical to tear-shaped, min. 0.6–0.8 µm wide..7

7. Spores *(11–)12–16.5(–18) × (2.3–)2.4–2.6(–2.7) µm, tail 4–7(–8) µm long; SBs (0.8–)1–1.2(–1.4) µm wide, often dumbbell-shaped; only globose SCBs present; glassy processes 0–10(–20) µm long; bark of *Cornus*, *Frangula*, warm-temperate humid eastern North America, cold-temperate central Europe .... ***O. clavuliaristata***, p. 706
Similar collections were on *Phragmites* (Luxembourg) and *Euphorbia* (Macaronesia, p. 709). A doubtful Pyrenean collection on *Cornus* mentioned under *O. frullaniae* differs in wider, tear-shaped SBs, less distinct spore tails, and crystalloid excipular SCBs (p. 704).
7. Spores *2–2.4 µm wide; SBs max. 1 µm wide (but overmature wider)..8

8. Spores *11.5–13.5 × 2–2.2 µm; SBs 1.6–2.2 µm long, ± tear-shaped; glassy processes 6–16 µm long, forming a crenulate margin; apothecia light cream-orange; bark of unidentified angiosperm, subtropical humid eastern Asia............................***O. brevicauda***, p. 705
8. Spores *(11.5–)14–21 × 2.1–2.5 µm; SBs 2–3.8 µm long, cylindrical to tear-shaped; glassy processes 20–60 µm long, forming distinct teeth at the margin; apothecia bright rose-red 9

9. SBs 2–3 µm long; spores *(11.5–)14–16(–17.5) µm long; lower (1–)2(–4) spores inverted; only globose SCBs present; on *Frullania* (on *Prunus*), cold-temperate humid subatlantic Europe .... ***O. frullaniae***, p. 704

A similar collection on *Cornus* bark from the Pyrenees possesses crystalloid SCBs (p. 704).

9. SBs 3–3.8 µm long; spores *14–17(–21) µm long; lower 0(–1) spores inverted; with or without crystalloid SCBs; bark of *Dodonaea*, subtropical semiarid western Australia .... ***O.* cf. *angustoaristata***, p. 701

A collection on bark of *Eucalyptus* (Pl. 526: 2), mentioned under *O. pseudoflagellispora* (section *Aurantiorubrae*, p. 951) and *O. flagellispora*, differs in slightly larger spores (*19–22 × 2.2–2.6 µm) with often one septum (overmature) and always slightly inflated tail base.

10. Spore heads strongly asymmetrical (± triangular), tail base always distinctly swollen; western Australia 11

10. Spore heads bilateral symmetrical or only slightly inequilateral 12

11. Spores *(13–)14–18(–19) × 3.8–4.7 µm (in profile view), often with a craw-like swelling below the head; marginal teeth 60–110 µm broad, 7–10 per apothecium; bark & wood of *Chamelaucium* & *Eucalyptus*, subtropical semihumid .... ***O. aviaristata***, p. 740

11. Spores *(18.5–)20–25 × 2.8–3.3(–3.6) µm (in profile view), never with a craw-like swelling; marginal teeth 20–80 µm broad, 15–22 per apothecium; bark & wood of *Acacia*, subtropical semiarid .... ***O. aviflagellata***, p. 738

12. Margin with 60–210 µm long, narrow hairs with thick walls and a septate lumen up to the apex; spores *19–21 × 3.9–4.2(–4.7) µm, with long and thin tails; bark of *Dodonaea*, subtropical semiarid western Australia .... ***O. fimbriata***, p. 728

12. Margin with 10–100 µm long glassy processes without lumen; spore heads predominantly < 3.8 µm wide 13

13. Spore heads subglobose to ovoid, ~1.2–1.8 × longer than wide; SBs 1.8–2.5 µm long 14

13. Spore heads ~2–3(–4)× longer than wide; SBs mostly > 2.5 µm long; SCBs never crystalloid 16

14. Apex of paraphyses uninflated or slightly spathulate, without exudate (or only fine granules); spores *(9–)12–17(–18.5) × 3.2–3.8(–4) µm, tail distinctly longer than head; crystalloid SCBs present in both paraphyses and excipulum; bark of conifers, cold-temperate to boreal (sub)humid western North America, orosubmediterranean humid southern Europe .... ***O. spermoides***, p. 734

14. Apex of paraphyses partly slightly to strongly capitate-clavate, covered by 0.3–3 µm thick refractive exudate; angiosperm bark 15

15. Spores *(9.5–)10–12(–13) × (2.8–)3–3.4(–3.6) µm, apex obtuse, tail shorter or only very slightly longer than head; crystalloid SCBs present in ectal excipulum; bark of *Cornus*, *Malus*, *Vitis*, temperate to subtropical humid eastern North America .... ***O. occulta***, p. 730

15. Spores *13–17 × 2.8–3 µm, apex subacute to acute, tail much longer than head; only globose SCBs present; bark of *Acacia*, subtropical semihumid western Australia .... ***O. austroocculta***, p. 733

16. Spores *(9.7–)10–12.5(–14) × 2.8–3.4 µm, head ellipsoid(-subfusoid), tail (2–)3–5.3(–6) µm long, shorter than head or only exceptionally slightly longer, basally uninflated; glassy processes 10–40 µm long; bark of *Ulex*, stems of *Rubus*, temperate humid, atlantic to subcontinental Europe .... ***O. breviaristata***, p. 724

A tropical humid eastern Australian collection on *Phragmites* deviates by shorter spores due to a shorter tail of 2.5–3.5 µm length (p. 725).

16. Spores min. *13–18 µm long, tail slightly to much longer than head, if shorter then basally inflated 17

17. Spore head 9–12.5 µm long, elongate-ellipsoid(-subfusoid), 3–4 × longer than wide; spores *(14–)16–26.5(–28.5) × (2.3–)2.6–3.3(–3.6) µm, tail base slightly to very strongly bulbous (*0.7–2.5 µm thick); apothecia with prominent teeth or nearly without; bark (& wood, rarely leaves) of gymno- & angiosperms, temperate to submediterranean (semi)humid Europe, subarctic to boreal humid Northern and subtropical semiarid Middle America .... ***O. flagellispora***, p. 695

17. Spore head 7–10 µm long, broadly ellipsoid(-subfusoid), 2–3 × longer than wide 18

18. Apothecial margin usually with prominent whitish teeth; spores *(16–)18.5–24.5(–27) × (2.5–)3–3.5(–3.8) µm, tail (10–)11–15(–16.5) µm long, base slightly to often distinctly inflated to *0.5–1.8 µm; bark (& wood) of various angio-, rarely gymnosperms, (sub)mediterranean semihumid to (oro)temperate humid, atlantic to subcontinental Europe, subtropical semiarid Macaronesia .... ***O. subaristata***, p. 719

18. Apothecial margin smooth or often with small, inconspicuous teeth; spores *(13–)14–22(–23) × (2.5–)2.7–3.3(–3.5) µm, tail (6–)8–12(–13) µm long, base not or only slightly inflated to *0.3–0.8 µm; bark (& wood) of various angio- & gymnosperms, boreal to submediterranean (sub)humid Europe, central Asia, western North America .... ***O. aristata***, p. 709

19. Spores *9–12.5 × 4.3–4.8 µm, tail much shorter than head; SBs 3–3.5 × 2–2.2 µm; margin with 20–30 µm long glassy processes; bark of *Eucalyptus*, warm-temperate humid eastern Australia .... ***O. megaocculta***, p. 727

19. Spores max. *3.8 µm wide; SBs max. 1.4 µm wide.......... 20

20. With small crystalloid SCBs in paraphyses and marginal excipulum; spores *(9–)11–14(–15) × 2.4–2.7 µm, SBs (3–)4–5(–5.5) µm long; wood of *Frangula*, temperate humid central Europe .... ***O. breviclava***, p. 689

20. Consistently without crystalloid SCBs 21

21. SBs 2–3 µm long 22

21. SBs 3–6 µm long 25

22. Margin with 4–30 µm long glassy processes; spores *9–12 × 2.3–2.6 µm; SBs 2.2–2.5 µm long; petioles of *Livistona*, subtropical subhumid eastern Australia .... ***O. parviclava***, p. 688

22. Margin without glassy processes 23

23. Spores (11–)12–17(–19) × (2.1–)2.3–2.8(–3.2) µm, western North America ....see ***O. navajoana* (series *Hesperideae*)**, p. 571

23. Spores *9–13 µm long.......... 24

24. Spores *9–12(–13) × 2.1–2.4 µm, with fusoid head; wood of *Melaleuca*, subtropical subhumid eastern Australia .... ***O.* aff. *parviclava*** (Pl. 318: 2)

24. Spores *10.5–13 × 2.4–3 µm, with cylindrical head; wood of *Larrea*, subtropical semiarid western North America .. ***O.* aff. *breviclava***, p. 690

25. Spores *11–14 µm long; margin without glassy processes .... compare ***O*. *breviclava*** (on *Frangula*), p. 689, and ***O*. cf. *subclavuliformis*** (on *Pinus*), p. 691
25. Spores *13–21 µm long 26

26. Spore tail always distinctly inflated at the base, spore head ellipsoid, *3.3–3.8 µm wide; SBs 3–4 µm long; glassy processes 20–70 µm long; bark & wood of *Salix*, orotemperate humid southwestern Europe .... ***O*. *asturiensis***, p. 686
26. Spore tail never inflated (or spores distinctly narrower); SBs 4–6 µm long 27

27. Spore head ellipsoid, *(2.5–)2.8–3.5(–3.7) µm wide; glassy processes always present, 3–5 up to 10–25(–40) µm long; wood & bark of gymno- & angiosperms, atlantic to continental, temperate to mesosubmediterranean (semi)humid Europe, hemiboreal to cold-temperate humid eastern & western North America .... ***O*. *clavuliformis***, p. 680
27. Spore head (sub)cylindrical, *2.2–2.7(–3) µm wide; glassy processes absent or up to 5(–7.5) µm long; wood & bark of gymno- & angiosperms, temperate humid to subtropical semihumid Europe, Macaronesia .... ***O*. *subclavuliformis***, p. 690

Key E (series *Hesperideae* & *Vibrioides* p.p., asci 8- or 16-spored)

1. Spores < 6 µm long, strongly cashew-shaped; asci 8-spored 2
1. Spores > 6 µm long 3

2. SBs filiform, 1.8–2.8 × 0.3–0.4 µm, turning tear-shaped only when overmature; spores *3.4–4.2(–4.7) × (1.4–)1.5–1.8(–1.9) µm; terminal cells of paraphyses 4–9.5 µm long; culms of *Phragmites* & *Ammophila*, temperate humid, atlantic to subcontinental Europe .... ***O*. *graminis***, p. 750
Collections on wood & bark of *Pinus sylvestris* from orosubmediterranean Europe differ in slightly larger spores of */†(3.8–)4.2–5.3(–5.8) × 1.5–1.8(–2.2) µm and slightly longer terminal cells of paraphyses (7.5–12 µm), p. 751.
2. SBs tear-shaped to globose, 1–2 × 0.7–1.3 µm; spores *(3.5–)3.8–5(–5.3) × (1.8–)2–2.5(–3.3); terminal cells of paraphyses 6–15 µm long; wood & bark of gymno- & angiosperms, orotemperate humid to subtropical semihumid Europe, Macaronesia, western North America .... ***O*. *vibrioides***, p. 747

3. Paraphyses spathulate to lageniform, firmly covered also laterally by a thin exudate; spores *(6.5–)8–11(–11.5) × (1.5–)1.6–1.8(–2) µm cylindric(-clavate); SBs ± ampulliform, 1.5–2.7 × 0.7–1 µm; marginal hairs 7–20 µm long, 0–1-septate, glassy processes absent; asci without apical thickening; wood of *Abies*, *Lonicera*, temperate to boreal (sub)humid western North America, central Asia .... ***O*. *concoloris***, p. 672
3. Paraphyses not spathulate-lageniform, usually loosely covered by thick cloddy exudate; asci with apical thickening 4

4. Spores often distinctly curved, without tail 5
4. Spores ± straight, sometimes with curved tail 8

5. Spore width < 2.3 µm; crystalloid SCBs present or absent; asci 8-spored; western Australia 6
5. Spore width > 2.7 µm; crystalloid SCBs present; asci 8–16-spored; Europe, America 7

6. Spores consistently strongly falcate, *(8–)10–13.5(–14.5) × (1.6–)1.8–2(–2.2) µm; SBs pear-shaped; crystalloid SCBs absent; bark of *Banksia*, subtropical semihumid .... ***O*. *curvatinavajoana*** (series *Hesperideae*), p. 575
6. Spores ± helicoid, *15–18 × 1.4–1.6(–1.7) µm; SBs ± subulate; crystalloid SCBs present; bark of *Acacia*, subtropical semiarid .... ***O*. *helicovinosa***, p. 630

7. Asci 16-spored; spores *(6–)6.5–8(–8.5) × 2.8–3.6 µm; SBs broadly tear-shaped, without filum; wood & bark of *Baccharis*, subtropical subhumid southeastern Northern America .... ***O*. *subcryptogena***, p. 665
7. Asci 8-spored; spores *11–18.7 × 3.5–5 µm; SBs rod-shaped, with short filum; bark of *Cercis* & *Ulmus*, southern & eastern Europe .... see ***O*. *cercidicola*** (section *Lentiformes*), p. 501

8. SBs ± globose, sometimes with a triangular upper part and/or a short filum .... see **section *Ovoideae* (subgenus *Orbilia*)**, compare also ***O*. *arizonensis*** (Pl. 213: 2)
8. SBs rod- to tear-shaped or ampulliform, min. 2 × as long as wide, without a filum .... (**series *Hesperideae***) 9

9. Asci 16-spored .... **key F**
9. Asci 8-spored 10

10. Spores min. *(2–)2.2–2.4 µm wide .... **key G**
10. Spores *1.3–2.2 µm wide .... **key H**

Key F (series *Hesperideae* p.p., asci 16-spored)

1. Spores *(11.5–)13–19(–21.5) × 1.6–2 µm; apothecial margin smooth, without glassy processes; wood of *Eucalyptus*, subtropical semiarid western Australia .... ***O*. *pleiovinosa***, p. 632
1. Spores min. *2–2.4 µm wide 2

2. Spores narrowly cylindrical to fusoid, *9.5–19 µm long, length/width ratio predominantly 4(–6) 3
2. Spores broadly (fusoid-)ellipsoid(-clavate), *6–13.5 µm long, length/width ratio 2–3 9

3. Without crystalloid SCBs; spores *(9.5–)11–14(–16) × (2–)2.2–2.6(–2.8) µm, base slightly to strongly attenuated; without glassy processes; wood of angiosperm shrubs, subtropical to temperate, semiarid to subhumid western North America .... ***O*. *pleionavajoana***, p. 573
3. With crystalloid SCBs 4

4. Spores *9.5–10.5 × 2–2.4 µm, SBs ?2 × 1 µm; *Larrea*, subtropical semiarid western North America .... ***O*. aff. *pleionavajoana***, p. 575
4. Spores *(10–)12–18.5 µm long 5

5. Spores *3–4(–4.5) µm wide 6
5. Spores *2–3(–3.2) µm wide 7

6. Spores with a distinct short tail-like base or tail; SBs 3–4.5 × 1–1.2 µm; wood of *Eucalyptus*, subtropical semiarid western Australia .... ***O*. aff. *pleioaustraliensis***, p. 562
6. Spores without a tail-like base; SBs ~2.5 × 1.5 µm; wood of *Parkinsonia*, subtropical semiarid western North America .... ***O*. aff. *megahesperidea***, p. 592

7. Margin with short glassy processes forming indistinct teeth; SBs 0.8–1 µm wide; spores *2–2.6 µm wide; wood & bark of *Acacia*, (sub) tropical arid western & central Australia .... ***O*. *pleiocoronohesperidea***, p. 586
7. Margin without glassy processes; SBs min. 1.2–1.3 µm wide 8

8. Spores *2.8–3(–3.2) µm wide; petioles of *Livistona*, subtropical subhumid eastern Australia .... ***O*. *pleiohesperidea***, p. 582
8. Spores *(2–)2.2–2.5(–2.6) µm wide; wood of *Acacia*, subtropical semiarid western Australia .... ***O*. aff. *pleiocoronohesperidea***, p. 588

9. Apothecia 0.2–0.8 mm diam., 0.13–0.3 mm high; spores *(7.5–)9–12(–13.5) × (2.7–)3.2–4.2(–4.7) µm; SBs 2.5–4.5 µm long; wood & bark of angiosperms, subtropical sub- and semihumid to arid Australia .... ***O*. *pleioaustraliensis***, p. 560
9. Apothecia 0.07–0.35 mm diam., 0.06–0.1 mm high; spores *(6–)7–9(–10.2) × (2.3–)2.5–3.5(–4) µm; SBs 2–3 µm long; culms of *Juncus roemerianus*, temperate humid eastern North America .... ***O*. *junci*** (?series *Vibrioides*), p. 766

Key G (series *Hesperideae*, asci 8-spored, spores predominantly > *(2–)2.2 µm wide)

1. With crystalloid SCBs (sometimes only in marginal excipulum) 2
1. Without crystalloid SCBs 10

2. Spores *(2.7–)3–4(–4.3) µm wide; SBs (0.9–)1.2–2(–2.3) µm wide; without glassy processes 3
2. Spores *(2–)2.3–3(–3.3) µm wide; SBs 0.6–1.5 µm wide; sometimes with glassy processes 6

3. Spores *(6.2–)7–9(–11) × (4–)4.5–5.5(–6) µm, broadly ellipsoid to ovoid; SBs tear- to pear-shaped, 3–5.5 × 1.7–2.3 µm; wood (& bark) of angio- & gymnosperms, temperate humid to semiarid western North America .... ***O*. *arizonensis***, p. 553
A sample from eastern North America on wood of *Carya* mentioned under *O. eremaeae* (section *Ovoideae*) has similar spores but almost globose SBs (p. 1286).
3. Spores predominantly > 9 µm long and < 4.5 µm wide 4

4. Spores *(8–)9–14(–16) × (2.5–)2.7–4(–4.3) µm, narrowly to broadly ellipsoid-fusoid; SBs 2.5–5.5 × 1–1.8 µm; wood & bark of various angiosperms, (sub)tropical semihumid to arid western & central Australia .... ***O*. *australiensis***, p. 556
4. Spores predominantly > 14 µm long, cylindric-clavate 5

5. Spores *(11.2–)14–17(–19.5) × (2.7–)3–3.5(–4) µm; SBs *4–5.8 × 1.3–2.3 µm; bark of *Ephedra*; subtropical semiarid western North America .... ***O*. *macrohesperidea***, p. 590
5. Spores *(14.5–)16–20(–21) × 3.4–4.4 µm; SBs 3–4 × 1.7–2 µm; bark of *Pittosporum*, temperate subhumid eastern Australia .... ***O*. *megahesperidea***, p. 591

6. With 3–40 µm glassy processes; spores *(12–)14–18(–19) µm long 7
6. Without glassy processes; spores *(7.5–)9–27(–30) µm long 8

7. Spores *(2–)2.3–3 µm wide; wood & bark of *Acacia*, petioles of *Livistona*, (sub)tropical sub- and semihumid to arid Australia .... ***O*. *coronohesperidea***, p. 583
7. Spores *(1.8–)2–2.4(–2.7) µm wide; Europe & North America .... see under 9 (*O. angiosubvinosa*)

8. Spores *(13–)18–27(–30) × 2–2.7(–3) µm; SBs 2.5–3.8 µm long; bark of *Adenocarpus*, supramediterranean semihumid Macaronesia .... ***O*. *adenocarpi***, p. 674
8. Spores max. 18–19 µm long; SBs partly longer than 4 µm 9

9. Spores *(7.5–)9–15(–18) × (1.9–)2.2–3(–3.3) µm; SBs 2.5–5 µm long; wood & bark of gymno- & angiosperms, warm-temperate to thermo-mediterranean humid to semiarid southern Europe, Macaronesia, Australia, western & southern North America .... ***O*. *hesperidea***, p. 576
Spore shape varies between cylindric-clavate and fusoid. If the spores are fusoid and > 2.7 µm wide compare *O. australiensis* (p. 556). Two collections on *Larrea* mentioned under *O. navajoana* (p. 572) deviate from *O. hesperidea* by < 3 µm long SBs.
9. Spores *(12.5–)14–17(–19) × (1.8–)2–2.4(–2.7) µm; SBs (2.7–)3.5–5.5(–7) µm long; wood of angiosperms, submediterranean (semi) humid Europe, mild-maritime humid western North America .... ***O*. *angiosubvinosa***, p. 620

10. SBs 4.5–5.5 µm long; spores *2.4–3.5 µm wide 11
10. SBs (1.8–)2.2–4(–4.7) µm long; spores *2–3 µm wide 12

11. Spores *13–15.5 × 2.4–2.9 µm, fusoid-clavate; glassy processes absent; wood of *Acacia*, tropical subhumid northern Australia .... ***O*. cf. *hesperidea***, p. 578
11. Spores *(13–)15–19(–21.5) × (2.7–)3–3.5(–3.7) µm, clavate with basal tail; glassy processes present; wood & bark of gymno- & angiosperms, temperate to submediterranean (semi)humid Europe, hemiboreal North America .... ***O*. *clavuliformis*** (series *Hemiorbilia*), p. 680

12. Spores *(6–)7–9(–9.8) × 2.1–2.5 µm; SBs (1.8–)2.3–2.8(–3.2) µm long; glassy processes 20–80 µm long; bark of *Eucalyptus*, *Polylepis*, subtropical (sub)humid montane South America .... ***O*. *colombiana*** (series *Hemiorbilia*), p. 679
12. Spores predominantly over 9 µm long; without glassy processes 13

13. Spores *(11–)12–17(–19) × (2.1–)2.3–2.8(–3.2) µm; SBs 2–2.8(–3) µm long; wood of angiosperms, cold-temperate to boreal (sub) humid western North America .... ***O*. *navajoana***, p. 571

13. Spores *(7.5–)9–13(–14) × (2–)2.2–2.7(–3) µm; SBs (2–)2.3–4(–4.7) µm long; boreal to mediterranean Europe 14

14. SBs (2–)2.3–3.2(–3.5) µm long; wood of gymnosperms, orotemperate to orosubmediterranean humid .... ***O. alpigena***, p. 595
14. SBs (2.5–)3–4(–4.7) µm long; wood of angiosperms 15

15. Spores *(2–)2.2–2.7(–3) µm wide, SBs 0.8–1.3 µm wide, boreal humid to mesomediterranean semihumid .... ***O. montigena***, p. 592
15. Spores *1.8–2.4 µm wide, SBs 0.5–0.7(–1.1) µm wide, orotemperate humid .... ***O. paramontigena***, p. 599

Key H (series *Hesperideae*, asci 8-spored, spores predominantly < *2.2 µm wide)

1. Glassy processes 40–200 µm long, forming distinct teeth at the margin; spores *(10.5–)12–14.5(–15.5) × (1.5–)1.6–1.8 µm; SBs 4–6 × 0.3–0.5 µm; bark & wood of *Proteaceae*, inflorescence stem of *Xanthorrhoea*, subtropical semihumid southwestern Australia .... ***Orbilia astrovinosa***, p. 629
1. Glassy processes absent or max. 20(–40) µm long, margin smooth to distinctly crenulate 2

2. Spores *6.5–12(–13) µm long; SBs (1.3–)1.5–3(–4) µm long 3
2. Spores *(10–)11–23(–30) µm long; SBs (2–)3–5(–6.5) µm long 9
If measurements intermediate see *O. hesperidea* (with crystalloid SCBs, p. 576) and *O. paramontigena* (without crystalloid SCBs, p. 599).

3. Glassy processes 10–40 µm long, margin with distinct whitish teeth; spores *(8.7–)9.5–12(–13) × (1.3–)1.4–1.6 µm; SBs 1.8–2.2 × 0.5–0.8 µm; excipular cells with small crystalloid SCBs; wood of *Pinus*, orotemperate humid subcontinental Europe .... ***O. crenatovinosa***, p. 643
3. Glassy processes absent or max. 12 µm long, margin therefore smooth or only finely crenulate 4

4. SBs 1.4–2.2(–2.5) µm long 5
4. SBs 2–3(–4) µm long 7

5. Spores ± cylindrical, *9–11.2 × 1.7–2 µm; paraphysis tips very slightly spathulate-lageniform, firmly covered also laterally by thin (0.2 µm) exudate; glassy processes absent; *Picea* wood, temperate humid subcontinental Europe .... ***Orbilia* aff. *concoloris***, p. 673
5. Spores fusoid-clavate; paraphysis tips uninflated or slightly clavate, loosely covered by (0.3–)0.5–2 µm thick cloddy-granular exudate.... 6

6. Spores *(6–)6.5–9.5(–10.5) × 1.5–2.2 µm; often with 1–10 µm long glassy processes; conidia trinacrium-like; bark & wood of angiosperms (rarely gymnosperms), atlantic to continental, temperate humid to mesomediterranean semihumid Europe .... ***O. aprilis***, p. 645
6. Spores *7.5–11 × 1.4–1.7 µm; without glassy processes; conidia vermispora-like; wood of angiosperms, warm-temperate to subtropical humid eastern North America .... ***O. georgiana***, p. 642

7. Excipular cells with globose and crystalloid SCBs; glassy processes 2–5 µm long; spores *8–11 × 1.7–1.9 µm; SBs 2–3 × 0.3–0.5 µm; wood of *Acacia*, tropical (sub)humid eastern Australia .... ***O. nothoaprilis***, p. 640
A similar collection from northeastern Australia (wood & bark of indet. angiosperm, Pl. 284: 2) differs in the slightly longer and narrower spores (*10–12 × 1.6–1.7 µm) and longer SBs (3–4 × 0.4–0.5 µm).
7. Excipular cells with only globose SCBs; glassy processes absent; SBs 0.5–0.7 µm wide 8

8. Spores *9–10 × 2–2.2 µm; SBs 2.3–3 µm long; herbaceous stems of *Anigozanthos*, subtropical semihumid western Australia .... ***O.* aff. *nothoaprilis***, p. 642
8. Spores *10–13 × 1.8–2.4 µm; SBs 3.5–4.5 µm long; wood of *Acer*, orotemperate humid southern Europe .... ***O. paramontigena***, p. 599

9. Spores *(14–)16–22(–30) × 1–1.3 µm; crystalloid SCBs present; wood of *Erica*, mediterranean semi- to subhumid Macaronesia .... ***O.* cf. *subulivinosa*** (Pl. 278), p. 634
9. Spores distinctly wider (min. *1.3–1.7 µm) 10

10. Spores *11–17 × 1.3–1.7 µm; SBs 2–4.2 µm long; asci *4–6.5 µm wide 11
10. Spores *10–22 × (1.3–)1.6–2.2 µm; SBs (3–)4–6(–7) µm long; asci *4.8–7 µm wide 12

11. Asci *5.5–6.5 µm wide; margin without glassy processes; wood of *Arctostaphylos patula*, cold-temperate subhumid western North America .... ***O.* cf. *vinosa*** (Pl. 259: 4)
11. Asci *4–4.5 µm wide; margin with distinct glassy processes; bark of *Pinus strobus*, cold-temperate humid eastern North America .... ***O.* cf. *vinosa*** (Pl. 259: 5)

12. Ascus apical dome immature †(1.8–)2–2.5(–3.5) µm thick; SCBs globose; wood & bark of angiosperms, subtropical semihumid to humid western and eastern Australia .... ***O. nothovinosa***, p. 627
12. Ascus apical dome immature †(0.8–)1–1.5(–2) µm thick 13

13. Ascospores *(15–)18–22.5(–25) × (1.3–)1.5–1.9(–2) µm; SCBs globose; wood & bark of *Erica*, mesomediterranean semihumid southern Europe .... ***O. subulivinosa***, p. 634
13. Ascospores *(10–)12–19(–22) × (1.6–)1.8–2.2(–2.7) µm; SCBs globose but often also crystalloid (small) 14

14. Conidia triradiate (2-armed, trinacrium-like); ascospores *(10–)11.5–18(–19) µm long, often < *2 µm wide; apothecia with a smooth or only very finely crenulate margin, pale to bright rose or orange; wood & bark of gymno- & angiosperms, boreal to mediterranean, humid to semiarid Europe, western Asia, Macaronesia, Africa, North America .... ***O. vinosa***, p. 599
14. Conidia twice dichotomously branched (4-armed, dwayaangam-like); ascospores *(12–)14–20(–22) µm long, often > *2 µm wide; apothecia often with a distinctly crenulate margin, usually bright orange(-red), rarely rosaceous 15

15. Conidia (presumed) with outwards curved arms; wood (rarely bark) of angiosperms, boreal to orotemperate or orosubmediterranean humid Europe .... ***O. arachnovinosa***, p. 622
15. Conidia with straight, parallel or diverging arms 16

16. Conidia *10.5–12.5(–13.5) µm wide in central part, at ends (13–)17–30(–36) µm wide when arms diverging; arms mainly *3.3–4.5 µm wide; wood of gymnosperms, (orotemperate to) orosub- (to suprasub-)mediterranean humid southern Europe ..... ***O. subvinosa***, p. 616

16. Conidia *10–11 µm wide in central part, at ends 12–21 µm wide when arms diverging; arms mainly *3–3.5 µm wide; wood of angiosperms, orosub- to suprasubmediterranean (semi)humid southern Europe .... ***O. angiosubvinosa***, p. 620

Series *Hesperideae*

Orbilia subgenus ***Hemiorbilia*** section ***Hemiorbilia*** series ***Hesperideae*** Baral & E. Weber, **ser**. **nov**., MB 815005 – Type species: *Orbilia hesperidea* Rolland

Etymology: named after the type species, *O. hesperidea*.

Latin diagnosis: *Apothecia (luteo-)aurantiaca vel aurantio-rosea, margine laevi vel ± dentato. Asci 8- ad 128-spori, apice in statu emortuo hemisphaerico, leniter ad modice crassitunicato. Ascosporae *(5–)6–25(–30) × (1–)1.5–4.5(–6) µm, subcylindricae ad fusoideo-clavatae vel ellipsoideae ad obovoideae, etiam semicirculares vel forma corculi, apice rotundato ad subacuto, raro acuto vel acuminato, rectae vel curvatae, in statu vivo corpusculum refringens lacrimi- ad ampulliformem vel bacilliformem ad subulatum continentes. Paraphyses ad apicem haud inflatae vel leniter ad modice (raro valde) clavato-capitatae. Habitat ad lignum vel corticem putridum ramorum gymno- vel angiospermarum, in aere prominentium, raro ad folios vel caules herbarum, in zona boreale ad tropica, humida ad arida.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–1(–1.3)((–1.5)) mm diam., light to bright orange to brick-red, also yellow-orange, orange-rose, or rose(-lilaceous), margin smooth to finely rough or crenulate, also whitish pubescent or with whitish teeth or hairs, sessile or with a short stipe. **Asci** *(35–)40–110(–135) × (4–)5–12(–16) µm, 8- up to 128-spored, lower spores inverted (1/4–3/4 of spores, strongly mixed if polysporous), rarely only 0–1 spores inverted; **apex** (†) hemispherical to slightly (rarely medium) truncate, with 0.4–1 or usually 0.7–2.5(–3.5) µm thick dome (but thin-walled in *O. concoloris*), often with distinct apical chamber; **base** L-, T-, Y- or h-shaped. **Ascospores** *(5–)6–25(–30) × (1–)1.5–4.5(–6) µm, cylindric- to fusoid-clavate or ellipsoid-fusoid to obovoid, falcate to comma- or cashew-shaped, heart-shaped, apex rounded to subacute (mostly obtuse), rarely acute to acuminate, partially with a tail-like base or sometimes distinct tail 3–5 × as long as wide, straight to slightly (rarely medium to strongly) curved, especially towards base; **SBs** mostly affixed to apical, rarely subapical or lateral spore wall, (1–)2–5.5(–6.5) × (0.2–)0.5–1.8(–2.5) µm, rod-shaped to vermiform or subulate, globose, tear- or pear-shaped to ampulliform, straight (rarely slightly flexuous), apically narrowed to a small or wide point, rarely with a very short filum. **Paraphyses** uninflated or slightly to medium (exceptionally strongly) clavate-capitate at the apex, rarely lageniform, terminal cells 0.5–1.5(–2)× as long as lower cells. **Ectal excipulum** cells near base *(5–)8–18(–30) × (4–)6–15(–20) µm, near margin of t. angularis to t. prismatica or t. porrecta, outer part oriented at a high to often medium or low angle, with or without 1–40 or rarely 30–150(–200) µm long **glassy processes**, rarely with up to 95 µm long septate **hairs**. **SCBs** globose or mixed with crystalloid ones. **Exudate** (0.1–)0.5–4(–10) µm thick, continuous to cloddy or granular, loosely attached, hyaline to bright yellow, rarely absent. — **ANAMORPH**: trinacrium-like, also dwayaangam- or vermispora-like. **Conidiophores** short (~1.5–30 µm). **Conidiogenous cells** monoblastic or sympodial. **Conidia** *12–22.5 × 2.5–3.2 or mostly *25–59 × 3.3–6.2 µm when phragmosporous, 3–9-septate, straight or curved in upper part; *14–55 × 12.5–75(–92) µm when trinacrium-like (2-armed), arms straight or somewhat curved downwards; *20–65 × 10.5–77 µm when dwayaangam-like (4-armed), arms straight or outwards curved.

Habitat: on wood and bark of angio- and gymnosperms, sometimes palm petioles or herbaceous stems and leaves, from boreal to tropical, humid to arid climates.

Recognized species: 47, plus 12 unnamed species (‘affinis’).

Taxonomic remarks. Series *Hesperideae* is characterized by ascospores which typically lack a distinct basal tail. Many of the included species are polysporous and only here some species possess distinct spore tails. Distinct, often pale reddish crystalloid SCBs are often present, but various species are without them. Glassy processes are usually absent but in some species they are short, and in two (*O. multicurvula*, *O. astrovinosa*) very long. *O. velutina* is extraordinary in having long hairs with a septate lumen. The exudate over the paraphyses and marginal cells is usually rather thick, externally rough, often ± yellow, but especially in *O. macrohesperidea*, *O.* aff. *macrocarpa*, *O. myriohesperidea* and *O. myrioaustraliensis* it is thin or even absent. *O. curvatinavajoana* deviates from the remaining species by asci with only 1–3 inverted lower spores.

The ascospores vary from narrowly or broadly ellipsoid- to cylindric-fusoid or fusoid-clavate. In some species the spores inconsistently or rather regularly possess a distinct short tail but, in contrast to series *Hemiorbilia*, all of these species are multispored and lack glassy processes. For instance, *O. multiaustraliensis* and *O. myrioaustraliensis* resemble taxa such as *O. breviaristata* or *O. megaocculta* in spore shape, while *O.* aff. *macrocarpa* and *O. myriohesperidea* resemble *O. parviclava* or *O. subclavuliformis*.

The longest spores of up to 30 µm were noted in *O.* cf. *subulivinosa* (Pl. 278) and *O. adenocarpi*, the former showing also the narrowest spores (1–1.3 µm), while in *O. velutina*, *O. myriomuscula*, and *O. corculispora* the spores are the shortest (~6–7.5 µm). *O. arizonensis* possesses about the widest spores (4–6 µm) and SBs (1.3–2.5 µm), and that even when considering the whole genus *Orbilia*. Some species are extraordinary in their consistently (*O. curvatinavajoana*, *O. multicurvula*, *O. cryptogena*, *O. subcryptogena*) or partially (*O. myriofusiclava*) strongly curved, falcate or cashew-shaped spores, and one has helicoid spores (*O. helicovinosa*). The spores of *O. myriomuscula* resemble mice with thin curved tails, while *O. corculispora* and *O. octocorculispora* possess triangular to heart-shaped spores in which the SBs are laterally inserted. A lateral insertion of SBs is also characteristic of the clavate spores of *O. myrioauris*.

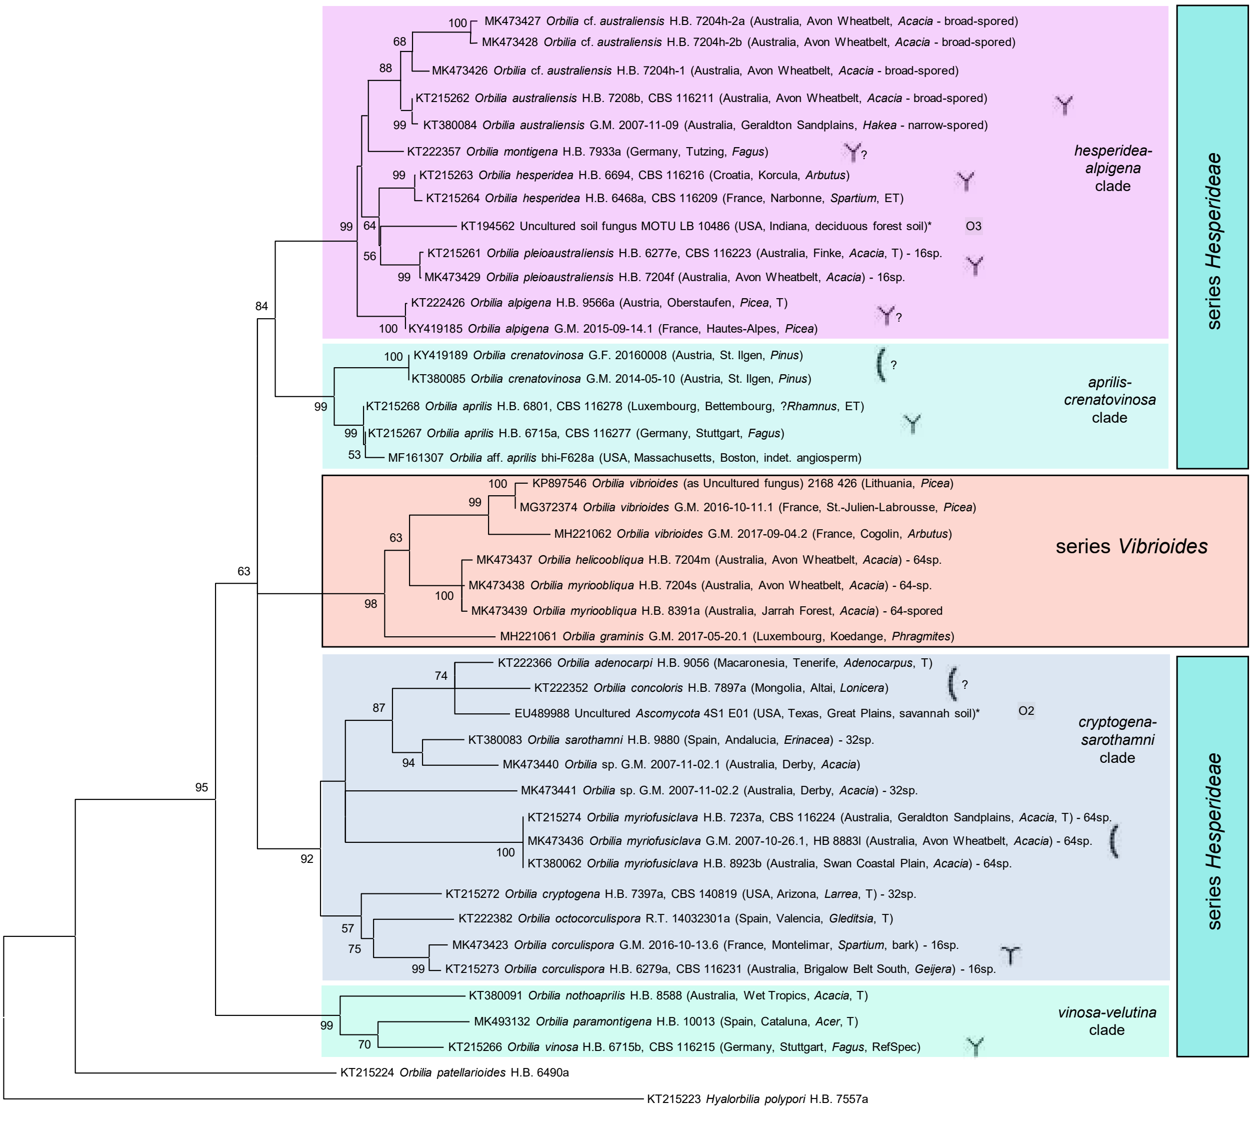
Species delimitation. Various aggregates exist in series *Hesperideae*, in which the limits between the species were difficult to assess. For instance, a rather high variation in ascospore size was noted in *O. australiensis* and the similar *O. hesperidea*, with some intermediate collections that were difficult to assign. In the *O. vinosa* aggregate, differently shaped conidia, being sometimes found on the natural substrate, provide the main morphological character to distinguish *O. vinosa*, *O. subvinosa*, and *O. arachnovinosa*, and their absence in many of the collections made a determination almost impossible.

Anamorph. In about a dozen species of series *Hesperideae* trinacrium-like anamorphs were observed, either in pure culture or on the natural substrate. Many of them resemble *Trinacrium robustum*, a species characterized by distinctly tapered conidial arms, whereas in *O. aprilis* (anamorph *T. tothii*), *O. vinosa* and *O. velutina* the arms often taper only slightly or not at all. Evident differences in conidial size and shape could not be found among those taxa with tapered arms, apart from how strongly the arms are narrowed towards their ends. In the absence of molecular data, the type of *T. robustum* cannot unequivocally be connected to a teleomorph.

Trinacrium-like conidia with arms curved downwards as in *T. incurvum* are connected to *O. corculispora*. Dwayaangam-like anamorphs were confirmed for *O. subvinosa* and possibly also occur in *O. angiosubvinosa* and *O. arachnovinosa*. *O. myriofusiclava*, *O. georgiana*, and possibly also *O. crenatovinosa* and *O. concoloris* are extraordinary in producing vermispora-like conidia.

Phylogeny. Series *Hesperideae* is circumscribed here in a wide sense, based predominantly on morphological criteria, since molecular data were absent in about 30 of the included ~60 taxa, and correlations between morphology and DNA data were not observed in various cases. Our phylogenetic analyses of ITS+LSU, ITS, or LSU (Phyls 9, 10, S13) provide evidence for a core group of series *Hesperideae* with high bootstrap support, here called *hesperidea-alpigena* clade, representing *O. australiensis*, *O. pleioaustraliensis*, *O. hesperidea*, *O. alpigena*, and *O. montigena*. Another strongly supported clade is formed by *O. angiosubvinosa*, *O. georgiana*, *O. multicurvula*, *O. nothoaprilis*, *O. paramontigena*, *O. subulivinosa*, *O. subvinosa*, *O. velutina*, and *O. vinosa*, here called *vinosa-velutina* clade, in which, however, also *O.* cf. *angustoaristata* of series *Hemiorbilia* clustered (Phyls 9, S13). Although *O. aprilis* and *O. crenatovinosa* are morphologically very similar to *O. nothoaprilis* and species around *O. vinosa*, they form a remote clade of their own (*aprilis-crenatovinosa* clade) which did not cluster with the *vinosa-velutina* clade in our analyses, except for the combined tree in Baral et al. (2017b), where they formed a weakly supported clade, or in our LSU analysis (S13), where they clustered unsupported. Instead, the *aprilis-crenatovinosa* clade clustered medium supported with the *hesperidea-alpigena* clade when analysing ITS (Phyl. 10).

Species of the *vinosa-velutina* clade are characterized by rather long and narrow, cylindrical to fusoid, partially clavate spores (except for *O.* cf. *angustoaristata* with a thin spore tail and *O. velutina* with very short spores), but some species intergrade with taxa of the *hesperidea-alpigena* clade in having wider spores, and also with the *aprilis-crenatovinosa*- clade which has rather short and narrow spores. The high molecular distance between the *vinosa-velutina* clade and the *aprilis-crenatovinosa* clade is



Phylogenetic analysis 10. Phylogram of series *Hesperideae* and *Vibrioides* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (43 sequences, 669 positions, aligned with MUSCLE, a short intron in the ITS1 of G.M. 2007-11-02.2 was deleted) using the TN+G+I model in MEGA6 (500 replicates). For a detailed tree of the *vinosa-velutina* clade see Phyl. 11. 3 environmental strains from GenBank are included, 2 of them representing unidentified species (O2, O3). The tree is rooted with *Hyalorbilia polypori* and *O. patellarioides*. Asci 8-spored except when otherwise stated; RefSpec = reference specimen, T = type, ET = epitype, * = without ITS1 and partial 5.8S.

surprising since the included species closely concur in both their anamorphs and teleomorphs. Because of this morphological resemblance and the lack of a sharp limit between these three clades, we refrained from recognizing different series for them.

Also the *cryptogena-sarothamni* clade received strong support only when analysing ITS (Phyl. 11). It is divided in our combined analysis into two medium supported subclades (Phyl. 9): *O. corculispora*, *O. octocorculispora*, and *O. cryptogena* clustered in one subclade, and *O. adenocarpi*, *O. concoloris*, *O. myriofusiclava*, and *O. sarothamni* in another subclade. The latter subclade is morphologically heterogeneous, since *O. adenocarpi* resembles *O. vinosa*, *O. concoloris* can easily be mistaken as a member of series *Regales* (section *Aurantiorubrae*), and *O. myriofusiclava* and *O. sarothamni* are reminiscent of *O. multiaustraliensis*. The latter species is without DNA data but is thought to be a close relative of *O. australiensis* and *O. pleioaustraliensis* which cluster in the *hesperidea-alpigena* clade.

In several clades of series *Hesperideae*, straight and curved ascospores occur mixed, indicating that spore curvature is of minor taxonomic importance above the species level. On the other hand, the similarity in ascospore shape between the 8-spored *O. vibrioides* and *O. graminis* (series *Vibrioides*) is correlated with similar molecular data, and also the similar spores of the 64-spored *O. curvatiobliqua* indirectly supports this correlation by sequences of two other species of this group with multispored asci but differently shaped spores. On the other hand, the 32-spored *O. cryptogena* has similar but larger spores and clustered in another clade. We assume that, based on a comparable spore morphology, two species without molecular data would cluster with their morphological siblings: the 16-spored *O. subcryptogena* with cashew-shaped spores and tear-shaped SBs with *O. cryptogena*, and the 64-spored *O. myrioauris* near the 16-spored *O. corculispora* because of its partially laterally inserted SBs.

Specific nucleotide positions. A remarkable symmetric pair of nucleotides is found in the SSU V8–V9 (pos. 154 & 166) which separates *O. australiensis*, *O. pleioaustraliensis*, *O. alpigena*, *O. cryptogena*, and *O. corculispora*, which cluster in two different clades (Phyl. 9), by **G**AGTCATCAGCT**C**, a motif being also characteristic of section *Habrostictis*, from all remaining sequences within section *Hemiorbilia* (including *O. hesperidea* and *O. myriofusiclava*) which have **A**AGTCATCAGCT**T** in concordance with any other member of *Orbiliomycetes* with available SSU data. In stem-loop B8 of 5.8S (pos. 121–134), the *vinosa-velutina* clade has **CTC**GGTATTCCG**GC** (in *O. subulivinosa* **TCC**GGTATTCCG**GC**) in contrast to the remaining taxa of section *Hemiorbilia* which mainly have **ATT**GGTATTCCG**AT** (in *O. sarothamni* **ACT**GGTATTCCG**GT**) (Tab. 18).

At pos. 1–4 of ITS2 (downstream of GAGCGTC), the general motif in section *Hemiorbilia* is ATTA (including series *Vibrioides* except for *O. graminis* which has ATCA), but the *O. cryptogena-sarothamni* clade has consistently ATTG (except for the uncultured strain 4S1 E01 which has ATTA). The motif ATTG also occurs in the entire section *Ovoideae* and some members of section *Orbilia*, but is not found in other *Orbiliomycetes* (Tab. 20). In the ITS alignment of series *Hesperideae*, the *cryptogena-sarothamni* clade is easily distinguished from other clades of this series and also from the entire section *Hemiorbilia* by showing a large gap at pos. ~18–32 of ITS2 (other taxa have here 10–19 additional nucleotides). This large gap is also shared by two unidentified and undocumented Australian collections on *Acacia aneura* (2.XI.2007), one with 8-spored asci (G.M. 2007-11-02.1) clustering strongly supported with *O. sarothamni*, and that with 32-spored asci (?*O. multiaustraliensis* or *O. macrocarpa*, G.M. 2007-11-02.2) unresolved in series *Hesperideae* (shown only in Phyl 10). The gap region occurs, however, also in some other groups, particularly section *Arthrobotrys*.

In the LSU D1–D3, several positions are characteristic for the *vinosa-velutina* clade (including *O.* cf. *angustoaristata*) vs. all remaining members of section *Hemiorbilia* and a majority or almost all other *Orbilia* spp.: pos. 105 is GCAA**G**AGCT vs. GCAA**C**AGCT, pos. 306 and 317 **G**TTTCATCTAA**G** vs. **A**TTTCATCTAA**A**, pos. 670 A**C**GCGAG vs. A**T**GCGAG, and pos. 726 is TGGGAG**C** vs. TGGGAG**T** (TGGGAG**C** also occurs in *O. crenatofalcata* and the entire section *Orbilia*).

The strongly supported *vinosa-subvinosa* subclade is recognizable in the LSU D2 (alignment of Phyl. S13) at pos. 439 and 489: AGACT**C**GC and GC**G**GGCCA vs. AGACT**T**GC and GC**A**GGCCA in other strains of section *Hemiorbilia*, besides some other positions. This subclade is also recognizable at pos. 76 of ITS1 and pos. 388 of ITS2 (alignment of Phyl. 11): GTGG**T** and TCGGY**C** vs. GTGR**A** and TCGGY**T** in the remaining taxa of the *vinosa-velutina* clade.

Ecology. Many species of series *Hesperideae* occur in subtropical to tropical, subhumid to arid regions, but many others were mainly collected in temperate to boreal-subalpine, humid regions. The apothecia grew on wood and bark of xeric branches and trunks of gymno- and angiosperm trees and shrubs. Some species occurred also on more or less herbaceous substrates: petioles of *Livistona* (*Orbilia australiensis*, *O. coronohesperidea*, *O. palmicola*, *O. parviclava*, *O. pleiohesperidea*), inflorescence stems of *Xanthorrhoea* (*O. astrovinosa*), stems of *Melilotus* (*O.* cf. *vinosa*), and stems of *Anigozanthos* and *Bambusa* (*O.* aff. *nothoaprilis*). Species of series *Hesperideae* occur worldwide. At present they were recorded in Europe, North America, Africa, Asia, and Australia.

Orbilia arizonensis Baral & G. Marson, **sp. nov.**, MB 813529 — Pls 213–214, Map 37

Etymology: named after the geographical origin of the first record, Arizona.
Typification: USA, Arizona, Montezuma Castle, branch of *Canotia holacantha*, 12.VI.2000, G. Marson (ex H.B. 7218a, M-0276434, holotype).

Latin diagnosis: *Apothecia 0.3–1.5 mm diam., sessilia, erumpentia, vivide aurantiaca vel lateritia, margine albido-pulverulenta vel irregulariter crenulata. Asci 8-spori. Ascosporae *6.2–11 × 4–6 µm, obovoideae, in statu vivo corpusculum refringens magnum lacrimi- vel saepe pyriformem, ad apicem affixum continentes. Cellulae vivae excipuli et paraphysium corpuscula crystalloidea continentes, excipulum marginale absque processis vitreis. Habitat ad corticem, raro lignum putridum ramorum siccorum fruticum angiospermarum vel arborum coniferarum in zona temperata humida ad semiarida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.9(–1.5) mm diam., 0.17–0.3 mm thick, light to deep pure or dirty orange to brick-red(-brownish), round to irregular elongate, scattered to (sub) gregarious; disc young concave, then flat, margin ± thick, 0–20 µm rising above disc, smooth, exterior whitish-powdered or irregularly crenulate; broadly sessile, slightly to strongly erumpent. **Asci** *78–97(–102) × 7.3–8.7 µm {2}, †(60–)65–90(–95) × 6.5–8(–8.7) µm {5}, 8-spored, spores (*) subbiseriate († uniseriate), (1–)3–5(–6) lower spores inversely oriented {3} (often mixed), pars sporifera *37–48 µm long; **apex** (†) hemispherical to slightly truncate, dome †0.9–1.5(–2) → (0.4–)0.8–1.2 µm thick {4}, with distinct apical chamber; **base**

with short to long, ± thick, flexuous stalk, Y-shaped or unbranched. **Ascospores** *(6.2–)7–9(–11)((–12)) × (4–)4.5–5.5(–6) µm {7}, †6.5–9.5(–10.5) × (3.3–)4.4–5 µm {2}, obovoid, apex rounded or obtuse, base slightly to strongly attenuated, rarely tail-like, straight to slightly inequilateral, rarely very slightly curved at base; **SBs** *3–5(–5.5) × (1.3–)1.7–2.3(–2.5) µm {4}, tear- to often pear-shaped, straight, apically narrowed to a small to wide point, overmature *2.5–3 × 2.5–2.7 µm. **Paraphyses** apically uninflated to slightly clavate-capitate, terminal cells *8–15(–20) × 2–3.2 µm {2}, †~6–16 × 1.7–2.8 µm {2}, lower cells *(8–)9.5–15.5(–18) × 1.5–2.2(–2.7) µm {2}, †~10–20 × 1.2–1.7 µm {1}; sometimes to frequently branched and often flexuous near apex {6}. **Medullary excipulum** pale rose, 20–85 µm thick, of medium loose to dense horizontal textura intricata-porrecta, with scattered to many inflated cells, sharply delimited. **Ectal excipulum** hyaline to very pale rose-orange, of slightly to medium gelatinized, vertically oriented t. angularis(-prismatica) from base to mid flanks, (30–)60–120 µm thick near base, cells */†(7–)10–19(–25) × 6–13 µm {3}; near margin (10–)20–40 µm thick (excl. covering hyphae), of t. prismatica oriented at 10–20°, marginal cortical cells */†(5–)7–10(–12) × 2.8–5(–6) µm {3}, running out into hyphae conglutinate by exudate, partially forming distinct irregular teeth, **glassy processes** absent. **Anchoring hyphae** sparse to very abundant, †1.5–3 µm wide, walls 0.2–0.4(–1) µm thick {3}, forming a covering layer on the flanks and margin of the ectal excipulum. **SCBs** in paraphyses and ectal excipulum crystalloid, subhyaline to pale orange, (1.5–)2–5(–6) × (0.5–)1–4(–5) µm, at margin and in paraphyses also globose. **Exudate** over paraphyses (0.2–)1–2(–3) µm thick, continuous to cloddy, ± loosely attached, disappearing in old apothecia; abundant also over margin. **— ANAMORPH**: trinacrium-like (presumed, from natural substrate {1}). **Conidiophores** not seen. **Conidia** Y-shaped, total size †26–33 × 24–35 µm, stipe †13–20 × 5–6 µm, 2–4-septate, arms tapering, †15–16 × 5.5–6.5 µm, (2–)3-septate {1}.

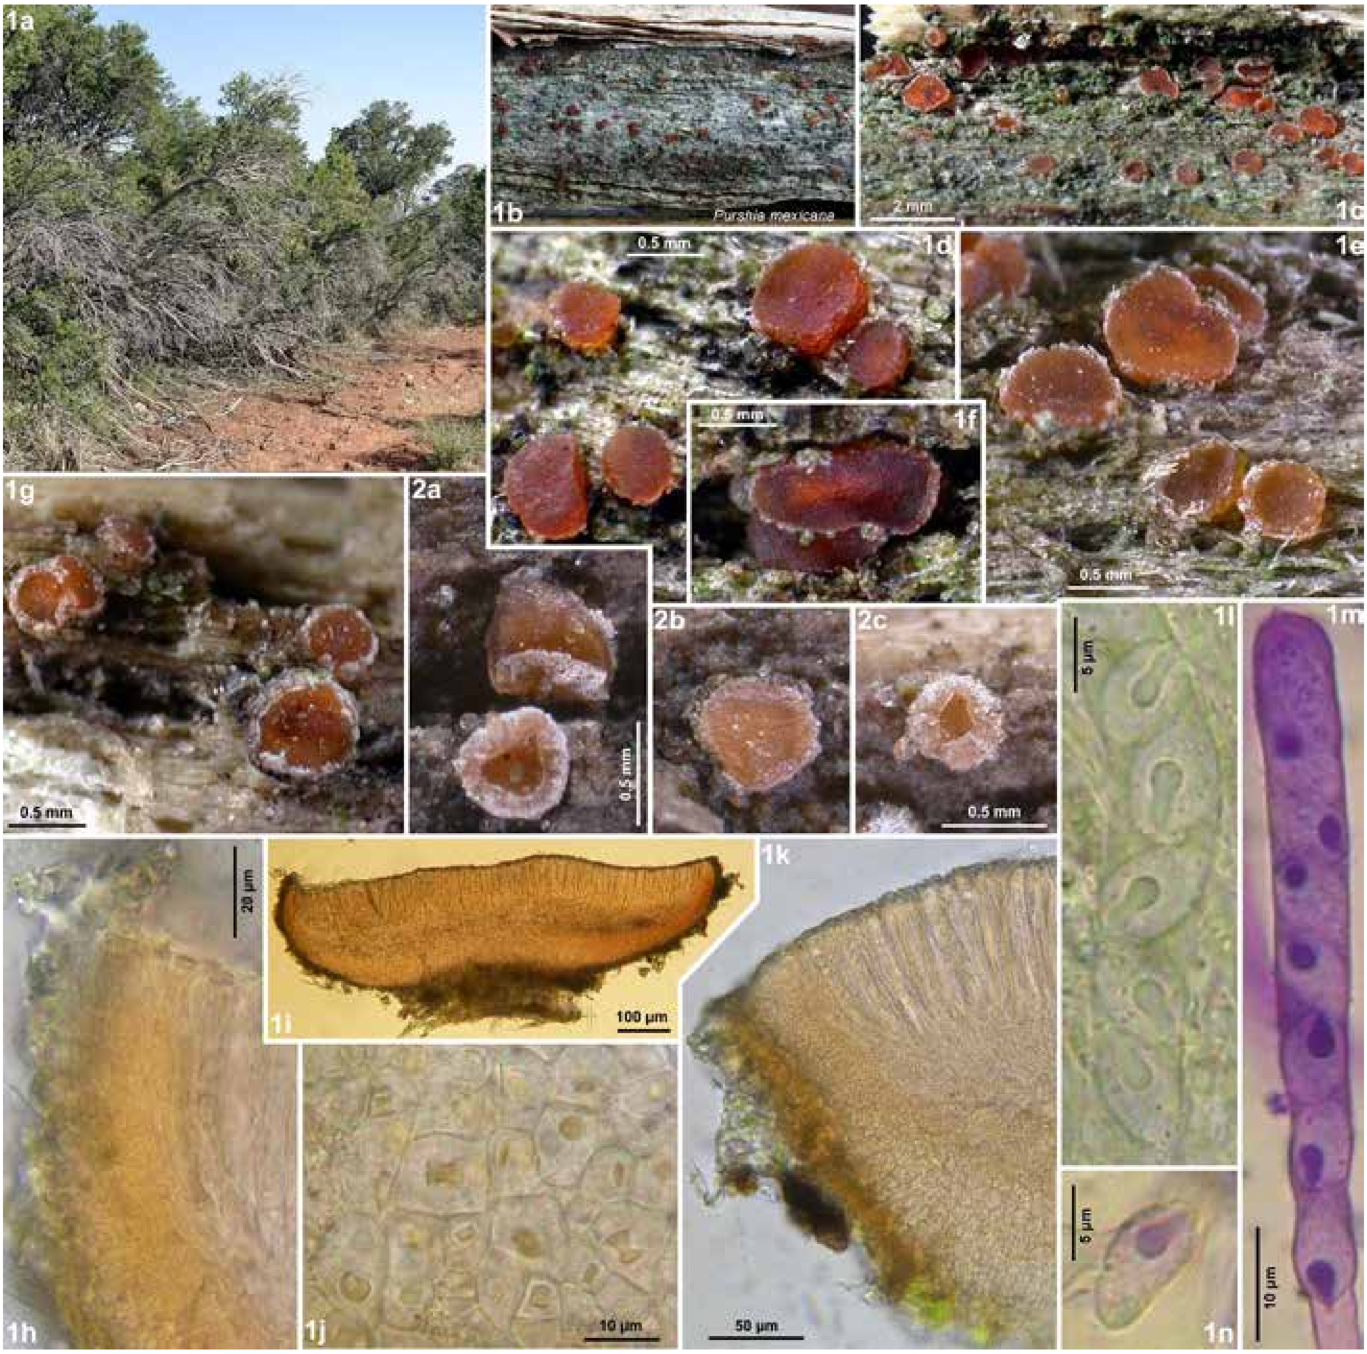

Plate 214. **1–2**: *Orbilia arizonensis*. – **1a**. subhumid montane shrubland with *Pinus edulis* (and *Juniperus osteosperma*), dead *Purshia* in foreground; **1b–g**, **2a–c**. rehydrated apothecia; **1j**. apothecium in median section; **1h–i**. marginal ectal excipulum in median section; **1k**. crystalloid SCBs in ectal excipulum (lower flanks); **1l–n**. asci and ascospores. – Living state (**1m–n** in CRB), except for asci in **1l–m**. — **1a–n**. H.B. 8002a: USA, Arizona, Fredonia, on *Purshia*; **2a–c**. H.B. 4566: USA, Arizona, Betatakin Ruins, on *Juniperus*.

Habitat: collected 0.2–2 m above the ground, partially to entirely decorticated, 6–23 mm thick branches of *Canotia holacantha* {1}, *Cercocarpus ledifolius* {1}, *Juniperus osteosperma* {1}, *Larrea tridentata* {1}, *Purshia stansburyana* {3}, on up to 0.5 mm deep medium decayed wood {5} or bark (bast) {1}, strongly greyed, green algae absent or sparse to abundant. **Associated**: *Caloplaca* sp. {1}, *Candelariella* sp. {1}, *Dothideales* {1}, *Hysterobrevium mori* {2}, *Odontotrema oregonensis* {1}, *Orbilia bicknellensis* {1}, *O. calyptrata* {2}, *O. cryptogena* {1}, *O. delphinus* {1}, *O. euonymi* {1}, *O. flexisoma* {1/2}, *O. ?gambelii* {1}, *O. lacrimispora* {2}, *O. ?lentiformis* {1}, *O. macrodelphinus* {4}, *O. maeandrina* {3}, *O. multigambelii* {1}, *O. multimaeandrina* {1}, *O. purshiae* {4}, *O. serpentina* {1}, *O. subovoidea* {1}, *O. ?vitalbae* {1}, *Patellaria* '*andina*' {1}, *P. atrata* {2}, *Symbiotaphrina desertorum* {1}. **Desiccation tolerance**: fully viable after 28(–30) months. **Altitude**: 975–2500 m a.s.l. **Geology**: Pennsylvanian-Permian and Tertiary (red) sand- and lime-, silt- or mudstone. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia arizonensis* is easily recognized by its extraordinarily wide ascospores and spore bodies. Within the *Orbiliomycetes* known at present only *O. megaocculta* has a comparable spore and SB width. The obovoid shape of ascospores and the pyriform shape of SBs are characteristic, also the conspicuous pale orange crystalloid SCBs. For the closely related *O. australiensis* see p. 556.

Variation. Spores and SBs varied somewhat in size among the collections, but this variation did not correlate with other features.

Anamorph. Trinacrium robustum-like conidia were once observed on the natural substrate. They are similar to those obtained in pure culture of the closely related *O. hesperidea* and *O. pleioaustraliensis*.

Map 37. Known distribution of *O. arizonensis* in North America.

Ecology. *O. arizonensis* grew on medium decayed wood (rarely bark) of xeric branches of several rather unrelated angiosperm shrubs, rarely also on gymnosperms, in cold-temperate subhumid pinyon-juniper woodlands and humid Douglas fir mixed forest of the Colorado Plateau and Southern Rocky Mountains, and in the warm-temperate semiarid Sonoran paloverde-mixed cacti desert scrub (Verde Valley at border between Mogollon Rim and Sonoran Desert) in the southwest of Northern America.

Specimens included. **USA**: **Arizona**, Navajo, 25.5 km WSW of Kayenta, Betatakin Ruins, 2045 m, fragment of *Juniperus osteosperma*, on wood, 5.X.1991, G. Marson (H.B. 4566, anam. substr.). – Grand Canyon, Kaibab Plateau, 28 km ESE of Fredonia, 13 km NNW of Jacob Lake, 2115 m, branch of *Purshia stansburyana*, on wood, 17.V.1995, G. Marson (H.B. 5295b ø). – ibid., branch of *P. stansburyana*, on wood, 15.VI.2003, G. Marson (H.B. 8002a). – 93 km SSE of Fredonia, S of North Rim, 2500 m, branch of *Cercocarpus ledifolius*, 17.V.1995, G. Marson (ø). – Coconino Plateau, 7.5 km ESE of Grand Canyon Village, 2205 m, branch of *P. stansburyana*, on wood, 16.VI.2003, G. Marson (H.B. 7462b). – Sonoran Desert, 65 km SSW of Flagstaff, 9 km NNE of Camp Verde, 4 km NE of Montezuma Castle, 1073 m, branch of *Canotia holacantha*, on bark, 12.VI.2000, G. Marson (ex H.B. 7218a, M-0276434, **holotype**). – ibid., 5.5 km NNE of Camp Verde, 975 m, branch of *Larrea tridentata*, on wood, 8.V.1995, G. Marson (H.B. 5684a).

Orbilia australiensis Baral & G. Marson, **sp. nov.**, MB 814365 — Pls 215–217, Map 38

Etymology: named after the continent Australia from which this species is so far known.

Typification: Western Australia, Barradale Roadhouse, twigs of *Acacia ?aneura*, 5.XII.2001, G. Marson (ex H.B. 7135a, MEL 2389218, holotype).

Latin diagnosis: *Similis* Orbiliae arizonensi *sed ascosporae breviores et angustiores*, *corpuscula refringentia angustiora*, *ab* O. hesperidea *gradatim differt ascosporis latioribus. Habitat ad lignum vel corticem leniter vel valde putridum ramulorum vel ramorum siccorum fruticum vel arborum angiospermarum*, *plerumque* Fabales, *in zona tropica vel subtropica humida ad arida Australiae occidentalis, septentrionalis et oridentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.18–)0.25–0.5(–0.8) × 0.18–0.5 mm diam., 0.1–0.25 mm high, light to bright brick-red-orange(-apricot), not or slightly translucent, round, rarely elliptical, scattered to subgregarious; disc flat, margin thin, 0–20(–30) µm protruding, smooth to ± rough; broadly sessile or with an obconical stipe 0.06–0.09 × 0.14–0.23 mm, superficial to slightly erumpent; dry bright brick-red. **Asci** *(50–)53–75(–82) {8} or 76–100 {2} × (6.5–)7–8.5(–9) µm {10}, †48–75 × 6–7.7 µm {5}, 8-spored, spores (*) biseriate, 2–6((–7)) lower spores inverted {14} (sometimes mixed), pars sporifera *34–42 µm long; **apex** (†) hemispherical, dome †1.2–2.2 → 0.7-2 µm thick {4}, with distinct apical chamber; **base** with short to medium long, thin or thick stalk, T-, L- or Y-shaped. **Ascospores** *((6.5–))(8–)9–14(–16)((–18)) {15} × (2.5–)2.7–3.5(–3.7) {14} or 3.2–4.3 µm {3}, †9–13(–15) × 3.5–4(–4.5) µm {2}, ellipsoid-fusoid to fusiform, apex obtuse, sometimes subacute or rounded, base mostly ± strongly attenuated, sometimes with a short tail-like end, straight or slightly curved at base; **SBs** *(2.5–)3–5(–5.5) × (0.9–)1.2–1.6(–1.8) ((–2.3)) µm {15}, pyriform to ampulliform, more rarely tear- or rod-shaped, apically narrowed to a small, sometimes wide point, straight, rarely slightly curved. **Paraphyses** apically uninflated to mostly slightly (rarely medium, exceptionally strongly) clavate-capitate (exceptionally spathulate to sublageniform), terminal cells *6–16(–20) × (2–)2.5–4(–4.8) µm {6}, lower cells *8–15 × (1.6–)1.8–2.5(–3) µm {5}; not or quite often branched at upper septum. **Medullary excipulum** hyaline to pale orange, 15–50 µm thick, of medium dense textura intricata with some or many inflated cells, sharply delimited. **Ectal excipulum** hyaline, of thin-walled († slightly gelatinized), vertically oriented t. globulosa-angularis(-prismatica) from base to mid flanks or margin, 25–110 µm thick near base, cells *(8–)10–25(–30) × 7–17(–20) µm {5}; 15–25(–30) µm thick near margin, of t. angularis or prismatica oriented at a 10–70° angle to the surface, marginal cortical cells *5–13 × 2.5–6(–8) µm {6}; **glassy processes** absent {9}. **Anchoring hyphae** sparse to abundant, */†1.8–3.3 µm wide, walls 0.2–0.3 µm thick {3}. **SCBs** in paraphyses and ectal excipulum globose, 1–3.6 µm diam., together with crystalloid SCBs {11}, hyaline or (especially in marginal excipulum) pale to light orange, 2.5–9 × 1.5–4 µm. **Exudate** over paraphyses 0.3–4 µm thick, granular-cloddy, hyaline to pale yellowish, ± loosely attached; over margin and flanks 0.7–7 µm thick. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1} but no data available).

Habitat: collected 0.1–3 m above the ground, corticated to decorticated, (1–)2–30(–100) mm thick twigs and branches of *Acacia* sp. {8}, *A. ?aneura* {1}, *A. cyperophylla* {1}, *Banksia cuneata* {1}, *B. grandis* {1}, *Calothamnus* sp. {1}, *Dodonaea viscosa* subsp. *angustissima* {1}, *Hakea* sp. {1}, *Jacksonia* sp. {2}, on 0.1–0.5 mm deep slightly to strongly decayed wood {10} and bark {15} (periderm & bast), greyed, green algae absent or sparse to abundant. **Associated**: *Acanthostigma ?minutum* {1}, *Amandinea* sp. {1}, *Caloplaca* sp. {3}, *Capronia* sp. {1}, *Claussenomyces* sp. {3}, *Coccomycetella* spp. {4}, *Durella* sp. {1}, *D.* aff. *connivens* {2/1}, *Gloniopsis* sp. {1}, *G. praelonga* {5}, *Hysterium angustatum* {1}, *Hysterobrevium mori* {2}, *Lecidea* sp. {1}, *Mycocalicium* sp. {1}, *Orbilia albidorosea* {1}, *O. allantoobliqua* {1}, *O. amberina* {1}, *O. anguliobliqua* {1}, *O. ?angustoaristata* {1}, *O. austrocylindrica* {1}, *O. austroobtusispora* {1}, *O. aviflagellata* {1}, *O. commarosa* {1}, *O. curvatiobliqua* {1}, *O. curvativitalbae* {2}, *O. eucalypti* {5}, *O. fimbriata* {1}, *O. helicoobliqua* {2}, *O. hesperidea* {4}, *O. kingsiana* {1}, *O. ?macrocarpa* {1}, *O. macrotrapeziformis* {1}, *O. microserpens* {2}, *O. multiaustraliensis* {1}, *O. multiserpens* {1}, *O. myrioeuonymi* {1}, *O. myriofusiclava* {5}, *O. myriolilacina* {2}, *O. myriomuscula* {1}, *O. myrioobliqua* {10}, *O. nothovinosa* {3/1}, *O. paraobliqua* {2}, *O. pleioaustraliensis* {3}, *O. pleioaustrocylindrica* {1}, *O. ?pleiocoronohesperidea* {1}, *O. ?pleiohesperidea* {1}, *O. pleiovinosa* {1}, *O. pleiovirgula* {1}, *O. ?pubescens* {1}, *Patellaria ?andina* {1}, *P. atrata* {1}, *Proliferodiscus griseoviolaceus* {1}, *Symbiotaphrina desertorum* {2/1}, *?Triblidium* sp. {3}. **Desiccation tolerance**: fully viable for at least 21 months. **Altitude**: 37–540 m a.s.l. **Geology**: Precambrian, Silurian & Jurassic-Cretaceous sedimentary rock, Cenozoic regolith; granite, granulite with granitic gneiss. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia australiensis* is characterized by comparatively large, (ellipsoid-)fusoid ascospores and conspicuous, pale orange crystalloid SCBs. *O. arizonensis* differs in shorter and wider spores, wider SBs, and larger apothecia, and in occurring in North America. *O. hesperidea* differs in narrower, subcylindrical spores with obtuse apices; yet, some collections have fusoid spores and are then not sharply separable from *O. australiensis*.

A few collections included in *O. hesperidea* (Pl. 237: 2, 5) show a spore width at the upper end of the range and appear to be intermediate to narrow-spored populations of *O. australiensis*,

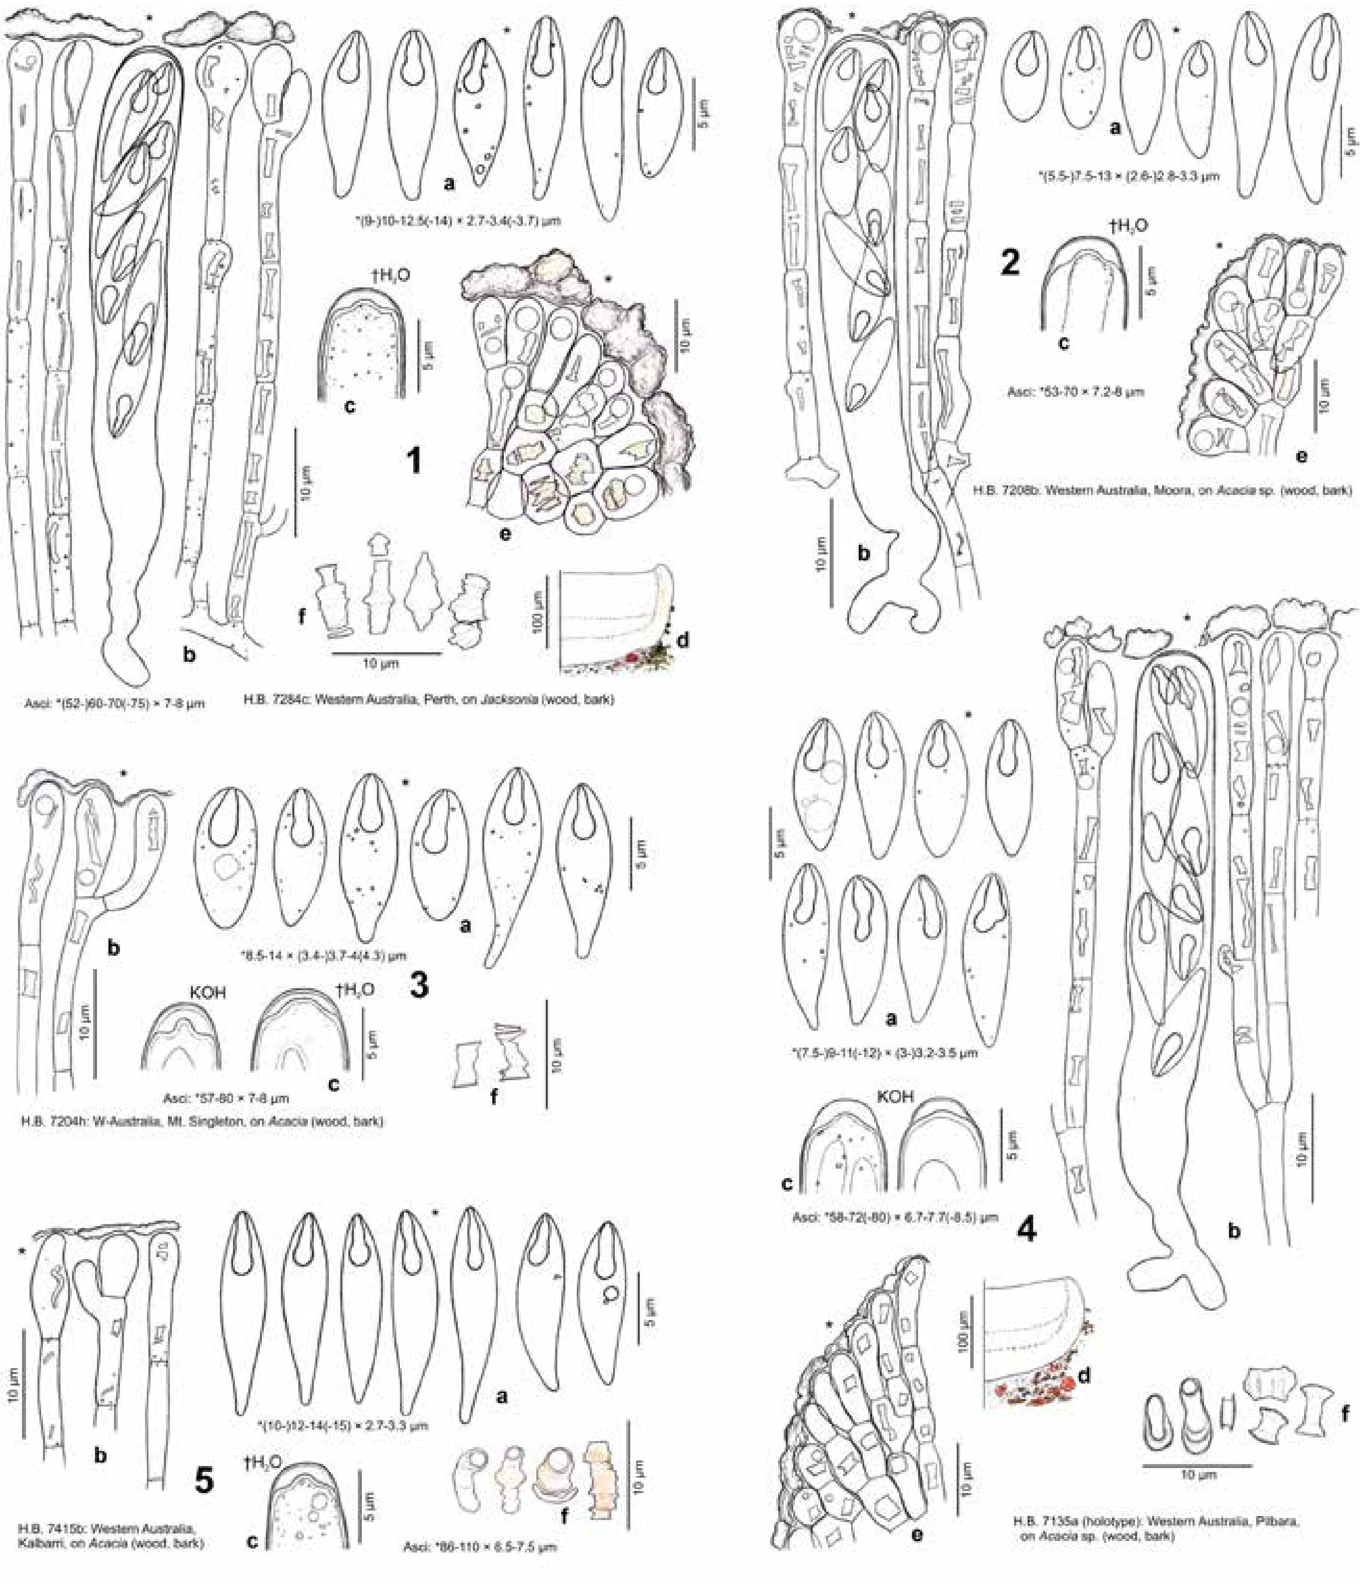

Plate 215. **1–5**: *Orbilia australiensis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., marginal ectal excipulum; **f**. crystalloid SCBs in excipular cells (flanks and margin).

but their cylindric-ellipsoid-clavate spore shape with an obtuse apex fits better typical *O. hesperidea*. However, also collections with fusoid spores similar as in *O. australiensis* though with a width of only *2.2–2.7 µm were included by us in *O. hesperidea*. In three samples (H.B. 7204, 6452, 8883) *O. australiensis* and *O. hesperidea* grew in association. In two of them, the two species were sharply separated into two populations based on spore width and partly also spore shape, but in H.B. 6452 the two populations could not very clearly be separated.

Variation. Rather great variability in size and shape of the ascospores is noted within the present concept of *O. australiensis*. In several collections including the holotype (Pls 215: 1–4; 216: 7), the spores are partly or consistently rather short and thick (*~8–14 × 2.7–4 µm), mainly fusoid with obtuse (to subacute) apex and tapered base, though ellipsoid spores also sometimes occur. Three of them are extraordinary

Plate 216. **1–10**: *Orbilia australiensis*. – **1a**. semihumid Eucalypt open woodland with predominant *Jacksonia*; **2a–b**. dead corticated or decorticated xeric branches of *Jacksonia*, **1b–d**, **2a–d**, **3a–b**, **d–e**, **9a**. rehydrated apothecia; **3c**, **8a**. dry apothecia; **2f**, **4**. apothecia in median section; **2e**. id., marginal ectal excipulum; **5**. id., crystalloid SCBs in basal excipular cells; **3f–g**, **6**. asci with mature spores; **2g**, **8b**. ascus apices; **7**, **9b**, **10**. ascospores. – Living state, except for asci in **2g**, **3f–g**, **6**, **8b** (all in H_2O). — **1a–d**. H.B. 7284c: Western Australia, Perth, on *Jacksonia*; **2a–g**. H.B. 8611b: ibid., on *Jacksonia*; **3a–g**. 3.IX.2006: ibid., on *Banksia*; **4**. H.B. 8478f: ibid., on *Acacia*; **5**. in their wide spores (*3.2–4.3 µm, Pls 215: 3; 216: 7; IVV: H.B. 6452d). In many other specimens the spores tend to be longer and especially narrower (*9.5–15 × 2.5–3.5 µm), and generally have a ± fusiform shape (Pls 215: 5; 216: 3, 6, 8–10). However, such spores may also occur in the first-mentioned group.

rDNA data suggest that two species are involved in our concept of *O. australiensis* (see below). However, since a sharp morphological limit could not be drawn, we refrained from splitting the species. The sequence of the broad-spored taxon became available only very recently, and it was confused with *O. myriobliqua* (H.B. 7204s) in the same collection, when the extract was done. Given that it belongs to H.B. 7204h, it would probably be representative also for the two other samples with extraordinarily broad spores.

Not included collections. Three very sparse samples from eastern Australia (Pl. 217: 1–2, H.B. 6809c [unillustrated]) differ in smaller spores and the absence of crystalloid SCBs. They probably represent a different species and should be recollected (see also a similar collection mentioned under *O. parviclava* in series *Hemiorbilia*, Pl. 320: 2).

Anamorph. In a pure culture of H.B. 7208b we obtained a few trinacrium robustum-like conidia when flooding an agar block with water. These closely resembled those of *O. pleioaustraliensis*, but were not documented.

Phylogeny. Sequences of *O. australiensis* s.l. were available from three collections from western Australia, two with comparatively narrow ascospores (ITS+LSU, from apothecia: spores *2.7–2.9 µm wide, IVV: 9.XI.2007; SSU+ITS+LSU, from pure culture: spores *2.6–3.3 µm wide, H.B. 7208b, Pl. 215: 2), and one from H.B. 7204, presumably H.B. 7204h with broad ascospores (Pl. 215: 3, spores *3.4–4.3 µm), in the following as *O.* cf. *australiensis* (ITS+LSU, from apothecia). The S1506 intron is present in the two more narrow-spored *O. australiensis* strains but absent in *O.* cf. *australiensis*. In the ITS the two samples of *O. australiensis* differ by 1 nt and 2 gaps (but 1 sequence is incomplete in the ITS2) and in the intron by 5 out of 315 overlapping nt (1.7 %), while in the LSU D1–D2 they are identical. *O.* cf. *australiensis* differs from them by 3.5 % in the ITS and 1 nt in the D2 of LSU.

The apothecia from which the sequence of *O.* cf. *australiensis* (uploaded as 7204h1) was taken were thought to belong to *O. myriobliqua*, but this seems very unlikely. The problem is that *O. myriobliqua* and *O. australiensis* occurred in this collection of *Acacia* branches together with at least 13 further *Orbilia* species. All three apothecia of *O. australiensis* that were examined in 2003 had broad ascospores. However, two further sequences from H.B. 7204 (ITS+LSU, 7204h-2a & -2b), also gained under the name *O. myriobliqua*, both possess the S1506 intron and resulted in another genotype of the *O. australiensis* complex. They differ from the above three sequences by 5.8–6.8 % in the ITS, 6.4–6.8 % in the intron, and 0.5–0.9 % in the LSU D1–D2, and from each other by 1.3 % in the ITS (7 nt), 1.1 % in the intron, and 0.3 % in the LSU (2 nt in D1). Therefore, they could either represent the true wide-spored *O. australiensis* H.B. 7204h or an unknown species, but hardly any of the 15 other species of this sample, which mostly belong to other sections of *Orbilia*.

When analysing (SSU+)ITS+LSU, ITS, or LSU, *O. australiensis* always clustered with high support in the *hesperidea-alpigena* clade, though without a supported association with any of its members (Baral et al. 2017b, Phyls 7, 9–10, S13). In the intron region (Phyl. S12), *O. australiensis* clustered highly supported with *O. pleioaustraliensis*, because other members of the *hesperidea-alpigena* clade do not possess the intron. The distance to these other members lies at 6–11 % in the ITS region, the lowest percentage being to *O. hesperidea* (6–7 % to narrow-spored *O. australiensis* and 8–11.5 % to the three *O.* cf. *australiensis* sequences). *O. pleioaustraliensis* shows a distance of 8–9 % in the ITS (9.5–11.5 % to the three *O.* cf. *australiensis* sequences) and ~12–13 % in the intron (overlapping 392 nucleotides). In the LSU (D1–D2) the distance to *O. hesperidea* is 2.8–3 % and to *O. pleioaustraliensis* 4.5 %.

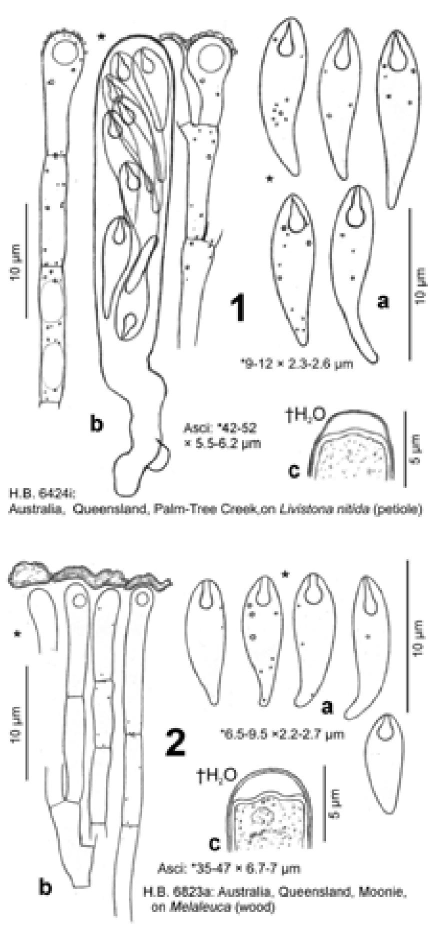

Plate 217. **1–2**: *Orbilia* aff. *australiensis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices.

Ecology. *O. australiensis* grew on slightly to strongly rotten wood and bark of xeric twigs and branches of various trees and shrubs, mainly of *Fabales* and *Proteales*, also *Sapindales* (*Dodonaea*). It is known from various sites of western and southwestern Australia, where it occurs in subtropical semiarid open acacia and other shrublands, and semihumid eucalypt (open) woodlands. A single collection is from northern Australia in a tropical arid open acacia shrubland (mulga). The not included collections from eastern Australia (Great Dividing Range) are in subtropical to warm-temperate semihumid eucalypt (open) woodlands.

Specimens included. **AUSTRALIA**: **Western Australia**, Gascoyne, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *Acacia cyperophylla*, on wood, 28.X.2007, G. Marson (H.B. 9695e). – Carnarvon (border to Gascoyne), 137 km SE of Exmouth, 18 km ENE of Barradale Roadhouse, 95 m, twigs of *A.* ?*aneura*, on bark & wood, 5.XII.2001, G. Orbilia pleioaustraliensis Baral & G. Marson, **sp. nov.**, MB 814368 — Pls 218–220, Map 39

Etymology: referring to the 16-spored asci and the otherwise close similarity with *O. australiensis*.

Typification: Australia, Northern Territories, Yulara, twigs of *Acacia jennerae*, 10.X.1998, G. Marson (ex H.B. 6277e, MEL 2389200A, holotype; ex-type culture: CBS 116223; sq.: KT215261).

Latin diagnosis: *Similis* Orbiliae australiensi *sed asci 16-spori. Habitat ad lignum vel corticem putridum ramulorum vel ramorum siccorum fruticum vel arborum angiospermarum in zona tropica vel subtropica subhumida ad arida Australiae occidentalis, centralis et orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.6(–0.8) mm diam., 0.13–0.23(–0.3) mm high, (light to) bright (dirty) orange(-rose) to brick-red, round, sometimes elliptical, scattered to gregarious (in ± small groups); disc slightly concave to flat, margin distinct, rising 0–30 µm above disc, ± glabrous; broadly sessile, ± erumpent, slightly to entirely immersed, sometimes deeply hidden in clefts. **Asci** *(70–)75–110(–120) × (8–)9–10(–11) µm {9}, †(48–)60–97(–110) × (6–)7–8.5 µm {9}, 16-spored (rarely 2–8 spores aborted), spores (*) 3–4-seriate, (5–)6–11(–12) lower spores inversely oriented {9} (slightly to strongly mixed), pars sporifera *45–60 µm long; **apex** (†) hemispherical (to slightly truncate), dome †1–1.7(–2) → 0.7–1 µm thick {6}, with wide apical chamber; **base** short- to rather long-stalked, L-, Y- or h-shaped. **Ascospores** *(7.5–)9–12(–13.5) × (2.7–)3.2–4.2(–4.7) µm {9}, †9–12(–13) × 3–4 µm {3}, ellipsoid(-clavate) to fusoid(-clavate), apex rounded to obtuse, base sometimes rounded, mostly distinctly tapered, sometimes or often with a distinct tail-like base or short, thick tail *1.5–3(–4) × (0.7–)1–1.3(–1.8) µm, straight, base sometimes slightly to medium curved; **SBs** (2.5–)3–4(–4.5) × (1.1–)1.3–1.6(–1.8) µm {7}, pear-shaped to ampulliform, rarely rod-shaped, apically narrowed to a small to wide point. **Paraphyses** apically slightly to medium (rarely strongly) clavate(-capitate), often flexuous, terminal cells (4.5–)6–20(–28) × (1.8–)2.5–4.5(–5.8) µm {6}, †2–3.5 µm wide {1}, lower cells (9.5–)11–15(–23) × 1.4–2.7 µm {4}; rarely to frequently branched at upper septum. **Medullary excipulum** pale orange(-rose), 15–40(–70) µm thick, of medium dense textura intricata or globulosa-angularis (with many inflated cells), sharply or indistinctly delimited. **Ectal excipulum** hyaline, near margin light to bright orange-rose, of (*) thin-walled, vertically oriented t. globulosa-angularis(-prismatica) from base to submargin, 25–130 µm thick near base, cells *9–20(–24) × 6–13(–15) µm {5}; 25–40(–60) µm thick at mid flanks, 20–40 µm near margin, upper margin of t. prismatica oriented at a 20–50° angle, marginal cortical cells *7–12(–14) × 3–5 µm {2}, walls (†) medium gelatinized, **glassy processes** absent. **Anchoring hyphae** abundant, */†2–4 µm wide {2}, walls 0.2–0.4 µm thick {2}, sometimes covering flanks and margin by a 3–10 µm thick hyaline layer. **SCBs** in paraphyses and cells from lower flanks to margin globose, low-refractive, mostly together with crystalloid ones {8}, refractive, pale to bright orange(-rose), 2.5–5.5 µm diam. **Exudate** over paraphyses 0.5–2(–4) µm thick, continuous to cloddy, very pale yellowish, loosely attached, marginal external hyphae immersed in hyaline exudate, sometimes with light honey-yellow exudate between hyphae and excipular cells. **— ANAMORPH**: trinacrium-like (from ascospore isolate {1} and natural substrate {1}). **Conidiophores** not seen. **Conidia** Y-shaped, total size *28–32 × 18–24 µm {1}, †22 × 25 µm {1}, stipe *14–20 × 6–7 µm, †12 × 5 µm, 2–3-septate, arms tapering, *9.5–14 × 5–6.5 µm, †14–14.5 × 5 µm, 2(–3)-septate.

Habitat: collected 0.2–3 m above the ground or lying on ground, partially to often entirely decorticated, 1.5–20 mm thick twigs and branches of *Acacia* sp. {4}, *A. cyperophylla* {1}, *A. estrophiolata* {1}, *A. jennerae* {1}, *Atriplex* sp. {1}, *Melaleuca* sp. {1}, *Pittosporum phillyreoides* {1}, *Vachellia farnesiana* {1}, on 0.1–1 mm deep strongly decayed wood {9} and bark (periderm & bast) {3}, ± greyed, green algae absent or sparse. **Associated**: *Amandinea* sp. {1}, *Baggea* sp. {1}, *Caloplaca* sp. {1}, *Claussenomyces* sp. {1}, *Coccomycetella* spp. {4}, *Dacrymyces* sp. {2}, *Exidia* sp. {1}, *Gloniopsis* sp. {1}, *Hyalorbilia ?erythrostigma* {4}, *Hysterobrevium mori* {3}, *Hysteropatella* sp. {1}, *Orbilia allantoobliqua* {1}, *O. amberina* {1}, *O. anguliobliqua* {1}, *O. angustoaristata* {2}, *O. australiensis* {3}, *O. austroobtusispora* {1}, *O. austropleiomicrosoma* {1}, *O. aviflagellata* {1}, *O. barrowensis* {1}, *O. corculispora* {1}, *O. coronohesperidea* {1}, *O. curvatimyriella* {1}, *O. curvatiobliqua* {1}, *O. farnesianae* {1}, *O. helicoobliqua* {2}, *O. hesperidea* {2}, *O. lanternae* {1}, *O. ?livistonae* {2}, *O. megahesperidea* {1}, *O. microserpens* {1}, *O. multiaustraliensis* {2}, *O. multiaustrocylindrica* {1}, *O. ?multigambelii* {1}, *O. multiserpens* {3/1}, *O. myriella* {2/1}, *O. myrioauris* {1}, *O. myriofusiclava* {2}, *O. myriolilacina* {2}, *O. myriomuscula* {1}, *O. myrionamibica* {1/1}, *O. myrionanosoma* {1}, *O. myriooblıqua* {2}, *O. ?myrioolneyae* {1}, *O. myriopseudoregalis* {1}, *O. nothovinosa* {1}, *O. octocercocarpi* {2}, *O. paraobliqua* {2}, *O. ?parviclava* {1}, *O. pleioaustrocylindrica* {1}, *O. pleiocoronohesperidea* {1/1}, *O. ?pleioserpens* {1}, *O. pleiovinosa* {1}, *O. pleistooblıqua* {1}, *O. ?saguarina* {1}, *Patellaria ?andina* {1}, *Ostropales* {3}, *Peniophora* sp. {1}, *?Stictis* sp. {1}, *Symbiotaphrina*

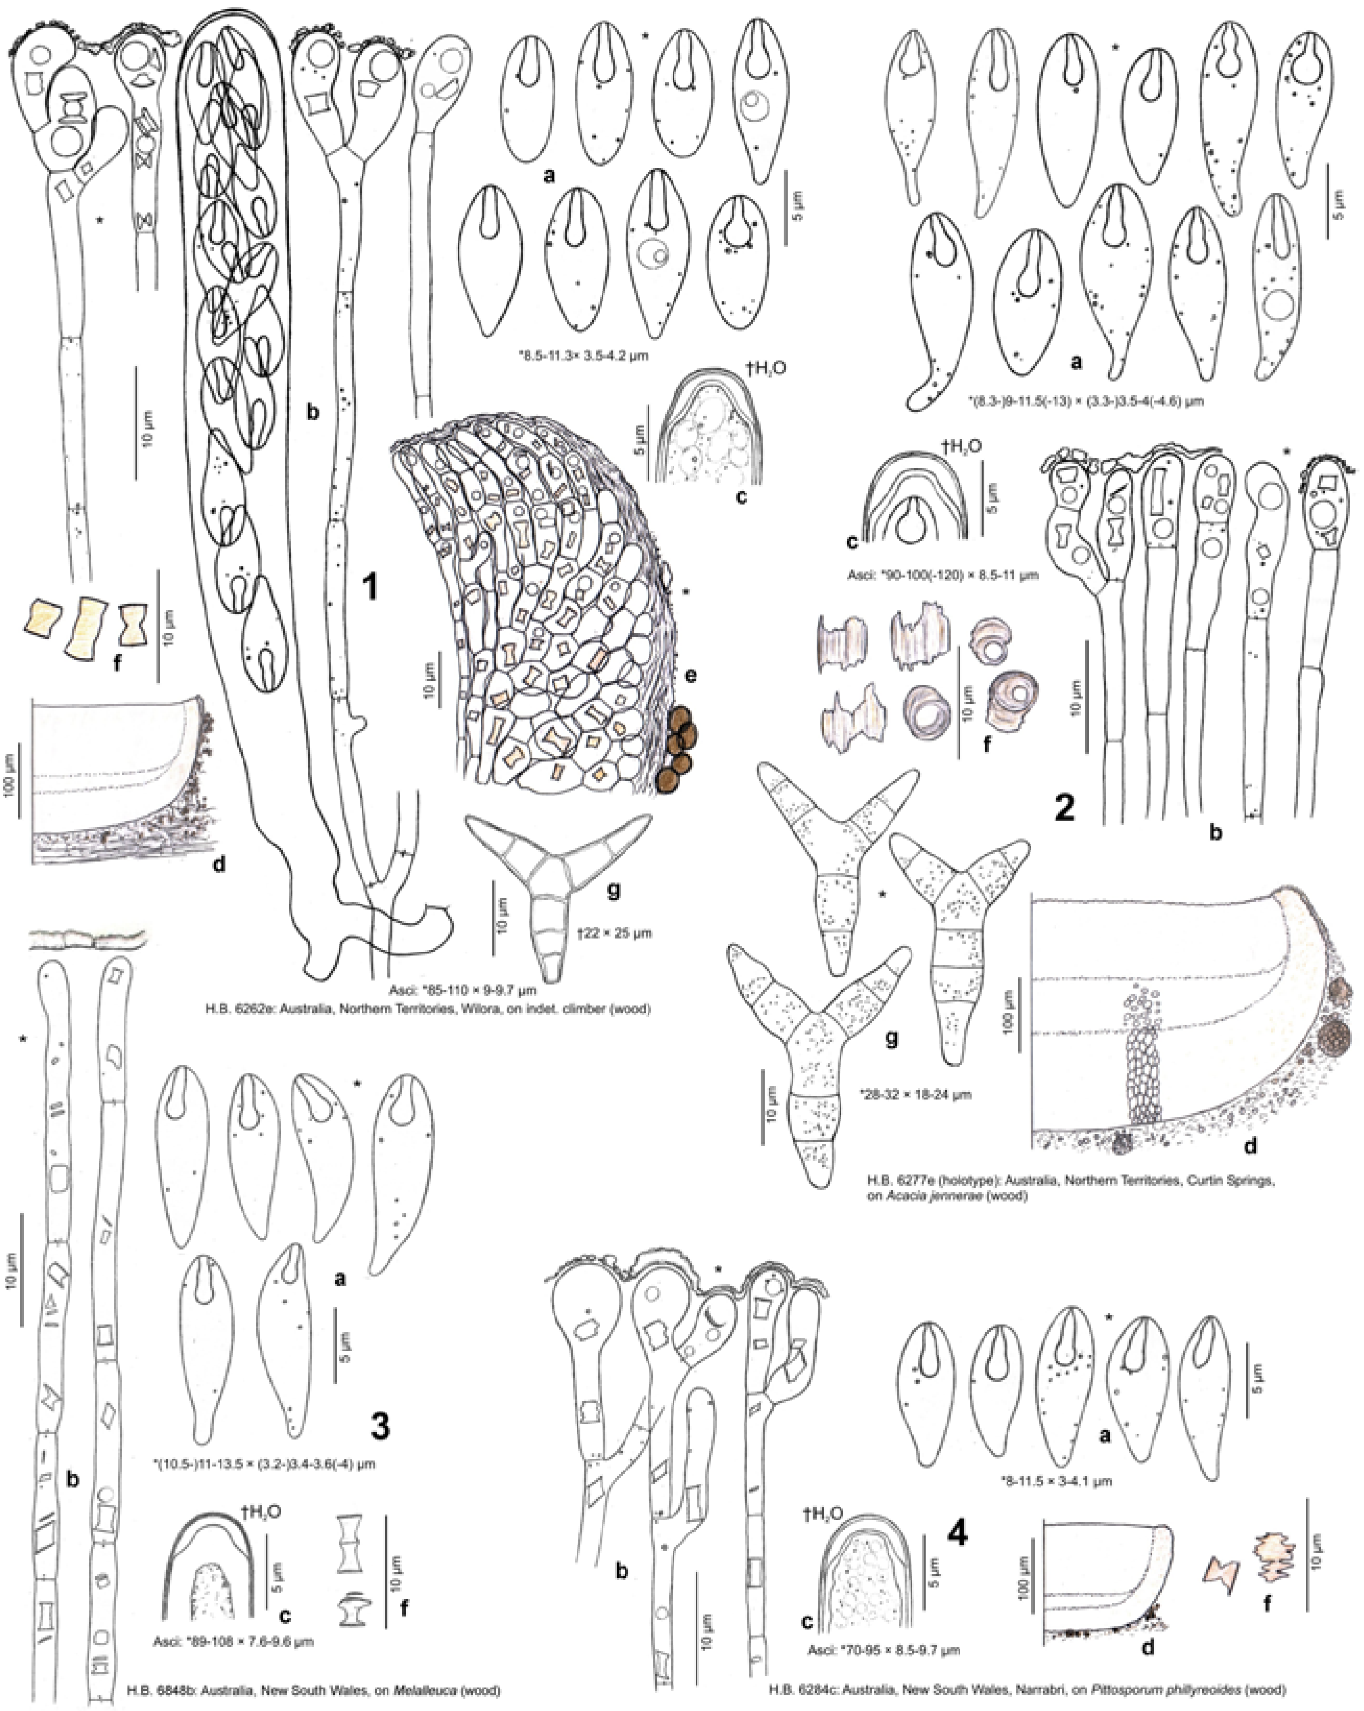

Plate 218. **1–4**: *Orbilia pleioaustraliensis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., marginal ectal excipulum; **f**. crystalloid SCBs in ectal excipular cells (margin and flanks); **g**. conidia (**1** from substrate, **2** from culture).

desertorum {3}, ?*Triblidium* sp. {3}, *Tryblidaria* sp. {1}, *Xylobolus* sp. {1}. **Desiccation tolerance**: ± fully viable for 33 months. **Altitude**: 13–613 m a.s.l. **Geology**: Archean, Mesoproterozoic, Devonian, Carboniferous & Cretaceous sediments, Cenozoic regolith (ochre to red-brown sand and gravel). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleioaustraliensis* is characterized by 16-spored asci, by which it differs from the otherwise very similar 8-spored *O. australiensis*, also it resembles the 32-spored *O. multiaustraliensis*. These taxa sometimes even grew in close association. Both *O. australiensis* and *O. pleioaustraliensis* differ from North American *O. arizonensis* especially in distinctly narrower ascospores and spore bodies.

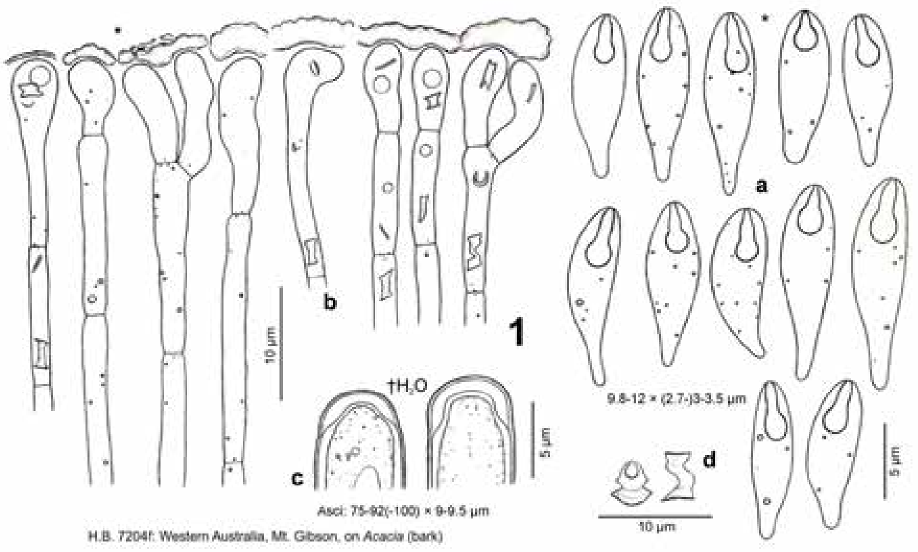

Plate 219. **1**: *Orbilia pleioaustraliensis*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices; **d**. crystalloid SCBs in marginal ectal excipulum.

Variation. A few 8-spored asci were very exceptionally observed within an apothecium among the 16-spored ones. In such asci the spores were longer (*12–14 × 3.4–3.6 µm) and the SBs slightly larger. The reverse case (a 16-spored ascus among 8-spored asci) was never observed in apothecia of *O. australiensis*. Some variation in spore size and presence of attenuated or tailed spore bases is noted among but also within collections.

Not included collection. A single apothecium on *Eucalyptus* (IVV: H.B. 9772b) deviates in extraordinarily long spores (*13.5–16.5 × 3.2–3.7 µm) which resemble those in Pl. 218: 3, also in the partial presence of a distinct tail and in narrower SBs (3–4.5 × 1–1.2 µm). Typical *O. pleioaustraliensis* occurred at the same site on *Acacia* (IVV: H.B. 9695b) and showed the characteristic spore size (*9.8–12.3 × 3.6–4.1 µm), while the here associated *O.* aff. *pleiocoronohesperidea* (Pl. 240) differs in much narrower spores.

Anamorph. Conidia were obtained in pure culture of *O. pleioaustraliensis* when flooded by water (Pl. 218: 2g). They resemble *Trinacrium robustum* and are also very similar to those of *O. australiensis*. A single conidium found on the natural substrate in another collection (Pl. 218: 1g) concurs with those from culture.

Phylogeny. Sequences of two samples of *O. pleioaustraliensis* were available: H.B. 6277e (Finke, holotype, from pure culture; Avon Wheatbelt, H.B. 7204f, from apothecia) comprises ITS and LSU (the former also SSU). The S1506 intron is present in the former but absent in the latter sample. The two sequences differ in the ITS by 3 nt and in the LSU D1–D2 also by 3 nt. In analyses of SSU+ITS+LSU, ITS+LSU, ITS, or LSU (Phyls 7, 9–10, S13) the species is found with high support in the *hesperidea-alpigena* clade, with an ITS distance of 8.2–10.5 % to the other included species. Although *O. pleioaustraliensis* differs from *O. australiensis* merely in 16-spored asci, the two species show a distance of 8.2 % to each other and do not cluster in a clade of their own (see also under *O. australiensis*, p. 559).

Ecology. *O. pleioaustraliensis* was found on rotten wood and bark of xeric twigs and branches of various angiosperm trees and shrubs or climbers. It is at present known from nine sites: in subtropical semiarid to arid open acacia shrublands of western Australia, in (sub)tropical arid open acacia shrublands of central Australia (around Macdonnell Ranges), and in subtropical subhumid eucalypt woodlands of eastern Australia (New England Range). Some of the collections contained only a few apothecia, whereas others were rather abundant, for instance, about 250 apothecia in the collection on *Pittosporum*. The not included collection on wood of *Eucalyptus* was in a subtropical semiarid acacia open woodland in the Gascoyne ecoregion of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 117 km NNE of Carnarvon, 7 km SSE of Minilya Roadhouse, Barrabiddy Creek, 13 m, branch of *Vachellia farnesiana*, on wood, 6.XI.2007, G. Marson (H.B. 8997f ø). – 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, Denham-Hamelin Road, 67 m, twig of *Acacia*, on bark, 7.XII.2001, G. Marson (H.B. 7215c). – ibid., twig of *Acacia*, on bark & wood, 6.XI.2007, G. Marson (H.B. 8727f). – Gascoyne, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *A. cyperophylla*, on wood, 28.X.2007, G. Marson (H.B. 9695b). – Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, twig & branch of *Acacia*, on bark, 24.XI.2001, G. Marson (H.B. 7204f; sq.: MK473429). – ibid., twig of *Acacia*, 26.X.2007, G. Orbilia multiaustraliensis Baral & G. Marson, **sp**. **nov**.,
MB 813531 — Pls 221–222

Etymology: referring to the 32-spored asci and the similarity with *O. australiensis*.

Typification: Australia, Northern Territories, Yulara, branch of *Acacia jennerae*, 10.X.1998, G. Marson (ex H.B. 6277j, MEL 2389203A, holotype).

Latin diagnosis: *Similis* Orbiliae pleioaustraliensi *sed asci 32-spori, ascosporae cauda longiore et angustiore praeditae. Habitat ad lignum putridum rami sicci* Acaciae *in zona subtropica (semi)arida Australiae occidentalis et centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.22–0.4(–0.5) mm diam., 0.13–0.2 mm high, bright brick-red-orange, round to elliptical, subgregarious in rather small groups; disc slightly concave to flat, margin distinct or indistinct, 0–10 µm rising above disc, ± smooth, externally somewhat powdered; broadly sessile, erumpent between wood fibres, partially to entirely immersed. **Asci** *90–112 × 8.3–9 {T} or 74–97 × 9–10 µm {1}, †(62–)70–77(–82) × (6.5–)7–8.5(–9.5) µm {2}, 32-spored, spores 4-seriate, lower spores inversely oriented (somewhat mixed) {2}, pars sporifera *50–65 µm long; **apex** (†) hemispherical to slightly truncate, dome †0.7–1 → 0.3 {1} or 1–2 → 0.8–1.3 {2} µm thick, with slight apical chamber; **base** ± unstalked or with short thick stalk, L-, Y- or h-shaped. **Ascospores** *(8.3–)9–11.5(–12.5) × (2.7–)2.9–3.5 µm {2}, †7.5–10 × 2.7–3 µm {T}, ellipsoid-fusoid, apex obtuse to subacute, base with a short to medium long tail (1–)2–3(–4)((–5.5)) × 0.4–0.7 µm (exceptionally without), †0.2–0.3 µm wide, sometimes gradually attenuated, straight to slightly curved at base; **SBs** *(1.4–)1.7–2.2 × 1–1.2 {1} or 2.5–3 × 1.4–1.5 {T} µm, pear-shaped to ampulliform, apically narrowed to a minute or mostly ± wide point; with some minute LBs. **Paraphyses** apically uninflated to medium clavate-capitate, terminal cells *(6–)8–12(–17) × 2.8–4.2 µm {2}, lower cells *(8–)14–20(–23) × 1.5–2.3(–3) µm {2}, sometimes branched at upper septum. **Medullary excipulum** hyaline, 15–30 µm thick, of dense horizontal textura intricata-porrecta with many inflated cells, rather sharply delimited. **Ectal excipulum** hyaline, pale orange near margin,

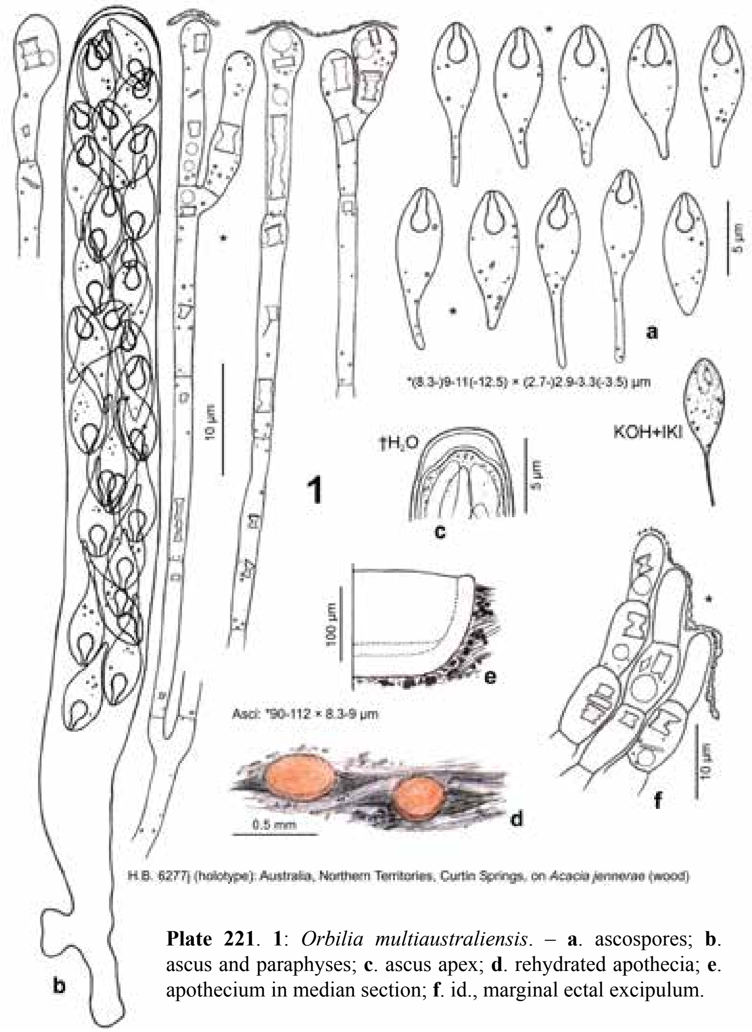

Plate 221. **1**: *Orbilia multiaustraliensis*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., marginal ectal excipulum.

of (†) thin-walled or slightly gelatinized, irregularly vertically oriented t. angularis from base to mid flanks, 30–40 µm thick near base, cells *(6–)8–13(–16) × 6–11 µm {2}; 25 µm thick near margin, of t. prismatica oriented at a 10–20° angle to the surface, marginal cortical cells */†7–11 × 3–4.5 µm {2}, **glassy processes** absent. **Anchoring hyphae** sparse, †1.5–2.5 µm, wall 0.2–0.7 µm thick {T}. **SCBs** in paraphyses and ectal excipulum globose, mixed with crystalloid ones, pale orange. ones {2**Exudate** over paraphyses 0.5–1 µm thick, continuous, rough, over margin and flanks granular, thin. **— ANAMORPH**: unknown.

Habitat: lying ± on the ground or 2.5–3 m above, 7–20 mm thick decorticated branches of *Acacia cyperophylla* {1}, *A. jennerae* {1}, on 0.3 mm deep very decayed wood {2}, strongly greyed, no algae. **Associated**: *Baggea* sp. {1}, *Coccomycetella* spp. {3}, *Hysterobrevium mori* {1}, *Orbilia allantoobliqua* {1}, *O. anguliobliqua* {1}, *O. angustoaristata* {1}, *O. australiensis* {1}, *O. austropleiomicrosoma* {1}, *O. coronohesperidea* {1}, *O. multiserpens* {1}, *O. myriella* {1}, *O. myrionamibica* {1}, *O. pleioaustraliensis* {2}, *O. pleiocoronohesperidea* {1/1}, *O. pleiovinosa* {1}, *Ostropales* {1}, *Symbiotaphrina desertorum* {1}. **Desiccation tolerance**: fully viable for 38 months. **Altitude**: 480–540 m a.s.l. **Geology**: Mesoproterozoic sedimentary rock (red-brown sandstone), Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multiaustraliensis* is very close to *O. palmicola*, from which it differs in distinctly longer SBs, also in the frequent presence of a spore tail. The tail is already present within the living premature asci, when the spores are still devoid of a spore body. Therefore, *O. multiaustraliensis* cannot be considered as a more mature stage of *O. palmicola*. *O. pleioaustraliensis* mainly differs in 16-spored asci and spores with shorter and thicker tails. *O. myrioaustraliensis* differs in larger apothecia, 64-spored asci, and spores with thicker, always distinct tails. *O. macrocarpa* differs in larger and thicker apothecia with strongly protruding margin, a thinner ascus apical dome, spores without distinct tails, and in the presence of yellow LBs in paraphyses, medullary and lower ectal excipulum, finally in occurring on bark. *O.* aff. *macrocarpa* (Pl. 229) has prominent spore tails similar as *O. multiaustraliensis*, but its spores are much longer, and its other features closely match *O. macrocarpa*.

Variation. The paratype concurred quite well with the holotype, except for distinctly shorter and narrower SBs and slightly shorter and wider asci.

Ecology. *O. multiaustraliensis* was found on rotten wood of xeric branches of *Acacia*. The species is known from two subtropical collection sites: from a semiarid acacia woodland in a dry riverbed (Gascoyne) of western Australia, and from an acacia shrubland in the arid sand dunes (Finke, south of MacDonnell Ranges) of central Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Gascoyne, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *Acacia cyperophylla*, on wood, 28.X.2007, G. Marson (H.B. 9695d). – **Northern Territories**, Finke, 100 km E of Yulara, 24 km ENE of Curtin Springs Roadhouse, 28 km NNE of Mt. Connor, 480 m, branch of *A. jennerae*, on wood, 10.X.1998, G. Marson (ex H.B. 6277j, MEL 2389203A, **holotype**).

Orbilia myrioaustraliensis Baral & E. Weber, **sp. nov.**, MB 814367 — Pls 223–224

Etymology: named after the 64-spored asci and a similarity with the 32-spored *O. multiaustraliensis.*

Typification: Western Australia, Tuckanarra, branch of *Acacia*, 27.X.2007, G. Marson (ex H.B. 8881a, MEL 2389262, holotype).

Latin diagnosis: *Similis* Orbiliae multiaustraliensi *sed asci 64-spori, ascosporae latiores, etiam caudae ascosporarum. Habitat ad corticem putridum ramorum siccorum* Acaciae *in zona (sub)tropica (semi)arida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4–0.7(–1) × 0.3–0.5 mm, 0.18–0.28(–0.4) mm high, light to bright orange, non-translucent, round to elliptical, scattered; disc slightly concave to flat, margin distinct, 25–40 µm protruding, ± smooth; sessile on an obconical base or with a distinct stipe up to 0.25 × 0.35 mm, slightly immersed; dry hysterioid or 3–4-angular, light to bright dirty orange. **Asci** *120–130 × 12–13 µm {2}, †95–120 × (9.5–)10–11.5(–12.5) µm {2}, 64-spored (54–58 spores counted), spores †4–5-seriate, lower spores inverted (strongly mixed), pars sporifera *100 µm long, †75–85 µm; **apex** (†) hemispherical irrespective of the viewing direction, dome †0.5–0.7 → 0.3–0.4 µm thick {1} (KOH 1–1.6 → 0.8–1 µm), immature with large, wide and high apical chamber; **base** with very short to medium long, thick stalk, L-, Y- or h-shaped. **Ascospores** *((7–))(9–)10–12.5(–15) × 3.5–4(–4.5) µm {2}, †(8.5–)9–13(–15) × 3–3.8 µm {2}, with ellipsoid(-fusoid) head and abrupt, cylindrical, basally sometimes slightly inflated tail */†(2–)3–5(–7) × 0.8–1.2 µm {2}, apex obtuse (to subacute), tail straight to slightly, exceptionally very strongly curved; **SBs** *(2.3–)2.6–3.2 × (1.2–)1.3–1.6(–1.8) µm {T}, tear-shaped, apically narrowed to a ± small point. **Paraphyses** apically slightly (rarely medium) clavate, terminal cells *10–18 × 2.5–3.5 µm {T}, †7.5–15(–22) × (1.8–)2.5–4.3 µm {1}, lower cells *10–19 × 2–3(–3.5) µm {T}, †11–17(–22) × 1.5–2 µm {1}; rarely to quite frequently branched at upper septum. **Medullary excipulum** 30–70 µm thick, of dense textura intricata with medium abundant inflated cells, sharply delimited. **Ectal excipulum** of hyaline, (†) slightly gelatinized, indistinctly to vertically oriented t. angularis(-prismatica) from base to mid flanks, 30–80 µm

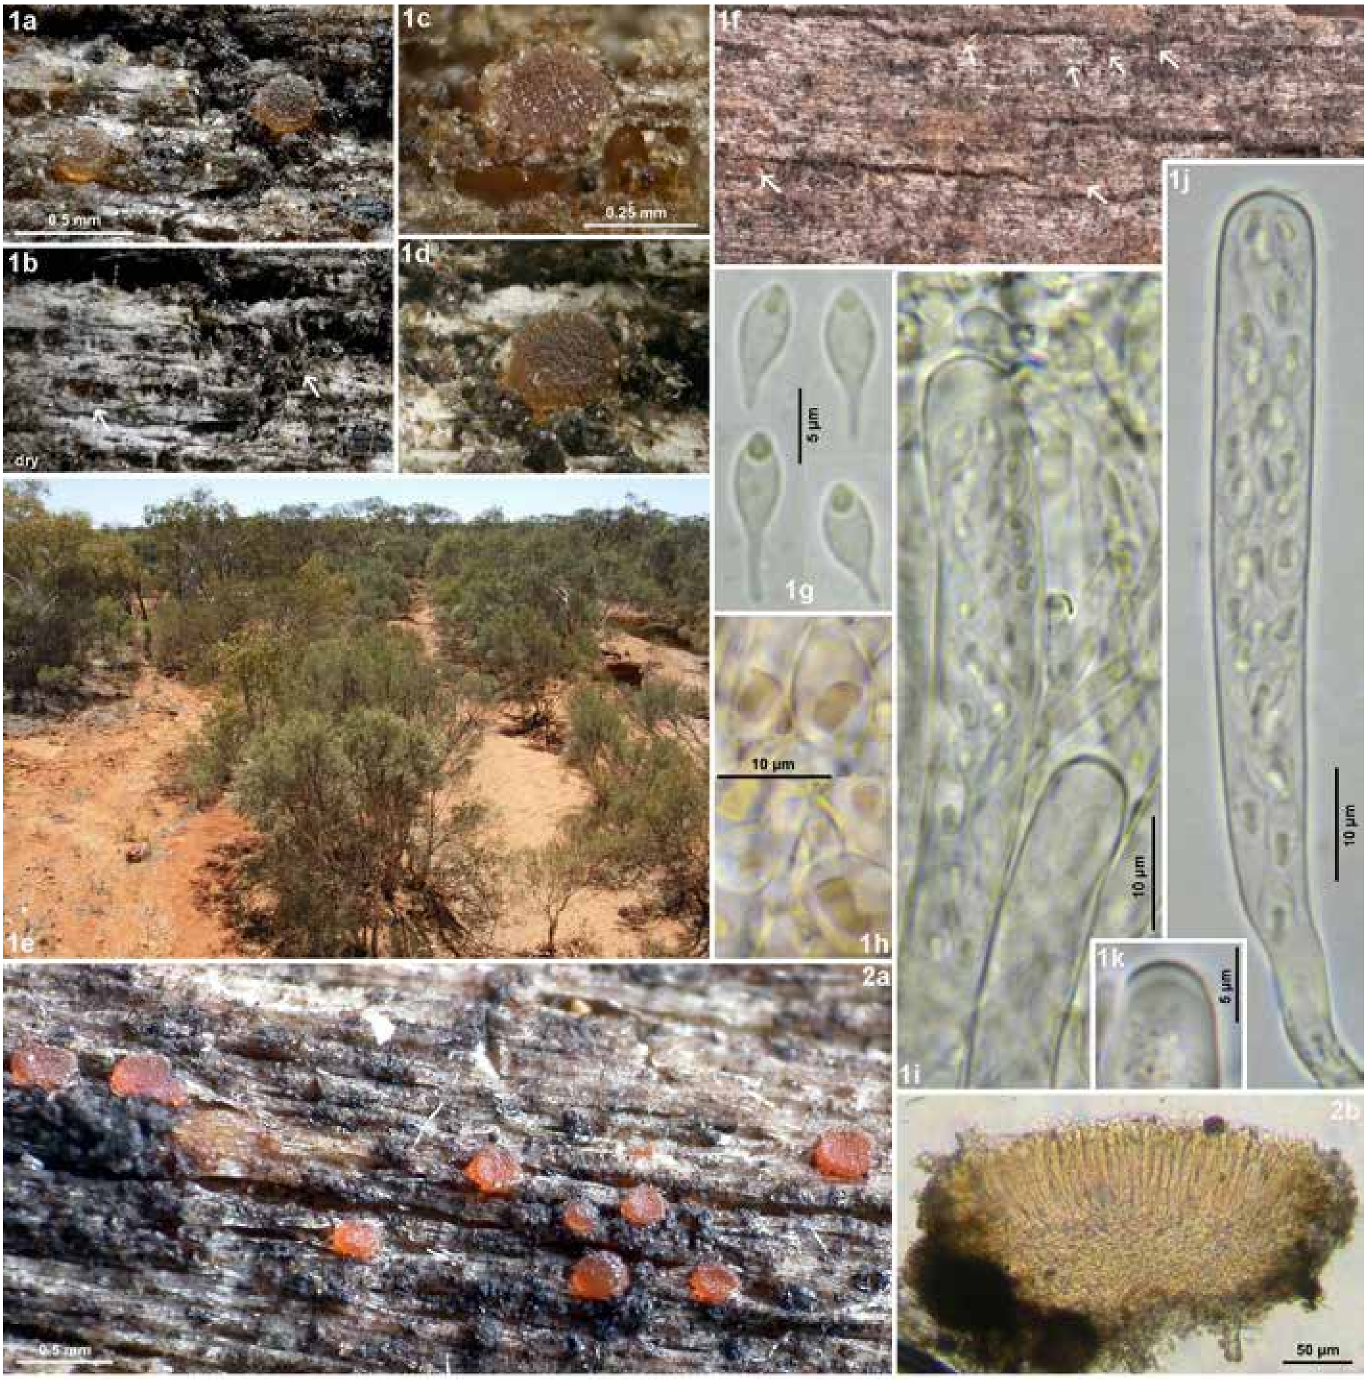

Plate 222. **1–2**: *Orbilia multiaustraliensis*. – **1e**. arid acacia open woodland; **1f**. closeup of branch (rehydrated); **1a**, **c–d**, **2a**. rehydrated apothecia; **1b**. dry apothecia (same sector as **1a**); **2b**. apothecium in median section; **1g**. ascospores (3 overmature); **1h**. crystalloid SCBs in marginal ectal excipulum; **1i–j**. asci and paraphyses; **1k**. ascus apex. – Living state, except for **1k**, **2b** (in KOH). — **1a–k**. H.B. 9695d: Western Australia, Gascoyne, on *Acacia*; **2a–b**. H.B. 6277j (holotype): Australia, Northern Territories, on *Acacia*.

thick near base, cells */†8–13(–15) × 6–8(–9) µm {2}, containing pale to light yellow-orange **LBs** 0.3–1.8 µm diam. (carotenoids, also in paraphyses) {3}; 20–40 µm thick near margin, of t. prismatica-porrecta oriented at a 0–20° angle to the surface, hyphae firm-walled, undulating and somewhat free in the outer layer, marginal cortical cells †8–16 × 3–4.3(–5) µm {1}, curved inwards; **glassy processes** absent. **Anchoring hyphae** abundant, †2–3(–4) µm wide, walls 0.2–0.3 µm thick {1}, forming a dense hyaline layer up to 35 µm thick near base (inner part light yellow), at flanks 20 → 10 µm thick. **SCBs** in paraphyses and marginal cells globose, 2.5 µm diam., mostly also with crystalloid (rod-shaped), pale yellow-orange SCBs in paraphyses (1.5–2 × 0.7–1.1 µm) and marginal excipulum {T}. **Exudate** over paraphyses 0.1–0.3 µm thick, granular, scattered, hyaline, loosely attached, over margin and flanks 0.2–1 µm thick, granular-cloddy. — **ANAMORPH**: unknown.

Habitat: collected 0.7–1.5 m above the ground, corticated, 8–12 mm thick branches of *Acacia* sp. {3}, on medium to strongly decayed bark {3} (bast), often on edges of bark, strongly greyed, without algae. **Associated**: ?*Baggea* sp. {1}, *Dinemasporium* sp. {1}, *Orbilia coronohesperidea* {1}, *O. myriomuscula* {1}, *O. phanosoma* {1}, *O. pleiocoronohesperidea* {1}, *O. pleioserpens* {3}, ?*Teichospora* sp. {1}. **Desiccation tolerance**: many submature asci still viable after 8 months. **Altitude**:: 467–690 m a.s.l. **Geology**: Precambrian sedimentary rock (red-brown gravel), mafic basaltic volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myrioaustraliensis* closely resembles *O. multiaustraliensis*, from which it mainly differs in 64-spored asci and wider spores with thicker tails. *O.* aff. *macrocarpa* (Pl. 229) differs in much narrower spore heads

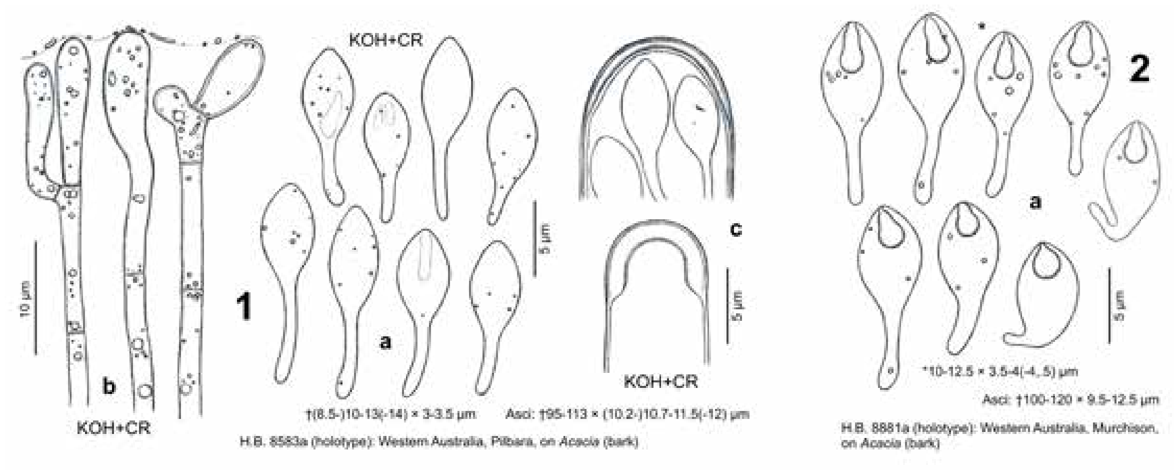

Plate 223. **1–2**: *Orbilia myrioaustraliensis*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices.

and 32-spored asci. *O. myriohesperidea* differs in much narrower spores.

Ecology. *O. myrioaustraliensis* was found on strongly rotten bark of dead xeric branches of *Acacia* in subtropical semiarid to tropical arid open acacia shrublands in dry riverbeds of the Murchison and Pilbara ecoregions in the mid west of Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Pilbara, N of Karijini, 1.5 km SW of Wittenoom, delta of Wittenoom Gorge, 467 m, branch of *Acacia*, on bark, 28.XI.2001, G. Marson (H.B. 8583a). – 49 km NW of Newman, northern border of Ophthalmia Range, 690 m, branch of *Acacia*, on bark, 28.X.2007, G. Marson (H.B. 8879c ø). – Murchison, 72 km SW of Meekatharra, 17 km W of Reedy, E of Tuckanarra, 493 m, branch of *Acacia*, on bark, 27.X.2007, G. Marson (ex H.B. 8881a, MEL 2389262, **holotype**).

Orbilia palmicola Baral, **sp. nov.**,

MB 813542 — Pls 225–226

Etymology: named after the substrate, the palm *Livistona nitida*.

Typification: Australia, Queensland, Taroom, leaves of *Livistona nitida*, 22.X.1998, G. Marson (ex H.B. 6424a, BRI AQ799184, holotype).

Latin diagnosis: *Similis* Orbiliae multiaustraliensi *sed ascosporae et corpuscula refringentia minora, ascosporae indistincte caudatae. Habitat ad petiolos putridos siccos* Livistonae nitidae *in zona subtropica subhumida Australiae orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.4 × 0.2–0.3 mm, 0.1–0.13 mm high, light to bright orange, ± round, scattered; disc flat, margin distinct, 0–10 µm rising above disc, smooth; broadly sessile, erumpent between host fibres. **Asci** *60–85 × 8–9.2 µm, †50–80 × 6.4–8 µm, exactly 32-spored, spores ± 4-seriate, lower spores inversely oriented (strongly mixed), pars sporifera *45–53 µm long; **apex** (†) hemispherical to slightly truncate, dome †H_2O 1 → 0.5 µm thick (KOH 1–1.5 → 0.6–1 µm), with apical chamber; **base** without or with or without short, thick or thin, flexuous stalk, L-, Y- or h- shaped. **Ascospores** *(5.7–)7–8.7(–10.5) × (2.7–)2.9–3.2 µm, †7–8 × 2.8–3 µm, broadly fusoid-clavate, apex rounded or often obtuse to subacute, base often tail-like, straight to very slightly curved at base; **SBs** *1.5–2 × 1–1.2 µm, tear-shaped to ampulliform, apically narrowed to a small to wide point, with some ± small LBs. **Paraphyses** apically uninflated to slightly clavate, rarely slightly spathulate, terminal cells *6–17 × 2–3.2 µm, lower cells *10–15 × 1.4–2 µm, basal cells *7–10 × 2–2.5 µm; not infrequently branched near apex. **Medullary excipulum** hyaline, 10–15 µm thick, of dense textura intricata with a few or many inflated cells, quite sharply delimited. **Ectal excipulum** hyaline, light orange near margin, of thin-walled, irregularly oriented t. angularis from base to mid flanks, 20–40 µm thick near base, cells *5–14 × 4–10 µm; 15–25 µm thick near margin, of t. prismatica-angularis oriented at a 10–45° angle to the surface, (†)

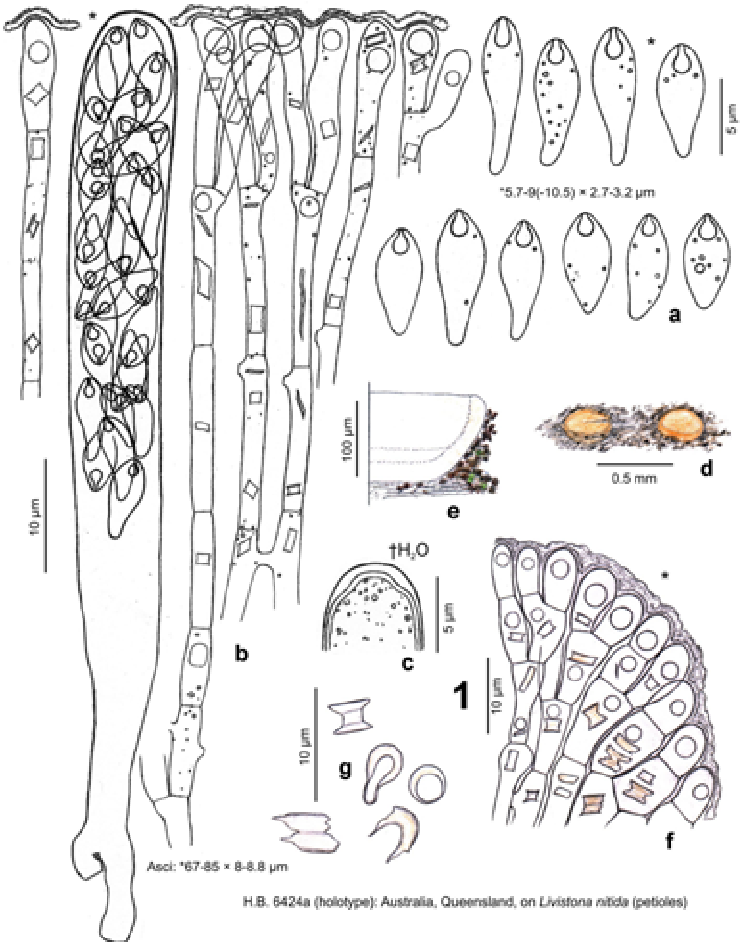

Plate 225. **1**: *Orbilia palmicola*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. id., ectal excipulum at margin; **g**. crystalloid SCBs in ectal excipular cells.

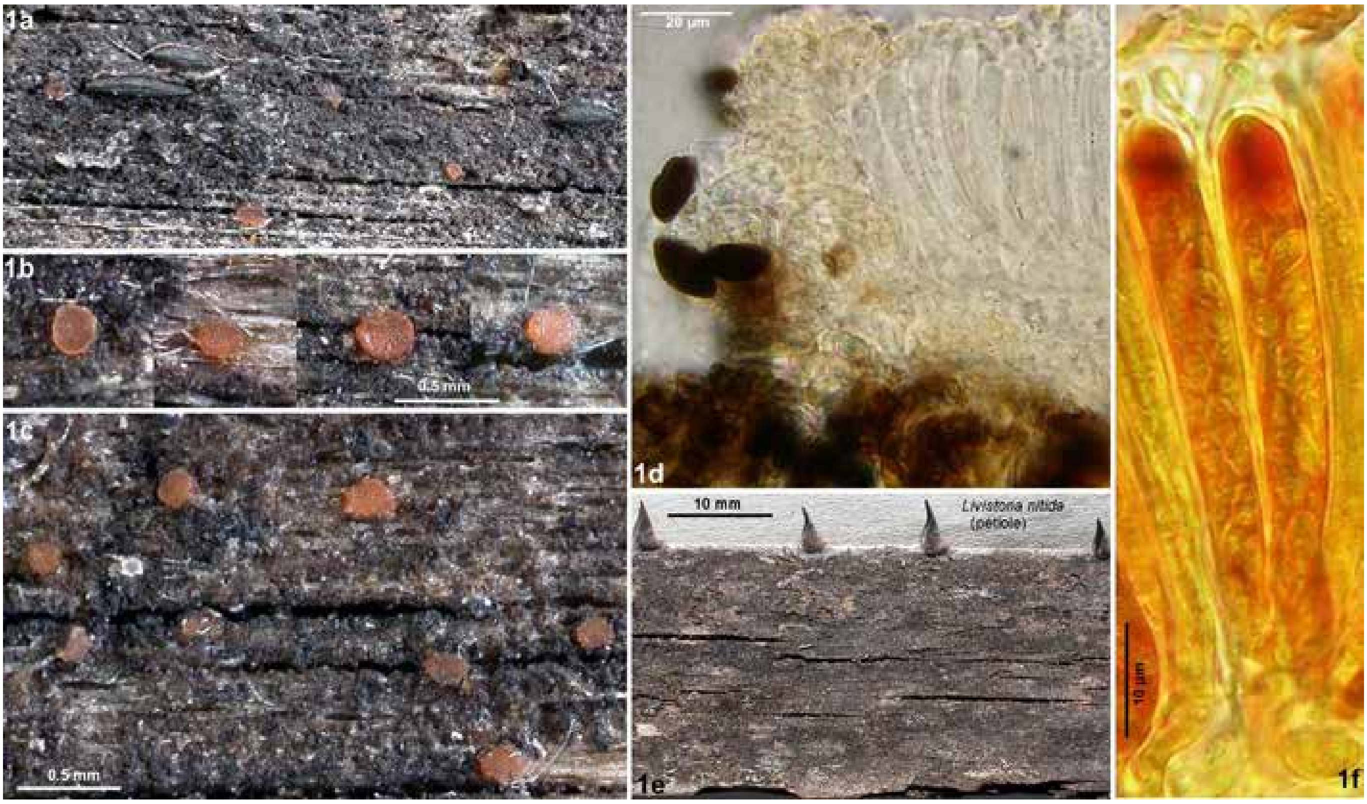

Plate 226. **1**: *Orbilia palmicola*. – **1e**. dead xeric petiole of *Livistona nitida* (upper side); **1a–c**. rehydrated apothecia (**1a** with *Gloniopsis* sp.); **1d**. apothecium in median section; **1f**. asci and paraphyses (in IKI). – Dead state (**1d** in KOH, **1f** in KOH+IKI). — **1a–f**. H.B. 6424a (holotype): Australia, Queensland, on *Livistona*.

slightly gelatinized, marginal cortical cells *6–12 × 3–4.5 µm, **glassy processes** absent. **Anchoring hyphae** sparse, †2–2.5 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses and ectal excipulum globose, and crystalloid, pale orange. **Exudate** over paraphyses 0.4–1.5(–2) µm thick, continuous, rough, loosely attached; over margin and flanks 1–2 µm thick, rough-cloddy. **— ANAMORPH**: unknown.

Habitat: collected 0.2–2 m above the ground, still-attached, 15–28 mm broad dead petioles of *Livistona nitida*, always on rather strongly decayed upper side, slightly to strongly greyed, green algae sparse. **Associated**: *Gloniopsis* sp., *Mellitiosporiella* sp., *Orbilia acaciae*, *O. ?australiensis*, *O. ?commarosa*, *O. coronohesperidea*, *O. ?dixiensis*, *O. livistonae*, *O. multiserpens*, *O. myrioeuonymi*, *O. parviclava*, *O. pleiohesperidea*, *?Phaeotrichoconis* sp. **Desiccation tolerance**: fully viable for at least 9 months. **Altitude**:: 200 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia palmicola* appears to be closely related to *O. pleioaustraliensis*, from which it differs in 32-spored asci and smaller ascospores with much smaller SBs. *O. multiaustraliensis* mainly differs in spores with thinner tails and longer SBs. *O. myriofusiclava* is also similar, but its spores are distinctly narrower and often curved, and have a bit more acute apices, also the asci are 64-spored.

Ecology. *O. palmicola* grew ± scattered over rather large areas of rotten, attached, hanging, xeric petioles of *Livistona* in a subtropical subhumid savannah eucalypt woodland in the Palm-Tree Creek at the Great Dividing Range of eastern Australia.

Globose, hyaline, single cells were observed in close proximity to some apothecia, which might be pollen grains or oospores (see Fig. 117). Most of them were infected by haustoria of mycelia which seem to belong to the *Orbilia*. A few conidia of *Trinacrium* sp. were observed in proximity to infected cells, but their connection to *O. palmicola* could not be confirmed.

Specimens included. **AUSTRALIA**: **Queensland**, Brigalow Belt South, 69 km SSW of Theodore, 15 km N of Taroom, Palm-Tree Creek, Roy Staines Bridge, 200 m, petioles of *Livistona nitida*, 22.X.1998, G. Marson (BRI AQ799184, **holotype**; MEL 2389207 & H.B. 6424a, **isotypes**).

Orbilia macrocarpa Baral & G. Marson, sp. nov.,
MB 813532 — Pls 227–228

Etymology: named after the comparatively large and thick apothecia.

Typification: Western Australia, Meekatharra, branch of *Acacia*, 26.XI.2001, G. Marson (ex H.B. 8697d, MEL 2389249, holotype).

Latin diagnosis: *Similis* Orbiliae multiaustraliensi *sed ascosporae cauda breviore praeditae, apothecia majores, margine projecto. Habitat ad corticem putridum ramorum siccorum* Acaciae *in zona subtropica (semi)arida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.27–)0.4–1 × (0.24–)0.3–0.5 mm, 0.2–0.4 mm high, light to bright orange(-brick-red), non-translucent, round to often elongate (laterally compressed), scattered to gregarious in small groups; disc slightly concave to flat, margin distinct, ± thick, 20–50 µm protruding, smooth to very slightly rough; broadly sessile, superficial or erumpent from cracks in periderm; dry usually hysterioid with ± closed disc. **Asci** †(80–)90–100(–110) × 7.3–8.8 µm {2}, 32-spored, spores †4-seriate, lower spores inverted {2} (strongly mixed), pars sporifera †64–75 µm; **apex** (†) hemispherical, dome †0.8–1.3 → 0.3–0.8 µm thick {1}, with apical chamber; **base** with short, thick, flexuous stalk, ?L-shaped. **Ascospores** *8.8 × 3.5 µm, †8–12 × 2.7–3.5 µm {2}, (ellipsoid-)fusoid to fusiform(-clavate), apex subacute to acute, base strongly attenuated, with or without a distinct tail or tail-like end, straight to sometimes slightly curved; **SBs** *~3.3 × 1-1.2 µm, narrowly tear-shaped (subulate). **Paraphyses** apically slightly to strongly clavate (rarely moniliform), terminal cells †7–20 {2} × 2–3 {1} or 3–4.5 µm {1}; sometimes branched at upper septum, lower half with light yellow-orange **LBs** (carotenoids) in the cells. **Medullary excipulum** pale to light yellowish to orange (or hyaline in lower part), 30–100 µm thick, of medium dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** hyaline, of (†) thin-walled to slightly gelatinized, vertically oriented t. angularis-prismatica from base to mid flanks, 90–200 µm thick near base, cells †(6–)9–15(–18) × (5–)6–11 µm {2}, common walls 0.5–1 µm; 50 µm thick on lower flanks, 20–30 µm near margin (up to 70 µm at protruding part including covering layer), pale to bright yellowish-orange, of t. prismatica-porrecta oriented at a 0–40° angle to the surface, marginal cortical cells †9–14 × 2.7–5 µm {1}, firm-walled (walls 0.2–0.4 µm thick); **glassy processes** absent. **Anchoring hyphae** sparse to abundant, †2–3(–4) µm wide, walls 0.2–0.3 µm thick {2}, forming a hyaline to light yellow-ochre, 10–20 µm thick t. intricata-porrecta at flanks and margin. **SCBs** no data available. **Exudate** over paraphyses and margin 0.2–1 µm thick, granular, loosely attached. — **ANAMORPH**: unknown.

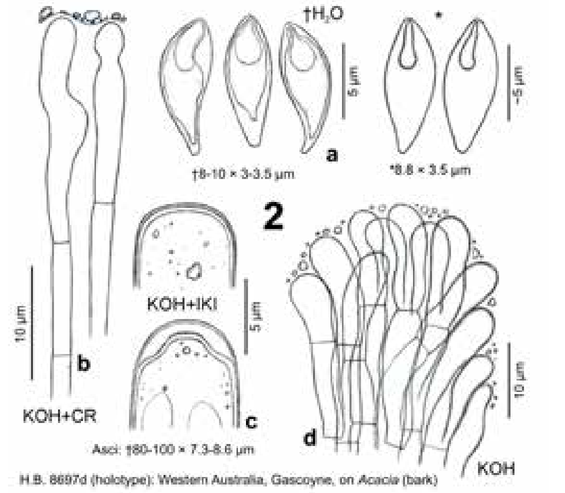

Plate 227. **1**: *Orbilia macrocarpa*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section.

Habitat: collected ~2 m above the ground, ± corticated, 4–15 mm thick branches of *Acacia* sp. {2}, on strongly decayed bark (bast) {2}, usually in cracks of periderm, rarely on inner surface of detaching bark, strongly greyed, no algae. **Associated**: *Orbilia anguliobliqua* {1}, *O. corculispora* {1}, *O. microserpens* {1}, *O. ?multiserpens* {1}, *O. ?multivirgula* {2}, *O. myriella* {1}, *O. myriomuscula* {1}, *O. myrioobliqua* {1}, *O. ?navajoana* {1}, *O. pleioungulata* {1}, *O. ?pseudeuphorbiae* {1}, *Ostropales* {1}, *Rhizodiscina* sp. {1}. **Desiccation tolerance**: unknown but certainly during min. 1 year. **Altitude**: 157–560 m a.s.l. **Geology**: Mesoproterozoic and Cretaceous sedimentary rock (red-brown sandstone). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia macrocarpa* differs from *O. multiaustraliensis* in larger and thicker apothecia with a strongly protruding margin, and in growing on bark, also in spores with shorter tails. The species was almost exclusively studied in the dead state, therefore, the vital characters are unknown, except for the spore bodies. *O.* aff. *macrocarpa* (Pl. 229) concurs very well with the present taxon, but differs in distinctly longer spores and an almost absent exudate *O. myriofusiclava* has similar apothecia but differs in 64-spored asci, smaller, often curved spores, and very abundant exudate.

Variation. Some variation between the two collected populations need to be mentioned: the holotype differs from the paratype in shorter and wider spores which are ± without a tail-like base, also in the paraphyses being apically only slightly inflated and therefore narrower. The other features are very similar between the two collections, and we are not in doubt that they are conspecific.

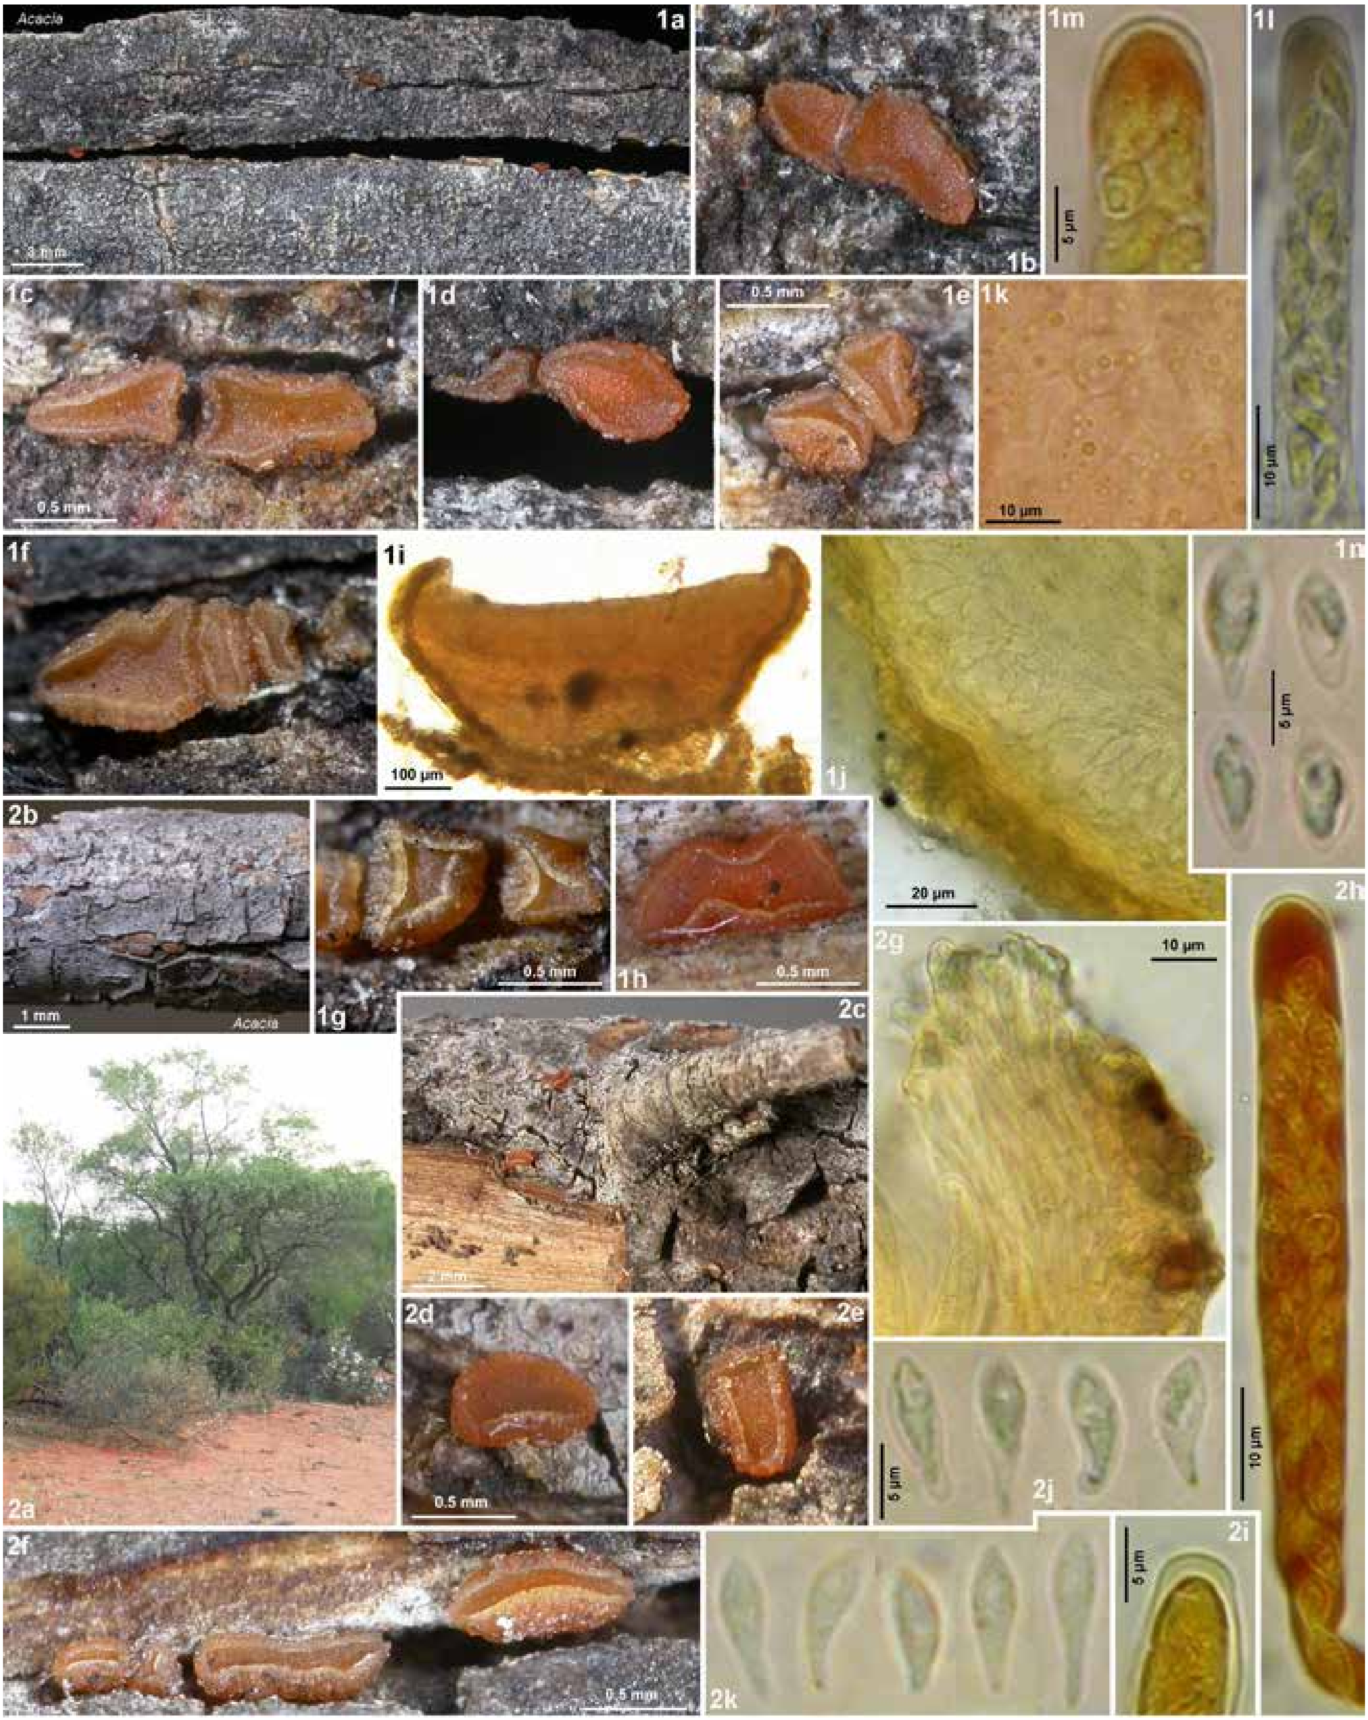

Plate 228. **1–2**: *Orbilia macrocarpa*. – **2a**. semiarid acacia shrubland; **1a**, **2b–c**. branches of *Acacia* (apothecia in cracks of bark, rehydrated), **1b–h**, **2d–f**. rehydrated apothecia; **1i**. apothecium in median section; **1j**, **2g**. id., ectal excipulum (flanks and margin); **1k**. lipid bodies in ectal excipulum (lower flanks); **1l**, **2h**. asci; **1m**, **2i**. ascus apices; **1n**, **2j–k**. ascospores. – All in dead state (**1n**, **2g**, **j** in H2O; **1j–k**, **2k** in KOH; **1l–m**, **2h–i** in KOH+IKI). — **1a–n**. H.B. 8697d (holotype): Western Australia, Gascoyne, on *Acacia*; **2a–j**. H.B. 9033d: ibid., Yalgoo, on *Acacia*.

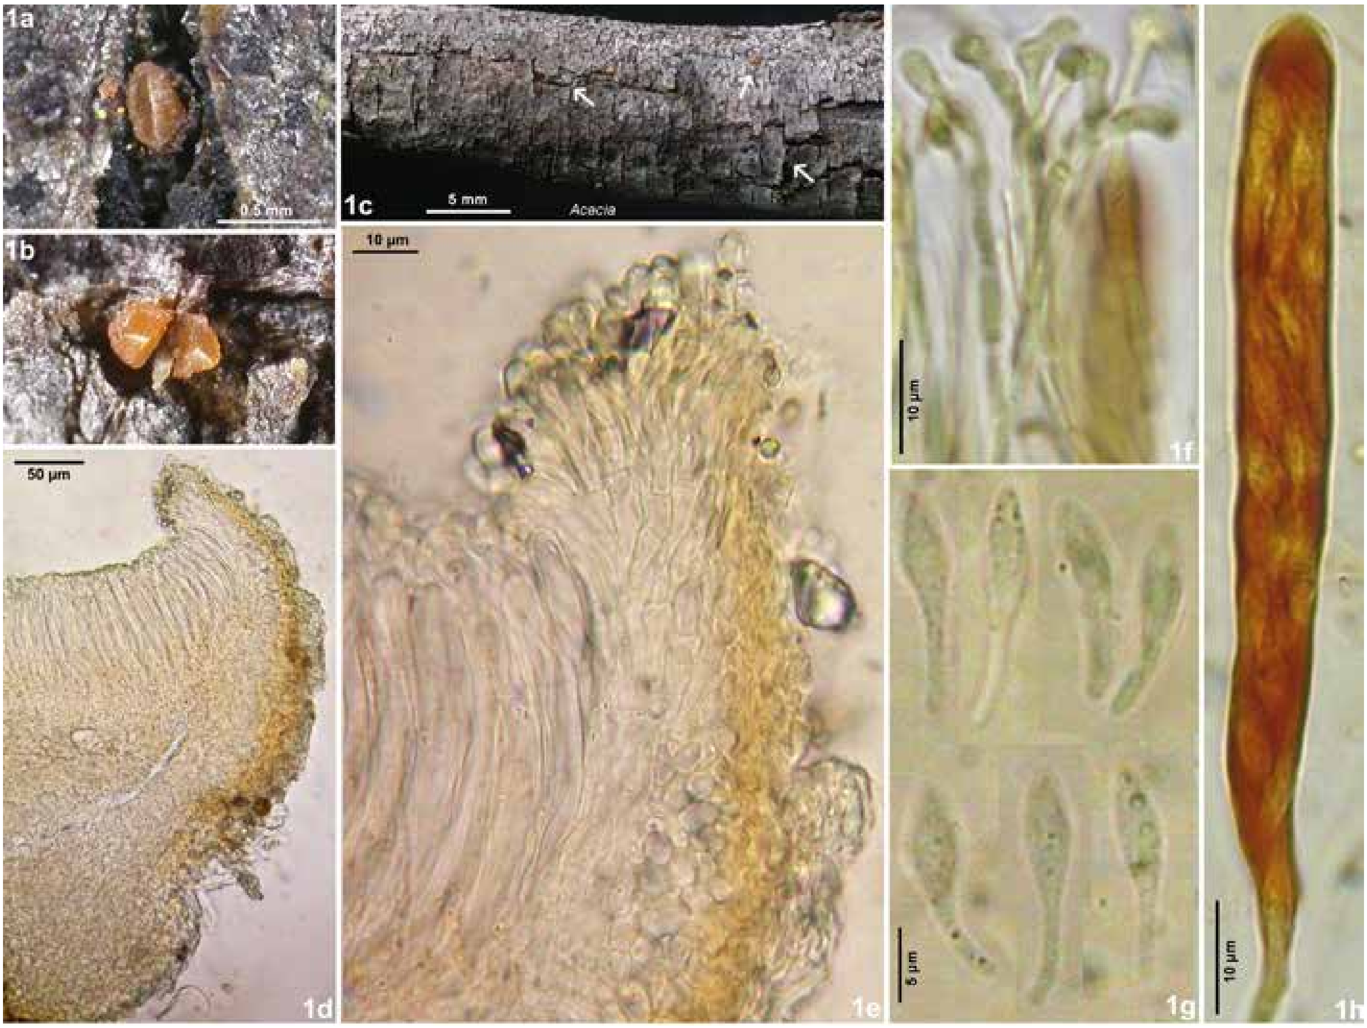

Plate 229. **1**: *Orbilia* aff. *macrocarpa*. – **1c**. dead corticated xeric branch of *Acacia*; **1a–b**. rehydrated apothecia (**1b** after a median section was taken); **1d**. apothecium in median section; **1e**. id., marginal ectal excipulum; **1h**. mature ascus; **1f**. paraphyses; **1g**. ascospores. – All in dead state (**1d–e**, **g** in KOH; **1f**, **h** in KOH+IKI). — **1a–h**. H.B. 7415f: Western Australia, Kalbarri, on *Acacia*.

Ecology. *O. macrocarpa* grew on rotten bark of xeric *Acacia* branches. The two known collections derive from subtropical semiarid to arid open acacia shrublands of western Australia (Yalgoo and Gascoyne ecoregion).

Specimens included. **AUSTRALIA**: **Western Australia**, Gascoyne, south-border of Collier Range, 175 km NE of Meekatharra, 41 km SW of Kumarina Roadhouse, 560 m, branch of *Acacia*, on bark, 26.XI.2001, G. Marson (ex H.B. 8697d, MEL 2389249, **holotype**). – Yalgoo, W of Toolonga, 200 km N of Geraldton, 15 km SSE of Wannoo Billabong Roadhouse, 157 m, branch of *Acacia*, on bark, 8.XII.2001, G. Marson (H.B. 9033d).

Orbilia aff. *macrocarpa* — Pl. 229

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.4 × 0.25–0.28 mm, 0.33 mm high (receptacle 0.13–0.18 mm), bright orange, scarcely translucent, ± angular to laterally compressed, scattered; disc flat, margin very distinct, 40–60 µm protruding, finely whitish pubescent; sessile on a small hidden stipe 0.1 × 0.17 mm, erumpent from cracks. **Asci** †100–110 × 8–8.5 µm, 32-spored (25–30 spores counted), spores †4-seriate, lower spores inverted (± mixed), pars sporifera †60–88 µm long; **apex** (†) hemispherical, dome †0.8–1.2 µm thick, with slight apical chamber; **base** with medium long and thin, flexuous stalk, L-shaped. **Ascospores** †13–16 × 2.8–3 µm, with a fusoid, 7.5–9 µm long head and a distinct tail 4.5–6.5 × 0.9–1.2(–1.6) µm, apex obtuse to subacute, tail straight to slightly curved, sometimes slightly inflated at base; **SBs** only sometimes faintly seen, ?narrowly tear-shaped. **Paraphyses** apically slightly to medium clavate, sometimes moniliform, terminal cells †10–20 × 2.5–3.5 µm, lower cells †8–18 × 1.4–1.8 µm; frequently branched near apex, containing pale yellow-orange **LBs** (carotenoids) in lower part, hymenium pale orange. **Medullary excipulum** pale orange, 60 µm thick, of medium dense textura intricata with many inflated cells, sharply delimited mainly at flanks. **Ectal excipulum** very pale orange, of slightly gelatinized, indistinctly vertically oriented t. angularis from base to submargin, ~170 µm thick near base, cells †8–12 × 7–12 µm; 50 µm thick on lower flanks, 15–20 µm at submargin, 30–40 µm at upper margin, here of thin-walled t. prismatica oriented at a 10–20° angle to the surface, marginal cortical cells †8–13 × 3–4.5 µm, ± firm-walled (walls 0.2–0.3 µm thick); **glassy processes** absent. **Anchoring hyphae** rather sparse, †2–3 µm wide, walls 0.2–0.3(–0.5) µm thick, forming a 10–20 µm thick layer of yellowish-orange (externally hyaline) hyphae over flanks and margin. **SCBs** no data available. **Exudate** over paraphyses absent; over margin and flanks 0.1 µm thick, continuous. — **ANAMORPH**: unknown.

Habitat: corticated, 11 mm thick branch of *Acacia* sp., on medium decayed bark, in cracks of periderm, ± greyed, without algae. **Associated**: *Gloniopsis* sp., *Hysterobrevium mori*, *Orbilia australiensis*, *O. commarosa*, *O.* ?*pleiohesperidea*. **Desiccation tolerance**: unknown but certainly during min. 1 year. **Altitude**: 160 m a.s.l. **Geology**: Silurian sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. The collection differs from *O. multiaustraliensis* in distinctly longer ascospores, and in larger and thicker apothecia with a strongly protruding pubescent margin, also in growing on bark. The spores are consistently provided with a distinct, rather long tail. A new species is not proposed here because merely two apothecia were available, and no vital characters could be studied. Moreover, separation from *O. macrocarpa* (Pls 227–228) is not certain. The apothecia were accidentally discovered when the associated *O. commarosa* was restudied almost 5 years after it was collected.

Ecology. *O.* aff. *macrocarpa* was found on medium rotten bark of a dead xeric branch of *Acacia* in a subtropical semiarid acacia shrubland at the border of Murchison Gorge of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Geraldton Sandplains, 80 km NNW of Northampton, 29 km ENE of Kalbarri, near meander of Murchison, 160 m, branch of *Acacia*, on bark, 9.XII.2001, G. Marson (H.B. 7415f).

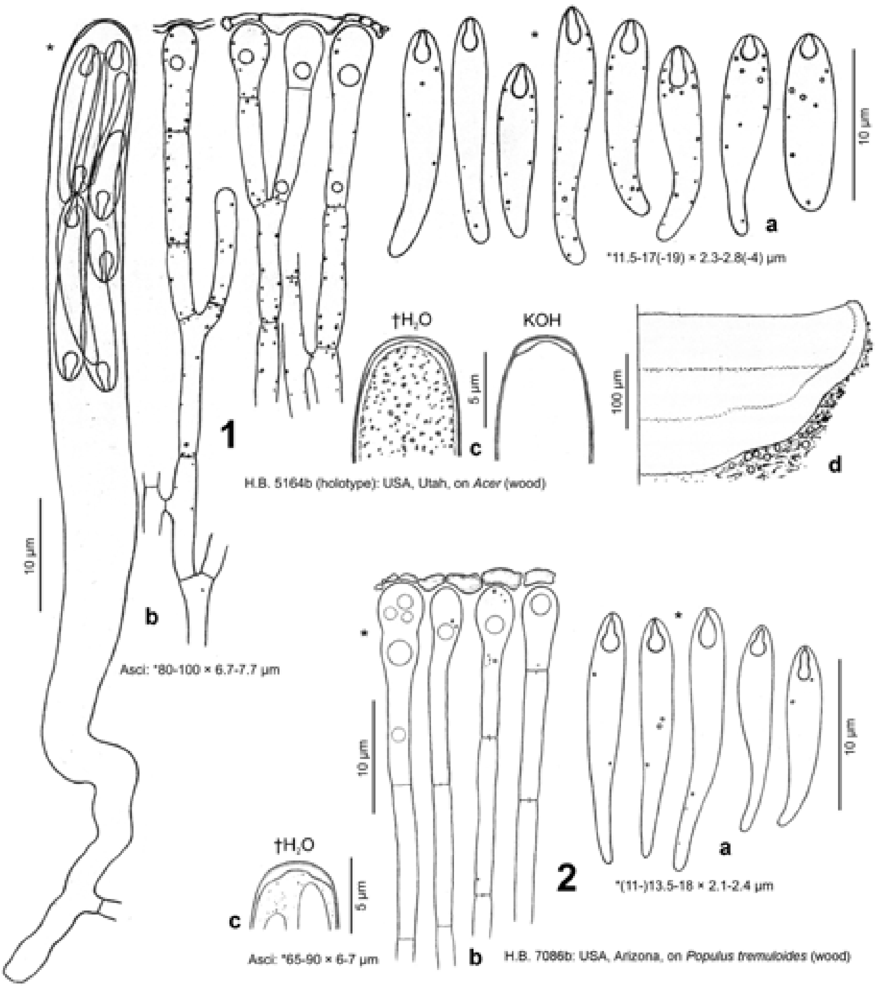

Plate 230. **1–2**: *Orbilia navajoana*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section.

Orbilia navajoana Baral & G. Marson, **sp. nov.**, MB 813544 — Pls 230–231, Map 40

Etymology: referring to the type locality, the Navajo trail in Bryce Canyon.

Typification: USA, Utah, Bryce Canyon, branch of *Acer*, 25.VIII.1994, G. Marson (ex H.B. 5164b, M-0276537, holotype).

Latin diagnosis: *Apothecia 0.2–0.7 mm diam., sessilia, erumpentia, aurantiaca, margine laevi vel subtiliter aspero. Asci 8-spori. Ascosporae *11–19 × 2.1–3.2 µm, subcylindrico- ad fusoideo-clavatae, apice obtusae, ad basim attenuatae et plerumque leniter curvatae, in statu vivo corpusculum refringens lacrimi- ad ampulliformem, ad apicem affixum continentes. Cellulae vivae exciputi marginalis et paraphysium corpuscula globosa continentes, excipulum marginale absque processis vitreis. Habitat ad lignum putridum ramorum siccorum angiospermarum vel coniferarum in zona temperata subhumida ad boreale humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.25–0.5(–0.7) mm diam., 0.12–0.22 mm high, light to bright orange(ochraceous), non-translucent, round (to elliptical), scattered to gregarious; disc medium concave to flat, margin distinct, medium thick, 0–10 µm protruding, smooth to finely rough; broadly sessile, slightly to half erumpent. **Asci** *(65–)80–90(–100) × 6–8(–8.8) µm {4}, †(55–)60–85 × 5–7 µm {4}, 8-spored, spores *3–4-seriate, 2–6 lower spores inverted {3} (often mixed), pars sporifera *34–42 µm long; **apex** (†) hemispherical to slightly truncate, dome †0.5–1.1 → 0.5–0.7 µm thick {3}, with slight apical chamber, wall sometimes almost unthickened, even when immature; **base** with short to long, ± thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(11–)12–17(–19) × (2.1–)2.3–2.8(–3.2) µm {4}, subcylindric- to fusoid-clavate, apex rounded to mainly obtuse, medium to strongly attenuated in a 0.7–1.5 µm wide tail-like base, straight to mostly slightly, sometimes medium curved near base; **SBs** *2–2.8(–3) × 1–1.3 µm {2}, tear-to pear-shaped, also ampulliform, apically narrowed to a small to wide point. **Paraphyses** apically slightly to medium capitate-clavate, terminal cells *6–18 × (2–)2.5–3.7 µm {2}, †(2.2–)2.5–3(–3.7) µm wide {1}, lower cells *(6.5–)9–15(–20) × 1.4–2.3 µm {2}, †1.2–1.5 µm wide {1}; rarely or frequently branched near apex. **Medullary excipulum** 60–70 µm thick, of medium dense textura intricata(-globulosa), sharply delimited. **Ectal excipulum** pale to light orange (especially towards margin), of thin-walled to slightly gelatinized, vertically oriented t. angularis(-prismatica) from base to mid flanks, 20–70 µm thick near base, cells *8–25 × 6–13.5 µm {2}; 30–60 µm thick at flanks, 15–30 µm near margin, of t. porrecta oriented at a 20–30° angle to the surface, marginal cortical cells *8–13 × 2–4 µm {2}; **glassy processes** absent. **Anchoring hyphae** abundant, *2.5–3.5 µm wide, walls 0.2–0.4 µm thick {1}. **SCBs** globose {5}, 0.8–2.2 µm diam. in paraphyses, 2–3.5 µm in ectal excipulum (near margin). **Exudate** over paraphyses and marginal excipulum 0.5–2 µm thick, cloddy-continuous, loosely attached. **— ANAMORPH**: trinacrium-like (presumed, from natural substrate {1}, only 1 conidium seen). **Conidiophores** not seen. **Conidia** Y-shaped, †24 × 42 µm, stipe 12 × 6 µm, 2-septate, arms 21–22 × 7 µm, 3-septate, strongly tapered {1}.

Habitat: collected up to 3 m above the ground, decorticated, 13–35 mm thick branches of *Acer* sp. {1}, *Juniperus osteosperma* {2}, *Populus tremuloides* {1}, *Salix ?bebbiana* {1}, on 0.2–0.5 mm deep medium to very decayed wood {4}, strongly greyed, with many green algae. **Associated**: *?Amandinea* sp. {1}, *Diplolaeviopsis* sp. {1}, *Hysterium* sp. {1/1}, *Hysteropatella* sp. {1}, *Mellitiosporiella macrospora* {1}, *M. pulchella* {1}, *Odontotrema* sp. {1}, *O. oregonensis* {1}, *Orbilia calyptrata* {1}, *O. cupularis* {1}, *O. delphinus* {1}, *O. dixiensis* {1}, *O. flexisoma* {1}, *O. gambelii* {2}, *O. macrodelphinus* {1}, *O. microsoma* {2}, *O. multimaeandrina* {1}, *O. ophiosoma* {1}, *O. tremuloidis* {1}, *Perrotia flammea* {1}, *Phragmiticola* sp. {1}, *Sclerococcum* sp. {1}, *Unguiculariopsis* sp. {1}. **Desiccation tolerance**: a few mature asci still alive after 17 months, excipular cells and some paraphyses even after 33 months. **Altitude**: 2068–2825 m a.s.l. **Geology**: Permian and Upper Cretaceous sand-, lime- and mudstone; mafic volcanic lava with basalt, andesite & rhyolite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia navajoana* is characterized by rather long, subcylindric- to fusoid-clavate spores with short, tear-shaped SBs. It differs from both *O. vinosa* and *O.*

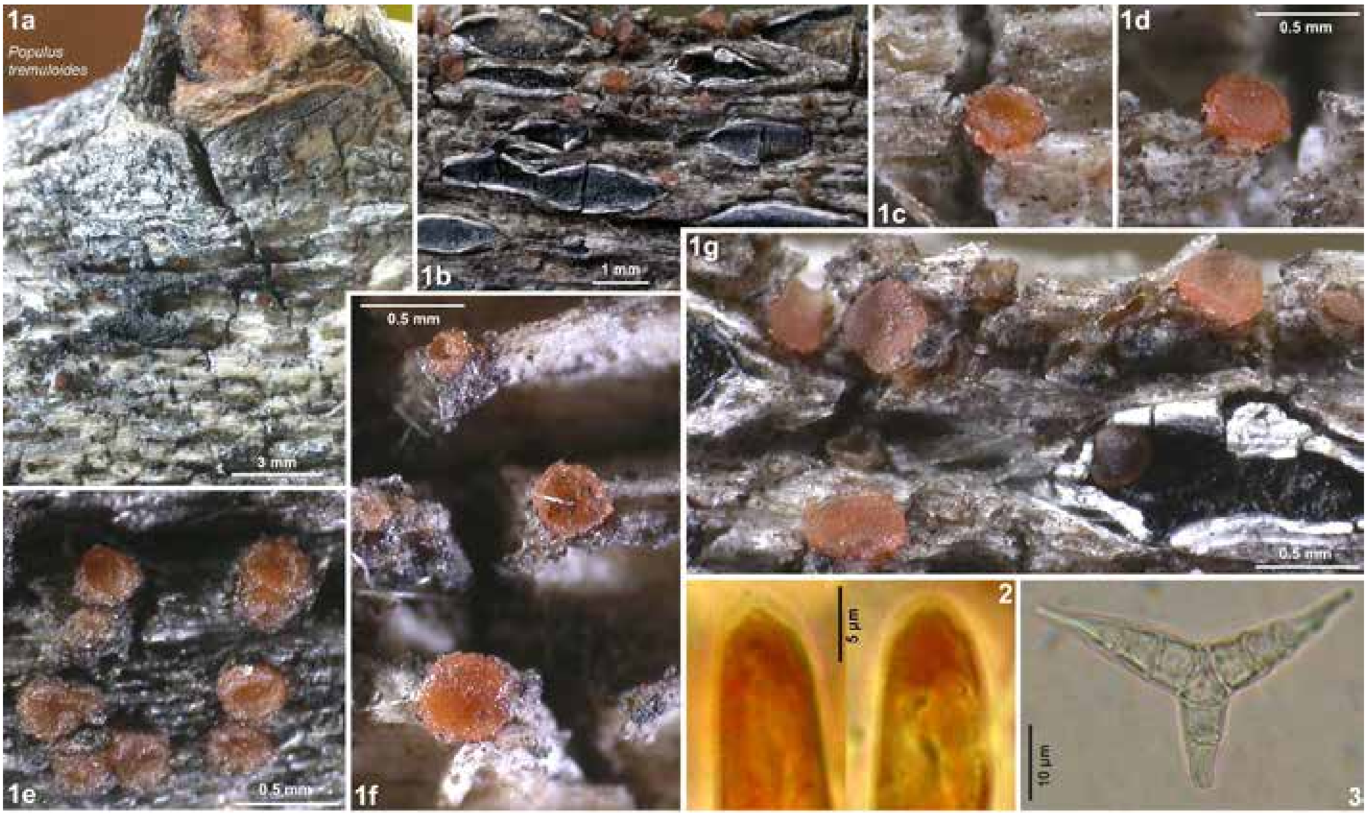

Plate 231. **1–3**: *Orbilia navajoana*. – **1a**. detail of decorticated xeric branch of *Populus tremuloides*; **1b–g**. rehydrated apothecia (with *Mellitiosporiella pulchella*); **2**. ascus apices. **3**. conidium from substrate. – Dead state (**2** in KOH+IKI, **3** in H_2O). — **1a–g**. H.B. 7086b: USA, Arizona, San Francisco Peaks, on *Populus*; **2**. H.B. 5362: ibid., Grand Canyon, on *Juniperus*; **3**. H.B. 5164b (holotype): USA, Utah, Bryce Canyon, on *Acer*.

hesperidea in the consistently shorter SBs, from the former also in wider spores, and from the latter in the consistent absence of crystalloid SCBs. The ascus apical thickening is also thinner than in these two species.

Variation. The spores of *O. navajoana* vary to some extent in length and especially width. The only abundant collection (on *Populus*) showed the narrowest spores, whereas the two on *Juniperus* had the widest spores (IVV: H.B. 5362, 8097c).

Not included collections. Two samples on *Larrea* from the Sonoran Desert scrub (IVV: H.B. 5658d, H.B. 5687f) have spores and SBs very similar to *O. navajoana*, but are not included because they possess crystalloid SCBs in the ectal excipulum and sometimes also in the paraphyses. For the similar Macaronesian *O. adenocarpi* see p. 674.

A sparse Australian specimen on *Acacia* (IVV: H.B. 9033a) was only studied in the dead state: it has similar ascus and spore dimensions but deviates in a hairy margin with thin-walled ~15–30 µm long projecting hairs.

Anamorph. The trinacrium robustum-like conidium observed in the holotype resembles those of *O. alpigena* and *O. montigena*.

Ecology. *O. navajoana* was collected on ± rotten wood of xeric branches of various trees including gymnosperms. The apothecia were mostly very sparse, only the sample on *Populus* was rich. It is so far only known from the mountainous southwest of Northern America (Colorado Plateau) from cold-temperate subhumid to humid pinyon-juniper woodlands and ponderosa pine forests and from a boreal Douglas fir mixed forest. The not included collections are from a subtropical semiarid Sonoran paloverde-mixed cacti desert scrub in western North America and from a subtropical semiarid acacia shrubland in western Australia.

Specimens included. **USA**: **Utah**, Utah Mts., Dixie Forest, 27 km SSE of Torrey, 18 km S of Grover, 2825 m, branch of *Salix ?bebbiana*, 15.V.1995, G. Marson (H.B. 5410c ø). – Bryce Canyon, 33 km SE of Panguitch, 8 km WSW of Tropic, Navajo Trail SE of Sunset Point, 2300 m, branch of *Acer*, on wood, 25.VIII.1994, G. Marson (ex H.B. 5164b, M-0276537, **holotype**, anam. substr.). – **Arizona**, Grand Canyon, Coconino Plateau, 3.5 km N of Tusayan, 2075 m, branch of *Juniperus osteosperma*, on wood, 17.VI.2003, G. Marson (H.B. 8097c ø). – 3 km N of Tusayan, 2068 m, branch of *J. osteosperma*, on wood, 28.VIII.1994, G. Marson (H.B. 5362). – Mogollon Rim, 23 km NW of Flagstaff, 10.5 km WNW of Humphreys Peak, 2450 m, branches of *Populus tremuloides*, on wood, 12.VI.2000, G. Marson (H.B. 7086b).

Not included. **USA**: **Arizona**, Sonoran Desert, 82 km NW of Phoenix, SE of Wickenburg, 615 m, branch of *Larrea tridentata*, on wood, 4.V.1995, G. Marson (H.B. 5658d). – 17.5 km NNE of Lukeville, Organ Pipe, Ajo Mountain

Orbilia pleionavajoana Baral & G. Marson, **sp. nov.**, MB 813547 — Pls 232–233, Map 41

Etymology: a 16-spored relative of *O. navajoana*.

Typification: USA, Arizona, Sedona, branches of *Arctostaphylos patula*, 8.V.1995, G. Marson (ex H.B. 5733a, M-0276562, holotype).

Latin diagnosis: *Similis* Orbiliae navajoanae *sed asci 16-spori. Habitat ad lignum putridum ramulorum et ramorum siccorum fruticum angiospermarum in zona subtropica ad temperata semiarida ad subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.25–)0.35–0.7(–1.2) mm diam., 0.14–0.26 mm high, light to bright or deep (yellow-) orange (apricot) to brick- or blood-red, ± round, sometimes elliptical, scattered to mostly ± gregarious; disc flat, margin distinct, smooth, 0–20 µm protruding; broadly sessile, slightly to strongly immersed in biofilm or fibres; dry bright to deep orange to blood-red. **Asci** *(57–)70–100(–120) × 7–8.5(–9.5) µm {4}, †66–82 × 6.5–7.5 µm {1}, 16-spored, spores 4–6-seriate, 4–8 lower spores inversely oriented {3} (± mixed), pars sporifera *37–50(–55) µm long; **apex** (†) hemispherical to slightly truncate, dome immature †0.7–0.9 {T+1}, 1–1.3 {1} or 1.3–2 µm {1} thick, mature 0.7–0.8 or 1–1.3 µm thick, with slight to distinct apical chamber; **base** with short to medium long, ± thick, flexuous stalk, ± L- or Y-shaped. **Ascospores** *(9.5–)11–14(–16) × (2–)2.2–2.6(–2.8)((–3)) µm {4}, 10–13 × 2–2.4 µm {1}, subcylindrical or cylindric- to fusoid-clavate, apex rounded or obtuse (to subacute), base slightly to strongly attenuated, sometimes or often tail-like, straight to very slightly curved near base; **SBs** *(2.3–)2.6–3.5(–4) × (0.7–)0.9–1.3(–1.5) µm {4}, tear- to pear-shaped, also ampulliform or subulate, apically narrowed to a small to mostly wide point. **Paraphyses** apically slightly to medium clavate-capitate, terminal cells *5.5–20 × 2.3–3.8 µm {2}, lower cells *(7.5–)10–18 × 1.5–2(–2.4) µm {2}; rarely branched near apex; hymenial layer very pale rose-orange to light pink. **Medullary excipulum** very pale rose(-orange), 30–60 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** (very) pale rose-orange, of thin-walled (externally slightly thick-walled), vertically oriented t. globulosa-angularis-prismatica from base to mid flanks, 30–100 µm thick near base, cells */†6–21 × 6–12(–15) µm {3}; 20–40 µm thick at mid flanks, 10–35 µm at margin, of t. prismatica oriented irreglarly at a 20–60° angle to the surface, marginal cortical cells */†(5–)7–11 × (2–)3–4.5(–6) µm {3}, **glassy processes** absent {4}. **Anchoring hyphae** sparse to medium abundant, */†2–3(–3.7) µm wide, walls 0.2–0.3(–0.4) µm thick {2}. **SCBs** globose {2}, 1 per cell, in paraphyses 1–2.7 µm diam., in excipulum 2.5–4 µm, crystalloid SCBs absent {3}. **Exudate** very pale yellowish-chlorinaceous, over paraphyses (0.5–)1–3(–4) µm thick {3}, continuous though broken into large clods, loosely attached; over margin and flanks rough, 2–5 µm thick. — **ANAMORPH**: unknown.

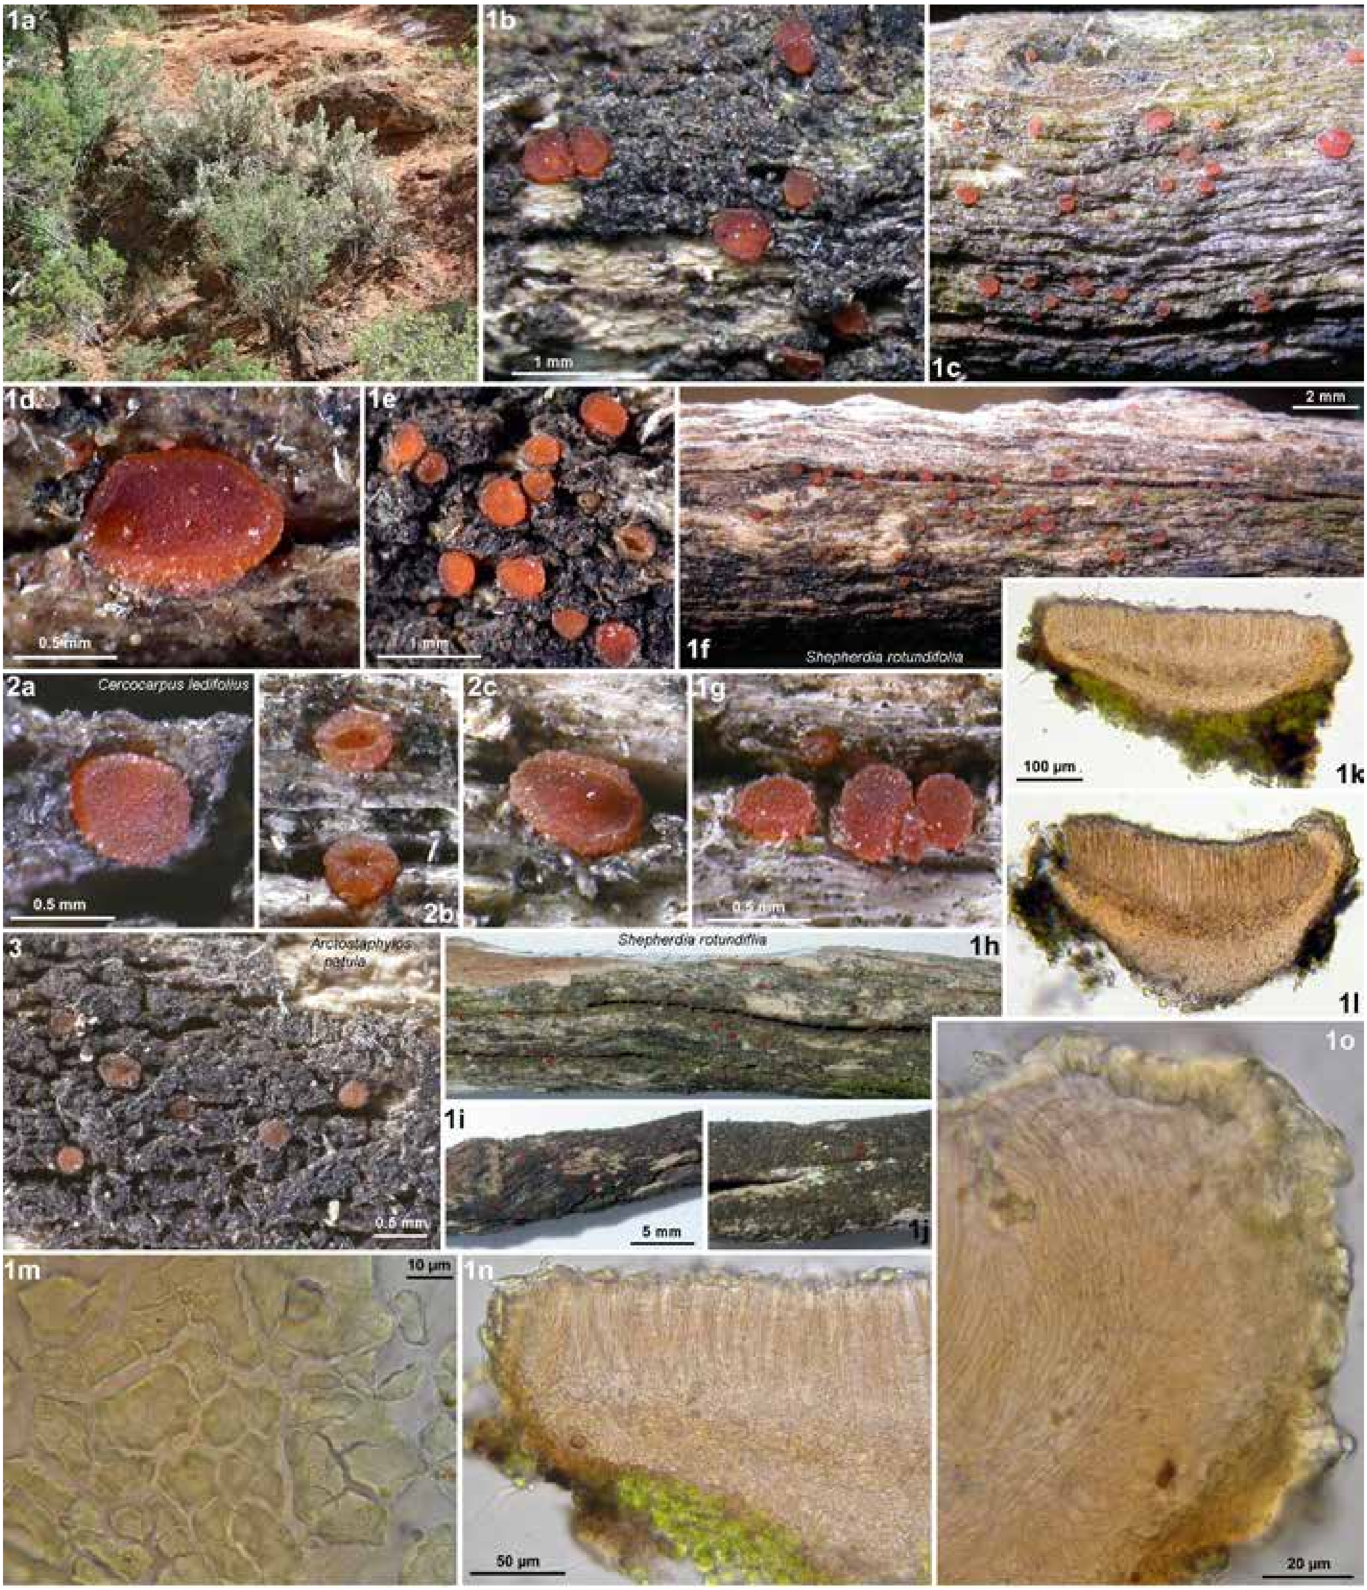

Plate 233. **1–3**: *Orbilia pleionavajoana*. – **1a**. semiarid mountain shrub with *Cercocarpus intricatus*, *Shepherdia rotundifolia* etc.; **1h–j**. decorticated xeric branches of *Shepherdia rotundifolia*; **1b–g**, **2a–c**, **3**. rehydrated apothecia; **1k–l**, **n**. apothecia in median section; **1o**. id., marginal region; **1m**. cloddy exudate on marginal excipulum (external view). – Dead state (in H_2O). — **1a–m**. H.B. 8049a: USA, Utah, Zion, on *Shepherdia*; **2a–c**. H.B. 6744a: ibid., Bryce Canyon, on *Cercocarpus*; **3**. H.B. 5733a (holotype): USA, Arizona, Sedona, on *Arctostaphylos*.

Habitat: collected 0.2–1.5 m above the ground, decorticated, 4–22 mm thick twigs and branches of ± dead shrubs of *Arctostaphylos patula* {1}, *A. pungens* {1}, *Cercocarpus ledifolius* {1}, *Parkinsonia microphylla* {1}, *Shepherdia rotundifolia* {1}, on 0.3–1.5 mm deep medium to strongly decayed and eroded wood {4}, on upper side, often along longitudinal cleft, often strongly greyed and covered by green algae. **Associated**: *Claussenomyces* sp. {1}, *Coccomycetella* sp. {1}, *Cryptodiscus foveolaris* {1}, *Dacrymyces* sp. {2}, *Diplolaeviopsis* sp. {1}, *Durella* sp. {2}, *D.* ?*connivens* {1}, *Gloniella* sp. {1}, *Gloniopsis subrugosa* {1}, *Hysterium* sp. {1}, ?*Hysteropatella* sp. {1}, *Mellitiosporiella pulchella* {2/1}, *Orbilia* ?*dixiensis* {1}, *O. hesperidea* {1}, *O. maeandrina* {1}, *O. pluristomachia* {1}, *O. vibrioides* {1}, *Ostropales* {1}, *Parmelia* sp. {1}, *Perrotia flammea* {2}, *Phragmiticola* sp. {4}, ?*Pragmopora* sp. {1}, *Propolis farinosa* {1}, ?*Triblidium* sp.

{1}. **Desiccation tolerance**: fully viable for at least 22 months, after 31 months still many immature and some mature asci alive. **Altitude**: ~1165–2300 m a.s.l. **Geology**: Triassic-Jurassic-Cretaceous red sand- and limestone, Oligocene felsic volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleionavajoana* differs from *O. navajoana* mainly in 16-spored asci, but perhaps also ecologically. The two taxa deviate from the similar taxon pair *O. hesperidea* (8-spored) and *O. pleiohesperidea* (16-spored) mainly in the absence of crystalloid SCBs.

Variation. The studied collections closely concur, except for some variation in apothecial size and spore shape. Abnormal ascospores over 14 µm long, with 4.5–4.8 µm long SBs, are formed inside asci with reduced spore numbers, e.g., in 10-spored asci.

Not included collection. A sample on *Larrea* (IVV: H.B. 5687g) differs from *O. pleionavajoana* in possessing crystalloid SCBs and slightly smaller spores (*9.5–10.5 × 2–2.4 µm), and probably represents a different species.

Ecology. *O. pleionavajoana* was found on ± rotten wood of xeric twigs and branches of various angiosperm shrubs in the mountainous southwest of Northern America. The collection sites include a subtropical semiarid paloverde-mixed cacti desert scrub in the Sonoran Desert, warm-continental subhumid manzanita chaparral scrublands in the Mogollon Rim and Sonoran and Chihuahuan Desert, a warm-temperate semiarid pinyon-juniper woodland cold-temperate subhumid ponderosa pine forest at the southern border of Utah Mountains. In the holotype collection, *O. hesperidea* grew in a close but separate population.

Specimens included. **USA**: **Utah**, Utah Mts., Bryce Canyon, 33 km SE of Panguitch, 8 km WSW of Tropic, Navajo Trail SE of Sunset Point, 2300 m, branches of *Cercocarpus ledifolius*, on wood, 20.VI.2000, G. Marson (H.B. 6744a). – Zion, south entrance, Pine Creek, The Great Arch, 1590 m, branches of *Shepherdia rotundifolia*, on wood, 14.VI.2003, G. Marson (H.B. 8049a). – **Arizona**, Mogollon Rim, 37 km SSW of Flagstaff, ~1 km NE of Sedona, 1320 m, branches of *Arctostaphylos patula*, on wood, 8.V.1995, G. Marson (M-0276562, **holotype**; H.B. 5733a, **isotypes**). – Sonoran Desert, 40 km NNE of Tucson, 11 km NE of Catalina, Casa del Oro, Biosphere, 1165 m, on *Parkinsonia microphylla*, 7.V.1995, G. Marson (ø). – Chihuahuan Desert, 150 km ESE of Tucson, NW end of Chiricahua Mts., E of parking area, ~1700 m, branches of *Arctostaphylos pungens*, on wood, 26.V.1996, G. Marson (H.B. 6051a).

Not included. **USA**: **Arizona**, Sonoran Desert, 17.5 km NNE of Lukeville, Organ Pipe, Ajo Mountain Trail, 710 m, branch of *Larrea tridentata*, 5.V.1995, G. Marson (H.B. 5687g ø).

Map 41. Known distribution of *O. pleionavajoana* in North America.

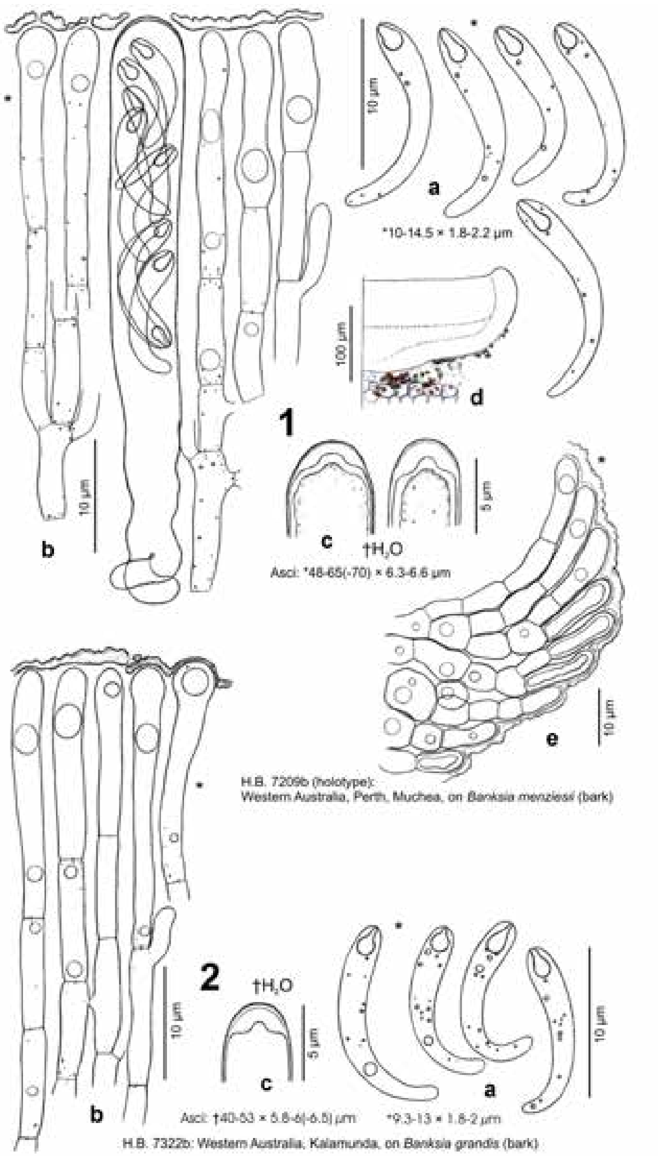

Plate 234. **1–2**: *Orbilia curvatinavajoana*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

Orbilia curvatinavajoana Baral & G. Marson, **sp. nov.**, MB 813548 — Pls 234–235

Etymology: referring to the strongly curved ascospores and a similarity with *O. navajoana*.

Typification: Western Australia, Muchea, trunk of *Banksia menziesii*, 23.XI.2001, G. Marson (ex H.B. 7209b, MEL 2389227, holotype).

Latin diagnosis: *Similis* Orbiliae navajoanae *sed ascosporae valde arcuatae. Habitat ad corticem siccum putridum ramorum vel truncorum* Banksiae *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.45 mm diam., 0.12–0.13 mm high, light orange(-rose-red), rarely pale yellowish-cream, medium translucent, ± round, (very) scattered; disc slightly concave to flat, margin distinct, 0–10 µm protruding, smooth; sessile, almost superficial to half immersed; dry bright orange-red to apricot. **Asci** *48–70 × 6–6.6 µm {2}, †(40–)44–59(–64) × 5.5–6(–6.5) µm {2}, 8-spored, spores *2–4-seriate, 1–2(–3) lower spores inverted {2} (not mixed), pars sporifera *~28–30 µm long; **apex** (†) hemispherical to slightly truncate, dome †1.2–2 → 1–1.5 µm thick {2}, with distinct apical chamber; **base** with very short to medium long, thin or thick, flexuous stalk, L, T- or h-shaped. **Ascospores** *(8–)10–13.5(–14.5) × (1.6–)1.8–2(–2.2) µm {2} [actual length ~(11–)12–15.5 µm], cylindric-clavate, apex rounded to obtuse, gradually tapered towards

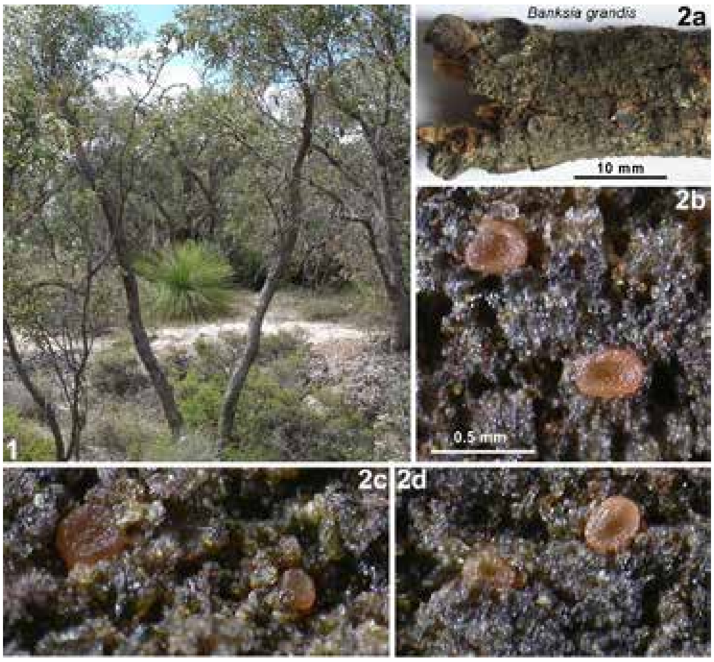

Plate 235. **1–2**: *Orbilia curvatinavajoana*. – **1**. semihumid open banksia-eucalypt woodland with *Xanthorrhoea*; **2a**. dead corticated xeric branch of *Banksia grandis*; **2b–d**. rehydrated apothecia (after 4.5 years). — **1**. 0.9–1.3 µm wide base, medium to very strongly curved (falcate, especially near base); **SBs** *(1.5–)1.8–2.5(–2.7) × 1–1.2(–1.4) µm {2}, pear-shaped to ampulliform, apically narrowed to a small to wide point. **Paraphyses** apically uninflated to slightly clavate-capitate, sometimes sublageniform, terminal cells *(11–)13–22(–28) × (2.2–)2.5–3.5 µm {2}, lower cells *(6–)8–13 × 1.7–2.7 µm {2}; very rarely branched at upper septum. **Medullary excipulum** hyaline, 30–40 µm thick, of medium loose or dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a 5 µm thick t. porrecta. **Ectal excipulum** hyaline, of (†) medium gelatinized, ± distinctly vertically oriented t. globulosa-angularis-prismatica from base to mid flanks or margin, 30–40 µm thick near base, cells *10–20 × 5–15 µm {2}; 25 µm thick at mid flanks, 15–30 µm near margin, here of t. (angularis-)prismatica oriented at a 45–70° angle to the surface, outer layer and uppermost margin of t. prismatica-porrecta oriented at 10–45°, marginal cortical cells *9–20 × 3.5–4.5 µm {2}, (†) slightly to strongly gelatinized (thick-walled), **glassy processes** absent. **Anchoring hyphae** ± sparse, */†2–3.5(–4) µm wide, walls 0.2–0.5 µm thick {2}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.5–3 µm diam. **Exudate** over paraphyses 0.3–1.5 µm thick, granular-cloddy, hyaline to pale chlorinaceous, loosely or later firmly attached; over margin and flanks 1–3 µm, also between cortical cells. **— ANAMORPH**: unknown.

Habitat: collected (0–)1–3 m above the ground, on 10–24 mm thick, corticated branches or a standing, sometimes still-living, ~15–20 cm thick trunk of *Banksia menziesii* {1}, *B. grandis* {1}, on medium to strongly decayed bark (periderm & bast) {2}, on very uneven surface, also along longitudinal cleft, partially detaching, slightly to strongly greyed, green algae sparse to abundant. **Associated**: *Exidia* sp. {1}, *Gloniopsis praelonga* {1}, *Orbilia aviceps* {2}, *O. eucalypti* {1}, *O.* ?*pleioserpens* {1}, ?*Teichospora* sp. {1}. **Desiccation tolerance**: fully viable for at least 16 months. **Altitude**: 188–370 m a.s.l. **Geology**: Archean granulite with granitic gneiss, granite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia curvatinavajoana* resembles the North American *O. navajoana* in size and shape of ascospores and SBs, but sharply differs in a strong spore curvature, also in much less inverted spores within the asci. *O. multicurvula* is perhaps closely related due to its very similar spore shape, but differs in narrower spores with vermiform to subulate SBs.

Ecology. *O. curvatinavajoana* was collected on ± rotten bark of dead xeric branches of *Banksia* in a subtropical semihumid open banksia-eucalypt woodland and open eucalypt forest (jarrah-marri) in the Darling Range of southwestern Australia. The two known collections consist of only a few rather remotely growing apothecia.

Specimens included. **AUSTRALIA**: **Western Australia**, Jarrah Forest, Darling Range, 54 km NNE of Perth, 11 km NE of Muchea, 188 m, trunk of *Banksia menziesii*, on bark, 23.XI.2001, G. Marson (ex H.B. 7209b, MEL 2389227, **holotype**). – 28 km E of Perth, 8 km ESE of Kalamunda, 4 km E of Bickley, junction of Lockwood and Gunjin Road, 370 m, branch of *Banksia grandis*, on bark, 13.XII.2001, G. Marson (H.B. 7322b).

Orbilia hesperidea Rolland, Bull. Soc. Mycol. Fr. 17: 118, pl. 4 fig. 1 (1901) — Pls 236–239, Map 42

Etymology: after the type substrate (hesperidoids = *Citrus*), collected in 'plantations d'orangers' (in reference to the Garden of Hesperides).
Typification: France, Antibes, branches of *Citrus aurantium*, II.1900, L. Rolland (PC, herb. Boudier, holotype); France, Languedoc-Roussillon, Narbonne, branch of *Spartium junceum*, 21.IX.1999, H.O. Baral (ex H.B. 6468a, M-0291758, epitype, designated here, MBT385113, ex-epitype culture: CBS 116209; sq.: KT215264).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–0.8(–0.9)((–1.4)) mm diam., (0.08–)0.1–0.2 mm thick, pale rose to mostly light to bright (dirty) (ochraceous-)orange(-rose) to apricot, also amber-yellow, not (or slightly) translucent, round or sometimes ± compressed, scattered to often gregarious; disc slightly concave to flat, margin indistinct or mostly ± thick, (0–)10(–20) µm protruding, smooth or rough; sessile, slightly or half immersed in rows between wood fibres; dry bright orange-red (or olivaceous-yellow). **Asci** *(36–)40–50 {6} or 50–75(–85) {17} or 75–103 {1} × (5.5–)6–8(–8.5) µm {20}, †35–42 {1} or 46–75(–84) {7} × (4.7–)5–7.3 {9} µm, 8-spored, spores ± 4-seriate, (2–)3–5(–6) lower spores inversely oriented {17} (sometimes mixed), pars sporifera *(19–)23–35 µm long; **apex** (†) hemispherical to very slightly truncate, dome 1.2–1.5(–2.5) → 0.7–1.3 µm thick {8}, or only 0.4–0.8 µm thick irrespective of maturity {3}, with or without distinct apical chamber; **base** with short to medium long, ± thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(7.5–)9–11(–12.5) {5} to (9–)11–15(–18)((–19.5)) {21} × (1.9–)2.2–3(–3.3) {24} µm, †(9.3–)10–15(–18.5) × (2–)2.2–2.8(–3.2) µm {7}, subcylindric-clavate to fusoid(-clavate), rarely fusiform, apex rounded or obtuse, rarely subacute, base slightly to strongly attenuated, often with a tail-like end, rarely with a distinct tail, straight to slightly (rarely medium) curved near base; **SBs** *(2.5–)3–4.5(–5) × (0.8–)1–1.3(–1.5) µm {23}, rod-shaped to ampulliform or subulate, also pear- or tear-shaped, apically narrowed to a ± wide (rarely small) point; overmature *2–3 × 1.5–1.7 µm, broadly tear-shaped. **Paraphyses** apically uninflated to slightly (rarely medium) clavate-capitate, terminal cells *6.5–15(–19) × (1.8–)2.2–3.5(–4) µm {6}, †7–18 × 1.7–2.8(–3.5) µm {T}, lower cells *6–15(–17.5) × 1.5–2.5(–3) µm {5}, †7–14 × 1–1.6 µm {T}; unbranched or sometimes branched near apex; hymenium pale rose. **Medullary excipulum** subhyaline, 20–70 µm thick, of dense textura intricata with many inflated cells, medium to sharply delimited. **Ectal excipulum** pale rose, of (†) thin-walled or distinctly gelatinized (common walls 0.5–1.5(–3) µm), ± vertically oriented t. angularis from base to mid flanks, 25–50 µm thick near base, cells *7–17.5 × 6–12 µm {3} †(6–)10–16(–26) × 6–11(–17) µm {2}; 10–30 µm thick near margin, upper margin of t. prismatica(-angularis) to t. prismatica(-porrecta) oriented at a 20–60° angle to the surface, marginal cortical cells *(4–)6–11 × (2.3–)3–4.5(–5.5) µm {3}, †2–3.2 µm wide, **glassy processes** absent {18}. **Anchoring hyphae** ± abundant, */†1.8–3 µm wide, walls 0.2–0.3(–0.4) µm thick {2}. **SCBs** in paraphyses and excipular cells (flanks and margin) crystalloid {21}, hyaline to light yellowish-orange, (1–)2–6(–9) × (0.5–)1–3.5(–4.5) µm, also some globose present. **Exudate** pale to bright chlorinaceous to sulphur-yellow, rarely hyaline, over paraphyses (1–)1.5–4(–6) µm thick, broken into clods, loosely attached; over margin and flanks 2–5(–7) µm thick, rough-cloddy, firmly attached. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1} and natural substrate {3}). **Conidiophores** not seen. **Conidia** Y-shaped, European specimens: total size */†19–28 × 19–26 µm {2}, stipe */†10.5–17 × 4.5–5.2 µm, 2–3-septate, arms tapering, */†10–15 × 4–4.5(–5.5) µm, (1–)2–3-septate; Australian specimen: total size *25–30 × 29.5–38 µm {1}, stipe *16–17.5 × 4–5 µm, 2–3-septate, arms tapering, *16–20.5 × 4–4.5 µm, 2-septate.

Habitat: collected 0.1–3 m above the ground, decorticated, rarely corticated, 2–70 mm thick twigs and branches, also 10–30 cm thick living trunks, rarely cones, of *Acacia* sp. {5}, *Arbutus unedo* {3}, *Arctostaphylos patula* {1}, *Bystropogon odoratissimus* {1}, *Calicotome villosa* {1}, *Calothamnus* sp. {1}, *Campsis* (?)*radicans* {1}, *Citrus aurantium* {1}, *Erica arborea* {3}, *Eucalyptus* sp. {1}, *Juniperus phoenicea* {1}, *Lonicera implexa* {1}, *Myrtus communis* {1}, *Olea europaea* {2}, *Parkinsonia microphylla* {1}, *Periploca laevigata* {2}, *Pinus halepensis* {3}, *Quercus coccifera* {1}, *Q. ilex* {1}, *Q. pubescens* {1}, *Spartium junceum* {1}, *Vitis* sp. {1}, on 0.1–2 mm deep (medium to) strongly decayed wood {26}, more rarely bark {10} (periderm or bast), sometimes with abundant beetle or ant galleries, sometimes on detaching bark, medium to strongly greyed, with or without a few to many green algae. **Associated**: *Amandinea* sp. {2}, *Arthonia crozalsiana* {1}, *Caloplaca* sp. {1}, *Claussenomyces* sp. {1}, *Coccomycetella* sp. {1}, *Cryptodiscus foveolaris* {2}, *Dacrymyces* sp. {2}, ?*Deltopyxis* sp. {1}, *Diplolaeviopsis* sp. {2}, *Durella* sp. {2/1}, *D. atrocyanea* {1}, *D.* ?*connivens* {1}, *Gloniella* sp. {1}, *Gloniopsis praelonga* {1}, *Holmiella* sp. {1}, *Hyalorbilia subfusispora* {1}, *H. texensis* {1}, *Hysterium* sp. {1}, *H. angustatum* {2}, *H. pulicare* {1}, ?*Hysterobrevium smilacis* {1}, ?*Hysteropatella* sp. {2}, *Mellitiosporiella pulchella* {2}, *Naemacyclus fimbriatus* {1}, *Orbilia amberina* {1}, *O. anguliobliqua* {1}, *O. aprilis* {3}, *O. australiensis* {4}, *O. austroobtusispora* {1}, *O. aviflagellata* {1}, *O. cejpii* {1}, *O. coniferarum* {1}, *O. curvatiobliqua* {1}, *O.* ?*dixiensis* {1}, *O. gambelii* {1}, *O. helicoobliqua* {2}, *O. microlentiformis* {1}, *O. microserpens* {1}, *O. multiserpens* {1}, *O. myriofusiclava* {1}, *O. myriolilacina* {2}, *O. myriomuscula* {1}, *O. myrioobliqua* {3}, *O. myriosphaera* {2}, *O. nothovinosa* {1}, *O. obtusispora* {1}, *O. paraobliqua* {2}, *O. pleioaustraliensis* {2}, *O. pleioaustrocylindrica* {1}, *O.* ?*pleiomesaverdiana* {1}, *O. pleionavajoana* {1}, *O.* ?*pleioungulata* {1}, *O. polyspora* {1}, *O. subaristata* {1}, *O. subulivinosa* {1}, *O. vibrioides* {1}, *O. vinosa* {3}, *Ostropales* {1}, }, ?*Parmelia* sp. {1}, *Patellaria* '*andina*' {1/1}, *Perrotia flammea* {1}, *Phragmiticola* sp. {2}, ?*Pragmopora* sp. {1}, *Proliferodiscus griseoviolaceus* {1}, *Propolis* ?*farinosa* {2}, *P. viridis* {5}, *Schismatomma* sp. {1}, *Symbiotaphrina* ?*desertorum* {1}, ?*Triblidium* sp. {2}. **Desiccation tolerance**: fully viable for at least 22 months, some conidia still alive after 3 years. **Altitude**: 1–410 m a.s.l. (Europe), 35–1320 m (North America), 222–380 m (Australia). **Geology**: Archean-Paleoproterozoic and Pennsylvanian-Permian sand-, lime- & mudstone, Cretaceous limestone & siliceous shale, Miocene limestone; gneiss, mica schist, basaltic flow. **Phenology**: XII–VI, VIII–IX (N-hemisphere, throughout the year, long-lived).

Taxonomic remarks. *Orbilia hesperidea* is characterized by ± straight, subcylindric-clavate but also fusoid ascospores with ± attenuated, often slightly curved bases but only exceptionally with short distinct tails, and ± obtuse apices containing medium long, rod-shaped to ampulliform SBs. Further diagnostic characters include the consistent presence of crystalloid SCBs and absence of glassy processes. The crystalloid SCBs permit clear separation from the following species in which only globose SCBs occur: *O. montigena* and *O. alpigena* from montane to subalpine Europe (the latter also deviates by shorter SBs), *O. clavuliformis* and *O. subclavuliformis* from temperate to mediterranean Europe (both having distinct spore tails), and *O. navajoana* from mountainous southwestern North America (also deviating by shorter SBs).

Four Australian species are similar to *O. hesperidea*: *O. coronohesperidea* differs in the presence of glassy processes and somewhat longer spores, *O. megahesperidea* in distinctly larger spores, and *O. pleiohesperidea* in 16-spored asci. *O. australiensis* differs in wider, never subcylindric-clavate spores, but intermediate collections occur. For the similar Macaronesian *O. adenocarpi* (p. 674) and the cosmopolitan *O. vinosa* (p. 599) and related species see there.

Variation in *O. hesperidea* is especially evident concerning ascus length, whereas ascus width varies only slightly and hardly correlates with ascus length. Even within a single collection (Pl. 237: 4), ascus size differed between populations collected from two closely growing trees, although spore size hardly differed (*9–12 × 2–2.7 vs. *11–12.5 × 2–2.3 µm, respectively). With *75–103 µm the longest asci were observed in a specimen from southern France (Pl. 237: 2). Two North American collections differ in much thinner apical domes, even when immature (Pl. 236: 1–2), whereas a third (on *Parkinsonia*, IVV: H.B. 8476c) showed †1.3 → 0.8 µm thick domes comparable to European and Australian specimens.

Also spore size strongly varies, particularly in length (e.g., between Pl. 237: 3–4 and 6). Within one collection (Pl. 237: 5) such variation was observed between different populations; the long-spored population in this sample is also exceptional in the frequent presence of distinct spore tails. Spore width varies between *2.2–2.5 and *2.5–3 µm, rarely only *1.9–2.3 µm (Pls 236: 2; 238: 6e).

Spore shape in *O. hesperidea* is usually cylindric-ellipsoid-clavate, with rounded to obtuse spore apices, especially in European collections, though a few fusoid spores may also occur. Exclusively fusoid spores with ± subacute apices were noted in a number of specimens from North America (Pl. 236: 2) and Australia (Pls 236: 3; 239: 1b, 3g). Such fusoid-spored populations are not always sharply separated from populations of *O. australiensis*, which sometimes grew in association. It remains unclear whether they belong to the scope of *O. hesperidea* as we assume here, or deserve distinction as a separate taxon.

Also the spore bodies in *O. hesperidea* show some variation in length and width, yet without apparent correlation to other features. In some collections the paraphyses are apically sometimes branched (e.g., in the holotype), while they are predominantly unbranched in many others. Apothecial size and colour varied from rarely small and pale rose (Pl. 234: 2) to usually rather large and bright orange.

Type studies. Although Rolland (1901) described *O. hesperidea* from a living collection, which is obvious from the distinct SBs in the drawn spores (Fig. 151: 2), no information on SCBs is available from his description. Rolland gave an ascus size of 70 × 7 µm and a spore size of *20 × 4 µm, but the present reexamination of the rather rich holotype revealed much smaller spores (Pl. 236: 4a). Rolland's figure is without a scale, but the spores inside the drawn ascus have a size of *~12.5–17 × 2.1–2.5 µm when taking an ascus length of 70 µm. Also the spore bases were found to be less tapered than Rolland illustrated, who named the spores 'napiform' (like a turnip or root). Rolland described the spore body as an 'ovoid guttule', which he figured a good distance from the spore apex without a visible connection. In the present reexamination, the SBs could be seen as a transparent region which extends up to the spore apex where it narrows to a point. Contrary to Rolland's

H.B. 5554b: USA, Texas, on *Vitis* (wood)

H.B. 7204c: Western Australia, Mt. Singleton, on *Acacia* (wood, bark)

PC (holotype): France, Alpes Maritimes, on *Citrus auranlium* (wood)

Plate 236. **1–4**: *Orbilia hesperidea*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia in median section; **e**. id., marginal ectal excipulum; **f**. crystalloid SCBs in excipular cells; **g**. conidium from substrate.

illustration, the lower spores are consistently inversely oriented within the asci. The observed micromorphology of the revised type material would also fit *O. montigena*. However, the mediterranean habitat excludes that species. Rolland mentioned that the inhabited wood was strongly greyed by a black yeast ('ad lignum torula infuscatum'). In order to fix the name we here designate a specimen from France (Narbonne, on *Spartium*, ex H.B. 6468a, Pls 237: 2; 238: 1), from which an ascospore isolate (CBS 116209) and a sequence were gained, as **epitype** *O. hesperidea*.

Not included collections. A very sparse, unillustrated Australian sample (on *Salix babylonica*) was only studied in the dead state (spores †15–16 × 2.7 µm, similar as in Pl. 237: 5a left). Another Australian collection (on *Acacia*, Pl. 237: 7) lacks crystalloid SCBs and has longer SBs (4.5–5.5 µm); with its fusoid spores this specimen resembles narrow-spored populations of *O. australiensis*.

Anamorph. The conidia obtained in pure culture of a sample from southern France developed only after flooding with water. They resemble *Trinacrium robustum* and are similar to those seen in *O. arizonensis* and *O. pleioaustraliensis*. Conidia more or less similar to the culture were found on the natural substrate.

Phylogeny. Sequences from pure cultures of two European collections of *O. hesperidea* were available (H.B. 6468a from France, H.B. 6694 from Croatia), both comprising SSU, ITS, and LSU. The S1506 intron is absent in both. In the ITS region

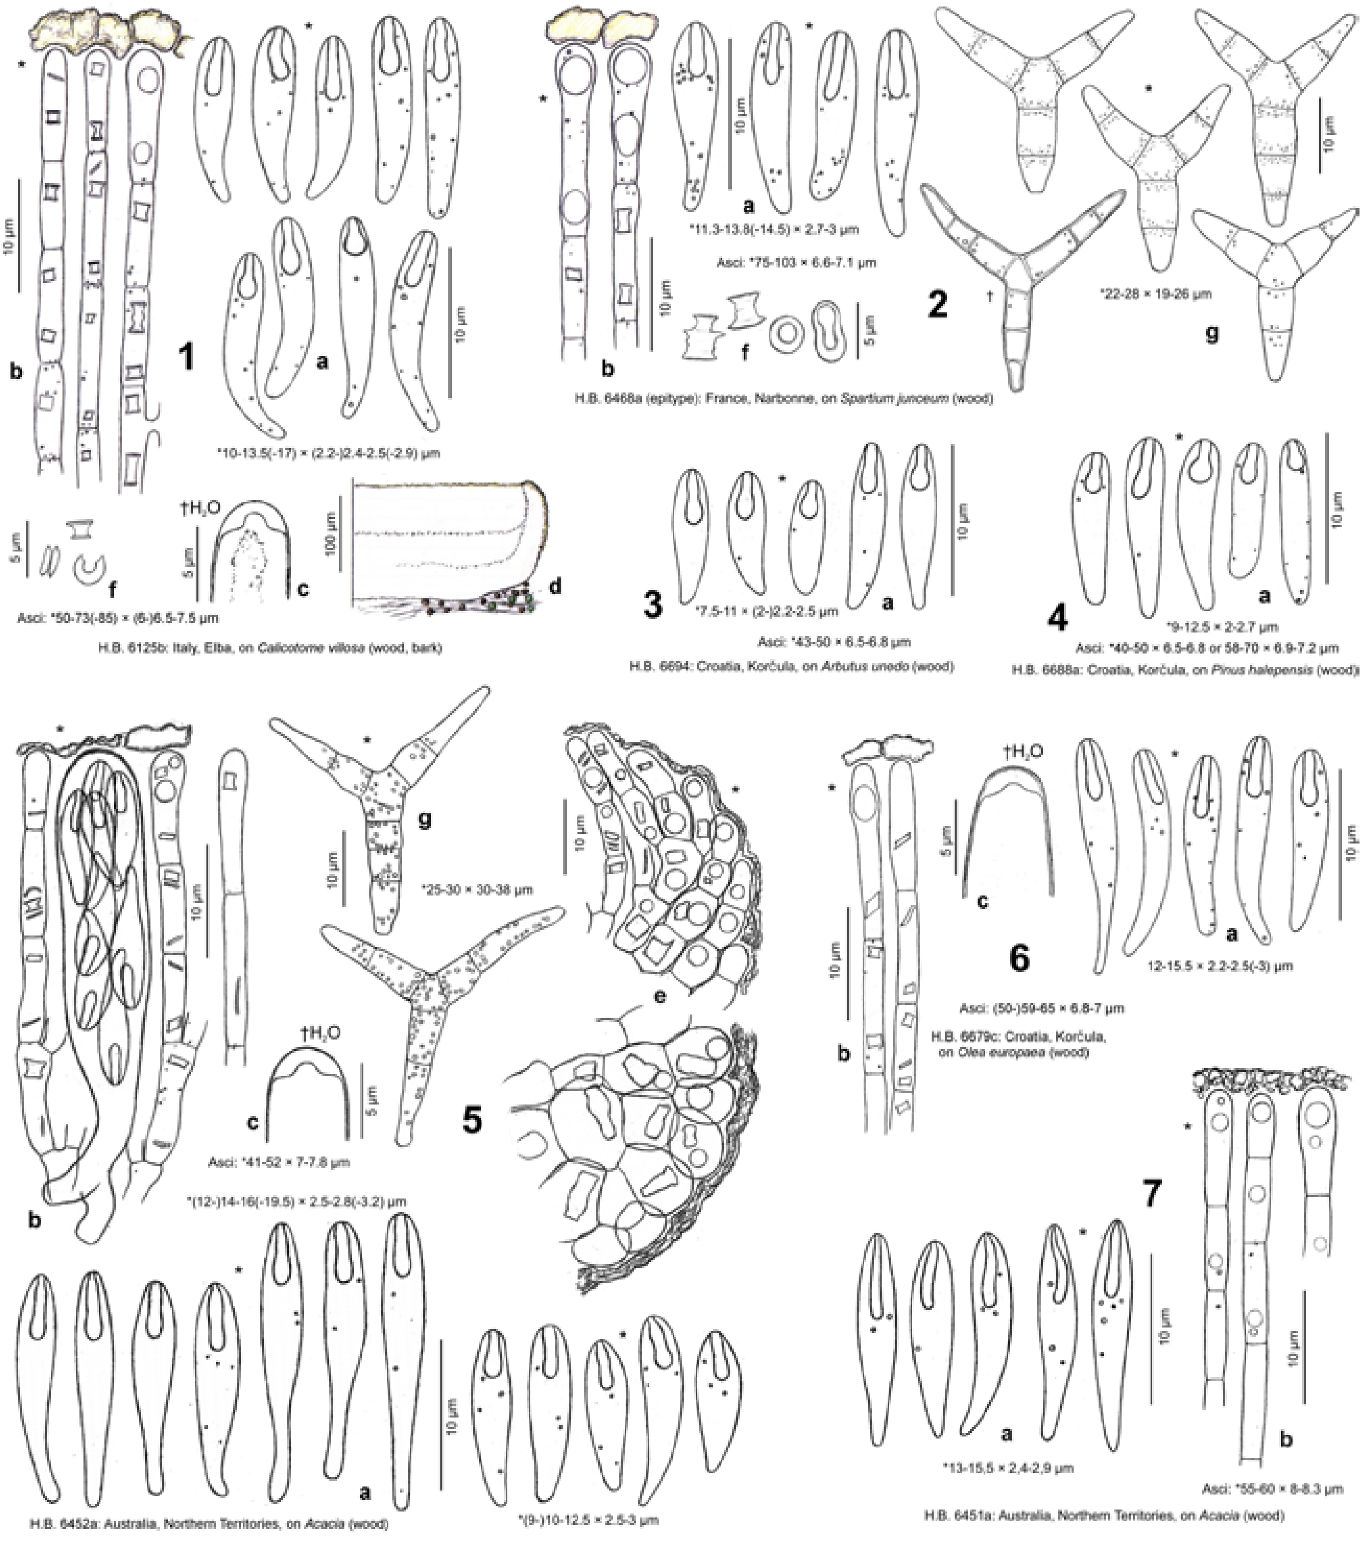

Plate 237. **1–6**: *Orbilia hesperidea*; **7**: *O.* cf. *hesperidea*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., ectal excipulum (margin and mid flanks); **f**. crystalloid SCBs in excipular cells; **g**. conidia from substrate (but in **2g** 4 living conidia from culture).

they show a distance of 1.2 % to each other, while the LSU (D1–D2) differs by 1 nt. When analysing SSU+ITS+LSU, ITS+LSU, ITS, or LSU, (Phyls 7, 9–10, S13), *O. hesperidea* clustered highly supported with *O. australiensis*, *O. pleioaustraliensis*, *O. alpigena* and *O. montigena* in the *hesperidea-alpigena* clade. The ITS distance to other species of this clade lies at 6.7–10 %, the lowest percentage being to *O. australiensis* (6.7–7 %).

Ecology. *O. hesperidea* inhabits ± rotten wood and bark of xeric branches of both gymno- and angiosperm trees and shrubs in the thermo- and mesomediterranean belt of southern Europe, where it was never found in more montane regions. Macaronesian records were made in inframediterranean semiarid to semihumid *Euphorbia atropurpurea* and *E. canariensis* scrubs (*Periploco laevigatae-Euphorbietum canariensis*) in the northeastern and eastern part of Tenerife. *O. hesperidea* also occurs in the southwest of Northern America, in the subtropical semiarid Sonoran paloverde-mixed cacti desert scrub and the subhumid warm-continental manzanita chaparral scrubland of adjacent

Marson (H.B. 7204c). – ibid., twig of *Acacia*, on bark, 26.X.2007, G. Marson (H.B. 8883b). – Geraldton Sandplains, 54 km N of Moora, 16.5 km N of Watheroo, Midlands Road, 292 m, twig of *Calothamnus*, on wood & bark, 25.X.2007, G. Marson (H.B. 8966c ø). – **Northern Territories**, Arnhem Plateau, 54 km ENE of Pine Creek, 6.3 km NE of Mary River Roadhouse, Kakadu, 222 m, branch of *Acacia*, on bark, 5.X.1998, G. Marson (H.B. 6295). – Davenport Murchison Ranges, 118 km NNW of Tennant Creek, 23 km NNW of Banka Banka Station, 300 m, branch of *Acacia*, on wood, 7.X.1998, G. Marson (H.B. 6452a, anam. substr.).

Not included. **AUSTRALIA**: **Northern Territories**, Daly Basin, 37 km ESE of Katherine, 11 km ESE of Cutta Cutta Caves, 180 m, branch of *Acacia*, on wood, 6.X.1998, G. Marson (H.B. 6451a). – **New South Wales**, South Western Slopes, 183 km NW of Sydney, 20 km SE of Mudgee, 537 m, twig of *Salix babylonica*, on wood, 25.X.1998, G. Marson (ø).

Orbilia pleiohesperidea Baral, **sp. nov.**, MB 813549 — Pls 240–241

Etymology: named after the similarity to *O. hesperidea* but deviating in 16-spored asci.

Typification: Australia, Queensland, Taroom, leaves of *Livistona nitida*, 22.X.1998, G. Marson (ex H.B. 6424d, BRI AQ799186, holotype).

Latin diagnosis: *Similis* Orbiliae hesperideae *sed asci 16-spori. Habitat ad petiolum putridum siccum* Livistonae nitidae *in zona subtropica subhumida Australiae orientalis.*

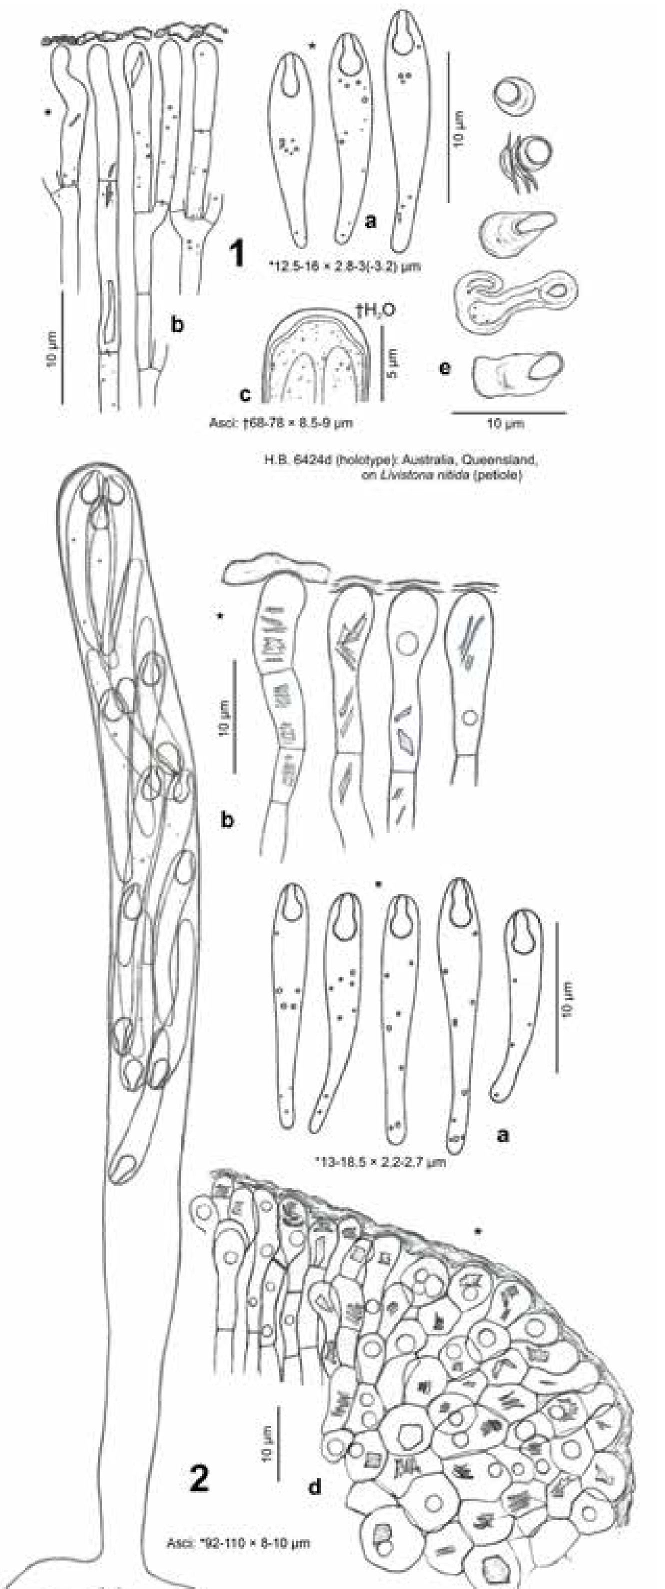

Plate 240. **1**: *Orbilia pleiohesperidea*; **2**: *O.* cf. *pleiohesperidea*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. median section of marginal ectal excipular cells; **e**. crystalloid SCBs in ectal excipular cells at flanks.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.35–0.45 mm diam., 0.14 mm high, light orange, round, scattered; disc flat to slightly convex, margin ± thick, not protruding, smooth; sessile, ± superficial. **Asci** †60–84 × 7.5–9 µm, 16-spored; **apex** (†) hemispherical (to slightly truncate), dome †0.8–1 → 0.5–0.7 µm thick,

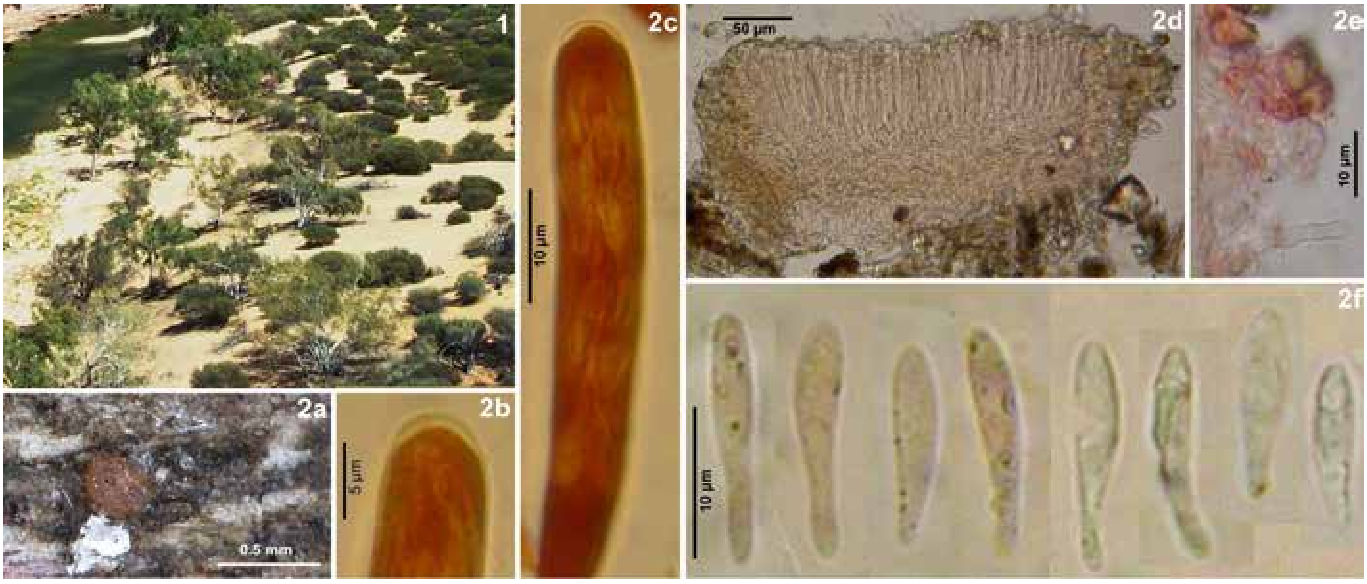

Plate 241. **1**: *Orbilia* cf. *pleiohesperidea*; **2**. *O. pleiohesperidea*. – **1**. ?semihumid Casuarina woodland; **2a**. rehydrated apothecium; **2d**. apothecium in median section; **2e**. marginal ectal excipulum with hair-like cortical hyphae; **2c**. mature ascus; **2b**. ascus apex; **2f**. ascospores. – Dead state (asci in KOH+IKI, spores left in KOH, right in H_2O). — **1**. H.B. 7415c: Western Australia, Kalbarri, on *Acacia*; **2a–f**. H.B. 6424d (holotype): Australia, Queensland, on *Livistona*.

with broad apical chamber; **base** with short to long, thin or thick, flexuous stalk, L-, Y-, or h-shaped. **Ascospores** *12.5–16 × 2.8–3(–3.2) µm, †12.2–15.5 × 2.5–3 µm, fusoid-clavate, apex obtuse, base medium to strongly attenuated in a tail-like end or distinct thick tail 3–4 × 1–1.2 µm, straight but often slightly curved near base; **SBs** *2.8–3.2 × 1.2–1.6 µm, pear-shaped to ampulliform, apically narrowed to a wide point. **Paraphyses** apically uninflated to slightly clavate, terminal cells *8–15 × 2–2.5 µm, lower cells *8–15 × 1.4–1.8 µm; often branched at upper septum. **Medullary excipulum** hyaline, 40 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** of (†) slightly gelatinized, vertically oriented t. angularis from base to mid flanks, 30–35 µm thick near base, cells †8–14 × 6–10 µm; 20 µm thick near margin, upper margin of hyphoid elements oriented at a 0–10° angle to the surface, marginal cortical cells near mid flanks †7–11 × 4–5 µm, at upper margin †8–12 × 2.5–3 µm; **glassy processes** absent. **Anchoring hyphae** abundant, †2–3 µm wide, walls 0.2–0.5(–0.8) µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) rod- or ring- to horseshoe-shaped, in excipulum 3.5–10 × 3–5 µm. **Exudate** over paraphyses 1–2.5 µm thick, cloddy, pale yellowish, loosely attached, over marginal excipulum 1.5–4 µm thick. **— ANAMORPH**: unknown.

Habitat: collected 0.2–2 m above the ground, petiole of *Livistona nitida*, on strongly decayed upper side, greyed, no algae. **Associated**: *Gloniopsis* sp., *Mellitiosporiella* sp., *Orbilia acaciae*, *O.* ?*australiensis*, *O.* ?*commarosa*, *O. coronohesperidea*, *O.* ?*dixiensis*, *O. livistonae*, *O. multiserpens*, *O. myrioeuonymi*, *O. palmicola*, *O. parviclava*. **Desiccation tolerance**: ascospores, paraphyses and excipular cells still viable after 9 months. **Altitude**: 200 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiohesperidea* is characterized by 16-spored asci and fusoid-clavate ascospores with a tail-like base or distinct thick tail. *O. hesperidea* mainly differs in 8-spored asci and ascospores only occasionally with tails. The North American *O. pleionavajoana* differs in lacking crystalloid SCBs. *O. pleiohesperidea* differs from *O. pleiocoronohesperidea* in much wider spores (values do not overlap) with sometimes thicker tails and rather short and thick SBs, also in the absence of glassy processes, though a deviating collection (*O.* aff. *pleiocoronohesperidea*, Pl. 246) also lacks them.

Not included collection. A somewhat intermediate sample on *Acacia* (Pl. 240: 2) deviates from *O. pleiohesperidea* in the marginal excipulum lacking hyphoid elements and in narrower, predominantly cylindric-clavate spores with rounded apices.

Ecology. The very sparse type collection was on petioles of *Livistona* in a subtropical subhumid (winter-dry, savannah) eucalypt woodland in the Palm-Tree Creek (Great Dividing Range, eastern Australia). The not included collection on *Acacia* was from a subtropical semihumid casuarina woodland on Silurian sedimentary rock in the Geraldton Sandplains of western Australia.

Specimens included. **AUSTRALIA**: **Queensland**, Brigalow Belt South, 69 km SSW of Theodore, 15 km N of Taroom, Palm-Tree Creek, Roy Staines Bridge, 200 m, petioles of *Livistona nitida*, 22.X.1998, G. Marson (ex H.B. 6424d, BRI AQ799186, **holotype**).

Not included. **Western Australia**, Geraldton Sandplains, 80 km NNW of Northampton, 29 km ENE of Kalbarri, near meander of Murchison, 160 m, branch of *Acacia*, 9.XII.2001, G. Marson (H.B. 7415c ø).

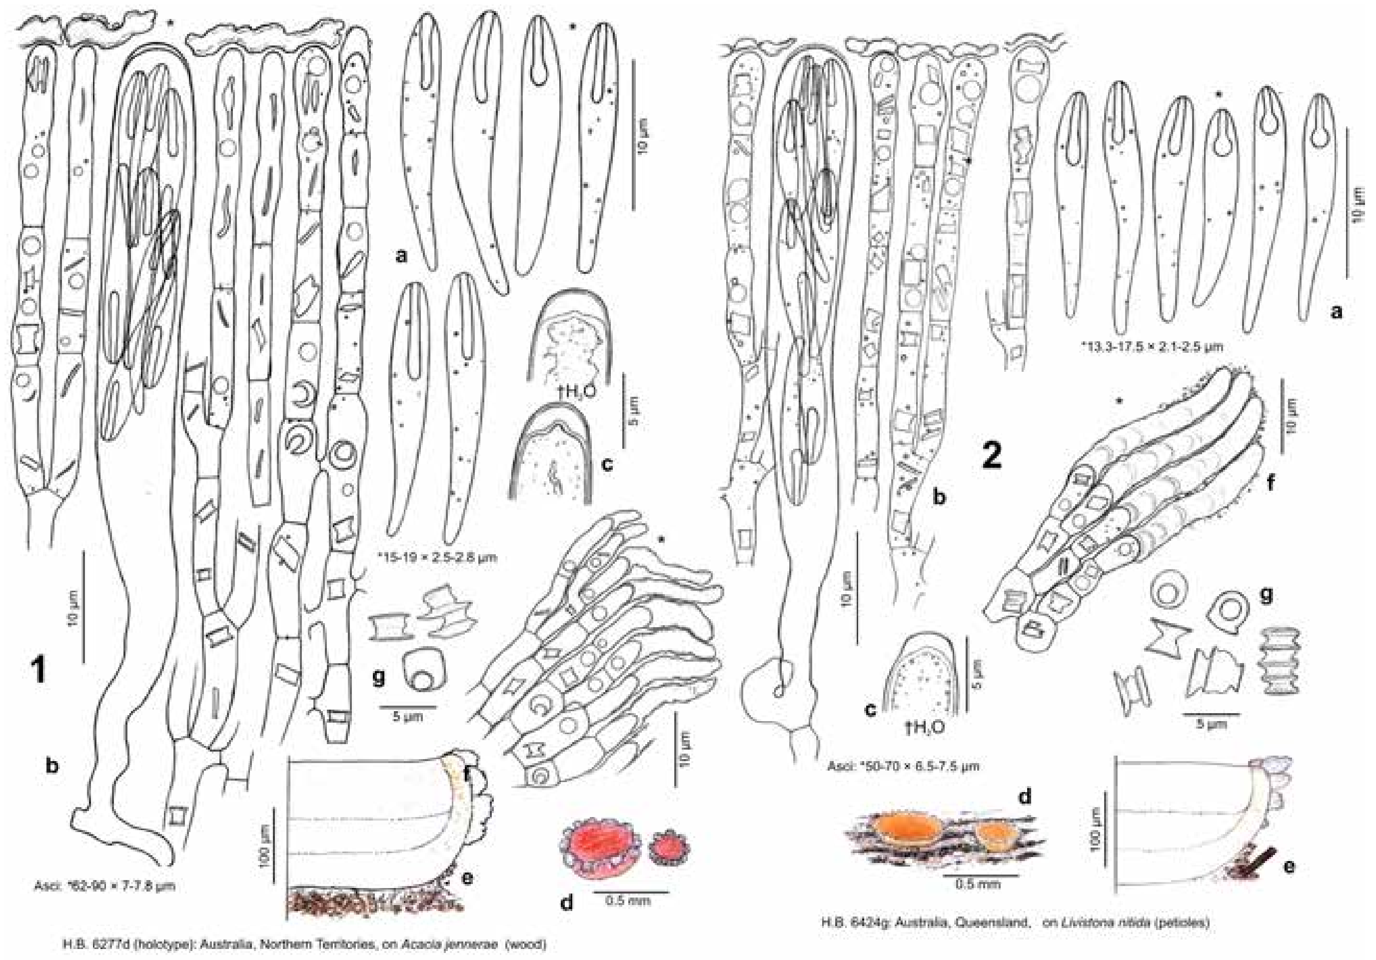
Orbilia coronohesperidea Baral, **sp. nov.**, MB 813551 — Pls 242–243, Map 43

Etymology: named after the similarity to *O. hesperidea* but margin with crown-like teeth.

Typification: Northern Territories, Curtin Springs Roadhouse, twig and branch of *Acacia jennerae*, 10.X.1998, G. Marson (ex H.B. 6277d, MEL 2389199, holotype).

Latin diagnosis: *Similis* Orbiliae hesperideae *sed excipulum marginale processis vitreis praeditum, ascosporae leniter longiores. Habitat ad lignum vel corticem putridum ramulorum vel ramorum siccorum* Acaciae *et ad petiolos putridos* Livistonae nitidae *in zona (sub)tropica arida ad semi- vel subhumida Australiae occidentalis, centralis et orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.5(–0.8) mm diam., 0.12–0.18(–0.21) mm high, light to bright (ochraceous-)orange or orange-rose, not or medium translucent, round (to elliptic), scattered to gregarious in small groups; disc flat (to slightly convex), margin distinct, finely to distinctly crenulate or with prominent whitish teeth, 5–15 µm protruding (incl. teeth); broadly sessile, superficial to slightly immersed, dry somewhat contracted, deep orange-red. **Asci** *50–70 {4} or 80–90 {T} × 6.5–7.8 µm {3}, †46–70 × 6–7(–7.5) µm {5}, 8-spored, spores *2–4-seriate, 2–4 lower spores inverted {3} (sometimes mixed), pars sporifera *30–42 µm long; **apex** (†) hemispherical to very slightly truncate, dome †1–1.8 → 0.5–1.2 µm thick {4}, with small apical chamber; **base** with short to medium to long, thick, flexuous stalk, L- to Y-shaped. **Ascospores**



H.B. 6277d (holotype): Australia, Northern Territories, on *Acacia jennerae* (wood)

H.B. 6424g: Australia, Queensland, on *Livistona nitida* (petioles)

Plate 242. **1–2**: *Orbilia coronohesperidea*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. id., marginal ectal excipulum, cortical cells with glassy processes; **g**. crystalloid SCBs in excipular cells.

*(12.2–)14–18(–19) × (2–)2.2–3 µm {5}, †15–18.5 × (2–)2.3–3(–3.5) µm {2}, subcylindric- to narrowly fusoid-clavate, apex rounded to obtuse, base slightly to mostly strongly attenuated in a tail-like end, straight to often slightly curved in middle part, also near base; **SBs** *4–5.5(–6.5) × 0.6–1.1 µm {3}, rod-shaped to subulate, apically narrowed to a wide point, straight; overmature *3–3.5 × 1.2–1.3 µm, ampulliform. **Paraphyses** apically uninflated to slightly clavate(-sublageniform), terminal cells *(7–)13–17(–21) × (1.8–)2.5–3.5(–4.5) µm {3}, lower cells *8–13 × (1.3–)1.8–2.5(–3) µm {3} (near base up to 4 µm wide); unbranched at upper septum, hymenium pale orange. **Medullary excipulum** subhyaline, 40–60 µm thick, of medium loose or dense textura intricata-globulosa, sharply delimited. **Ectal excipulum** pale orange (light orange at margin), of (†) thin-walled to medium gelatinized, vertically oriented t. globulosa(-prismatica) from base to mid flanks, 25–80 µm thick near base, cells *9–20 × 8–14 µm {2}; 20–25 µm thick near margin, of t. prismatica-porrecta oriented at a 10–45° angle to the surface, marginal cortical cells *6–12 × 3–4.5 µm {2}; **glassy processes** 3–20 {4} or 20–40 {2} × (2–)3–4(–5.5)((–7)) {5} µm, high-refractive, stratified or not, straight to irregularly curved, coherent to form ± distinct teeth. **Anchoring hyphae** medium abundant, *2.5–3 µm wide, walls 0.2–0.4 µm thick {1}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–3 µm diam., also crystalloid {6}, in excipulum 3–6 × 1.5–5 µm, pale to light yellowish-orange-rose. **Exudate** over paraphyses 0.5–3 µm thick, cloddy, pale to light yellowish-chlorinaceous, loosely attached; over margin and flanks absent or 1–2 µm thick. **— ANAMORPH**: unknown.

Habitat: collected 0–2 m above the ground, on decorticated or partially corticated, 2.5–12 mm thick twigs and branches, also trunks, of *Acacia* sp. {3}, *A. jennerae* {1}, *Eucalyptus* sp. {1}, on 0.3–0.5 mm deep strongly decayed wood {4} or bark (periderm & bast) {3}, petioles of *Livistona nitida* {1}, strongly greyed, without algae. **Associated**: *Baggea* sp. {1}, *Coccomycetella* sp. {1}, *Dinemasporium* sp. {1}, *Gloniopsis* sp. {1}, *Hyalorbilia* ?*erythrostigma* {1}, *Lophiostoma* sp. {1}, *Mellitiosporiella* sp. {1}, *Orbilia acaciae* {1}, *O. angustoaristata* {1}, *O.* ?*australiensis* {1}, *O. austropleiomicrosoma* {1}, *O.* ?*commarosa* {1}, *O. corculispora* {1}, *O.* ?*dixiensis* {1}, *O. livistonae* {1}, *O. microserpens* {1}, *O. multiaustraliensis* {1}, *O. multiserpens* {2}, *O. myriella* {1}, *O. myrioaustraliensis* {1}, *O. myrioeuonymi* {1}, *O. myriofusoidea* {1}, *O. myrionamibica* {1}, *O. octocercocarpi* {1}, *O. octoserpentina* {1}, *O. palmicola* {1}, *O. parviclava* {1}, *O. pleioaustraliensis* {1}, *O. pleiocoronohesperidea* {3}, *O. pleiohesperidea* {1}, *O. pleioserpens* {2}, *O. serpentina* {1}, *Ostropales* {1}, *Patellaria* '*andina*' {2}, ?*Stictis* sp. {1}, *Symbiotaphrina desertorum* {1}, ?*Teichospora* sp. {1}, ?*Trimmatostroma* sp. {1}. **Desiccation tolerance**: fully viable for at least 9 months, after 17 months some mature asci still alive. **Altitude**: 200–480 m a.s.l. **Geology**: Precambrian and Jurassic-Cretaceous sedimentary rock, Cenozoic regolith; Archean granulite with granitic gneiss. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia coronohesperidea* differs from *O. hesperidea* in the presence of short to long glassy processes forming white, small to large teeth on the apothecial margin, and in somewhat longer ascospores. From *O. vinosa* it differs in wider spores, more distinct, orange crystalloid SCBs, and longer glassy processes. *O. angiosubvinosa* from ± temperate (semi)humid Europe and North America differs in slightly narrower spores and is characterized by dwayaangam-like conidia. *O. pleiocoronohesperidea* differs in 16-spored asci and slightly narrower spores.

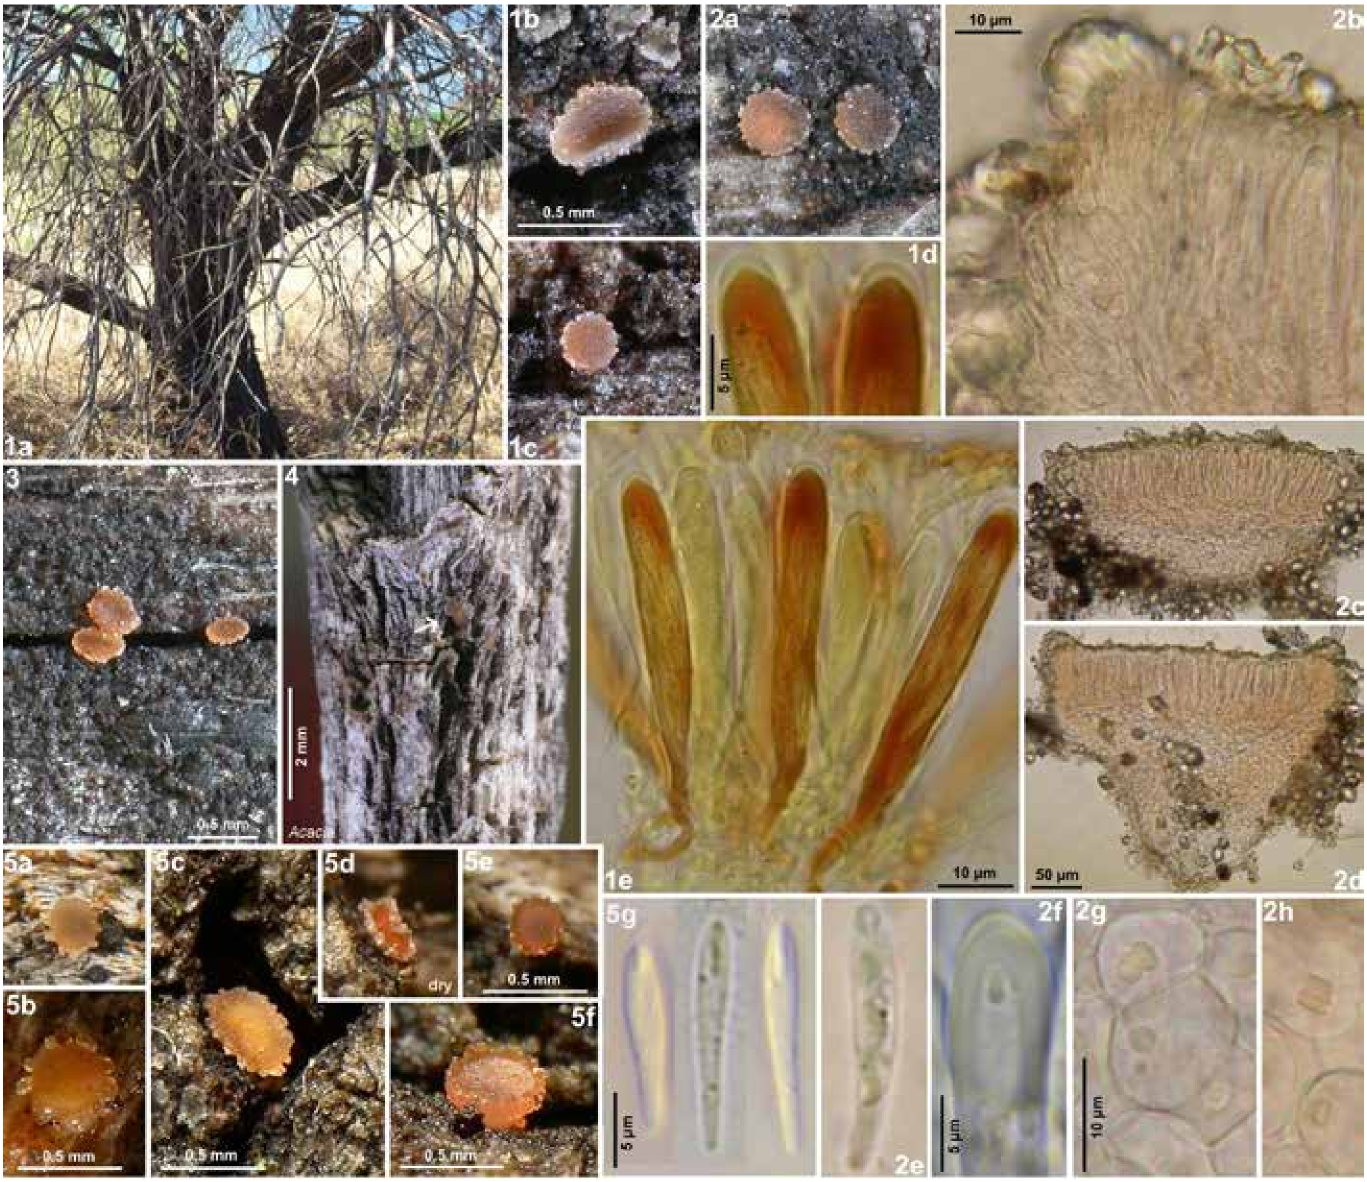


Plate 243. **1–5**: *Orbilia coronohesperidea*. – **1a**. arid acacia shrubland and hummock grassland, *Acacia* with dead attached branches; **4**. decorticated rotten xeric twig of *Acacia* (rehydrated); **1b–c**, **2a**, **3a**, **5a–c**, **e–f**. rehydrated apothecia; **5d**. apothecium in dry state; **2c–d**. apothecia in median section; **2b**. id., marginal ectal excipulum; **2g–h**. crystalloid SCBs in excipular cells; **1e**. asci and paraphyses; **1d**, **2f**. ascus apices; **2e**, **5g**. ascospores. – Living state, except for **1d–e** (in KOH+IKI), **2e**, ascus in **2f** (in H_2O). — **1a–e**. H.B. 8583c: Western Australia, Pilbara, on *Acacia*; **2a–h**. H.B. 8976a: ibid., on *Acacia*; **3**. H.B. 6424g: Australia, Queensland, on *Livistona*; **4**. 6609f: ibid., on *Acacia*; **5a–g**. 4.IX.2006: Western Australia, Bindoon, on *Eucalyptus*.

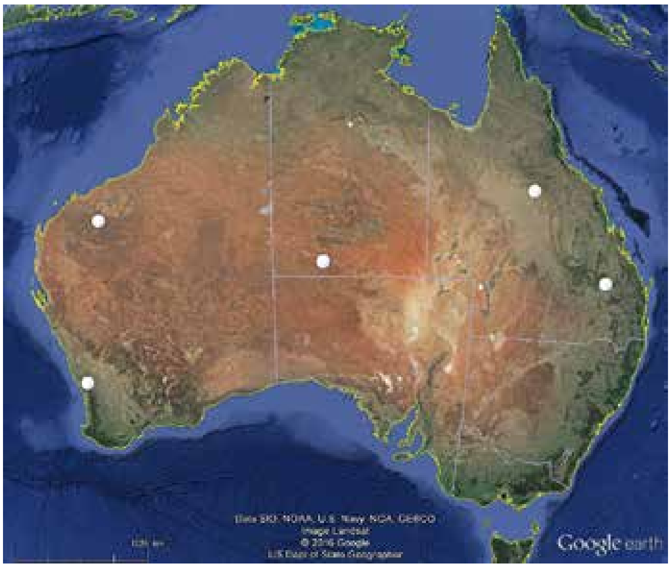
Variation. The collections on *Livistona* and *Eucalyptus* differ from those on *Acacia* in longer glassy processes and somewhat smaller, especially narrower spores. In the holotype (Pl. 242: 1) the asci were exceptionally long (*80–90 µm), but on a different twig in the same sample they measured only *62–65 µm.

Ecology. The often rather sparse collections of *O. coronohesperidea* originate from a few very remote areas of Australia. In eastern Australia the species was found on xeric, decayed, attached petioles of *Livistona* in a subtropical subhumid (winter-dry, savannah) eucalypt woodland (Great Dividing Range). Those samples on rotten wood and bark of xeric twigs and branches of *Acacia* are from (sub)tropical (semi)arid open acacia shrublands in western and (north)eastern Australia, e. g., in the dry delta of the Wittenoom Gorge of the Pilbara, and in central Australia south of MacDonnell Ranges, and that on bark of *Eucalyptus* from a subtropical semihumid eucalypt woodland (upper edge of Jarrah Forest ecoregion) in southwestern Australia.



Map 43. Known distribution of *O. coronohesperidea* in Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Pilbara, 1.5 km SW of Wittenoom, N of Karijini, delta of Wittenoom Gorge, 467 m, branch of *Acacia*, on bark & wood, 28.XI.2001, G. Marson (H.B. 8583c). – ibid., branch of *Acacia*, on bark & wood, 29.X.2007, G. Marson (H.B. 8976a). – Jarrah Forest, 25 km NNE of Bindoon, 12 km ESE of Wannamal, 271 m, branch of *Eucalyptus*, on bark, 4.IX.2006, G. Marson (ø). – **Northern Territories**, Finke, 100 km E of Yulara, 24 km ENE of Curtin Springs Roadhouse, 28 km NNE of Mt. Connor, 480 m, twig & branch of *Acacia jennerae*, on wood, 10.X.1998, G. Marson (ex H.B. 6277d, MEL 2389199, **holotype**). – **Queensland**, Brigalow Belt South, 69 km SSW of Theodore, 15 km N of Taroom, Palm-Tree Creek, Roy Staines Bridge, 200 m, petiole of *Livistona nitida*, 22.X.1998, G. Marson (H.B. 6424g). – Desert Uplands, 29 km E of Hughenden, 13 km W of Prairie, 390 m, twigs of *Acacia*, on wood, 16.X.1998, G. Marson (H.B. 6609f).

Orbilia pleiocoronohesperidea Baral & G. Marson, **sp. nov.**, MB 813552 — Pls 244–245

Etymology: named after the similarity to *O. coronohesperidea* but with 16-spored asci.

Typification: Northern Territories, Curtin Springs Roadhouse, branches of *Acacia jennerae*, 10.X.1998, G. Marson (ex H.B. 6277l, MEL 2389204, holotype).

Latin diagnosis: *Similis* Orbiliae coronohesperideae *sed asci 16-spori, ascosporae paulo angustiores. Habitat ad lignum putridum ramorum siccorum* Acaciae *in zona tropica arida Australiae occidentalis et centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.6(–0.7) mm diam., 0.1–0.18(–0.22) mm high, pale to bright (brick-)orange-rose, not or slightly translucent, ± round, scattered to (sub)gregarious in small groups; disc slightly concave or usually flat, margin 5–20 µm protruding, ± distinctly whitish pruinose to denticulate or often with distinct small whitish teeth; broadly sessile or with obconical base, superficial to slightly erumpent; dry with hardly contracted brick-orange disc. **Asci** *52–64 × 7.4–7.7 µm {1} or 70–85 × 8–8.8 µm {T}, †46–70 {2} or 77–101 {T} × 6.3–7.5(–8) {3} µm, 16-spored, spores *~4–5-seriate, 8–10 lower spores inverted {1}, pars sporifera *55 µm long; **apex** (†) hemispherical, dome †1.5–2 → 0.8–1.3 µm thick {3}, with or without distinct apical chamber; **base** with short to long, thin or thick, flexuous stalk, L-, T-, Y- or h-shaped. **Ascospores** *(13–)14.5–18.5 × 2–2.2 {2} or 2.4–2.6 µm {T}, †12.5–17 × 1.8–2.1 µm {2}, narrowly fusoid- to cylindric-clavate, apex rounded to obtuse, base medium to strongly attenuated, usually tail-like, straight to slightly curved; **SBs** *3–3.5 {1} or 4–5(–5.5) {T} × 0.8–1 {2} µm, rod-shaped to subulate or slightly ampulliform, apically narrowed to a ± wide point, straight. **Paraphyses** apically uninflated to slightly clavate, sometimes sublageniform, terminal cells *(7–)10–16(–18) × 2.5–3.5 µm {2}, †8–12 × 2–2.8 µm {1}, lower cells *(8–)10–13.5 × 1.7–3.5 µm {2}, †9–11 × 2–2.2 µm {1}, unbranched near apex. **Medullary excipulum** pale rose-orange, 20–60(–80) µm thick, of medium loose to dense textura intricata, horizontally oriented, with many inflated cells, medium sharply delimited. **Ectal excipulum** of (†) slightly gelatinized, vertically oriented t. angularis(-prismatica) from base to submargin, 20–60 µm thick near base, cells *8–20(–25) × 7–13(–16) µm {2}, †8–18 × 4–12 µm {2}; 15–20 µm thick near margin, of t. prismatica-porrecta oriented at a 10–30° angle to the surface, marginal cortical cells *7–15 × 3–4 µm {1}, †9–11 × 2.5–3 µm {1}; **glassy processes** 2–10(–20) × 2.5–3.5(–4) µm {3}, high-refractive, slightly stratified, straight to irregularly curved, somewhat coherent to form ± distinct small teeth. **Anchoring hyphae** abundant, †2–3(–3.5) µm wide, walls 0.2–0.3(–0.5) µm thick {2}, sometimes forming strands. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2 µm diam., also crystalloid {3}, hyaline to pale orange, in excipulum 2.5–7 × 1.5–5 µm (from base to margin). **Exudate** over paraphyses 0.5–2 µm thick, cloddy-continuous, loosely attached, pale to light sulphur-yellow, over margin absent or 0.2–2 µm thick. **— ANAMORPH**: unknown.

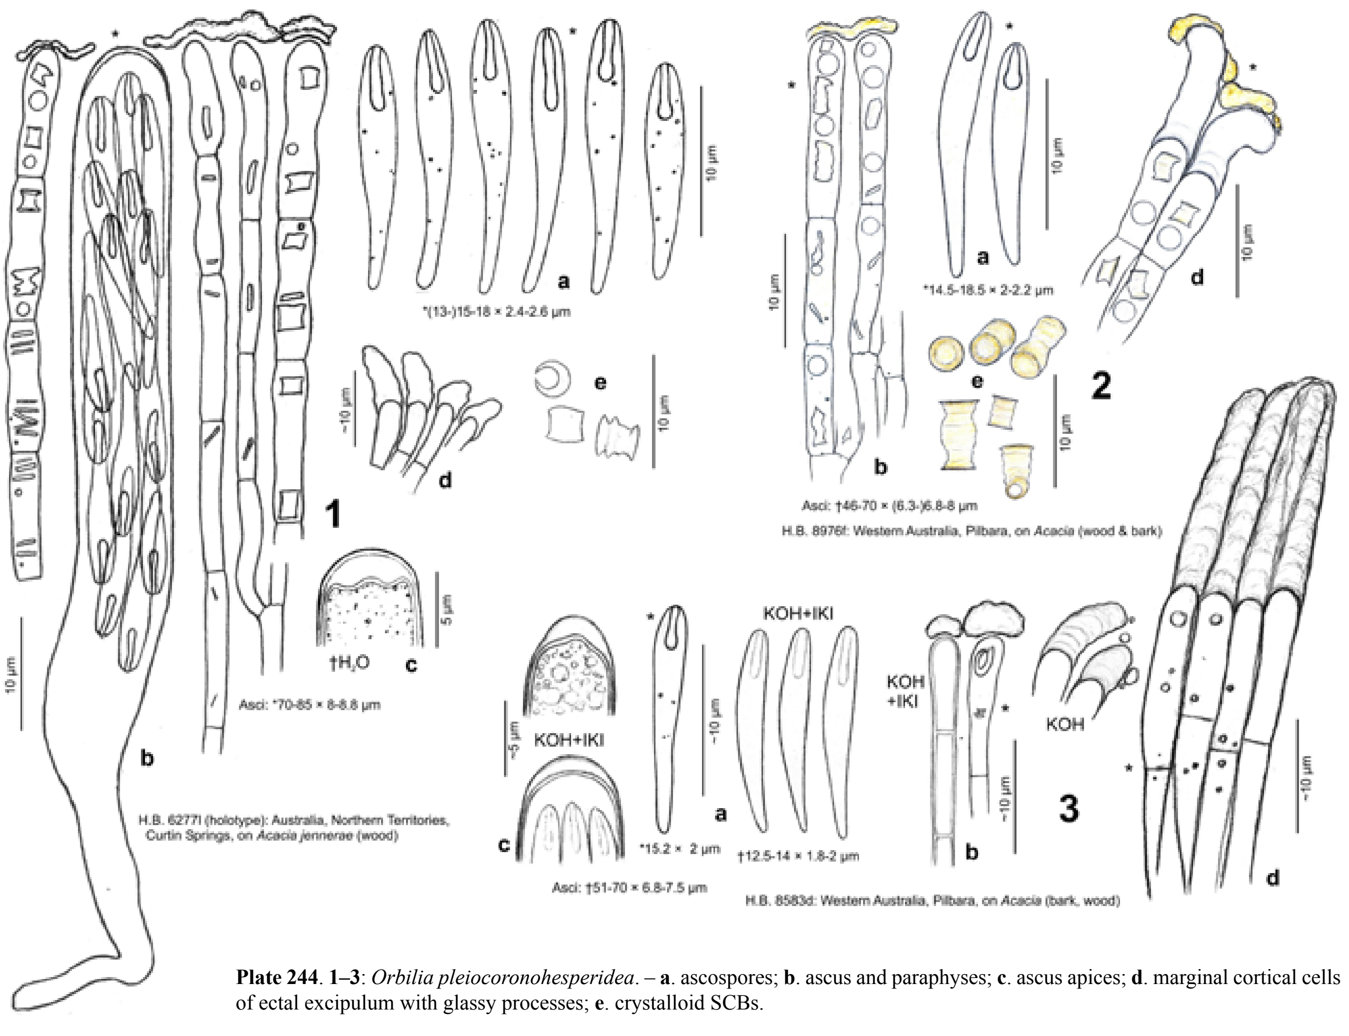


Plate 244. **1–3**: *Orbilia pleiocoronohesperidea*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. marginal cortical cells of ectal excipulum with glassy processes; **e**. crystalloid SCBs.

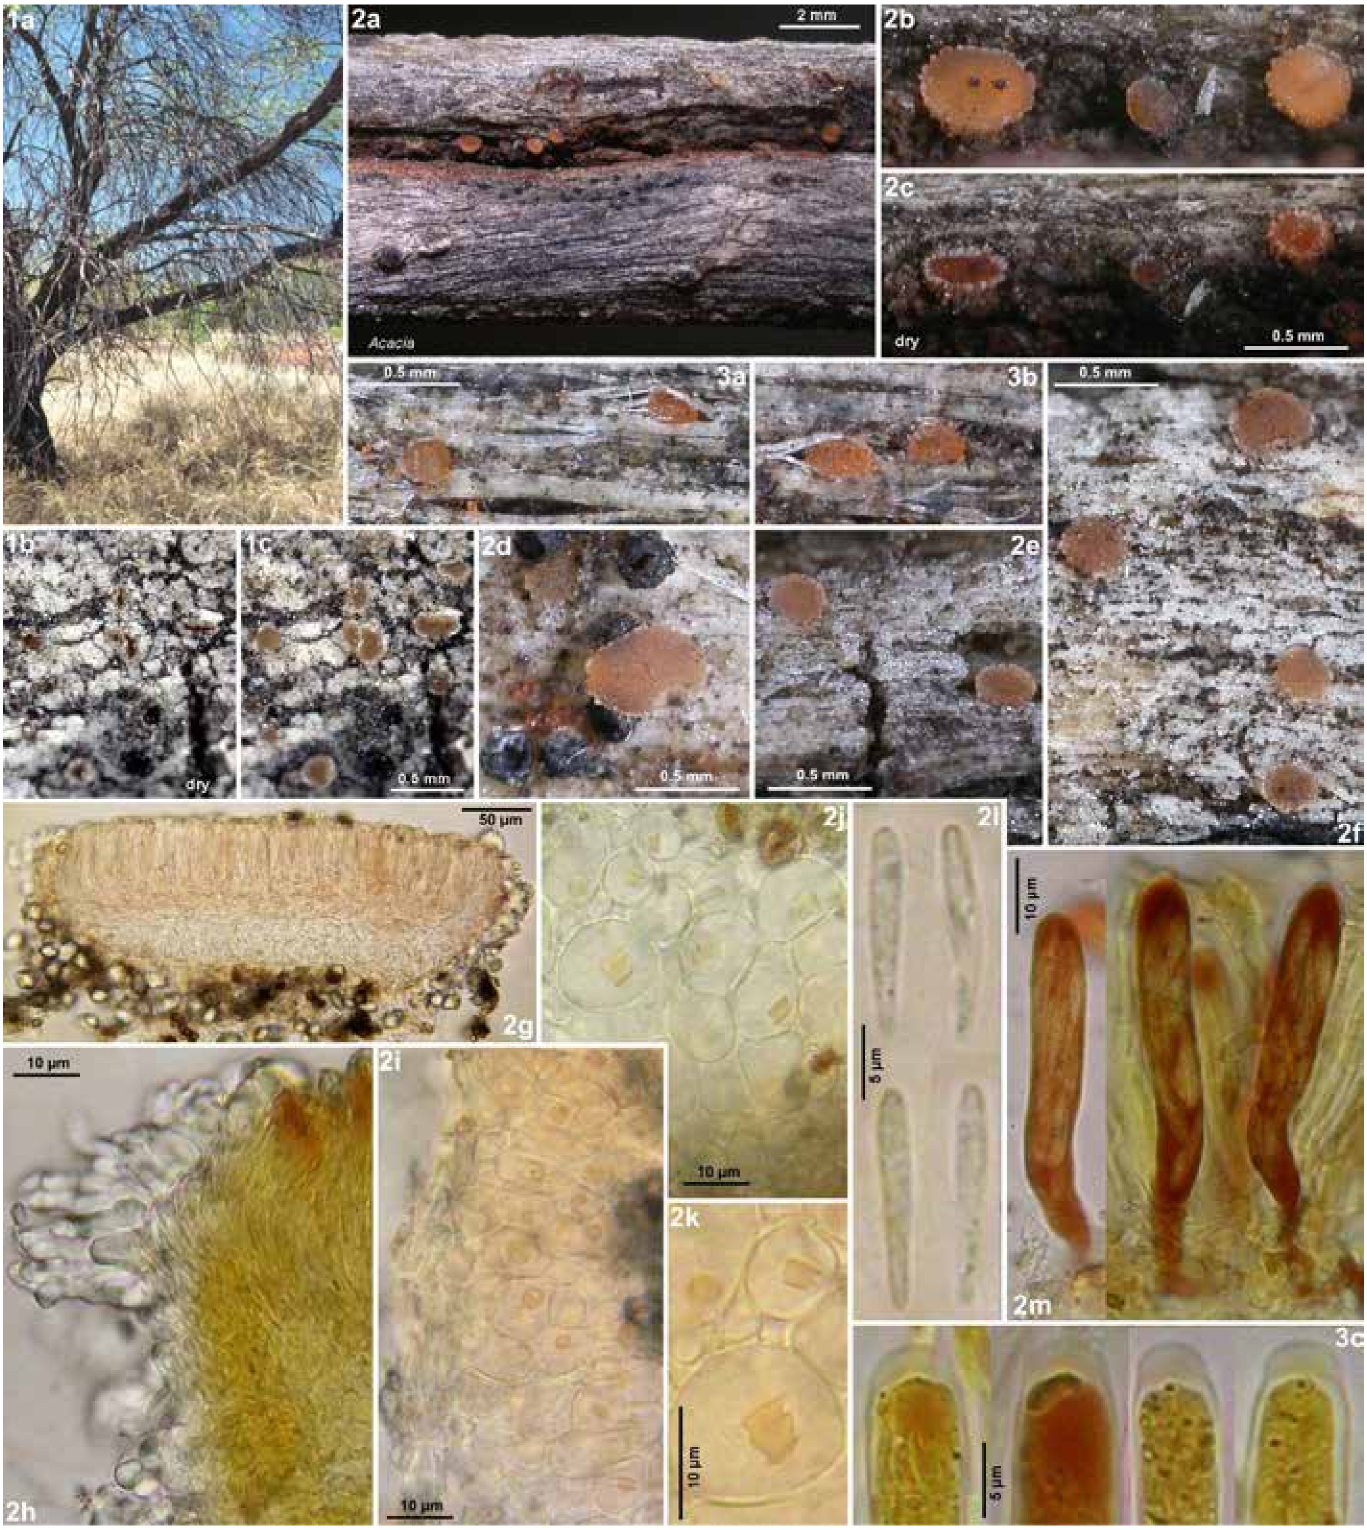

Plate 245. **1–3**: *Orbilia pleiocoronohesperidea*. – **1a**. arid acacia shrubland and hummock grassland; **2a**. decorticated xeric branch of *Acacia*; **1c**, **2b**, **d–f**, **3a–b**. rehydrated apothecia; **1b**, **2c**. dry apothecia (**1b–c** after almost 6 years); **2g**. apothecium in median section; **2h–i**. id., marginal ectal excipulum; **2j–k**. crystalloid SCBs in basal excipular cells; **2m**. asci and paraphyses; **3c**. ascus apices; **2l**. ascospores. – Living state, except for **2g**, **l** (in H_2O); **2h**, **m** (in IKI), **3c** (KOH+IKI). — **1a–b**. H.B. 8583: Western Australia, Pilbara, on *Acacia*; **2a–m**. H.B. 8976: ibid., on *Acacia*; **3a–c**. H.B. 6277l (holotype): Australia, Northern Territories, on *Acacia*.

Habitat: partially to entirely decorticated, 6–14 mm thick xeric branches of *Acacia* sp. {2}, *A. jennerae* {1}, on 0.3–0.5 mm deep very decayed wood {3} or bark {1}, strongly greyed, without algae. **Associated**: *Baggea* sp. {1}, *Coccomycetella* sp. {1}, *Dinemasporium* sp. {1}, *Hyalorbilia ?erythrostigma* {1}, *Lophiostoma* sp. {1}, *Orbilia angustoaristata* {1}, *O. austropleiomicrosoma* {1}, *O. coronohesperidea* {3}, *O. microserpens* {1}, *O. multiaustraliensis* {1}, *O. multiserpens* {1}, *O. myriella* {1}, *O. myrioaustraliensis* {1}, *O. myriofusoidea* {1}, *O. myrionamibica* {1}, *O. pleioaustraliensis* {1}, *O. pleioserpens* {2}, *Ostropales* {1}, *Patellaria* '*andina*' {1}, *Symbiotaphrina desertorum* {1}, ?*Teichospora* sp. {1}, ?*Trimmatostroma* sp. {1}. **Desiccation tolerance**: excipular cells and paraphyses, also many immature asci still viable after 14 months. **Altitude**: 467–480 m a.s.l. **Geology**: Archean & Paleoproterozoic sedimentary rock, Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiocoronohesperidea* is very similar to *O. coronohesperidea*, from which it merely differs in 16-spored asci and somewhat narrower ascospores.

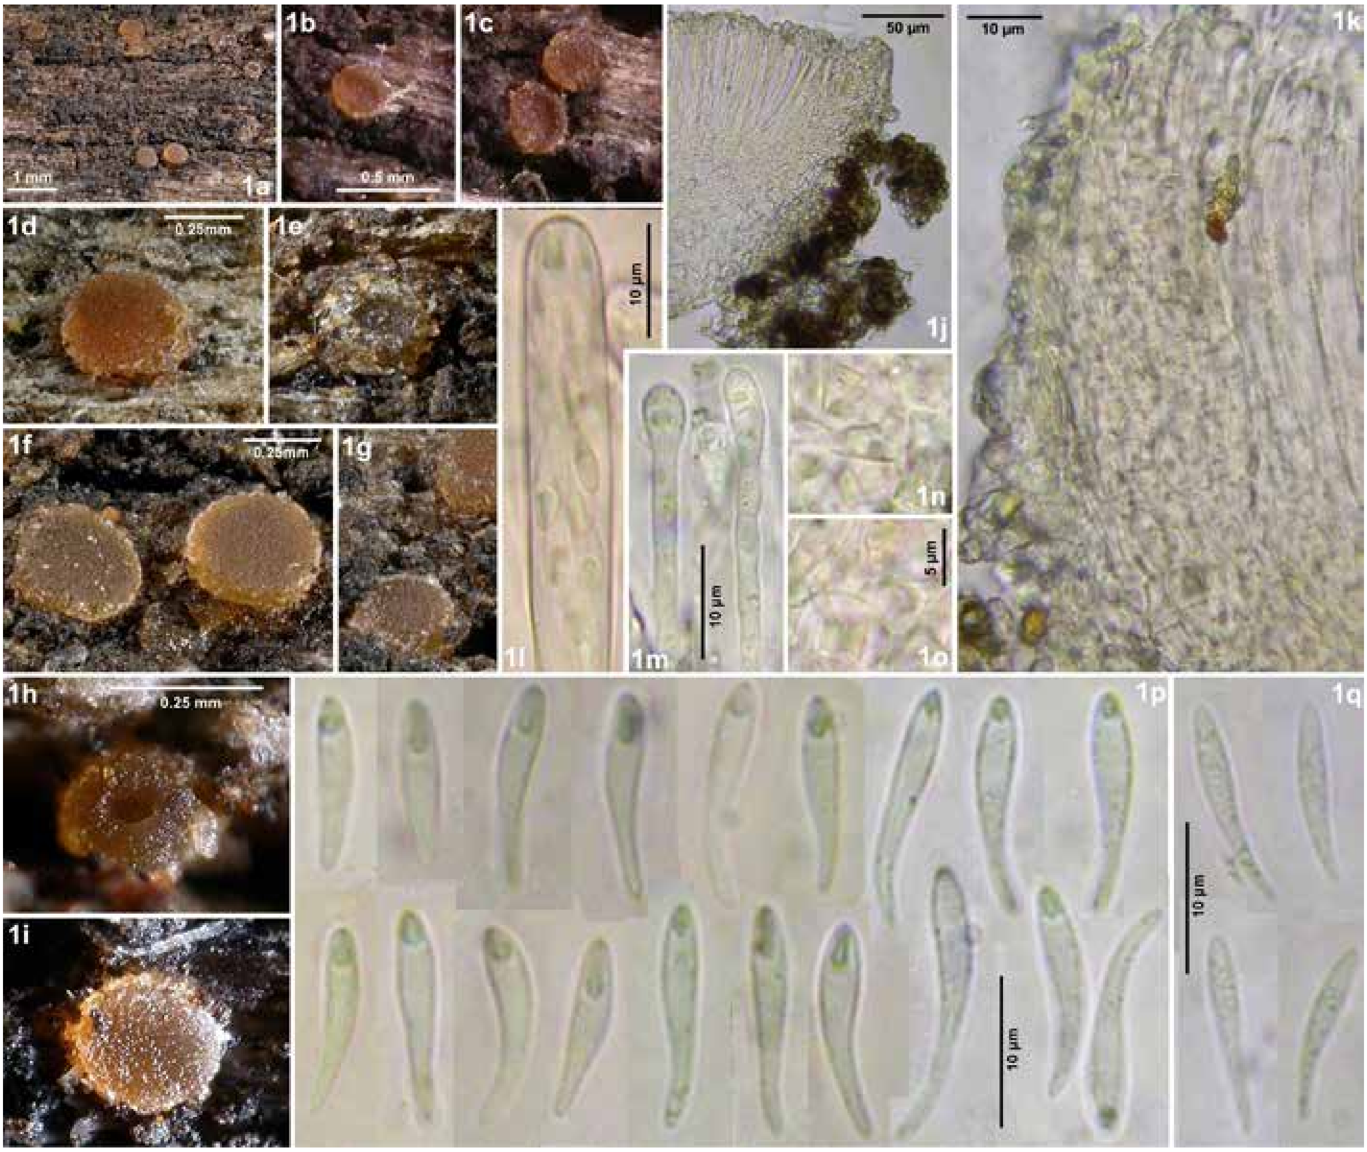

Plate 246. **1**: *Orbilia* aff. *pleiocoronohesperidea*. – **1a–i**. rehydrated apothecia; **1j**. apothecium in median section; **1k**. id., marginal ectal excipulum; **1n–o**. crystalloid SCBs in excipular cells; **1l**. ascus; **1m**. paraphyses; **1p–q**. ascospores. – Living state, except for **1q** (in KOH). — **1a–q**. H.B. 9695g: Western Australia, Gascoyne, on *Acacia*.

O. pleiohesperidea deviates in shorter and wider SBs and in the absence of glassy processes. A deviating collection in which glassy processes could not be observed is described below (Pl. 246): although the apothecia may show a crenulate margin, the marginal excipulum is composed merely of hyphoid elements here.

Variation. The two collections from Western Australia differ from the holotype from central Australia in narrower spores, but otherwise seem to fit very well.

Ecology. The three collections were made on rotten wood of xeric branches of *Acacia* sp. in tropical (to subtropical) arid open acacia shrublands of western (Pilbara desert) and central Australia (south of MacDonnell Ranges). *O. coronohesperidea* grew in association in all three collections but in separate populations. At the Pilbara site *O. coronohesperidea* grew predominantly on bark, whereas *O. pleiocoronohesperidea* was in 2001 always found on wood, but in 2007 mainly on bark.

Specimens included. **AUSTRALIA**: **Western Australia**, Pilbara, 1.5 km SW of Wittenoom, N of Karijini, delta of Wittenoom Gorge, 467 m, branch of *Acacia*, on wood, 28.XI.2001, G. Marson (H.B. 8583d). – ibid., branches of *Acacia*, on bark & wood, 29.X.2007, G. Marson (H.B. 8976f). – **Northern Territories**, Finke, 100 km E of Yulara, 24 km ENE of Curtin Springs Roadhouse, 28 km NNE of Mt. Connor, 480 m, branches of *Acacia jennerae*, on wood, 10.X.1998, G. Marson (ex H.B. 6277l, MEL 2389204, **holotype**).

Orbilia* aff. *pleiocoronohesperidea — Pl. 246

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.48 mm diam., 0.17–0.22 mm high, light orange(-red) or orange-brownish, round, scattered or in small groups; disc flat, margin thin, indistinct, 10–15 µm protruding, smooth or ± rough; broadly sessile, ± erumpent. **Asci** 75–87(–100) × 7.2–8.5 µm, †58–68 × 5.5–6.2 µm, 16-spored, spores *3–4-seriate, 7–8 lower spores inverted (hardly mixed), pars sporifera *60–65 µm long; **apex** (†) hemispherical (to slightly truncate), dome †1–1.2 → 0.7–0.9 µm thick, with indistinct apical chamber; **base** with short to long, thin or thick, flexuous stalk, h-shaped. **Ascospores** *(10–)11.5–16(–18) × (2–)2.2–2.5(–2.6) µm, †12–15 × 1.7–2.2 µm, fusoid-clavate, apex obtuse (rarely rounded), base medium to mostly strongly attenuated in a tail-like end or sometimes distinct thick tail 3–6(–7.5) × (0.8–)1–1.3(–1.5) µm, mostly slightly to medium curved near base; **SBs** *(2.5–)3–4(–4.5) × 1.2–1.3 µm, rod- to elongate tear-shaped, apically narrowed to a wide point, overmature 2.3–2.8 × 1.4–1.5 µm, tear-shaped to ampulliform. **Paraphyses** apically slightly clavate, terminal cells *(6–)8–15(–19) × 3–4 µm, lower cells *(11–)13–20 × 1.7–2.4 µm (up to 3 µm wide near apex); quite frequently branched at upper septum. **Medullary excipulum** hyaline, 30–50 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** of (†) thin-walled (to slightly gelatinized), vertically oriented t. globulosa-angularis from base to mid flanks, 50–90 µm thick near base, cells †8–18(–20) × 6–13 µm; 20–25 µm thick near margin, of t. prismatica-porrecta oriented at an 0–10° angle to the surface, marginal cortical cells */†7–12 × 3.5–4 µm; **glassy processes** absent. **Anchoring hyphae** sparse, *2–3 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses and marginal ectal excipulum globose, 2 µm diam., but mainly crystalloid, very pale orange, at lower flanks absent. **Exudate** over paraphyses 0.2–0.3 µm thick, granular, loosely attached over gel, over marginal excipulum 0.5–1 µm thick. — **ANAMORPH**: unknown.

Habitat: collected 2.5–3 m above the ground, corticated, 16–20 mm thick branch of *Acacia cyperophylla*, on very decayed wood, ± greyed, no algae. **Associated**: *Coccomycetella* spp. {2}, *Hysterobrevium mori*, *Orbilia allantoobliqua*, *O. australiensis*, *O. multiaustraliensis*, *O. pleioaustraliensis*, *O. pleiovinosa*, *Ostropales*. **Desiccation tolerance**: paraphyses and excipular cells still viable after 34 months (and 57 months including a singular rehydration). **Altitude**: 540 m a.s.l. **Phenology**: long-lived.

Taxonomic remarks. This collection deviates from *O. pleiocoronohesperidea* in lacking glassy processes at the margin, also in slightly wider SBs. For the similar *O. pleiovinosa*, with which it grew in association, see under that species (p. 632).

Ecology. *O.* aff. *pleiocoronohesperidea* was found on rotten wood of a decorticated xeric branch of *Acacia* in a subtropical (almost tropical) semiarid (almost arid) acacia open woodland of western Australia

Specimens included. **AUSTRALIA**: **Western Australia**, Gascoyne, bridge over Gascoyne River, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *Acacia cyperophylla*, on wood, 28.X.2007, G. Marson (H.B. 9695g).

Orbilia myriohesperidea Baral, **sp. nov.**, MB 813541 — Pl. 247

Etymology: named after the 64-spored asci and the ascospores resembling those of *O. hesperidea*.

Typification: Western Australia, Toolonga, branch of *Acacia*, 8.XII.2001, G. Marson (ex H.B. 9006b, MEL 2389272, holotype).

Latin diagnosis: *Similis* Orbiliae hesperideae *sed asci 64-spori. Habitat ad corticem putridum rami sicci* Acaciae *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.35 mm diam., 0.19 mm high, bright orange-red, non-translucent, ± round, scattered; disc flat, margin distinct, 20–25 µm protruding, smooth; broadly sessile, ± superficial. **Asci** †81–90 × 8.5–9(–9.5) µm, 64-spored (~40–50 spores counted), spores ~8-seriate, lower spores inverted (strongly mixed); **apex** (†) hemispherical to slightly truncate, dome †1.3–1.6 → 0.8–1 µm thick, with slight apical chamber; **base** with short, ± thick, flexuous stalk, L-shaped. **Ascospores** †9–12 × 2.3(–2.4) µm, ellipsoid(-fusoid)-clavate, apex obtuse, base with a distinct cylindrical tail 2.5–4.5 × 0.9–1.2(–1.4) µm, straight to mostly slightly to medium curved or geniculate near base; **SBs** sometimes visible as a transparent region in spore apex (dead state), ?narrowly tear-shaped, ?2–2.5 × 0.6–0.8 µm. **Paraphyses** apically uninflated or slightly (to medium) clavate, terminal cells †(5–)8–15 × 3–4.2 µm; frequently branched at upper septum, hymenium pale orange. **Medullary excipulum** 30–40 µm thick, of medium dense textura intricata with some distinctly inflated cells in chains, sharply delimited. **Ectal excipulum** pale orange, of (†) thin-walled, vertically oriented t. angularis-prismatica at base and lower flanks, 30 µm thick near base, cells †10–16 × 6–9 µm; at mid flanks of t. prismatica oriented at a 20° angle, 20 µm thick at margin, of t. prismatica-porrecta oriented at 10°, marginal cortical cells †9–11 × 3–4 µm; **glassy processes** absent. **Anchoring hyphae** abundant, †1.3–2(–2.5) µm wide, walls 0.2–0.3 µm thick, forming at flanks a dense, hyaline, slightly gelatinized t. porrecta 20–25 µm thick. **SCBs** no data available. **Exudate** over paraphyses and margin 0.2–0.3 µm thick, continuous. — **ANAMORPH**: unknown.

Habitat: ± corticated, 9–10 mm thick xeric branch of *Acacia* sp., on strongly decayed bark (bast), greyed, green algae absent. **Associated**: *Orbilia myrionanosoma*. **Desiccation tolerance**: unknown but certainly min. 1 year. **Altitude**: 157 m a.s.l. **Geology**: Cretaceous sedimentary rock (red-brown sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myriohesperidea* is readily recognized by its multispored asci and fusoid-clavate ascospores with thick tails. *O. myriofusiclava* differs in much shorter spores with more subacute apices and not forming such prominent tails, also in the presence of thick exudate. The species might also be closely related to the 32-spored *O.* aff. *macrocarpa* which has much larger spores with more fusoid heads (Pl. 229). *O.*

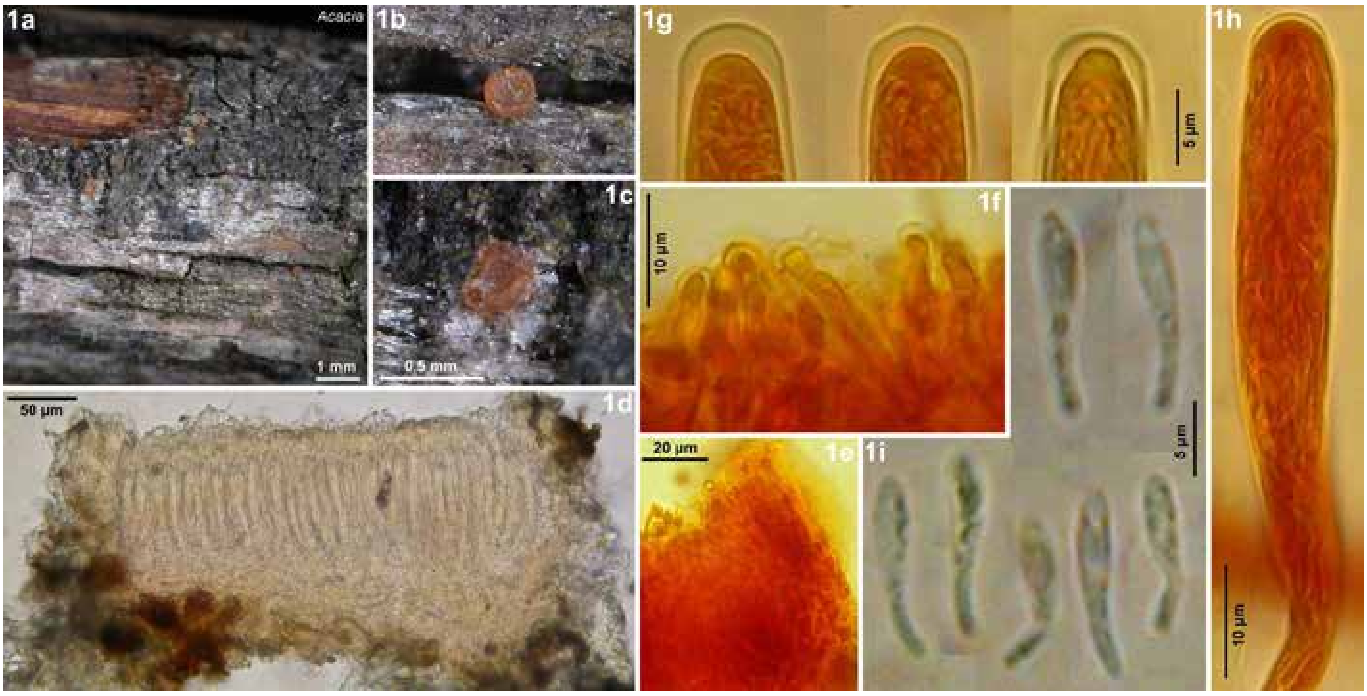

Plate 247. **1**: *Orbilia myriohesperidea*. – **1a**. dead corticated xeric branch of *Acacia* (rehydrated); **1b–c**. rehydrated apothecia (after > 7 years); **1d**. apothecium in median section; **1e**. id., marginal ectal excipulum, **1f**. paraphyses; **1g**. ascus apices; **1h**. mature ascus; **1i**. ascospores. – All in dead state (**1d**, **i** in KOH, **1e–h** in KOH+IKI). — **1a–i**. H.B. 9006b (holotype): Western Australia, Yalgoo, on *Acacia*.

myriohesperidea resembles *O. hesperidea* and *O. pleiohesperidea* in spore shape, the latter having a similar spore tail, but differ in 8- and 16-spored asci, respectively. No vital characters are known in this species, which was detected during a restudy of *O. myrionanosoma* more than 7 years after it was collected.

Ecology. *O. myriohesperidea* grew on rotten bark of a xeric branch of *Acacia* in a subtropical semiarid acacia shrubland in the Yalgoo ecoregion of the Darling Plateau (western Australia).

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 200 km N of Geraldton, 15 km SSE of Wannoo Billabong Roadhouse, W of Toolonga, 157 m, branch of *Acacia*, on bark, 8.XII.2001, G. Marson (ex H.B. 9006b, MEL 2389272, **holotype**).

Orbilia macrohesperidea Baral & G. Marson, **sp. nov.**, MB 813553 — Pls 248–249

Etymology: named according to the similarity to *O. hesperidea* but deviating in larger ascospores.

Typification: USA, Arizona, Wickenburg, branch of *Ephedra ?viridis*, 4.V.1995, G. Marson (ex H.B. 5894c, M-0276504, holotype).

Latin diagnosis: Similis *Orbiliae hesperideae sed asci, ascosporae et corpuscula refringentia latiora, excipulum marginale pilis brevissimis tenuitunicatis praeditum. Habitat ad corticem putridum ramorum siccorum* Ephedrae *in zona subtropica semiarida Americae septentrionalis.*

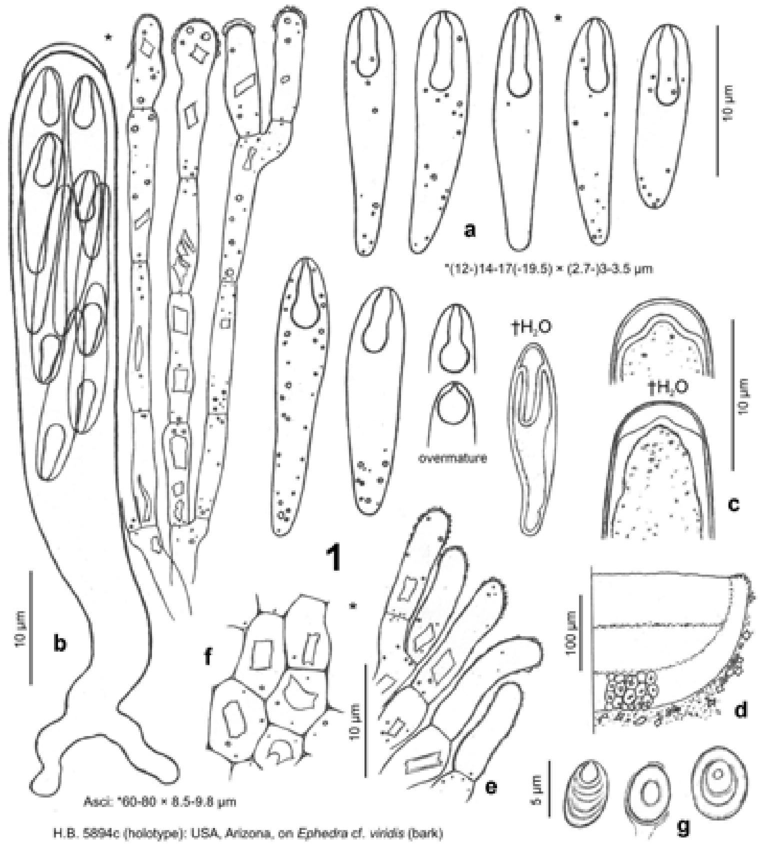

Plate 248. **1**: *Orbilia macrohesperidea*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. id., mid flanks (cells containing crystalloid SCBs); **g**. crystalloid SCBs in basal excipular cells.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.5 mm diam., 0.15–0.18 mm high, pale (dirty) orange-ochraceous, non-translucent, round, scattered; disc slightly concave to flat, margin distinct, 0–5 µm protruding, slightly whitish pubescent; broadly sessile, ± superficial. **Asci** *57–80(–105) × 8.5–9.8 µm, †48–68 × 7.5–8.8 µm, 8-spored, spores *2–3-seriate, (3–)4(–7) lower spores inverted (sometimes mixed), pars sporifera *35–40 µm long; **apex** (†) hemispherical to slightly truncate, dome immature †1–1.4 µm thick, with small apical chamber; **base** with short, thick, flexuous stalk, Y- to h-shaped. **Ascospores** *(11.2)14–17(–19.5) × (2.7–)3–3.5(–4) µm, cylindrical to clavate or fusoid-clavate, apex rounded to obtuse, base slightly (to strongly) attenuated, sometimes tail-like, straight, sometimes slightly curved near base; **SBs** *4–5.8 × 1.3–2(–2.3) µm, pear-shaped to ampulliform, apically narrowed to a ± wide point, straight. **Paraphyses** apically uninflated to slightly (rarely medium) clavate-capitate, rarely sublageniform, terminal cells *6–14 × 2.5–4 µm, lower cells *9–15 × 1.8–3 µm; sometimes branched at upper septum. **Medullary excipulum** subhyaline, 40–50 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** subhyaline, of (†) slightly gelatinized, vertically oriented t. angularis from base to submargin, 40–50 µm thick near base, cells *8–22 × 7–18 µm; 20–30 µm thick near margin, upper margin of t. porrecta oriented at a 40–50° angle to the surface, marginal cortical cells *8–15 × 3(–4) µm, forming ± free hair-like protrusions; **glassy processes** absent. **Anchoring hyphae** sparse, 2–3 µm wide, walls 0.2–0.3 µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) crystalloid, refractive, in excipular cells 4–8 × 3–5 µm, pale yellowish(-orange). **Exudate** over paraphyses and marginal cells 0.1–0.5 µm thick, granular(-continuous), firmly attached. **— ANAMORPH**: unknown.

Habitat: partially decorticated, 10–13 mm thick xeric branches of *Ephedra ?viridis*, on strongly decayed bark (bast), greyed, with sparse algae. **Associated**: *?Baggea* sp., *Hysterobrevium mori*, *Melaspilea emergens*, *Orbilia calyptrata*, *O. lacrimispora*, *O. maeandrina*, *O. multiserpens*, *O. sonorensis*, *Peniophora* sp. **Desiccation tolerance**: many mature asci still viable after 28 months. **Altitude**: 615 m a.s.l. **Geology**: Oligo- & Miocene sand- & mudstone; volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia macrohesperidea* is similar to *O. hesperidea*, from which it differs in wider asci, ascospores and SBs, also in hair-like protrusions at the margin. For the similar Australian *O. megahesperidea* see below.

Ecology. *O. macrohesperidea* grew on rotten bark of xeric branches of *Ephedra* in a subtropical semiarid paloverde-mixed cacti desert scrub in the Sonoran Desert of the southwest of Northern America.

Specimens included. **USA**: **Arizona**, Sonoran Desert, 82 km NW of Phoenix, SE of Wickenburg, 615 m, branch of *Ephedra ?viridis*, on bark, 4.V.1995, G. Marson (ex H.B. 5894c, M-0276504, **holotype**).

Plate 249. **1**: *Orbilia macrohesperidea*. – **1a**. dead, corticated xeric branch of *Ephedra* with *Peniophora*; **1b–c**. rehydrated apothecia (after 11 years). — **1a–c**. H.B. 5894c (holotype): USA, Arizona, on *Ephedra*.

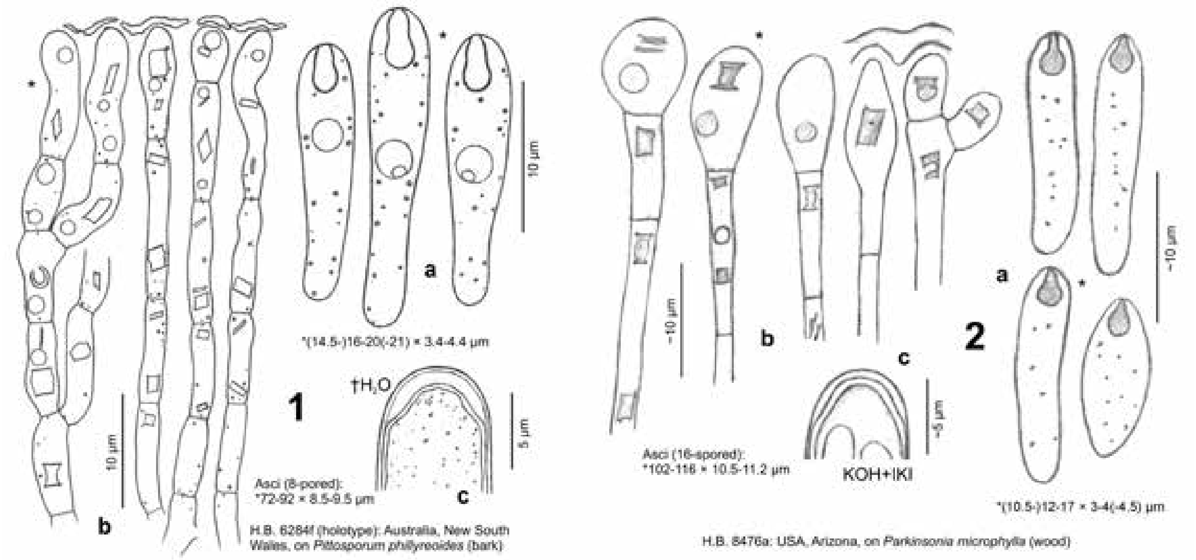

Plate 250. **1**: *Orbilia megahesperidea*; **2**: *O.* aff. *megahesperidea* (16-spored). – **a**. ascospores; **b**. paraphyses; **c**. ascus apex.

Orbilia megahesperidea Baral & G. Marson, **sp. nov.**, MB 813554 — Pls 250–251

Etymology: named after the similarity to *O. hesperidea* but with much larger ascospores.

Typification: Australia, New South Wales, Narrabri, twig and branch of *Pittosporum phillyreoides*, 24.X.1998, G. Marson (ex H.B. 6284f, MEL 2389205, holotype).

Latin diagnosis: *Similis* Orbiliae macrohesperideae *sed ascosporae leniter majores*, *basi leniter inflatae*, *corpuscula refringentia breviora*, *apothecia minuta*, *excipulum marginale absque pilis. Habitat ad corticem putridum ramorum siccorum* Pittospori phillyreoidis *in zona temperata subhumida Australiae orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.3 mm diam., ~0.2 mm high, light orange, round, barrel-shaped, scattered; disc flat, margin smooth; broadly sessile, superficial to slightly immersed. **Asci** *72–92 × 8.5–9.5 µm, 8-spored, spores 2–3-seriate, 3–5 lower spores inverted; **apex** (†) hemispherical, dome †1–1.2 µm thick, with small to large chamber; **base** with short, thick stalk, h-shaped. **Ascospores** *(14.5–)16–20(–21) × 3.4–4.4 µm, cylindric-clavate, apex rounded (to obtuse), base slightly to medium attenuated, sometimes dumbbell-shaped, straight to very slightly curved; **SBs** 3–4 × 1.7–2 µm, tear-shaped to pyriform or ampulliform, apically narrowed to a wide point. **Paraphyses** apically slightly (rarely medium) clavate, sometimes moniliform or spathulate, terminal cells *5–16 × 2.2–3.5 µm, lower cells *8–11 × 2–2.5(–3.3) µm (near base 7 × 3 µm); sometimes branched near apex. **Medullary excipulum** not examined. **Ectal excipulum** at flanks of t. angularis, margin not examined; **glassy processes** presumably absent. **Anchoring hyphae** not examined. **SCBs** in paraphyses and ectal excipulum globose, 1–1.5 µm diam., and angular, hyaline. **Exudate** over paraphyses 0.5–1.5 µm thick, cloddy, hyaline, loosely attached. **— ANAMORPH**: unknown.

Habitat: collected 248 m above the ground, partially decorticated, 4–15 mm thick twigs and branches of *Pittosporum phillyreoides*, on very rotten bark (periderm & bast), sometimes in clefts, strongly greyed, green algae very sparse. **Associated**: *Claussenomyces* sp., *Gloniopsis* sp., *Orbilia angustoaristata*, *O.* ?*livistonae*, *O. multiserpens*, *O.* ?*myrioolneyae*, *O. pleioaustraliensis*, *Polynema* sp., *Symbiotaphrina desertorum*, ?*Triblidium* sp., *Xylobolus* sp. **Desiccation tolerance**: fully viable (except for mature asci) for 25 months. **Altitude**: 615 m a.s.l. **Geology**: Cenozoic regolith; interlayered sedimentary and volcanic rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia megahesperidea* is characterized by large, cylindric-clavate, often slightly dumbbell-shaped ascospores with comparatively short and wide, ampulliform to pyriform SBs. From the similar North American *O. macrohesperidea* it deviates in slightly larger spores with ±

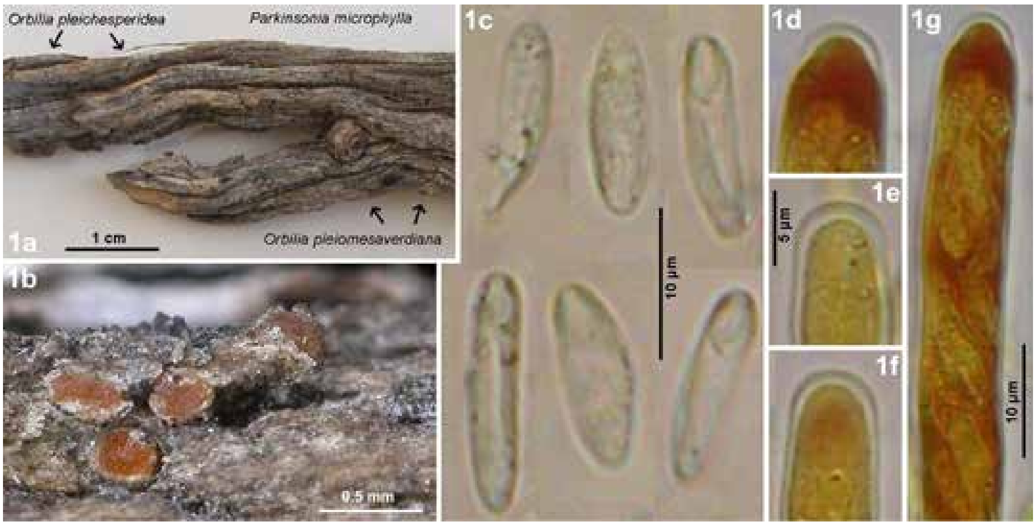

Plate 251. **1**: *Orbilia* aff. *megahesperidea*. – **1a**. decorticated xeric branch of *Parkinsonia microphylla*; **1b**. rehydrated apothecia (after 9 years); **1g**. mature ascus; **1d–f**. ascus apices; **1c**. ascospores. – Dead state (asci in KOH+IKI, spores in H_2O). — **1a–g**. H.B. 8476a: USA, Arizona.

inflated bases, and in shorter SBs, also in smaller yellow-orange apothecia with a smooth margin. The nucleus in the living spores is visible when stained in IKI (Pl. 250: 1a).

Not included collection. A deviating North American sample has similar ascospores but 16-spored asci (Pls 250: 2; 251).

Ecology. *O. megahesperidea* grew on rotten bark of a xeric branch of *Pittosporum phillyreoides* in a warm-temperate subhumid eucalypt woodland in eastern Australia west of the Great Dividing Range. The not included collection on wood of *Parkinsonia* (foothill paloverde) was from the subtropical semiarid Sonoran paloverde-mixed cacti desert scrub in the southwest of Northern America.

Specimens included. **AUSTRALIA**: **New South Wales**, Brigalow Belt South, 20 km SW of Narrabri, 248 m, twig & branch of *Pittosporum phillyreoides*, on bark, 24.X.1998, G. Marson (ex H.B. 6284f, MEL 2389205, **holotype**).

Not included. **USA**: **Arizona**, Sonoran Desert, 82 km NW of Phoenix, SE of Wickenburg, 615 m, branch of *Parkinsonia microphylla*, on wood, 4.V.1995, G. Marson (H.B. 8476a).

Orbilia montigena Baral & E. Weber, **sp**. **nov**., MB 813556 — Pls 252–253, Map 44

Etymology: referring to the montane distribution of the first collections.
Typification: Germany, Bayern, Spitzingsee, branch of *Sorbus aucuparia*, 3.VII.2005, P. Karasch (ex H.B. 7838b, M-0276517, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.4–0.8(–1.1) mm diam., 0.15–0.25(–0.33) mm high (receptacle 0.1–0.15 mm), light to bright orange(-red), rarely rose-red, scarcely translucent, round (to elliptical), subscattered to subgregarious; disc slightly (to medium) concave or flat, margin ± thick, 5–20 µm protruding, ± smooth or (very) finely to distinctly crenulate; broadly sessile or with a short and broad obconical stipe 0.06–0.1 × 0.25–0.4 mm, superficial or slightly immersed, sometimes immersed in clefts; dry bright (orange-)red, with contracted margin. **Asci** *(49–)60–82(–90) × (5.8–)6–7.2(–7.5)((–8.5)) µm {6}, †(44–)48–64(–85) {5} × (5–)5.3–6.3(–6.8) µm {3}, 8-spored, spores 2–4-seriate, ((1–))(2–)3–4(–5)((–6)) lower spores inversely oriented {8} (rarely to often mixed), pars sporifera *(25–)28–30(–37) µm; **apex** (†) hemispherical, dome †(0.5–)0.7–1(–1.2) µm thick {5}, usually with apical chamber; **base** with short to long, thin or thick, ± flexuous stalk, L-, h- or Y-shaped. **Ascospores** *((7.5–))(8.3–)9–13(–14)((–15.5))((–17)) × (2–)2.2–2.7(–3) µm {14}, subcylindric-fusoid or -ellipsoid to fusoid-clavate or clavate, apex rounded to obtuse, base sometimes tail-like, rarely with distinct short tail, straight or (very) slightly (to medium) curved near base; **SBs** *((2–)) (2.5–)3–4(–4.7) ((–5.5)) × 0.8–1.3 {7}, tear- to pear-shaped, or rod-shaped to vermiform or ampulliform, apically narrowed to a small to wide point, overmature *1.5–3 × 1.2–1.4(–1.6) µm. **Paraphyses** apically uninflated or slightly (rarely medium) clavate, sometimes sublageniform or spathulate, terminal cells *(7–)9–20((–25)) × ((1.5–))(1.7–)2–3((–3.5)) µm {5}, lower cells *(7–)9–14(–15)((–18)) × 1.6–2.6(–2.8) µm {5}; rarely to infrequently branched near apex; hymenium pale rose to orange. **Medullary excipulum** subhyaline to pale rose, 40–60 µm thick, of rather dense textura intricata with many inflated cells, medium to very sharply delimited from ectal excipulum (sometimes by a 10 µm thick yellowish t. porrecta). **Ectal excipulum** hyaline to pale rose, of (†) thin-walled (to slightly gelatinized), vertically oriented t. globulosa-angularis-prismatica from base to midflanks or submargin, (40–)50–80(–100)((–200)) µm thick near base, cells *(6–)8–16(–19) × (5–)6–11(–13) µm {5}; 20–30 µm thick at flanks, 25–40 µm thick near margin, of t. prismatica-angularis to prismatica-porrecta oriented at a 20–30 up to 50–70° angle to the surface, marginal cortical cells *(6–)7–10(–15) × 2.5–4.5(–5.2) µm {4}, †(7–)8–12(–13) × 2–2.5 or 3–4 µm {2}, **glassy processes** absent {8}. **Anchoring hyphae** medium to very abundant, */†2–3 µm wide, walls 0.2(–0.3) µm thick {4}, forming a dense, up to 70–100 µm thick, non-gelatinized t. intricata at base, also covering the flanks. **SCBs** globose {10}, in paraphyses 1–3 µm diam.; in excipular cells 1.5–3.5(–4) µm diam. **Exudate** hyaline to light chlorinaceous- or sulphur-yellow, over paraphyses (0.3–)1–3(–5) µm thick, broken into externally rough clods, usually loosely attached; over margin and flanks rough-cloddy to granular, 0.5–4 up to 5–10 µm thick. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {3}). **Conidiophores** not seen. **Conidia** Y-shaped, total size *(26–)30–34(–39) × (30–)35–50(–69) µm, †37 × 52 µm, stipe *10–15 × 5.5–6.5(–8.2) µm, (1–)2(–3)-septate, arms strongly and abruptly tapering, *(16–)19–33(–40) × 6–7(–8) µm, †5.5 µm wide, (2–)3–4(–5)-septate {3}.

Habitat: collected 0.5–4 m above the ground (rarely on the ground), 3–80 mm thick, still-attached, decorticated twigs and branches or logs of *Carpinus betulus* {1}, *Cornus mas* {1}, *Corylus avellana* {1}, *Fagus sylvatica* {1}, *Koelreuteria paniculata* {1}, *Laburnum anagyroides* {1}, *Populus alba* {1}, *P. tremula* {1}, *Quercus* sp. {1}, *Q. petraea* {1}, *Q. robur* {1}, *Robinia pseudoacacia* {2}, *Sorbus aucuparia* {1}, *Ulex parviflorus* {2}, on wood {16}, 0.5–1 or rarely 5–10 mm deep (medium to) strongly decayed, sometimes very eroded, ungreyed to strongly greyed, green algae sparse to abundant. **Associated**: *Durella connivens* {2}, '*Helotium*' *uvidulum* {2}, *Hyalorbilia hergiswiliana* {2}, *H. subfusispora* {1}, *Lecanora* sp. {1}, *Mycocalicium ?parietinum* {1}, *Orbilia aprilis* {2}, *O. arachnovinosa* {1}, *O. corculispora* {1}, *O. microsoma* {1}, *O. pleioeuonymi* {1}, *O. ?pleiogambelii* {1}, *O. pleiomicrosoma* {1}, *O. pleistoeuonymi* {1}, *O. polyspora* {1}, *O. vinosa* {1}, *Perrotia flammea* {1}, *Strossmayeria basitricha* (anamorph) {1}. **Desiccation tolerance**: some paraphyses, ascospores, and immature asci still alive after 22 months. **Altitude**: 150 m a.s.l. (hemiboreal Europe), 130–1585 m (central Europe), 255–1250 m (southern Europe). **Geology**: Lower to Upper Jurassic, Cretaceous & Tertiary marl-, lime- & sandstone, flysch, Quaternary glacial or fluviatile sand & gravel; serpentinite. **Phenology**: III, V–X, XII (throughout the year, long-lived).

Taxonomic remarks. *Orbilia montigena* resembles the mediterranean *O. hesperidea* in ascospore shape and in the absence of glassy processes, but differs in the consistent absence of crystalloid SCBs and in occurring in montane to subalpine climatic zones. *O. vinosa* differs from *O. montigena* in narrower and longer spores, longer SBs, and in the partial presence of crystalloid SCBs. For the morphological differences between *O. montigena* and *O. alpigena* see under the latter species (p. 595). The two species were at first believed to represent a single taxon, but differences in SB size and molecular data suggest that samples on coniferous wood need to be separated from those on angiosperm wood.

Variation. *O. montigena* varies somewhat in the size of asci, spores, and SBs. Spore shape was rather consistent, although a few spores showed tail-like bases in most of the collections.

Not included collection. A sample on unidentified angiosperm wood from the lowlands of eastern North America studied by E. Crenson (pers. comm., IVV: 4.IX.2017) is not included in the description, particularly because of the geographical origin and the lack of data about SCBs, also because the margin is finely denticulate, perhaps by short glassy processes. In the spores and SBs this sample would well fit *O. montigena*.

Anamorph. Trinacrium-like conidia more or less indistinguishable from those associated with *O. alpigena* were repeatedly found in association with apothecia of *O. montigena*. Likewise indistinguishable appears to be the single conidium observed in the similar North American *O. navajoana*. Also the conidia of *O. hesperidea* are similar, but have narrower and shorter, also often less strongly tapered arms. Trinacrium-like conidia observed in the Slovakian sample on *Quercus* deviate in less tapered, obtuse arms and are therefore considered as uncertain.

Phylogeny. Sequences of two *O. montigena* samples (on *Fagus* from Bayern, montane; on *Quercus* from Slovakia, colline), gained from apothecia and comprising the ITS region (S1506 intron absent), concur by only 1 nt difference in the ITS2. The species shows an ITS distance of 9 % to *O. alpigena*. In our phylogenetic analysis of the ITS region, *O. montigena* clustered with high support in the *hesperidea-alpigena* clade (Phyls 9–10), with a distance of ~7.5–10.5 % to other members of the clade, the lowest percentage being to narrow-spored *O. australiensis*.

Ecology. *O. montigena* inhabits strongly rotten wood of xeric branches of various angiosperm trees and shrubs. The species was found in calcareous, orotemperate (montane: Schwäbische Alb, German and French Alps and Prealps) but also supratemperate (colline: Danubian floodplain, Fruška Gora), humid regions of central and southern Europe, where it occurred in rich deciduous forests, e.g., a thermophilous (xerophilous) pannonian oak grove with *Cornus mas*, a *Querco-Fagetum* with *Lilium martagon* and *Vincetoxicum officinale*, or one with *Tilia tomentosa* and *Staphylea pinnata*. The sample on *Sorbus* was in the subalpine *Pinus mugo* belt. In the Sebezh National Park of northwestern Russia *O. montigena* was found in the hemiboreal southern taiga. Two collections on *Ulex parviflorus* are from mesosub- or supramediterranean semihumid Massif central and Sistema Ibérico, but they did not differ in their micromorphology from typical samples from cooler sites. One sample from the lowlands of Fruška Gora was at a more suprasubmediterranean subhumid site.

Specimens included. **RUSSIA (West)**: **Pskov**, **Sebezh**, ~18 km SE of Sebezh, Lake Osyno, 150 m, branch of *Corylus avellana*, on wood, 16.VII.2006, V.A. Melnik, vid. E.S. Orbilia alpigena Baral & E. Weber, **sp**. **nov**., MB 813557 — Pls 254–255, Map 44

Etymology: referring to its predominant occurrence in the region of the Alps.
Typification: Austria, Vorarlberg, Eineguntkopf, branches of *Picea abies*, 2.VII.2011, H.O. Baral (ex H.B. 9566a, M-0276432, holotype; sq.: KT222426).

Latin diagnosis: *Similis* Orbiliae montigenae *sed corpuscula refringentia ascosporarum breviora, habitat ad lignum ramulorum vel ramorum siccorum arborum coniferarum.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.25–)0.3–0.7(–0.8) mm diam., 0.15–0.2(–0.26)(–0.33) mm high (receptacle 0.1–0.15 mm), pale to bright orange-rose or orange-red, faintly translucent, round, scattered to subgregarious; disc flat to slightly convex, margin indistinct or thin to thick, 0–5 µm protruding, smooth to slightly rough; broadly sessile or with a short obconical stipe 0.06 × 0.2 mm, superficial; dry deep orange-red, margin scarcely raised. **Asci** *(52–)55–65(–75) × 5.5–6.5 µm {3}, †(42–)45–55(–57) × (4.7–)5–5.5(–5.8) µm {2}, 8-spored, spores 2–4-seriate, 3–5(–6) lower spores inversely oriented {5} (sometimes to often mixed); **apex** (†) hemispherical to slightly (rarely medium) truncate, dome †0.7–1.5(–2) → (0.3–)0.5–1.3 µm thick {4}, with or without apical chamber; **base** with short to long, medium thick, flexuous stalk, Y-, L- or h-shaped. **Ascospores** *((6–))(7.5–)9–13(–14) × (2–)2.2–2.7(–2.9) µm {8}, †8.5–13 × 2–2.5(–2.8) µm {3}, (cylindric-)fusoid to fusiform or fusoid- to fusiform-clavate, apex obtuse to subacute, base rarely tail-like or with a tail 1–3(–6) × 1–1.4 µm, straight to slightly curved near base; **SBs** *((1.8–))(2–)2.3–3.2(–3.5)((–4)) × (0.8–)1–1.5(–1.6) {7}, tear- to pear-shaped, apically narrowed to a ± small point. **Paraphyses** apically uninflated or slightly (to medium) clavate or ellipsoid, terminal cells *(6–)8–15(–19) × 2–3(–3.5) µm {3}, lower cells *7.5–13(–14.5) × 1.5–2.5 µm {2}; rarely to infrequently branched near apex; hymenium pale rose(-orange). **Medullary excipulum** pale rose, 50–90 µm thick, of rather dense textura intricata with many inflated cells, medium to sharply delimited from ectal excipulum (sometimes by a 5–10 µm thick yellowish t. porrecta). **Ectal excipulum** hyaline to pale rose, of (†) thin-walled (to slightly gelatinized), vertically oriented t. angularis from base to submargin, 40–100 µm thick near base, cells *7–14 × 6–12 µm {2}; 20–25 µm thick at flanks, 15–20(–40) µm near margin, of t. prismatica-angularis to prismatica-porrecta oriented at a (30–)50–80° angle to the surface, marginal cortical cells *5–10 × (2.5–)3–4.5 µm {2}, **glassy processes** absent {8}. **Anchoring hyphae** ± abundant, forming strands, *2–3 µm wide, walls 0.2–0.3 µm thick {1}. **SCBs** globose {7}, in paraphyses (1–)1.5–3 µm diam.; in excipular cells 1.8–3.2 µm diam. **Exudate** hyaline to pale yellow, over paraphyses 1–3(–4) µm thick, cloddy to continuous, externally ± rough, ± loosely attached; over margin and flanks rough-cloddy to granular, 2–3(–5) µm thick. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {5}). **Conidiophores** not seen. **Conidia** Y-shaped, total size *25–37 × 36–48 µm, †25 × 39 µm, stipe *10–11.5(–14.5) × 5.7–7.2 µm, †10.5 × 6 µm, 2-septate, arms strongly and abruptly tapering, *17.5–27 × 5.7–7.8 µm, †19–21 × 5–5.5 µm, 3(–4)-septate {3}.

Habitat: collected 1–2 m above the ground, corticated to decorticated, 3–28 mm thick, still-attached twigs and branches of *Picea abies* {13}, *Pinus sylvestris* {1}, on wood {14}, 0.2–0.3 mm deep medium to strongly decayed, often in old beetle galleries, strongly greyed or not, green algae sparse to abundant. **Associated**: *Amphosoma resinicola* {1}, *Cryptodiscus muriformis* {1}, *C. pini* {1}, *Hypogymnia physodes* {2}, *Lachnellula abietis* {1}, *L. resinaria* {1}, *Mellitiosporiella* cf. *macrospora* {1}, *Mellitiosporium propolidoides* {4}, *Orbilia aprilis* {1}, *O. cylindrospora* {1}, *O. euonymi* {4}, *O. flagellispora* {2}, *O. patellarioides* {1}, *O. subvinosa* {1}, *O. vinosa* {2}, ?*Pragmopora* sp. {1}, *Propolis hillmanniana* {1}, *P. rhodoleuca* {1}, *Pseudevernia furfuracea* {2}, *Resinomyces griseus* {1}, *Therrya* cf. *fuckelii* {1}, crustose lichens. **Desiccation tolerance**: fully viable for at least 1 month. **Altitude**: 870–1760 m a.s.l. **Geology**: Buntsandstein, Middle & Upper Jurassic and Cretaceous marl- & limestone, dolomite, Jurassic & Tertiary mud- & sandstone, molasse, Pleistocene till; amphibolite, gneiss, pelite, phyllite, mica schist. **Phenology**: IV–X (but probably throughout the year, long-lived).

Taxonomic remarks. Like *O. montigena*, *O. alpigena* resembles the mediterranean *O. hesperidea*, from which both differ in the absence of crystalloid SCBs and in the preference for montane to subalpine climatic zones. Morphologically, *O. montigena* cannot easily be distinguished from *O. alpigena*. The main indication for two separate taxa was suspected to lie in the length of spore bodies. *O. montigena* shows a distinct tendency to longer SBs, ranging at (2.5–)3–4(–4.7) µm compared to (1.8–)2–3.5(–4) µm in *O. alpigena*. This feature was found to correlate with the substrate: angiosperms in *O. montigena*, gymnosperms in *O. alpigena*. Furthermore, apothecia of *O. alpigena* are slightly smaller, never concave, with a hardly protruding, always ± smooth margin, and the spores are more fusoid, with a sometimes subacute apex and an always narrow attachment of the SBs.

Variation. *O. alpigena* varies somewhat in ascus length, thickness of apical dome, and in spore and SB size. Variation in spore length and shape was especially seen in the first collection of *O. alpigena* (H.B. 4801a), the spores showing sometimes distinct and rather long tails.

Anamorph. Trinacrium-like conidia were repeatedly found in association with apothecia of *O. alpigena*. They are rather characteristic in their very broad and strongly tapered arms and stipes. Therefore, we believe that it is possible to recognize the species from its anamorph even if no mature teleomorph is present. An unlocalized French, probably montane collection on a *Larix* branch consisted only of a single immature apothecium with asci with thick-walled apices and paraphyses with globose SCBs; the abundantly associated conidia obviously belonged to *O. alpigena* (Pl. 254: 4). However, conidia found in the very similar *O. montigena* and the North American *O. navajoana* appear to be indistinguishable.

Phylogeny. Sequences of *O. alpigena* were gained from apothecia of two collections (Vorarlberg and Hautes-Alpes),

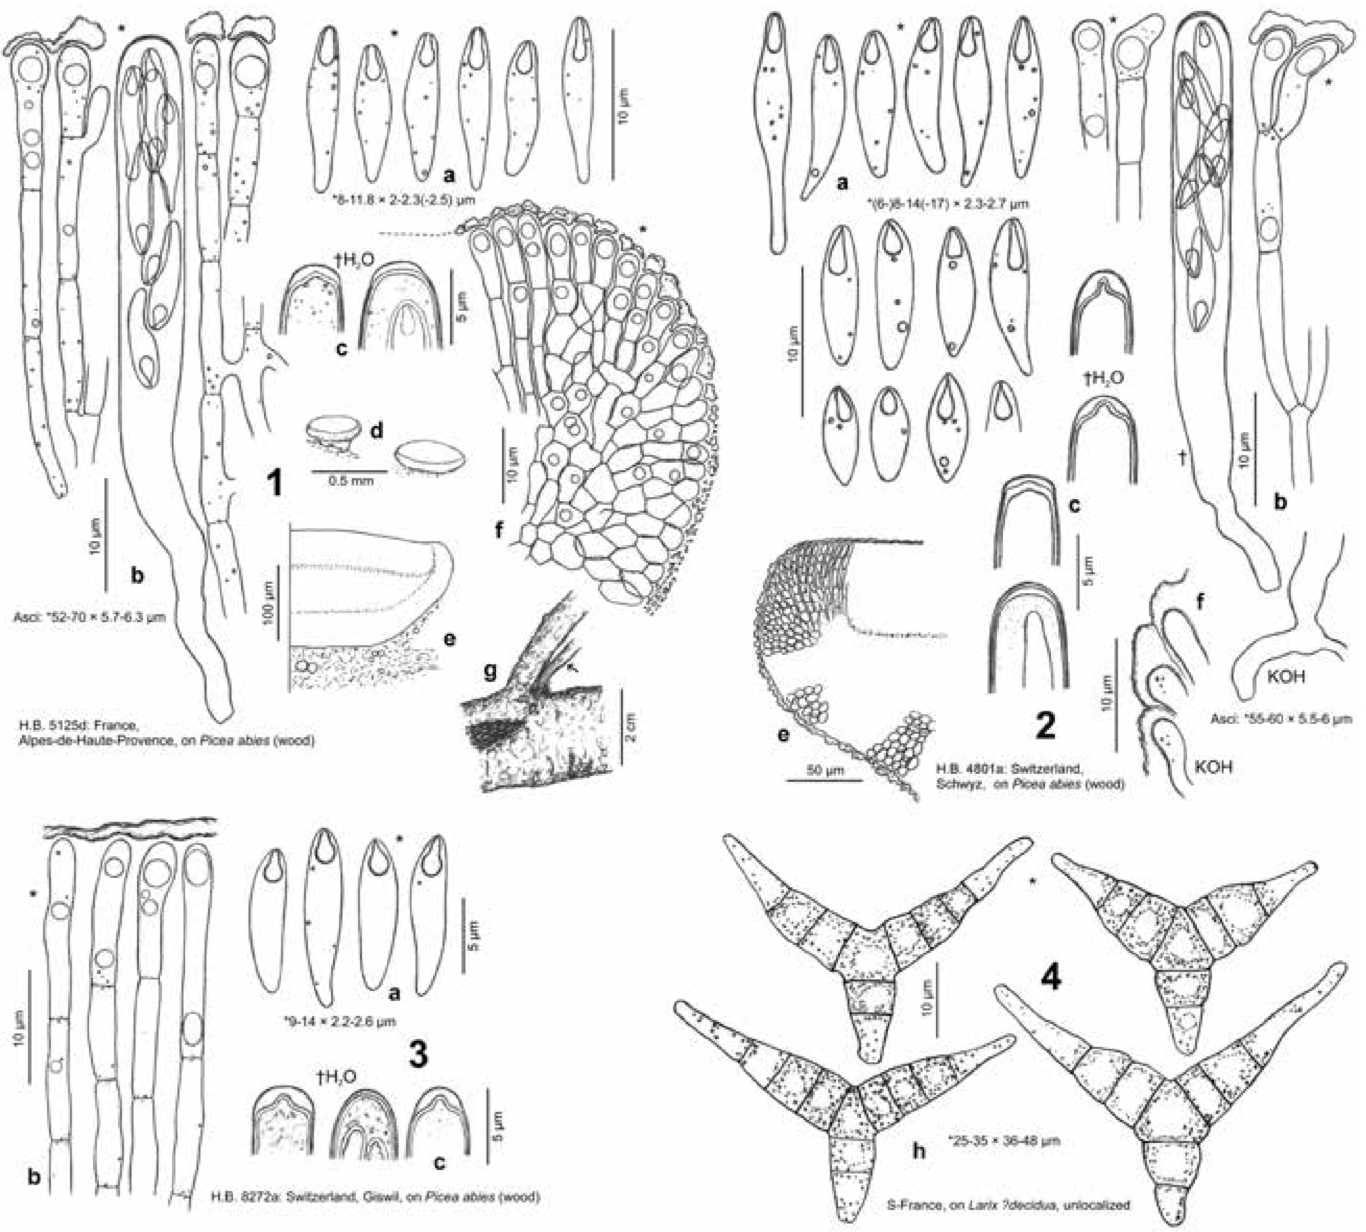

Plate 254. **1–4**: *Orbilia alpigena*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. id., ectal excipulum (margin and mid flanks); **g**. corticated xeric branch with a thin decorticated side twig; **h**. conidia from substrate (associated teleomorph immature).

comprising SSU (only Vorarlberg), ITS, and LSU (the S1506 intron is absent in both). In the ITS region and in the overlapping part of LSU (D1–D2) the two strains are completely identical. In our phylogenetic analyses, *O. alpigena* clustered highly supported in the *hesperidea-alpigena* clade (Phyls 9–10, S13), showing an ITS distance of 8.5–10.5 % to other members of the clade. The high distance of 9 % to *O. montigena*, with which it does not form a clade, confirms separation from that species.

Ecology. *O. alpigena* inhabits medium to strongly rotten wood of xeric branches of gymnosperm trees. The species was so far only found in central and southern Europe (Schwarzwald, Alps) where it appears to be restricted to montane to subalpine, orotemperate humid, rarely orosubmediterranean zones. It occurs in *Picea* forests, e. g., with *Vaccinium* and *Calluna*, or *Gentiana lutea*, on acidic but also calcareous soils.

Specimens included. **GERMANY**: **Baden-Württemberg**: Schwarzwald, 8.3 km WNW of Villingen, 1 km NW of Unterkirnach, E of Behringerhof, 870 m, branch of *Picea abies*, on wood, 19.VIII.2005, H.O. Etymology: referring to the microscopical resemblance to *Orbilia montigena*. **Typification**: Spain, Cataluña, Ripoll, Gombrèn, branch of *Acer* sp., 19.VI.2016, J. Bometón, L. Sánchez, J. Ballarà (ex J.B. 658/16 & ex H.B. 10013, AH 52843, holotype; sq.: MK493132).

Latin diagnosis: *Similis* Orbiliae montigenae *sed ascosporae angustiores, corpuscula refringentia angustiora. Habitat ad lignum valde putridum rami sicci* Aceri *in zona orotemperata humida Europae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.8(–1.2) mm diam., 0.13–0.17 mm high (receptacle 0.11–0.12 mm), light orange-rose to bright orange, medium translucent, round to elongate-elliptical, undulating when large, subgregarious; disc flat, margin thin, 0–8 µm protruding, smooth; broadly sessile, superficial but often deeply immersed in clefts; dry bright orange-red, hardly margin. **Asci** *42–54 × 6–6.5 µm, †35–47 × 5–5.5 µm, 8-spored, spores 2–4-seriate, ~4 lower spores inversely oriented, pars sporifera *22–23 → 19 µm long; **apex** (†) ± hemispherical (subconico-subtruncate), dome †0.7–1 µm thick, no apical chamber seen; **base** with short to long, thin or thick, flexuous stalk, L-, T- or Y-shaped. **Ascospores** *10–13 × 1.8–2.4 µm, †9.5–12(–13) × 1.6–2(–2.2) µm, fusoid to fusoid-clavate, apex obtuse, base often tail-like, straight to sometimes slightly curved towards base; **SBs** *3.5–4.5 × 0.5–0.7 → 2.5–3.5 × 1–1.1 µm, vermiform with basal inflation, apically attached by a wide point. **Paraphyses** apically uninflated or usually slightly (to medium) clavate, terminal cells *7–12 × 2.3–3.5 µm, †2–2.5 µm wide, lower cells *5–11 × 1.7–2.6(–3) µm, *1.5–2 µm wide; unbranched near apex; hymenium hyaline to pale yellow. **Medullary excipulum** very pale orange, 30–40 µm thick, of dense textura intricata with many inflated cells, ± sharply delimited from ectal excipulum (sometimes by a 5–10 µm thick t. porrecta). **Ectal excipulum** hyaline, of (†) thin-walled, indistinctly vertically oriented t. globulosa-angularis from base to midflanks, 60–100 µm thick near base, cells *8–20(–23) × 7–14 µm; 20–40 µm thick at flanks, 15–20 µm near margin, of t. prismatica oriented at a 30–70° angle to the surface, marginal cortical cells *6–9 × 3–4.5 µm, slightly projecting and converging to form radial ribs, **glassy processes** absent or 1–3 × 3 µm. **Anchoring hyphae** sparse, †1.3–2 µm wide, walls 0.2 µm thick. **SCBs** globose, medium refractive, in paraphyses 1.5–2.7 µm diam.; in excipular cells 1.8–3 µm diam. **Exudate** pale yellow, over paraphyses 1–2 µm thick, cloddy, ± loosely attached; over margin and flanks 0.5–3 µm thick, firmly attached. **— ANAMORPH**: unknown.

Habitat: 60 mm thick, fallen, decorticated branch of *Acer* sp., on 0.5–1 mm deep strongly decayed wood, strongly greyed, green algae very sparse. **Associated**: *Dacrymyces* sp. **Desiccation tolerance**: many excipular cells and some immature asci still alive after 1 year. **Altitude**: 1235 m a.s.l. **Geology**: Cretaceous limestone, marl & clay. **Phenology**: VI (possibly throughout the year, long-lived).

Taxonomic remarks. *Orbilia paramontigena* resembles *O. montigena* (series *Hesperideae*), from which it differs in somewhat narrower ascospores containing distinctly narrower SBs. In SB size and shape the species resembles *O. vinosa*, but differs in distinctly shorter and slightly wider spores. In spore width *O. paramontigena* comes close to *O. angiosubvinosa*, which differs in longer spores and SBs and in possessing crystalloid SCBs. *O. paramontigena* is described as a new species mainly because of its deviating molecular data.

Phylogeny. A sequence gained from apothecia comprises the ITS region and the S1506 intron. When analysing the ITS, *O. paramontigena* clustered highly supported in the *vinosa-subvinosa* subclade of the *vinosa-velutina* clade (Phyls 9, 11), with a distance of 9–9.7% to *O. vinosa* and 12.5–13% to *O. subvinosa*, *O. angiosubvinosa*, and *O. nothoaprilis*. In comparison, the distance between *O. paramontigena* and *O. montigena* is 18%. In the intron region (Phyl. S12), *O. paramontigena* clustered highly supported with *O. subulivinosa*, distant from the *vinosa-subvinosa* subclade. Affiliation in the *vinosa-subvinosa* subclade is supported by specific nucleotides at pos. 76 and 388 (see under series *Hesperideae*, p. 553), whereas at pos. 482 the *vinosa-subvinosa* subclade has GCT**A** while *O. paramontigena* matches the remaining taxa of the *vinosa-velutina* clade (GCT**C**, rarely GCG**C**).

Ecology. *O. paramontigena* was collected on a decorticated, xeric branch of *Acer* in a thermophilous angiosperm woodland of *Quercus*, *Fagus*, *Acer*, and *Buxus* on a S-exposed slope in the orotemperate humid eastern Pyrenees.

Specimens included. **SPAIN**: **Cataluña**, **Girona**, 12 km NW of Ripoll, 2.2 km NNW of Gombrèn, Solell de la Molina, 1235 m, branch of *Acer*, on wood, 19.VI.2016, J. Bometón, L. Sánchez, J. Ballarà (ex J.B. 658/16, ex H.B. 10013, AH 52843, **holotype**; sq.: MK493132).

Orbilia vinosa (Alb. & Schwein.) P. Karst., Bidr. Känn. Finl. Nat. Folk 19: 101 (1871) — Pls 257–262, Map 45

Etymology: *vinosa*: referring to the wine-red colour of the apothecia; *scotica*: from Scotland; *granulosa*: apothecia resembling small granules; *pulcherrima*: means 'most beautiful' (after the spectacular fire-red colour); *tricuspis*: according to the associated trinacrium-like anamorph; *prunorum*: growing on *Prunus domestica*.

Typification: Germany, Oberlausitz, branch of *Quercus* etc., undated, ?J.B. Albertini (type of ***Peziza vinosa***, unlocated); Germany, Stuttgart, Wolfbusch, branch of *Fagus sylvatica*, 25.VI.2000, H.O. Baral (H.B. 6715b, RefSpec, designated here, CBS 116215, sq.: KT215266). – Great Britain, Scotland, Aboyne, branch of ?*Acer*, IX.1870, collector unknown (K(M) 36051, holotype of ***Orbilia scotica***). — Czechia, Mnichovice, between Kunice and Stráncice, branch of *Ligustrum vulgare*, VIII.1925, J. Velenovský (PRM 147400, holotype of ***O. tricuspis***). – Czechia, Mirošovice, branch of *Carpinus betulus*, X.1928, J. Velenovský (PRM 152457, lectotype of ***O. granulosa***, designated by Svrček 1954: 15). – Czechia, Hrusice, branch of *Quercus*, 27.II.1928, J. Velenovský (PRM 147776, lectotype of ***O. pulcherrima***, designated by Svrček 1954: 19). – Czechia, Mnichovice, trunk of *Prunus domestica*, 1.VII.1926, J. Velenovský (lectotype of ***O. prunorum***, illustration in Velenovský's manuscript in PRM, designated here, MBT382113).

Misapplied names: Crouan & Crouan (in sched.), as *Peziza luteorubella*; Feltgen (1899: 55), as *O. chrysocoma*.

Misinterpretation of *O. vinosa*: Bachman (1908: 57), ?= *Orbilia* sp.; Baral (in Baral & Krieglsteiner 1985: 28), = *O. aurantiorubra*; Costantin (1888), ?= *O. rosea*; Feltgen (1899: 55), = *O. luteorubella*; Fuckel (1874: 57), = *O. sarraziniana*; Jaap (1922: 15), ?= *O. luteorubella*; Persoon (1822: 303, as *Peziza*), = *O. auricolor*; Phillips (1887: 333, pl. 10 fig. 63, as *Calloria*), ?= *O. auricolor* agg.; Schweinitz (1832: 177, as *Peziza*), = *O. tenuispora* & *O. aurantiorubra*; Seaver (1911: 108), = *O. tenuispora*; Svrček (1954: 10), = *O. aprilis* (holotype); Benedict's strain (CBS 917.72), = *O.* aff. *sinensis*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.12–)0.2–0.9(–1.2) mm diam., (0.1–)0.12–0.21(–0.25) mm high (receptacle 0.09–0.12 mm), (very) pale to bright (salmon-)rose(-pink) but often also (yellowish-)orange(-red), rarely cream-ochraceous or greyish-cream, slightly to strongly translucent, round, rarely elliptical, somewhat undulating when large, very scattered to gregarious; disc slightly concave to flat, also slightly convex, margin ± distinct, 0–10 µm protruding, smooth, sometimes finely crenulate, in older apothecia sometimes immarginate; sessile or with an ill-defined, rarely abrupt broad stipe ~0.035–0.1 × 0.1–0.25 mm, superficial to slightly immersed; dry light to deep pure rose, (ochraceous-)rose-orange or orange-red.

Asci *(37–)40–65(–72) × (4.8–)5–6.5(–7)((–7.7)) {38} µm, †((30–))(33–)40–60(–65)((–70)) × (4–)4.5–5.5(–6)((–7)) {33} µm, 8-spored (very rarely 4–7-spored), spores (2–)4(–6)-seriate, ((0–))(1–)2–4((–5)) lower spores inversely oriented {30} (not or rarely slightly mixed), pars sporifera *25–28(–34) → 16–22 µm long (†25–31 µm); **apex** (†) hemispherical to slightly truncate, dome †(0.8–)1–1.5(–2) → 0.3–1 µm thick {17}, often with slight to distinct apical chamber; **base** with medium to long, thin or medium thick, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *((9.5–))(10–)11.5–18(–19)((–23)) × ((1.5–))(1.6–)1.7–2.1(–2.2)((–2.4)) µm {178}, †(9–)11–17(–18) × (1.3–)1.5–1.9(–2) µm {28}, narrowly cylindric-clavate to often fusoid-clavate, apex obtuse, sometimes rounded or subacute, base slightly to mostly medium to strongly attenuated, often ± tail-like, rarely with distinct tail *4–5 × 0.5–1 µm, straight to slightly (exceptionally medium) curved, especially near base; **SBs** *((2.5–))(3–)3.5–5.5(–6)((–7)) × (0.4–)0.5–0.8(–1)((–1.2)) {133} µm, rod-shaped (vermiform) to subulate, straight (rarely somewhat flexuous), overmature tear-shaped to ampulliform, *1.8–4 × (0.8–)1–1.3(–1.5) µm, apically narrowed to a ± wide, rarely small point. **Paraphyses** apically uninflated to slightly (rarely medium) clavate-capitate, terminal cells *(4–)8–19 × (1.8–)2.2–3.5(–3.8) µm {9}, †11–20(–22) × (1.5–)1.8–3(–3.5) µm {4}, lower cells *((2.5–))5–12(–14) × (1.4–)1.7–2.5(–3)((–4.5)) µm {6}, †6–8.5 × 1.4–1.8 µm {1}; rarely branched at upper septum, hymenium pale to light rose. **Medullary excipulum** pale rose (or often lower part hyaline), 25–70 thick, of loose to dense textura intricata-globulosa with many inflated cells, indistinctly to sharply delimited from ectal excipulum (sometimes by a thin t. porrecta). **Ectal excipulum** hyaline to pale rose, of thin-walled or slightly gelatinized, vertically oriented t. (globulosa-) angularis-prismatica from base to mid flanks, 20–40 up to 60–100 µm thick near base, cells *(7–)10–20(–30) × (5–)8–13(–16) µm {9}; 15–30(–50) µm thick at flanks; 15–25(–30) µm near margin, of t. prismatica-porrecta oriented at a (10–)30–60(–80)° angle to the surface (cortical layer often under a lower angle than inner layer), marginal cortical cells *(5–)7–12 × (2.3–)3–4 µm {8}, †(5–)6–10 × 2.5–3.5(–4) µm {3}, **glassy processes** 0–2 µm {86}, 2–6 {21} or 5–10(–18) {16} × (2–)2.5–4(–4.5) µm, low- to high-refractive, stratified, cortical cells (including glassy processes) often converging to form minute teeth at mid flanks and margin. **Anchoring hyphae** medium to very abundant, *1.8–3 µm wide, walls 0.2–0.3(–0.5)((–1)) µm thick {9}, forming a ± dense, 5–20 µm thick t. intricata-porrecta (sometimes also at flanks), sometimes as strands. **SCBs** in paraphyses and excipular cells globose to ellipsoid, 1–3.5 µm diam., usually associated in lower parts with crystalloid SCBs {61} (1–)2–5(–6) × (0.3–)1–2.5(–3) µm, low- to high-refractive, hyaline, rarely devoid of any SCBs {6}; **LBs** in paraphyses and marginal ectal excipulum sparse, minute, hyaline. **Exudate** hyaline to light yellow-chlorinaceous, over paraphyses (0.5–)1–2(–5) µm thick, continuous though broken into rough clods, loosely attached; over margin and flanks 2–5(–8) µm thick, roughly warted, covering marginal teeth by forming radial ribs 60–70 µm long and 15–20 µm wide in surface view. — **ANAMORPH**: trinacrium-like (from ascospore isolate {7} and natural substrate {32}). **Conidiophores** *~11–23 × 2.3–3 µm, unbranched. **Conidia** Y-shaped (exceptionally tuning fork shaped), total size *(14–)23–45(–48) × (19–)25–39(–54), stipe *(9–)13–28 × 3.3–5.2 µm, 2–4(–5)-septate, arms cylindrical, not or only slightly tapering towards the rounded to obtuse end, *12–25(–30) × (3–)3.5–4.5(–5.5) µm, (1–)2–5(–6)-septate {13}, also some unbranched conidia present in pure culture: straight, *(30–)32–53(–59) × (3.6–)4–5.6 µm, 4–8(–9)-septate {4}.

Habitat: collected (0.1–)0.5–3(–16) m above the ground, corticated or decorticated, (2.5–)5–50(–65) mm thick branches, rarely up to 20 cm thick trunks, also on timber, rarely on cones, of *Abies Phenology of *O. vinosa* (N-hemisphere)											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
17	20	26	29	31	54	30	41	37	33	17	29

Taxonomic remarks. The characteristics of *O. vinosa* are mainly those of the ascospores which are rather long and narrow, fusoid-clavate, nearly straight, mainly strongly tapered below but only slightly so above, with ± obtuse apex. At the mature stage the spores contain ± straight, rod-shaped SBs 3–6 × 0.4–1 µm. *O. aprilis* is very similar to *O. vinosa* in morphology as well as ecology, but is less frequent in montane regions and sharply differs in shorter spores (up to 9.5, rarely 10.5 µm) and SBs (1.5–2.2, rarely 2.5 µm). The mediterranean *O. hesperidea* and montane *O. montigena* and *O. alpigena* differ in distinctly wider, often also shorter spores, *O. hesperidea* also in the presence of larger, pale orange crystalloid SCBs.

Four Australian taxa match *O. vinosa* quite well in spore morphology, but differ in at least one feature: the ascus apical dome of *O. nothovinosa* is always distinctly thicker, *O. astrovinosa* has very long glassy processes that form prominent teeth, *O. helicovinosa* deviates in medium helicoid spores, and *O. pleiovinosa* in 16-spored asci.

The orosubmediterranean *O. subvinosa* (on conifer wood, mainly *Pinus*) and the montane *O. arachnovinosa* (on angiosperm wood) deviate only tentatively from *O. vinosa* in the teleomorph, showing a tendency to more intensely pigmented, mostly orange(-red) apothecia with a usually distinctly crenulate margin, also a tendency to slightly larger spores. Their main characteristic lies in the dwayaangam-like conidia, which consistently branch twice dichotomously to form 4-armed structures with two of the branches pointing downwards. *O. subulivinosa* from mesomediterranean to orotemperate southern Europe differs in longer ascospores, but the morphological limits to *O. vinosa* are not sharp.

Species of section *Helicoon* (with a hygric to semiaquatic habitat), but also those of section *Habrostictis* (with a xeric habitat), such as *O. subtrapeziformis*, *O. obtusispora*, or *O. filiformis*, may be confounded with *O. vinosa* on account of a similar spore shape and an often rose-orange colour. These species are readily distinguished by their truncate and thin-walled ascus apices and by longer and in O. *filiformis* also thinner, often more flexuous SBs.

Variation. Within the present concept of *O. vinosa*, rather great variability is observed in several features. Comparatively small apothecia of (hydrated) 0.12–0.4 mm diam. were sometimes encountered (see, e. g., Pl. 260: 4), but populations with 0.5–1.2 mm diam. also occurred, while most collections were in the range of 0.3–0.8 mm. Apothecial colour varied between pale and bright salmon-rose, but often the apothecia showed a rose-orange, yellowish-orange, or even orange-red colour (see Pls 260, 262).

The margin was generally smooth or only slightly rough, though sometimes finely crenulate, due to exudate and occasionally short glassy processes. The length of these processes turned out to be rather variable within the present concept of *O. vinosa*. In about 30 % of > 100 specimens tested for this character, glassy processes longer than 1–2 µm were noted, and these occurred on both gymno- and angiosperm substrate. The longest processes were recorded in montane specimens on *Acer* from Poland (up to 14 µm), on *Pinus* from Arizona (up to 13 µm. Pl. 259: 3), and three on *Cistus* from Spain (7–10 µm, Pl. 262: 2a). Several further samples showed a length of up to 7–9 µm, e. g., a colline sample on *Prunus* from Luxembourg (Pl. 257: 3). We have somewhat arbitrarily excluded records with processes longer than 15 µm from the description of *O. vinosa*, but mention them either here or under *O. subvinosa*.

Glassy processes may also vary within a given record. They were often only present in a part of a population or even an apothecium, e. g., in the type of *O. tricuspis* (Pl. 257: 9), or they varied in length, e. g., between 0–2 and 4–9 µm between populations on different branches (see collection on *Fagus* from Vosges, IVV: H.B. 5569). The occasional mixed occurrence of *O. vinosa* with *O. subvinosa* or *O. arachnovinosa*, which both predominantly possess glassy processes, complicates a correct identification. Besides all this, the processes are easily overlooked if shorter than about 5 µm, because they are often tightly covered by thick refractive exudate.

Considerable variation in ascus and spore dimensions was noted. Asci varied between *37–47 and 60–72 µm in length (mainly 45–60 µm) and between *4.8–5.2 and 6.5–7(–7.7) µm in width (mainly 5–6.5 µm). Ascospores ranged in length between *10–14 and 16–19 µm (mainly 12–17 µm), and in width between *1.6–1.8 and 2–2.2 µm (mainly 1.8–2 µm). Thereby, ascus length was not clearly correlated with spore length, for instance, the specimen with the longest living asci observed (*60–72 × 5–6.3 µm, H.B. 5004) showed a spore size of only *11–16.5 × 1.7–1.8(–2.2) µm. Ascus and spore size did not correlate with the geographical origin or the host. All ranges of spore length were noted, e. g., in the mediterranean region. A spore length of up to 18–19 µm was observed especially at montane and boreal (e. g., on *Acer*, IVV: H.B. 8235a) but also at orosubmediterranean sites (on *Quercus rotundifolia* and *Cistus*, Pl. 262). The longest spores in these samples closely resemble those of *O. subulivinosa* (Pl. 279), and it remains unclear where these samples actually belong. In some other collections spore length was at the lower range, e. g., on *Picea* (Pl. 257: 4). Spore bodies in mature spores varied between (2.5–)3–4 and 5–6(–

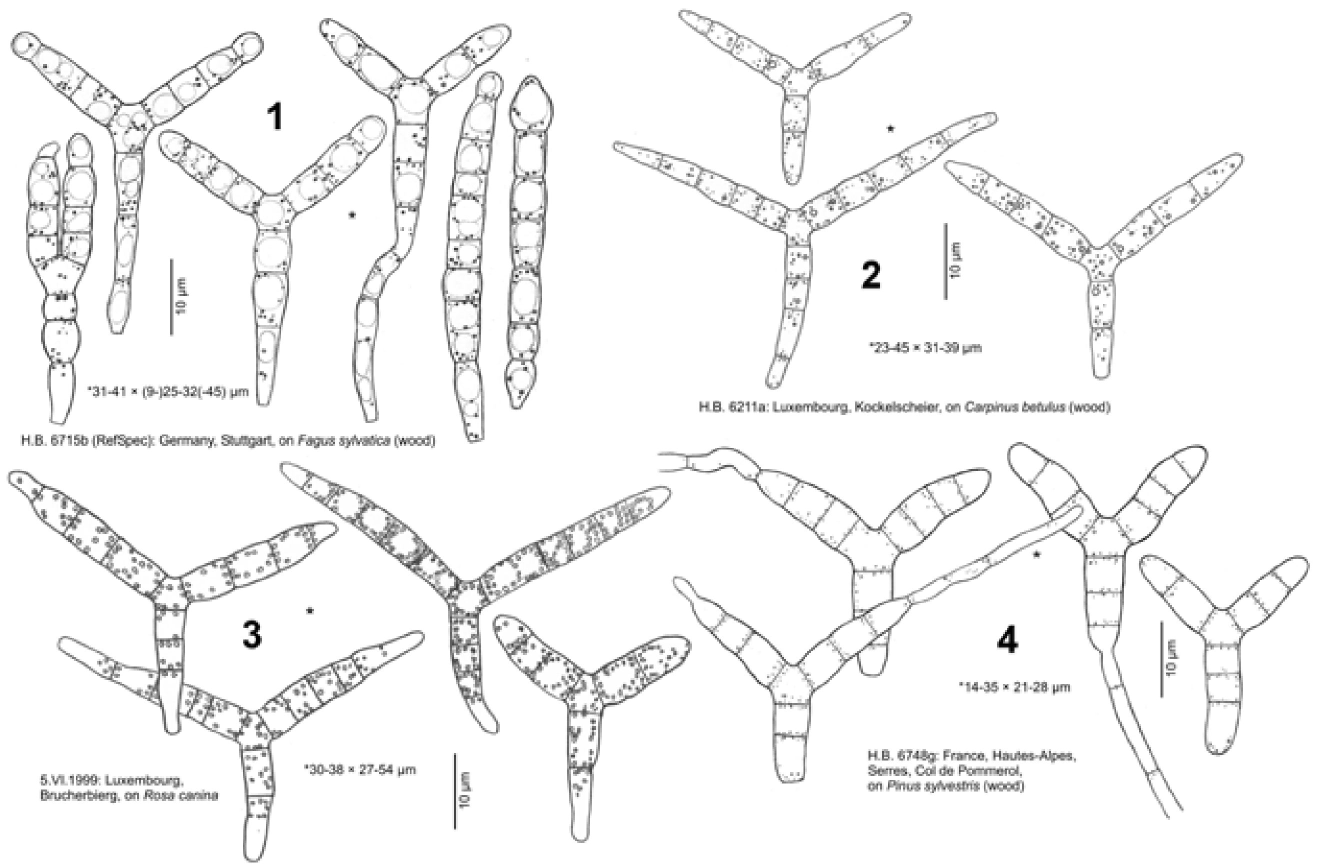

Plate 258. **1–3**: *Orbilia vinosa*; **4**: *O.* cf. *vinosa*. – Conidia from substrate (**2**, **3**) and culture (**1**, **4**).

7) µm in length (mostly 4–5.5 µm) and between 0.4–0.6 and 0.8–1(–1.2) µm in width (mostly 0.5–0.8 µm), without obvious correlation with spore size.

Crystalloid SCBs were seen in most of the collections of *O. vinosa* studied in the living state. They are comparatively small and never clearly pigmented. Frequently they occur in association with globose SCBs, but often only crystalloid SCBs were seen, and in a few specimens only globose SCBs were observed, or no SCBs at all. In a few samples the presence of these organelles varied from one apothecium to another.

Svrček (1954: 20) mentioned conspicuous variation in the thickness of the exudate (as 'epithecium') in *O. vinosa* in correlation to the habitat. Apothecia growing on branches in the tree canopy developed a thicker 'epithecium' than those on less arid substrates. This observation was also noted by Velenovský (1934: 97) who distinguished between *O. vinosa* (on wood lying on moist ground) and *O. pulcherrima* (on sun-exposed wood of attached branches). However, such correlation could not be confirmed in the present study: in the few samples of *O. vinosa* in which the branches were lying on or sticking in moist ground (e. g., H.B. 5569, IVV), the exudate had the very same thickness as in collections on xeric branches. Svrček (l.c.) also observed great variability in exudate thickness within the lectotype of *O. pulcherrima*. Two apothecia of this material (1 on bark, 1 on wood) were examined in the present study and found to have consistently thick exudate (Pl. 257: 7b). The fact that the exudate in section *Hemiorbilia* easily detaches during preparation might be one reason for the reported variation.

Spore numbers fewer than 8 were noted in a few collections from Southern French Prealps. In two specimens (H.B. 4992a, 5142b) the spore number varied between 4, 5, 6, 7 and 8, and in one (H.B. 4987b, unillustrated, tentatively assigend to *O. subvinosa*) the asci were consistently 4- or 5-spored. The phenomenon is obviously a result of incomplete development. Size of spores and SBs in asci with reduced spore numbers was slightly larger compared to 8-spored asci in the same apothecium.

Nomenclature, **type studies and literature reports**. The epithet ***vinosa*** is adopted here in the sense of Rehm (1891: 457, p.p.) for a desiccation-tolerant lignicolous species of section *Hemiorbilia*. It traces back to Persoon (1801) who described under the name *Peziza vinosa* a caulicolous fungus. Without reference to Persoon, Albertini & Schweinitz (1805) used *P. vinosa* for a lignicolous fungus. Fries (1822: 141) adopted the name *P. vinosa* by referring to Albertini & Schweinitz, again without a clear reference to *P. vinosa* Pers. Due to this lack of citation, the true origin of the epithet *vinosa* fell into oblivion.

That Albertini & Schweinitz did not describe a new species is obvious: (1) the authors marked all of their new taxa by the addition 'NOBIS', but there is no such note for *P. vinosa*, and (2) they did not list the taxon in their 'Catalogus fungorum novorum' (Albertini & Schweinitz l.c.: XV-XVI). Fries's (1822) reference to Albertini & Schweinitz attributes the diagnosis of these authors the status of a new species. According to Art. F.3.2 (Turland et al. 2018), *P. vinosa* Alb. & Schwein. is a sanctioned species, and *P. vinosa* Pers. a homonym without priority. Therefore, later authors like Spooner (1987) correctly considered the description of Albertini & Schweinitz as the protologue of *Peziza vinosa*.

Fries (1822: 141) believed that Persoon's caulicolous fungus, which he had not personally seen, 'appears to be different' from the lignicolous fungus. Apparently because Fries knew only lignicolous collections with a resemblance to the descriptions of *P. vinosa*, he referred *P. vinosa* to Albertini

& Schweinitz by reducing Persoon's taxon to a variety of their taxon. Therefore, he changed Persoon's epithet *vinosa* to *vinosella*, although Persoon was the first to publish the epithet *vinosa*. Two authentic specimens of *P. vinosa* in the Persoon Herbarium were found in the present study to belong to *O. auricolor* (see under that species, p. 1528). Because no holotype material could be located, *P. vinosa* Pers. is treated here as a possible synonym of *O. auricolor*.

Albertini & Schweinitz (1805) referred to *P. vinosa* two lignicolous, externally different, but in colour (rehydrated flesh-coloured) and consistency (gelatinous) similar forms. Both grew on wood of projecting branches of *Quercus* and other trees in spring, rarely autumn, in the vicinity of Niesky near Görlitz (Oberlausitz, eastern Germany). One (*α*, *planiuscula*: Fuchssteine; Basalthügel; Sohlander Berg, on *Taxus* etc.) had flat fruitbodies, the other more rare form (*ßß*, *subteres*: Haide) subcylindrical with slightly concave disc. The authors also stated that the gelatinous ('*tremellosa*') fruitbodies strongly swelled upon rehydration. Persoon (1822: 304) referred to these forms when stating that they are 'apparently scarcely different' from his caulicolous fungus.

According to Spooner (1987: 184), type material of *P. vinosa* 'has not been located and is unlikely to have survived'. Therefore, Spooner relied on Rehm's (1891) interpretation of *Orbilia vinosa* when redescribing the exsiccatum indicated there (Ascomyc. 17, on decorticated, rotten, hanging young twigs of *Quercus*, forest near Sugenheim, Mittelfranken, southeastern Germany) 'which is on the substrate of the type and from the same part of Europe' (the distance is over 300 km, however). Spooner's description is sufficient enough to recognize the species as interpreted in the present monograph. A duplicate of this collection in M was examined in the present study though not illustrated (asci †50–60 × 5–5.5 µm, apex hemispherical, with apical wall thickening, spores †13.5–16 × 1.7–1.8 µm, straight, tapering below, paraphyses apically uninflated, covered by 1–2 µm thick exudate). It should be noted that the label of the specimen in M bears the remark 'on hanging young twigs', whereas Spooner noted in error 'on decorticated fallen trunk'.

Spooner also believed that Svrček (1954) adopted the name *Orbilia vinosa* in the same sense, an opinion which is confirmed in the present reexamination in most cases. In our opinion, the same interpretation was shared with more or less high probability, e.g., by Ellis (NAF 1313), Karsten (1869, 1871), Nylander (1869: 56), Massee (1895: 145), Schröter (1908: 120), Velenovský (1934: 97), Nannfeldt (1936: 199), Grelet (1948a: 49), Dennis (1954: 297, 1978: 189), and Malençon & Llimona (1980: 54).

Considering the fact that the epithet *vinosa* has rather consistently been adopted in the more recent literature, we feel justified to conserve this usage rather than propose extensive name changes. Therefore, we adopt Spooner's interpretation based on Rehm (Ascomyc. 17), although Rehm's concept of *O. vinosa* was obviously heterogeneous (see below). In order to emphasize this interpretation, we here designate a collection from Germany (Stuttgart-Wolfbusch, H.B. 6715b, CBS 116215; sq.: KT215266) as **Reference Specimen** of *O. vinosa*. Its documentation includes light rose apothecia with a smooth margin, asci *(37–)44–48 × 5.2–5.4 µm, spores *13–15(–16.5) × 1.7–1.9 µm, SBs (3–)4–5 × 0.5–0.7(–1) µm, and a trinacrium-like anamorph formed in pure culture (Pl. 258: 1).

According to Spooner (1987: 186), Albertini & Schweinitz's diagnosis of *Peziza vinosa* 'is so brief, and without illustration, that there can be little confidence that this fungus [Ascomyc. 17] is that with which they [Albertini & Schweinitz] were dealing'. Schweinitz (1832: 177) reported *P. vinosa* also for the North American continent, but undated and unlocalized authentic specimens in the Schweinitz Herbarium (925-182, PH, BPI) listed under *P. vinosa* are reidentified here as *O. tenuispora* (section *Helicoon*, on wood, Pl. 562: 3). Yet, the specimens from PH contained also abundantly *O. aurantiorubra* (on bark), though on different pieces of substrate (IVV: H.B. 7726a). Undoubtedly, Schweinitz believed the two populations belonged to a single species.

Fries's (1822) description of *P. vinosa* is based on collections which he referred to the flat form of Albertini & Schweinitz. Fries described the fruitbodies as gelatinous, nearly immarginate, '1 lin.' diam. (~2 mm). He repeated the fact that they nearly disappear on drying and swell up when rehydrated. Apparently Fries's branches were collected on the ground since he replaced Albertini & Schweinitz's '*projectis*' by '*dejectis*'.

Karsten (1861: 37, 1869: 176, 1871: 101) referred to *P. vinosa* or *O. vinosa* collections from Finland on wood of *Quercus* branches. His descriptions from 1869 and 1871 quite clearly refer to an *Orbilia*, possibly *O. vinosa* s. Spooner (apothecia 0.4–0.7 mm diam., bright flesh-red or flesh-orange, asci 45–55 × 4–5 µm, spores acicular-filiform, 11–16 × 1–1.5 µm, paraphyses apically inflated).

Rehm (1891: 457) reported *O. vinosa* from rotten hanging twigs, mainly *Quercus*, more rarely *Rosa*, *Fagus* etc., from central Europe, in the Alps also on *Pinus cembra* and *Rhododendron ferrugineum*. As exsiccata he cited Rabenhorst, Fungi Eur. Exs. 1412 and Rehm, Ascomyc. 17 (both belonging to the same collection). Though the stated that spore characters (filiform-fusoid, straight, acute, 12–17 × 1.5–2 µm) and habitat (xeric twigs) fit the current concept of *O. vinosa*, Rehm described the paraphyses as 'mostly filiform, 1.5 (as 0.15) µm wide, above more or less roundish, enlarged to an ovoid, up to 4 µm wide apex'. Also Rehm's (1891: 447, I figs 1–5) illustration of *O. vinosa* (see Fig. 149) does not permit recognition of the species, except that the strongly capitate paraphyses clearly exclude *O. vinosa* and related species. We conclude that his illustration can hardly originate from Ascomyc. 17, though the substrate is said to be *Quercus* in both. The given ecology (xeric twigs) excludes a member of section *Helicoon*, given that this statement applies to all included collections.

Saccardo (1889: 622) reported quite a large number of substrates for *O. vinosa*, but without stating humidity and exposition. Based on the given diagnosis (asci 35 × 5 µm, paraphyses very slightly inflated, spores 13–14 × 0.7–1.5 µm, acicular, often slightly curved) the identity of these records remains uncertain, whereas his treatment of 'β. *O. vinosella* Pers. Myc. Eur. p. 303 (Pez.)' is a mere copy of Fries's note.

When revising Velenovský's type specimens of *Orbilia*, Svrček (1954: 23) concluded that material referred by Velenovský (1934: 97, pl. XI fig. 28) to *O. vinosa* is conspecific with five taxa described by Velenovský in the same volume. Svrček believed that his species concept of *O. vinosa* concurred with that of 'Rehm, Saccardo, and Seaver etc.'. Reexamination of Velenovský's five taxa actually indicates that 3 represent *O. vinosa* s. Spooner, whereas one belonged to a distinct species (*O. aprilis*) and one was empty. Velenovský's original manuscript drawings of several samples under the name *O. vinosa* (on *Quercus*, also *Frangula alnus*) clearly concur with the present concept of *O. vinosa*.

Beyer (1998: 192) reported in a sample on *Salix* from Kulmbach (Oberfranken, IVV: 28.II.1997) narrowly clavate, cuneate ascospores with ellipsoid to subglobose SBs, but the same sample was also examined in the present study,

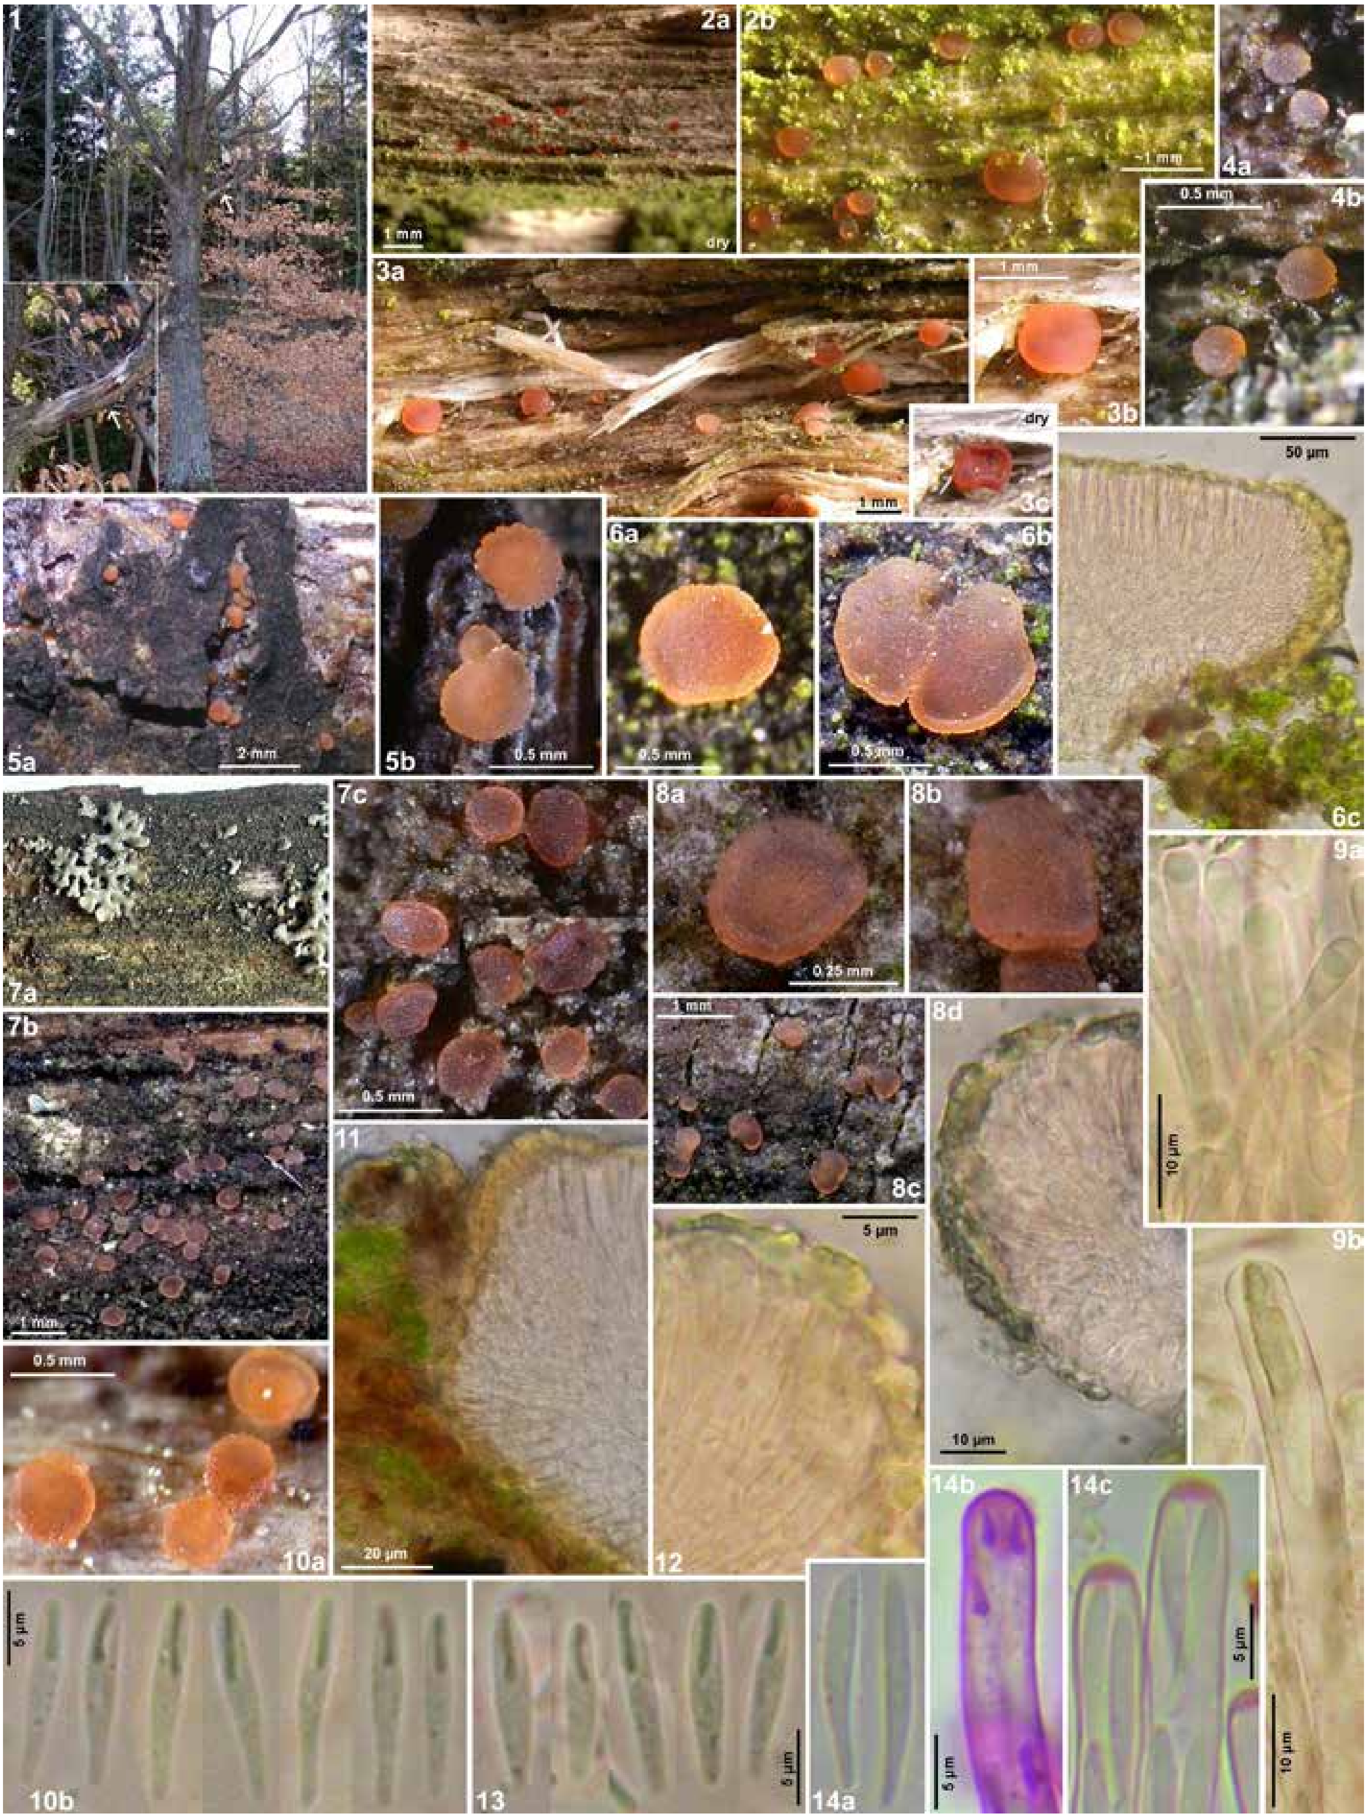

Plate 260. **1–4**, **6–14**: *Orbilia vinosa*; **5**: *O.* cf. *vinosa*. – **1a**. decorticated branch attached to standing *Quercus* tree in ~2.3 m above the ground; **2a**, **7a**. decorticated xeric branches of *Quercus robur*, with green air algae (**2**) and *Hypogymnia physodes* (**7**); **2b**, **3a–b**, **4a–b**, **5a–b**, **6a–b**, **7b–c**, **8a–c**, **10a**. rehydrated apothecia; **2a**, **3c**. dry apothecia; **6c**. apothecium in median section; **8d**, **11**, **12**. id., marginal ectal excipulum; **9a**. paraphyses; **9b**, **14b–c**. mature asci (**9b** fully turgescent); **10b**, **13**, **14a**. ascospores. – Living state (**14b** in CRB) except for **14a**, **c** (in CR_{SDS}), ascus in **14b** (CRB). – **1**: phot. likewise in the living state, where it showed fusoid spores with subulate SBs.

Some doubts remain regarding the type material of ***O. scotica***. In the original description Massee gave the information that the taxon is based on a single specimen from Aboyne (Aberdeenshire) deposited in 'herb. Berk., Kew, under the name of *Peziza vinosa* (= *Calloria vinosa*)'. Nannfeldt (1936) discovered a specimen on a sheet of *O. vinosa* at Kew, marked in Berkeley's handwriting: '*Pez*. (*Mollisia*) – Aboyne, Sept. 1870', and assumed that this is the holotype of *O. scotica* 'though it bears no note at all in Massee's hand'.

Massee (1894a: 99, 1895: 144) described the spores as 'elliptic-oblong, ends obtuse, 4 × 1 µm' and the paraphyses 'about 1 µm thick, tips subglobose'. Later, Massee (1895) compared *O. scotica* with *O. coccinella* (s.auct.), 'differing in the narrower spores and the much smaller cells of the excipulum'. Nannfeldt discovered a few free spores in the presumed holotype which strongly deviated from those seen by Massee, being needle-shaped, 12 × 1–1.5 µm. He concluded that Massee's spore description must be erroneous, based on the experience that spores of *Orbilia* are usually difficult to see in herbarium material.

The specimen studied by Nannfeldt was reexamined here (Pl. 257: 6). It grew on unidentified, decorticated, rotten wood, possibly of *Acer*, according to the wood anatomy. Nannfeldt's opinion that *O. scotica* is a synonym of *O. vinosa* is confirmed, with a spore width at the lower end of the range. In the case the specimen was studied while it was still viable, Massee's report of small oblong spores might refer to the spore bodies which have just about that size in *O. vinosa*.

The lectotype of ***O. granulosa*** (on trunk of *Carpinus* in a shady forest in lowland Bohemia) contains ~40 mature apothecia, contrary to Svrček (1954: 15) who found only a single apothecium 0.1 mm diam. They measured rehydrated 0.12–0.35 mm diam. (protologue 0.1–0.2 mm), and are now very pale cream (fresh wine-rose, shining). Svrček's opinion that this represents *O. vinosa* is confirmed here. The margin is without glassy processes (Pl. 257: 8). The other specimen mentioned in the protologue was on a *Betula* branch from the same locality. The manuscript sketch shows apparently the lectotype and gives the spores as 16–18 µm, although the protologue says 12–16 µm.

The abundant lectotype of ***O. pulcherrima*** grew on a hanging, partially decorticated branch of *Quercus* far up in the canopy. Svrček (1954: 19) referred this taxon to synonymy with *O. vinosa*, which is confirmed here (Pl. 257: 7). The apothecia were described as igneous blood-red, 1–1.5 mm diam. (rehydrated 0.2–0.7 mm diam. and pale rose-ochraceous in present study). The margin was not examined. Velenovský considered this to be a very common taxon on xeric, sun-exposed wood of various angiosperm substrates, in contrast to *O. vinosa* which he applied to populations with pure rose apothecia on fallen, hygric angiosperm wood. The two diagnoses in Velenovský (1934) give 15–20 µm long spores, whereas his manuscript notes give them for *O. pulcherrima* as 12–16 (*Betula*) and 15–18 µm (*Quercus*), and for *O. vinosa* as 10–15, 10–16, and 15–20 µm.

The holotype of ***O. tricuspis*** grew on a decorticated branch of *Ligustrum vulgare* in lowland Bohemia. It was regarded to be a synonym of *O. vinosa* by Svrček (1954: 21), which is confirmed here (Pl. 257: 9). The rather large apothecia (1–1.5 mm diam., rehydrated 0.3–1 mm in present study) were described as lilaceous honey-coloured (lilacino-melina), but are now light dirty orange(-apricot). Short glassy processes occurred at the margin, but only at one side of the apothecium examined. For the name-giving triradiate conidia see under Anamorph.

O. prunorum was published by Velenovský (1934) based on two collections: on trunk of *Prunus domestica* (1.VII.1926), on trunkbase of *Cornus* (VII.1926), both from lowland Bohemia. In his unpublished manuscript he provided a sketch (probably from the *Prunus* specimen), from which the ascus and spore measurements in the protologue were taken. The protologue reports very small, vinaceous-yellowish apothecia (0.1 mm diam.; manuscript: 0.1–0.2 mm on *Prunus*, 0.1 mm on *Cornus*), hardly inflated paraphyses covered by thick exudate, and narrowly acicular, 12–15 µm long spores with both ends acute (on his sketch about 0.7–1 µm wide, one end slightly curved).

No material of the *Prunus* sample could be located at PRM, and in the *Cornus* sample (PRM 152416) no apothecia relating to this fungus could be found, neither by Svrček nor in the present study. There were only some overmature apothecia of what could have been *Arachnoscypha aranea* (abundant subiculum, asci with croziers, with amyloid apical rings, ascospores sometimes septate, oblong, 10 × 2.7 µm). The substrate does not have the appearance of xeric wood, so one does not expect to find *O. vinosa* here.

Velenovský separated *O. prunorum* from *O. vinosa* because of much smaller, hardly visible apothecia. Based on his diagnosis, Svrček (1954: 19) assumed conspecificity with *O. vinosa.* Velenovský's sketch could indeed refer to *O. vinosa*, but also to *O. aurantiorubra*, although the latter species is unknown to occur on these two hosts. The sketch in Velenovský's unpublished manuscript is designated here as **lectotype** of *O. prunorum* (Art. 8.1 ICN).

Misapplication. The epithet ***vinosa*** has been applied in the past also to several other, mainly desiccation-sensitive species which we assign to different sections or even subgenera. Persoon (1801) and Phillips (1887) named collections *Peziza* or *Calloria vinosa* which are assigned here to *Orbilia auricolor* (section *Arthrobotrys*). But also highly desiccation-tolerant species, such as *O. aprilis* (section *Hemiorbilia*, Svrček 1954) and *O. aurantiorubra* (section *Aurantiorubrae*, Schweinitz 1832 p.p., Baral & Krieglsteiner 1985) were misidentified as *O. vinosa*. To members of section *Helicoon* the epithet *vinosa* was attached by Schweinitz (1832 p.p.), Fuckel (1870, 1874), Costantin (1888), and Seaver (1911). Also Jaap (1922: 15) used the name *O. vinosa* for a fungus growing in a wet habitat, which was here reexamined and tentatively assigned to *O. luteorubella*. A strain from CBS (917.72, R.G. Benedict, X.1972) is found under the name *O. vinosa* in many molecular treatments; its rDNA sequence clustered in Hagedorn & Scholler's (1999) and our phylogenetic analyses near '*O. luteorubella*' (= *O.* aff. *sinensis*, series *Pseudotripoconidium*).

P.L. & H.M. Crouan (in sched., unlocalized, 15.X.1868, on *Ulmus*) figured and preserved under the name *Peziza luteorubella* a species with long-acicular spores, according to the unpublished original water colour drawing. J.P. Priou (pers. comm., unillustrated) restudied the specimen and found

immature asci with a thick-walled, hemispherical apex which points to *O. vinosa*. Fuckel's (1870: 283, 1874: 57) very brief reports of *Calloria vinosa* refer to a fungus with capitate paraphyses, growing on various broad-leaved trees including *Ulmus campestris* (= *U. minor*). Reexamination of the *Ulmus* specimen in M (Fungi Rhenani ed. I. 2569, on bark of a branch, near Hattenheim, Mainz, Germany) suggests that Fuckel's concept of this taxon concerns *O. sarraziniana*. This collection was also studied by Rehm (1891: 455) who described the paraphyses as filiform, apically inflated to a roundish 3–5 µm wide tip, and referred it to *O. luteorubella*. Phillips (1887: 333, pl. 10 fig. 63) reported paraphyses with 'globose, pyriform or thickened apices'. Together with the spores being 'filiform-acicular' and 'straight or curved, 10–15 × 1 µm', his interpretation of *Calloria vinosa* appears to refer to a taxon of *O. auricolor* agg. Costantin (1888) provided a detailed description of samples which he referred to *O. vinosa*, but his illustration shows that they belong to section *Helicoon*, possibly to *O. rosea* (see p. 966). A specimen referred by Feltgen (1899: 55) to *O. vinosa* (on *Salix*) was found to belong to section *Helicoon* and is tentatively assigned here to *O. luteorubella*, whereas another one referred by him to *O. chrysocoma* (on *Quercus*) represents *O. vinosa*. Bachman (1908: 57) reported an interesting fungus of unknown identity under the name *O. vinosa* (from Ohio, on wood and bark), with large (1–2.5 mm) first funnel-shaped, bright red apothecia with a 1 mm long stout stipe, paraphyses with inflated, often globose apex, and acicular spores 10–14 × 1 µm.

Not included collections. Two samples on *Pinus strobus* from lowlands of Massachusetts (Pl. 259: 5, 260: 5) and New Jersey (IX.1887, J.B. Ellis, herb. Petrak, unillustrated) differ from *O. vinosa* in distinctly narrower asci (*53–58 × 3.9–4.3 µm, †40–56 × 3.5–4 µm) and a spore size at the lower end of the range (*11–14.5 × 1.5–1.7 µm, †11–14 × 1.3–1.5 µm). The glassy processes had a length of 3–20 µm. Such narrow asci and spores in combination with distinct glassy processes are quite unusual in taxa around *O. vinosa*. Another specimen of J.B. Ellis (NAF 1313, on textile) concurs in the length of glassy processes, but has wider asci (†4.7–5.5 µm) and spores (†11–14 × 1.8–2 µm). Since glassy processes longer than 15 µm were not accepted in the present circumscription of *O. vinosa*, the three records are not included in the description. Other short-spored collections on gymnosperms (e.g., Pl. 259: 3, *Pinus ponderosa*; Pl. 257: 4, *Picea abies*) differ from those on *P. strobus* in wider spores, more or less wider asci, and shorter glassy processes.

Conspecific with the above narrow-spored samples might be some on angiosperm wood. One from Massachusetts (on *Acer*, IVV: bhi-F731) has 7–15 µm long glassy processes, rather narrow spores (*11–13.6 × 1.2–1.6 um) but asci of *50–55 × 4–4.6 µm; available DNA data place it very distant from *O. vinosa*. Also a sample from Utah (on *Arctostaphylos*, Pl. 259: 4) has similar but longer spores, wider asci, and distinctly shorter SBs (2–4 µm) than typical *O. vinosa*; glassy processes are very short or absent here.

An exceptional collection of a single apothecium on a herbaceous stem (Luxembourg, Ettelbruck, *Melilotus*, 6.VII.2002, unillustrated, associated with *O. subclavuliformis* and *O. flavida*) contained only a single submature ascus. Although resembling collections of *O. vinosa* s.l. on ligneous substrate, it had rather wide asci (*60–71 × 6.5–6.7 µm) and exceptionally wide spores (*16–19.5 × 2.2–2.4 µm). The SBs were rather short (3–3.3 × 1–1.1 µm, perhaps not fully developed), the paraphyses contained crystalloid SCBs, and the margin was without glassy processes. The record is not included in either description of the *O. vinosa* aggregate, mainly because of the deviating substrate and spore width.

An Australian collection mentioned under *O. nothoaprilis* (Pls 284: 2; 285: 5) is difficult to place: it has spores and SBs intermediate in length to *O. vinosa*, but the asci are rather short.

For the not included *O. prunorum* see under Type studies.

Anamorph. *Orbilia vinosa* produces in pure culture a trinacrium-like anamorph similar to *Trinacrium tothii*, the anamorph of *O. aprilis*, but with usually distinctly longer arms (Pls 257: 3i, 5i; 258: 1–3; 261). On the natural substrate the same type of triradiate conidia was frequently observed, sometimes emerging from the excipulum of the apothecia.

Velenovský (1934: p. 97, plate XI, fig. 29) described *O. vinosa* under the name *O. tricuspis*, based on tricuspidate structures which grew out of the basal excipulum. These most probably represent the anamorph, though his schematic sketch

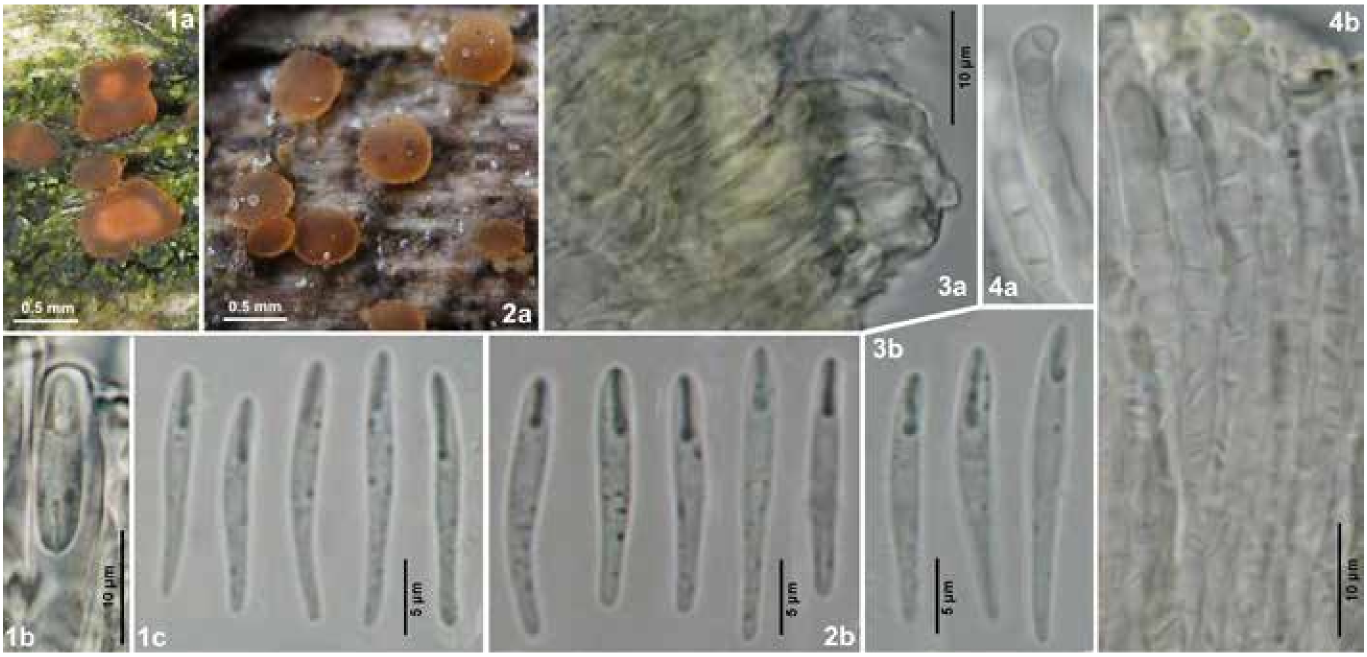

Plate 262. **1–4**: *Orbilia vinosa* (with rather long spores). – **1a**, **2a**. rehydrated apothecia; **1b**. tip of fully turgescent ascus; **1c**, **2b**, **3b**. ascospores; **3a**. marginal cortical cells with glassy processes; **4a–b**. paraphyses with crystalloid SCBs. – Living state. – **1–4**: phot. shows aseptate arms and stipes with acute ends. In the holotype these structures could not be rediscovered, neither by Svrček (1954) nor in the present examination.

In 12 collections of *O. vinosa* s.l. (including *O. arachnovinosa* and *O. angiosubvinosa*), 2–3(–4)-armed dicranidion-like conidia were detected on the natural substrate, sometimes emerging from the hymenium of some apothecia (see Pl. 137: 1d; 138: 1m). We assume that these conidia belong to a parasite which seems specific to apothecia of *O. vinosa* s.l., because it often occurred mixed with the typical conidia of the host species (trinacrium tothii-like in *O. vinosa*, dwayaangam-like in *O. arachnovinosa* and *O.* cf. *subvinosa*). We further imagine that these conidia represent the anamorph of *Hyalorbilia hergiswiliana* (see p. 433).

A pure culture gained from ascospores (H.B. 6748g, CBS 116208, Col de Pommerol, on *Pinus*, IVV: H.B. 6748f), which formed the typical trinacrium-like conidia of *O. vinosa*, was at first thought to belong to *O. subvinosa* by macroscopy and especially because of abundantly associated dwayaangam-like conidia which undoubtedly belong to *O. subvinosa*. However, its sequence placed it intermediate between *O. vinosa* and *O. subvinosa* (see below) and suggests that it belongs to a separate species. Because we saw no difference in conidial morphology, we have included it in the description of *O. vinosa*. The teleomorph was not documented and no herbarium specimen of this population was retained.

Phylogeny. *O. vinosa* clustered with *O. subvinosa*, *O. angiosubvinosa*, *O. arachnovinosa*, *O. paramontigena*, and two unnamed genotypes (H.B. 6748g, bhi-F731) in a strongly supported clade (Phyls 9, 11, S13), here called *vinosa-subvinosa* subclade. Eight sequences belonging to *O. vinosa* in the here defined sense were available (Tab. 66). They comprise mostly ITS+LSU, rarely also SSU (H.B. 6715b) or only ITS (G.M. 2011-04-19.1), and vary in the ITS region by 0–1.9%. This variation is at present remarkably correlated with the geographical origin: five sequences are from Luxembourg and vary by 0–0.7%; they differ by 1.3–1.9% from the one from Stuttgart and likewise by 1.3–1.9% from two identical sequences from southern France. Also between the latter two genotypes a distance of 1.9% is observed.

Further seven sequences belong to *O. subvinosa* and show a distance of 9.5–11% to *O. vinosa*, which strongly supports separation of *O. subvinosa* at the species level. However, the isolate with typical trinacrium-like *O. vinosa* conidia (H.B. 6748g, CBS 116208), is intermediate by showing a 10.5–11.5% ITS distance to *O. subvinosa* and 8.5–9% to *O. vinosa*. Especially in the ITS2 this strain is distinctly closer to *O. vinosa*.

A sequence of the sample from Massachusetts (on *Acer*, bhi-F731) also clustered intermediate between *O. vinosa* and *O. subvinosa*, but shows a high distance to all strains of the subclade, the minimum being 10.5% to *O.* cf. *vinosa* (H.B. 6748g).

Also in the LSU (D1–D2) *O. vinosa* and *O. subvinosa* cluster in two different subclades, with a distance of 1.1–1.3% (7–8 nt) between them (Phyl. S13). 1 nucleotide position (632) at the very 3'-end of D2 deviates in H.B. 6715b (*O. vinosa*) in having GTAAGCG**G**C as in *O. subvinosa* and the intermediate strains from Col de Pommerol (H.B. 6748g) and Boston (bhi-F731), instead of GTAAGCG**A**C as in the remaining *O. vinosa* sequences. In fact, the strain from Col de Pommerol is in the LSU surprisingly closer to O. subvinosa by showing a 0.3% distance (2 nt) but 0.8–0.9% (5–6 nt) to O. vinosa.

The S1506 intron is present in all seven sequences of O. vinosa and in that from Col de Pommerol. It varies by 0.5–2.7% among the *O. vinosa* sequences, whereas the strain from Col de Pommerol differs by 6–6.5%. The intron is absent in those four sequences of *O. subvinosa* which cover the 3'-end of SSU, and also in *O. angiosubvinosa* and the Boston strain (bhi-F731). This supports a closer relatedness between the intermediate strain from Col de Pommerol and *O. vinosa*, and between *O. subvinosa* and *O. angiosubvinosa*. For the distance to the similar *O. aprilis*, *O. nothoaprilis*, *O. crenatovinosa*, and *O. paramontigena* see under these species.

The semi-conservative Orb28s2R primer region in the LSU D2 domain upstream of the LR3 primer deviates in *O. vinosa* and *O.*

Table 66. Available sequences of the *vinosa-subvinosa* subclade together with *O. subulivinosa* and *O.* aff. *subulivinosa*. Note that *O. vinosa and O.* cf. *vinosa* with trinacrium-like anamorph possess the S1506 intron whereas *O. subvinosa* and *O. angiosubvinosa* with dwayaangam-like anamorphs lack this intron. DNA isolation from pure culture (cult. = ascospore isolate, con. isol. = conidial isolate) or from apothecia (ap.); T = holotype, RS = reference specimen.

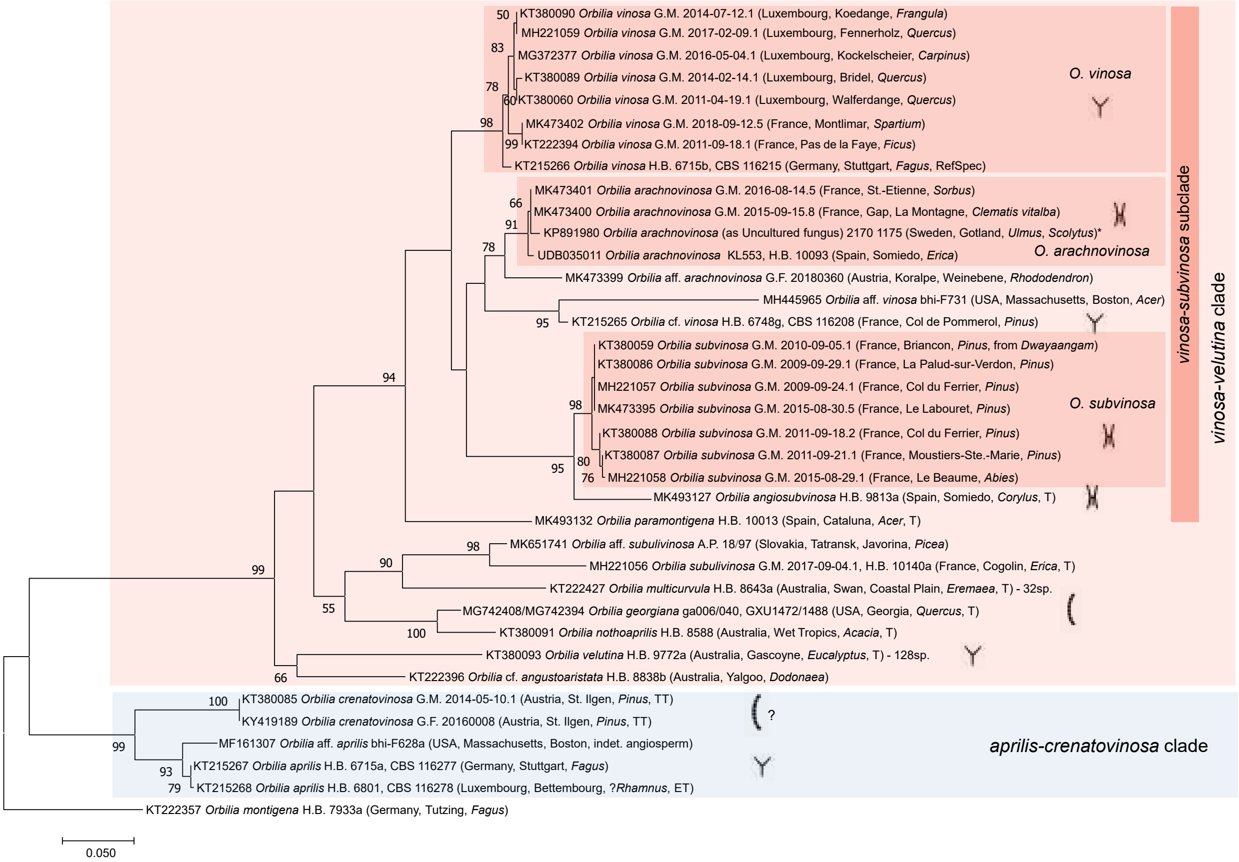
subvinosa (11 strains, including strains H.B. 6748g and bhi-F731) at 2 positions (611 and 626: GGA**C**GCTGGCTTAATGGT**C**GT) from all remaining taxa of *Orbiliomycetes* with available LSU which have GGA**T**GCTGGCTTAATGGT**T**GT, except for a few further variants (Tab. 19). The sequence of *O. multicurvula* does not cover this region.

Ecology. A total of ca. 260 specimens here referred to *O. vinosa* (including somewhat uncertain or deviating samples) have been examined by the first author and further > 120 records seen from documentations of other workers. The species grows on xeric branches (rarely trunks) of a wide variety of trees and shrubs. Decorticated areas are strongly preferred over bark (over 6:1). Also cones of *Pinus* and stems of *Rubus* are sometimes inhabited. Samples on herbaceous substrates are unknown.

The species predominantly occurs on angiosperm substrates. The most favoured host genera in our collections were *Quercus* {75}, followed by *Salix* {36}, *Fagus* {23}, *Pinus* {22}, *Rosa* {15}, *Corylus* {15}, *Prunus* {9}, *Cistus* {13}, and *Carpinus* {8}. A clearly fungicolous growth was only exceptionally noted. In a single collection its anamorph grew on the intact perithecia of an unidentified *Lasiosphaeriaceae* (H.B. 5941). Quite often the apothecia grew on very senescent, hardly recognizable basidiomata of *Vuilleminia*. Among the many fungi occurring associated with *O. vinosa*, *Durella connivens* (42 ×) is by far the most frequently noted species, followed by *Cryptdiscus foveolaris*, *O. aprilis*, *O. eucalypti*, and *Propolis farinosa*.

O. vinosa belongs to the most common xerobiotic orbiliaceous species of Europe. We met it from planar to subalpine regions, and at atlantic to continental as well as mediterranean and boreal sites. It was most often collected in cold-temperate humid central Europe, but is similarly frequent in orotemperate to orosubmediterranean zones and in warm-temperate humid or suprasub- to inframediterranean sem339ihumid regions. Only a few samples are from hemi- to supraboreal sites. Although often collected on calcareous or neutral soils, *O. vinosa* also occurs on acidic soils, e. g., on Devonian slates in the Ardennes or Buntsandstein in the Rheinland-Pfalz region, where the species diversity of *Orbilia* and other ascomycetes is comparatively poor. Mature apothecia of *O. vinosa* occur all over the year. An apparent maximum in spring and autumn is probably due to more frequent collecting activities in these seasons.

Most of our collections were made within Europe, but a few records indicate that *O. vinosa* also occurs in North America and Africa. The studied western North American collections are from cold-temperate to boreal humid ponderosa pine and Douglas fir forests of the Middle Rocky Mountains and Mogollon Rim. Other collections are from the cold-temperate humid northeast of North America. The mentioned deviating North American collections are from cold- to warm-temperate humid eastern areas, but the one on *Arctostaphylos* from a cold-temperate subhumid Douglas fir forest of the Utah Mountains. *O. vinosa* was also recorded from Tenerife (Macaronesia) in the inframediterranean lower semiarid (to semihumid) cardonal xerophytic scrubland (*Periploco laevigatae-Euphorbietum canariensis*) and in the thermomediterranean semihumid Canary pine forest (*Sideritido solutae-Pinetum canariensis cistetosum monspeliensis*), also in the north-exposed upper mesomediterranean subhumid *Pinus canariensis* forest, on substrates such as *Chamaecytisus proliferus*, *Cistus monspeliensis*, *C. symphytifolius, Euphorbia atropurpurea, Lavandula canariensis, Periploca laevigata,*



Phylogenetic analysis 11. Phylogram of *vinosa-velutina* clade inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (32 sequences, 595 positions, aligned with MUSCLE) using the K2+G model in MEGA7 (500 replicates). The tree is rooted with *O. montigena*. Asci 8-spored except when otherwise stated; RefSpec = reference specimen, T = type, ET = epitype, TT = topotype, * = without ITS1 and partial 5.8S.

Pinus canariensis, and *Rhamnus crenulata*, but never on succulents (Quijada et al. 2016). On Réunion (Mascarene Islands east of Madagascar) *O. vinosa* occurred on *Acacia* under a temperate humid (winter-dry) mountain climate.

Literature reports of *O. vinosa* are rather numerous, and the given spore size clearly excludes in all cases the similarly frequent *O. aprilis*. Yet, the often brief or even lacking descriptions do not always exclude members of other subgenera of *Orbilia*, particularly section *Helicoon*. These reports include Northern, Middle, and South America (Saccardo 1889: 622, Seaver 1951: 156), Asia (India and Sri Lanka, Saccardo l.c., Sharma 1983: 104), southeastern Australia (Beaton & Weste 1979), and New Zealand (Colenso 1887). However, the North American report by Schweinitz was found to belong to *O. tenuispora* (section *Helicoon*). From Australia we have not seen typical collections, and it is possible that the report by Beaton & Weste (1979) refers to the very similar *O. nothovinosa*, or to a member of section *Helicoon*. Hosts not reported by us are *Ailanthus*, *Broussonetia*, *Liriodendron*, *Morus*, *Vitis* (Saccardo 1889: 622), and *Pinus cembra* (Rehm 1891: 457). A report on *Clerodendron* from India (Sharma 1983: 104) is without description.

Specimens included. **GREAT BRITAIN**: **Scotland**, **Aberdeenshire**, Scottish Highlands, Grampian Mts., ~40 km WSW of Aberdeen, Aboyne, ~200 m, branch of ?*Acer*, on wood, IX.1870, collector unknown (K(M) 36051, **holotype** of *O. scotica*, H.B. 5451 ø). – **Yorkshire**, **South Yorkshire**, 3.5 km S of Barnsley, 1.3 km SW of Worsbrough, Country Park, 70 m, branch of *Salix cinerea*, on wood, 20.V.2011, H.O. Baral (ø). – 7.5 km NNW of Sheffield, 1 km WNW of Grenoside, Greno Wood, 240 m, branch of *Ilex aquifolium*, on wood, 18.V.2011, H.O. Baral (ø). – West Midlands, 17 km NNW of Birmingham, 6.7 km NNE of Walsall, Clayhanger Common, 142 m, *Quercus robur*, on wood and *Hysterobrevium mori*, 15.XI.2015, P. Thompson (P.T. 15/11/2015-2, doc. vid.). – **East Egland**, **Suffolk**, 12.5 km SSW of Southwold, 2.5 km NE of Leiston, NW of Sizewell, Kenton Hills, 4 m, branch of *Salix cinerea*, on bark, 17.VI.2004, E. Batten (E.B. 4526, K(M) 158849, doc. vid.). – ibid., 28.IV.2005, E. Batten (E.B. 4606, K(M) 158754, doc. vid.). – ibid., twigs of *Lonicera periclymenum*, on wood, 23.XII.2005, E. Batten & S.M. Francis (E.B. 4659, K(M) 159053, doc. vid.). – 4 km ESE of Halesworth, NNW of Wenhaston, Bicker's Heath, 15 m, branch of *Ulex europaeus*, on wood, 10.I.2004, E. Batten (E.B. 4475, K(M) 158925, doc. vid.). – 7.3 km SW of Southwold, 2 km WNW of Dunwich, Dunwich Forest, 18 m, twig of *Quercus robur*, on wood, 11.II.2005, E. Batten (E.B. 4591, K(M) 158820, doc. vid.). – 1.5 km WSW of Dunwich, Dunwich Forest, 12 m, branch of *Q. robur*, on wood, 14.VIII.2004, E. Batten (E.B. 4551, doc. vid.). – ~1 km WSW of Dunwich, marsh near Dunwich River, 5 m, branch of *Salix*, on wood, 4.IX.2004, E. Batten (E.B. 4557, doc. vid.). – 0.7 km NW of Dunwich, 15 m, branch of *Q. robur*, on wood, 29.VIII.2004, E. Batten (E.B. 4556, K(M) 159055, doc. vid.). – 1,2 km NW of Dunwich, 18 m, twig of *Lonicera*, on wood, 7.XII.2005, S.M. Francis (E.B. 4651, doc. vid.). – **Cambridgeshire**, 8 km WNW of Peterborough, 1.5 km NE of Upton, 45 m, branch of *Ulex europaeus*, on wood, 16.IV.2017, H.O. Baral (H.B. 10057d ø). — **NORWAY**: **Nordland**, 28 km NW of Namsos, SE of Aglen, 8 m, branch of ?*Salix*, on wood, 29.VII.2010, H.O. Baral (H.B. 9401a). – **Oppland**, 20 km SE of Dovre, 3 km E of Sel, Gudbrandsdal, E of Fugleskjelle, 370 m, branch of *Betula pubescens*, on wood, 30.VII.2010, H.O. Baral (H.B. 9408a). – **Hedmark**, 8.5 km SSW of Stange, Rotlia, 200 m, branch of *Juniperus communis*, on wood, 3.VII.2016, P. Vetlesen (doc. vid.). – **Buskerud**, 18 km WSW of Hokksund, 6.5 km NW of Kongsberg, 177 m, branch of *Betula*, on wood, 21.VII.2011, S. Helleman (ø, doc. vid.). — **SWEDEN**: **Gävleborg**, 12 km SSW of Hudiksvall, 3.5 km SSW of Iggesund, NE of Njutånger, 18 m, branch of *Populus tremula*, on wood, 23.VII.2010, H.O. Baral & P. Perz (H.B. 9366a ø, anam. substr.). – **Skåne**, Kullaberg, 8.5 km NNW of Höganäs, 1 km SSE of Mölle, NW of Vattenmöllan, Möllehässle, 5 m, branch of *Rosa*, on wood, 8.VI.2006, H.O. Baral (H.B. 8204a). – Söderåsen, 6 km WNW of Röstånga, Kvärkabäckens ravine, 135 m, branch of *Ulmus glabra*, on wood, 3.VI.2006, H.O. Baral (ø). – branch of *Acer*, on wood, 3.VI.2006, H.O. Baral (ø). – branch of *Corylus avellana*, on wood, 3.VI.2006, J.G.B. Nielsen (ø). – 3.2 km NW of Röstånga, 1.2 km W of Härsnäs, Härsnäsdammen, 145 m, branch of ?*Fagus sylvatica*, on wood, 5.VI.2006, H.O. Baral (ø). — **FINLAND**: **North Karelia**, 42 km WNW of Joensuu, WNW of Outokumpu, Raivionmäki, 140 m, branch of *Prunus padus*, on wood, 30.I.2011,

M. Pennanen (ø, doc. vid.). — **RUSSIA (West)**: **Pskov**, **Loknya**, 42 km NW of Velikiye Luki, 9.5 km N of Nasva, NW of Bashovo, 140 m, twig of *Salix caprea*, on wood, 28.VII.2011, E.S. Popov (LE 247495, ESP-11-0002, doc. vid.). – **Novgorod**, **Valday**, 51 km SW of Borovichi, 16.5 km N of Valday, Krasnaja Gorka, 245 m, branch of *Quercus robur*, on wood, 22.IX.2011, E.S. Popov (LE 294567, non vid.). — **DENMARK**: **Nordjylland**, Jutland, 8 km NW of Brovst, 3 km W of Tranum, SSE of Naturcenter Fosdalen, Lien, 15 m, branch of *Quercus*, on wood, 14.V.2005, B.M. Spooner (ø). – **Sjælland**, 5.5 km NW of Sorø, SE of Bromme, Lillesø, 35 m, branch of *Corylus avellana*, on wood, 27.V.2007, H.O. Baral (ø). – 2.5 km SE of Sorø, 1.3 km NE of Frederiksberg, NNW of Kristiansminde, 45 m, branch of *Q. robur*, on wood, 28.V.2007, H.O. Baral (S). — **POLAND**: **Lower Silesia**, 10 km W of Kłodzko, 3 km N of Polanica Zdrój, Wolany, 365 m, branch of *Quercus*, on wood, 2.IV.2006, P. Perz (P.P. 20060402-2, doc. vid.). – 12 km NNW of Kłodzko, 3 km SE of Słupiec, ENE of Koszyn, 500 m, branch of *Quercus*, on wood, 3.VIII.2006, P. Perz (P.P. 20060803-1, doc. vid.). – 6 km ENE of Kłodzko, 2 km ENE of Wojciechowice, ~450 m, branch of *Quercus*, on wood, 28.XI.2006, P. Perz (P.P. 20061128-2, doc. vid.). – 9 km S of Kłodzko, 2 km S of Żelazno, Bielica Mt., 430 m, branch of *Rosa*, on bark, 29. XII.2006, P. Perz (P.P. 20061229-2, doc. vid.). – 10 km SSE of Bystrzyca Kłodzka, 1.5 km E of Domaszków, Polna ulica, 445 m, board of *Picea abies*, on wood, 25.IX.2009, P. Perz (H.B. 9234d ø). – 13 km SE of Bystrzyca Kłodzka, 11 km SW of Stronie Slaskie, 5 km WNW of Śnieżnick, 790 m, branch of *Salix*, on wood, 28.X.2007, P. Perz (ø, non vid.). – 18 km SSE of Bystrzyca Kłodzka, 5 km E of Miedzylesie, SW of Jodłów, 750 m, branches of *Alnus*, on wood, 13. VIII.2006, P. Perz (P.P. 20060813-1A); – ibid., branch of *Acer*, on wood (P.P. 20060813-1B). – 2 km NE of Jodłów, 820 m, branch of *Sorbus*, on wood, 15. VIII.2006, P. Perz (H.B. 8992, P.P. 200608015-3). – 11.5 km S of Bystrzyca Kłodzka, 1.2 km SE of Gniewoszów, 530 m, branch of ?*Fagus sylvatica*, on wood, 16.IV.2006, P. Perz (P.P. 20060416-2, non vid.). — **CZECHIA**: **Central Bohemia**, 8 km ESE of Beroun, 1 km NNW of Karlštejn, Dub sedmi bratři, 300 m, branch of *Salix*, on wood, 22.IX.2009, H.O. Baral & M. Chlebická (H.B. 9190a). – 23 km SE of Praha, ~2 km WNW of Mnichovice, hill between Kunice and Stráncice, ~450 m, branch of *Ligustrum vulgare*, on wood, VIII.1925, J. Velenovský (PRM 147400, **holotype** of *O. tricuspis*, H.B. 6413 ø, anam. substr.). – 3 km SSE of Mnichovice, E of Mirošovice, viaduct, 350 m, branch of *Carpinus betulus*, on wood, X.1928, J. Velenovský (H.B. 6178 ø, PRM 152457, **lectotype** of *O. granulosa*). – 3 km SE of Mnichovice, Hrusice, ~360 m, branch of *Quercus*, on bark & wood, 27.II.1928, J. Velenovský (PRM 147776, **lectotype** of *O. pulcherrima*, H.B. 6266 ø). – **South Bohemia**, 4.3 km ESE of Kasperske Hory, NE of Retenice, 905 m, branch of *Betula pendula*, on wood, 18.VIII.2008, H.O. Baral (H.B. 8913a ø). — **SLOVAKIA**: **Trnava**, 20 km NW of Trnava, 3 km WSW of Smolenice, Jahodník, 290 m, branches of *Pinus sylvestris*, on wood, 10.III.2016, A. Polhorský (A.P. 18/54,_anam. substr., doc. vid.). – **Prešov**, Carpathian Mts., Vysoké Tatry, 2 km S of Tatranská Lomnica, Stará Lesná, 803 m, branch of *Salix caprea*, on wood, 19.VIII.2019, A. Polhorský (A.P. 19/32c, non vid.). — **GERMANY**: **Brandenburg**, Cottbus, Spreewald, 4.5 km SW of Cottbus, 2.5 km NW of Kahren, W of Nutzberg, 88 m, stem of *Rubus fruticosus*, 10.IV.2004, V. Kummer (V.K.). – **Sachsen-Anhalt**, 6.5 km SE of Braunlage, WNW of Sorge, 490 m, branch of *Salix cinerea*, on wood, 20.V.2012, S. Helleman (ø, non vid.). – **Sachsen**, 2.5 km SE of Lößnitz, 1.6 km SSW of Dittersdorf, Sonntagswiese, 570 m, branch of *Betula*, on wood, 7.X.2016, B. Mühler (doc. vid.). – **Thüringen**, 3.2 km W of Sonneberg, 1.2 km W of Bettelhecken, Mürschnitzer Sack, 380 m, branch of ?*Salix*, on wood, 7.II.2009, I. Wagner (ø, doc. vid.). – ibid., twig of *Alnus glutinosa*, on wood, 14.XII.2013, I. Wagner (ø, doc. vid.). – ibid., 1.5 km W of Bettelhecken, 355 m, branch of *Fagus sylvatica*, on wood, 18.II.2010, I. Wagner (ø, doc. vid.). – ibid., 1.8 km W of Bettelhecken, 375 m, branch of *Frangula alnus*, on wood, 24.I.2013, I. Wagner (ø, doc. vid.). – 9.3 km SSE of Sonneberg, NNW of Rotheul, 345 m, branch of *Populus tremula*, on wood, 15.VII.2017, I. Wagner (ø, doc. vid.). – **Hessen**, 1.3 km E of Breitscheid, 0.8 km SW of Erdbach, Erdbachschlucht, 380 m, branch of *Prunus spinosa*, on wood, 2.V.2000, H.O. Baral (ø). – 21 km NW of Marburg, NW of Biedenkopf, Schlossberg, 350 m, branch of *Quercus*, on wood, 30.IV.2000, H.O. Baral & L.G. Krieglsteiner (ø). – **Rheinland-Pfalz**, 11 km N of Daun, E of Heyroth, 465 m, branch of *Quercus*, on wood, 7.VIII.2016, S. Helleman (doc. vid.). – 14 km SE of Pirmasens, SE of Dahn, military cemetery, 250 m, branch of *Quercus*, on wood & bark, 2.X.1994, H.O. Baral & G. Marson (H.B. 5159a). – ibid., branch of *Salix caprea*, on wood, 1.X.1994, H.O. Baral & G. Marson (ø). – 13 km SE of Pirmasens, 1 km W of Dahn, Kauert, 270 m, branch of *Fagus sylvatica*, on wood, 30.IX.1994, H.O. Baral (ø). – **Saarland**, 18 km NE of Merzig, Weiskirchen, park, 360 m, branch of *Amelanchier* ?*lamarckii*, on wood, 18.IV.2004, H.O. Baral (ø). – 15 km W of Idar-Oberstein, 7.7 km NW of Birkenfeld, NE of Thranenweier, Riedbruch, 582 m, branch of *F. sylvatica*, on wood, 16.IV.2004, S. Helleman (ø). – **Baden-Württemberg**, 12.5 km NE of Mosbach, ~5 km NE of Dallau, near Rittersbach, Elzbachtal, 275 m, branch of *Quercus*, on bark and *Colpoma quercinum*, 1.III.1997, A. Kaiser (H.B. 5726b). – 5.5 km NW of **Stuttgart**, 1.3 km S of Weilimdorf, SE of Wolfbusch, Waldfriedhof, 360 m, branch of *Fagus sylvatica*, on wood, 25.VI.2000, H.O. Baral (H.B. 6715b, **RefSpec** of *O. vinosa*, CBS 116215, anam. cult.; sq.: KT215266). – 5.3 km NW of Stuttgart, 1.5 km WNW of Feuerbach, Tannhäuserstraße, 320 m, branch of *Pyrus communis*, on wood, 16.X.1995, H.O. Baral (ø). – 3.5 km NW of Stuttgart, 1.5 km SW of Feuerbach, Heimberg, 360 m, branch of *Quercus*, on wood, 13.III.2003, H.O. Baral (ø). – 5 km WNW of Stuttgart, 1.2 km NE of Solitude, Sandkopf, Daimlerplatz, 426 m, branch of *Salix*, on wood, 18.XII.1989, H.O. Baral (H.B. 3946). – 0.3 km SE of **Tübingen**, west-end of Österberg, Wielandshöhe, 390 m, branch of *Cotinus coggygria*, on wood, 13.VII.2002, H.O. Baral (ø, anam. substr.). – 3 km SW of Tübingen, 1.3 km NNW of Weilheim, W of Ödenburg, 400 m, branch of *Carpinus betulus*, on wood, 21.XII.2003, H.O. Baral (ø, anam. substr.). – ibid., branch of *Prunus* (?) *domestica*, on wood, 21.XII.2003, H.O. Baral (ø). – 3 km NNW of Tübingen, N of Morgenstelle, Heuberg, 500 m, branch of *Salix caprea*, on wood, 5.IX.2003, H.O. Baral (ø). – E of Morgenstelle, Madenhalde, 425 m, branch of *Malus domestica*, on wood, 19.VII.1994, H.O. Baral (ø). – 4 km N of Tübingen, 1 km WSW of Bebenhausen, Goldersbach, 380 m, branch of *Prunus spinosa*, on wood, 27.VIII.1992, H.O. Baral (H.B. 4736 ø). – ibid., 20.IV.1993 (H.B. 4869 ø). – 2.6 km NW of Bebenhausen, pond W of Teufelsbrücke, 400 m, branch of *Carpinus betulus*, on wood, 17.IV.2003, H.O. Baral (ø). – ibid., S of Teufelsbrücke, 390 m, branch of *Fagus sylvatica*, on wood, 1.V.2002, H.O. Baral (ø). – 1.5 km SE of Bebenhausen, Kirnbachtal, S of Olgahain, 400 m, twig of *Lonicera xylosteum*, on wood, 4.XI.2001, H.O. Baral (H.B. 7060a). – ibid., 360 m, branch of *Ulmus*, on wood, 19.VII.1998, H.O. Baral (ø). – 8 km NW of Tübingen, 4 km N of Pfrondorf, NW of Eisenbachhain, 495 m, branch of *Quercus robur*, on wood, 17.III.1991, H.O. Baral (H.B. 4364). – 3.3 km NNE of Pfrondorf, Moosplatte, 460 m, branches of *Q. robur*, on wood, 1.VII.2000, H.O. Baral (H.B. 6717, anam. cult.). – ibid., branch of *Picea abies*, on wood (H.B. 6718, anam. substr.). – 1.8 km NNW of Pfrondorf, Zeitungseiche, 470 m, branch of *Ligustrum vulgare*, on wood, 30.I.2000, H.O. Baral (ø, anam. substr.). – 0.8 km N of Pfrondorf, Brandklinge, 410 m, branch of *Q. robur*, on wood, 3.X.2002, H.O. Baral & E. Weber (ø). – ibid., 430 m, trunk of *Malus domestica*, on bark, 9.I.2005, H.O. Baral (H.B. 7646b ø). – E of Pfrondorf, Tiefenbach, S of Einsiedlersteg, 385 m, branch of *Quercus*, on wood, 8.IV.1989, H.O. Baral (ø). – ibid., 410 m, branch of *Acer campestre*, on wood, 1.VI.1994, H.O. Baral & G.J. Krieglsteiner (ø). – ibid., branch of *Quercus robur*, on wood, 1.III.1996, H.O. Baral (ø). – ibid., 26.V.2006 (ø, anam. substr.). – ibid., branch of *Q. robur*, on bark & wood, 18. VII.1993, H.O. Baral & E. Weber (H.B. 4917). – ibid., branch of *Prunus* (?) *domestica*, on wood, 29.VI.1997, G. Marson (ø). – ibid., branch of *Populus tremula*, on wood, 11.VII.2000, H.O. Baral (ø). – 1.5 km NNE of Pfrondorf, Brand, 460 m, trunk of *Fagus sylvatica*, on wood, 30.VII.2000, H.O. Baral (ø). – 2 km SE of Pfrondorf, Hinterpfand, 370 m, branches of *Q. robur*, on wood, 10.III.2002, H.O. Baral (ø). – 0.8 km SE of Pfrondorf, Höhberg, 400 m, branch of *Salix caprea*, on wood, 27.I.2001, F. Baral-Weber (ø). – 0.5 km S of Pfrondorf, Haldenbach, 390 m, branch of *Picea abies*, on wood & bark, 8.VI.1997, H.O. Baral (ø, anam. substr.). – ibid., Mähder, branch of *Malus domestica*, on wood, 28.VII.2009, B. Liu & H.O. Baral (ø). – ibid., plank of (?)*P. abies*, on wood, no date, H.O. Baral (ø). – ibid., branch of *M. domestica*, on wood, 4.X.1994, H.O. Baral & K. Siepe (ø). – 0.9 km S of Pfrondorf, Bitzle, 350 m, branch of *Quercus robur*, on wood, 30.XI.2005, H.O. Baral (H.B. 8003a ø). – 1.3 km SW of Pfrondorf, quarry near Bitzle, 420 m, branch of *Salix caprea*, on wood, 26. III.1996, H.O. Baral (ø). – 0.3 km SW of Pfrondorf, S of Albstraße, 410 m, branch of *M. domestica*, on bark, 28.XI.1999, E. Weber & H.O. Baral (ø). – **Schwäbische Alb**, 2.5 km E of Reutlingen, 1.3 km NW of Eningen, Achalm ruin, 685 m, branch of *Acer campestre*, on wood, 25.VII.1999, H.O. Baral (ø). – 3 km SE of Urach, 1 km W of Wittlingen, Hohenwittlingen ruin, 650 m, branch of *Rosa*, on wood & bark, 16.III.2003, H.O. Baral (ø). – 6 km E of Reutlingen, 3 km ENE of Eningen, Hännersteigfels, 735 m, branch of *Quercus*, on wood, 3. III.2002, H.O. Baral (ø). – 8.5 km SSE of Reutlingen, 1.5 km SSW of Unterhausen, Gießstein, 775 m, branch of *Fagus sylvatica*, on wood, 1.IX.1999, H.O. Baral (ø). – 3.2 km SW of Urach, 1.9 km NNE of Bleichstetten, Buckenläre, 770 m, branch of *F. sylvatica*, on wood, 1.VI.1998, H.O. Baral (ø). – 3 km SE of Urach, 1 km W of Wittlingen, Hohenwittlingen farm, 680 m, branch of *Syringa vulgaris*, on wood, 16.III.2003, H.O. Baral (ø). – 3 km SW of Mössingen, 1.4 km S of Belsen, Alter Morgen, 570 m, branch of *Rosa*, on wood, 23.VI.2002, H.O. Baral (ø). – 5 km S of Gammertingen, 0.7 km E of Hermentingen, SW of Eichhalde 687 m, branch of *Salix*, on wood, 28.VI.2002, G. Marson (ø). – 16 km NE of Tuttlingen, 4 km NNW of Irndorf, Irndorfer Hardt, 870 m, branch of *Betula pendula*, on wood, 27.VI.1993, H.O. Baral (H.B. 4903a). – 14 km NNE of Ulm, ~5 km NW of Langenau, S of Lonetal, 570 m, trunk of *Picea abies*, on wood, 17.VI.1998, E. Weber (ø). – 7 km SSE of Bad Saulgau, 3 km NW of Altshausen, NW of Hirschegg, 635 m, branch of *Fagus sylvatica*, on wood, 26.VI.2005, G. Marson (ø). – **Bayern**, **Oberfranken**, 11 km NNW of Bayreuth, 3 km NW of Harsdorf, E of Fohlenhof, Trebgasttal, 333 m, branch of *Salix*, on bark, 28.II.1997, W. Beyer (ø). – 3.8 km E of Marktredwitz, S of Brand, Kleeschlag, 570 m, branch of *Acer pseudoplatanus*, on wood, 17.III.2019, M.

Map 45. Known distribution of *O. vinosa* in North America, Europe, and Tenerife (Macaronesia).

Reul (M.R. 6762, doc. vid.). – **Mittelfranken**, 40 km SE of Würzburg, ~12 km WNW of Neustadt a. d. Aisch, forest near Sugenheim, ~400 m, branch of *Quercus*, on wood, summer 1869 & 1870, H. Rehm (M, Rehm, Ascomyc. 17, Rabenhorst, Fungi Eur. Exs. 1412). – **Unterfranken**, 17 km NW of Würzburg, 2 km W of Zellingen, Hügelspitz, 260 m, branch of *Rosa*, on wood & bark, 11. XI.1995, H.O. Baral & L.G. Krieglsteiner (L.K.). – **Oberpfalz**, 12 km NNE of Amberg, 1.5 km W of Hirschau, Moosweiher, 420 m, branch of *Populus tremula*, on wood, 29.XII.2003, H.O. Baral (H.B. 7451). – ibid., 1.VIII.2005 (ø). – ibid., branch of *Quercus robur*, on wood, 30.XII.2003 (H.B. 7449a, anam. substr.). – 2 km W of Hirschau, Haarbühl, 445 m, branch of *Q. robur*, on wood, 29.XII.1993, H.O. Orbilia subvinosa G. Marson, Baral & E. Weber, **sp. nov.**, MB 813559 — Pls 263–265, Map 46

Etymology: referring to the similarity with *O. vinosa*.

Typification: Spain, Teruel, branch of *Pinus sylvestris*, 26.IX.1999, G. Marson & H.O. Baral (ex H.B. 6490b, M-0281034, holotype).

Latin diagnosis: *Similis* Orbiliae vinosae *sed ascosporae paulo majores, apothecia plerumque intense aurantiaca, margine minute crenulata, conidia typo* Dwayaangam*, duplex dichotomiter ramosa differt. Habitat ad lignum putridum ramorum siccorum* Pini, *raro* Piceae, *plerumque in zona orosubmediterranea Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.8(–1.05) mm diam., 0.15–0.22 mm high (receptacle 0.12–0.15 mm), light to bright orange, sometimes rose-orange or rose-red, not or only slightly translucent, ± round, scattered to medium gregarious; disc slightly concave to flat, finally slightly convex, margin distinct, thin, 5–10 µm protruding, finely to distinctly crenulate, rarely ± smooth; broadly sessile, superficial, rarely immersed in cracks; dry bright to deep orange-red, with thick protruding margin. **Asci** *((45–))(50–)55–77(–88) × (5.5–)6–7 µm {7}, †(51–)60–70(–80) × (4.7–)5–6(–6.5) µm {3}, 8-spored (rarely 4–7-spored), spores *3–4-seriate, 3–4 lower spores inverted {3} (not or somewhat mixed), pars sporifera *30→ 20 µm long; **apex** (†) hemispherical, dome †0.5–0.6 or 1–1.8 → 0.3–0.4 or 0.8–1.2 µm thick {2}, with indistinct or distinct apical chamber; **base** with medium to very long, thin, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(12.7–)14–20(–22) × (1.7–)1.9–2.2(–2.5) µm {10}, †14–19 × 1.8–2.2 µm {2}, cylindric-fusoid to fusoid-clavate, apex obtuse, rarely subacute, base gradually or more abruptly attenuated in a tail-like end or distinct tail *(3–)4–5(–7) × 1–1.2 µm, straight to very slightly curved near base; **SBs** *4–6(–7)((–8)) {10} × ((0.5–))(0.6–)0.7–0.9(–1) µm {8}, vermiform, often with a ± distinct basal inflation, apically

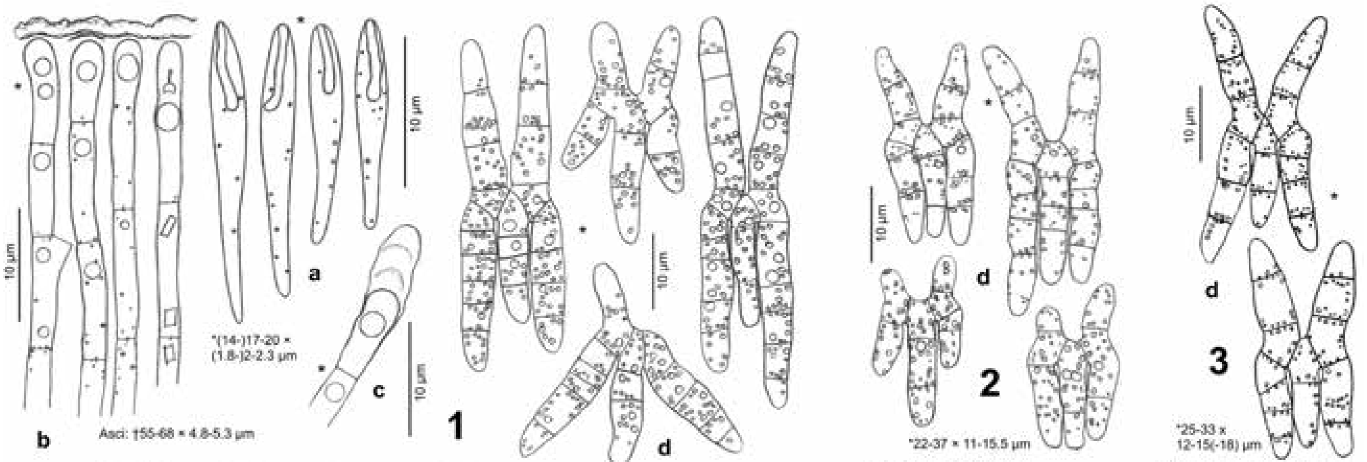

Plate 263. **1–3**. *Orbilia subvinosa*. – **a**. ascospores; **b**. paraphyses; **c**. cortical cells with glassy process; **d**. conidia (from substrate).

narrowed to a wide point or not narrowed, straight or very slightly flexuous, overmature ampulliform, (1.8–)2.5–3.5(–4.5) × 1–1.3 µm; with a few minute LBs. **Paraphyses** apically uninflated to very slightly clavate, terminal cells *6–18 × 2.2–2.8 µm {1}, †11–16 × 2–3 µm {1}, lower cells *8.5–12 × 2–2.5(–3) µm {1}, †7–14 × 1.8–2.5 µm {1}; unbranched at upper septum, hymenium pale yellow-orange, also rose. **Medullary excipulum** pale rose to orange, 50–120 µm thick, of dense (or loose in lower part) textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** subhyaline at base, pale rose to orange towards margin, of (†) not or slightly gelatinized, vertically oriented t. globulosa-angularis-prismatica from base to mid flanks, 45–60 µm thick near base, cells *(5–)6–13(–14) × (4–)5–8(–10) µm {2}; 20–35 µm thick near margin, of t. porrecta oriented at a (45–)60–90° angle to the surface, (10–)60–80° at upper margin, marginal cortical cells *6–11 × 2.5–4 µm {3}; **glassy processes** 0–3 {2} or 3–10 {7} or 10–15(–18) {3} × 3–4 µm, ± high-refractive, stratified, coherent to form small teeth. **Anchoring hyphae** abundant, †1.8–2.8 µm wide, walls 0.2 µm thick {2}. **SCBs** in paraphyses and ectal excipulum (at margin) globose, (0.8–)1.3–2.5(–2.8) µm diam., in lower part of paraphyses and in ectal excipulum at flanks and margin (also at base and in medullary excipulum) crystalloid {7}, (0.9–)1.5–2.5(–3.2) × 1–2.3 µm, very pale orange, also absent {3}; **LBs** in lower part of paraphyses and in ectal excipular cells at mid flanks and margin minute, ± sparse, pale yellowish-orange or sometimes rose-orange (carotenoids). **Exudate** over paraphyses 1–2(–3) µm thick, rough-cloddy, (very) pale yellow, loosely attached, over margin and flanks 1–5 µm thick, cloddy, hyaline or usually pale to light sulphur-yellow or chlorinaceous. — **ANAMORPH**: dwayaangam-like (from ascospore isolate {1} and natural substrate {9}). **Conidiophores** *30 × 2.8 µm, 1-septate. **Conidia** resembling clothes-pegs, total size *(20–)26–54(–60) × 10.5–12.5(–13.5) µm {8}, (13–)17–30(–36)((–55)) µm wide when arms diverging; stipe *(8.5–)10–18(–19) × (2.5–)2.8–4(–4.8) µm, (1–)2–3(–4)-septate, usually shorter than basal arms; twice dichotomously branched: 2 arms pointing upwards, 2 downwards, arms straight, not or slightly to medium tapered near the ends, *((5–))(8–)11–27((–33)) × (3–)3.3–4.5((–5.5)) µm, (0–)2–5(–7)-septate, containing some or many minute LBs, sometimes also some with 1–2 µm diam.

Habitat: collected 1–4 m above the ground, on attached (rarely broken), ± decorticated (rarely corticated with resinous wound), 11–35 mm thick branches of *Abies alba* {1}, *Pinus* sp. {3}, *P. sylvestris* {17/2}, *P. brutia* {1}, on 0.1–0.5, sometimes up to 1–2 mm deep slightly to strongly decayed wood {24} often in beetle galleries, slightly to strongly greyed, green algae sparse to abundant. **Associated**: *Amphosoma resinicola* {1}, *A. atroolivaceum* {1}, *Capronia* sp. {2}, *Ciliolarina pinicola* {1}, *Coniochaeta malacotricha* {1}, *Cryptodiscus pini* {1}, *Dacrymyces* sp. {3}, '*Helotium*' *uvidulum* {1}, *Hypogymnia physodes* {1}, *Lachnellula resinaria* {1}, *Lophium mytilinum* {1}, *Melanelia glabratula* {1}, *Melaspilea emergens* {1}, *Orbilia alpigena* {1}, *O. aristata* {1}, *O. coniferarum* {1}, *O. cylindrospora* {2}, *O. delphinus* {1}, *O. eucalypti* {2}, *O. euonymi* {1}, *O. flagellispora* {1}, *O. gambelii* {1}, *O. ?ocellata* {1}, *O. patellarioides* {11}, *O. pleiomicrosoma* {1}, *O. sphaerospora* {4}, *O. subaristata* {1}, *O. subcylindrospora* {1}, *O. subtrapeziformis* {1}, *O. trapeziformis* {1}, *O. vinosa* {2}, ?*Pragmopora* sp. {1}, *Propolis betulae* {1}, *Pseudevernia furfuracea* {1}, *Pseudohelotium sordidulum* {2}, *Resinomyces griseus* {1}, *R. kirschsteinianus* {1}, *Sarea resinae* {1}, *S. difformis* {1}. **Desiccation tolerance**: fully viable for at least 3 months, after 9 months paraphyses and immature asci still alive, after 1 year many spores still viable, conidia germinated when transferred to agar 10 months after being collected. **Altitude**: 860–1830 m a.s.l. (but 425 m in western Anatolia). **Geology**: Lower to Upper Jurassic & Cretaceous marl- & limestone, Mio- to Pliocene marl, Cenozoic silt. **Phenology**: IV, VII–X (possibly throughout the year, long-lived).

Taxonomic remarks. *Orbilia subvinosa* is segregated from *O. vinosa* and *O. arachnovinosa* mainly because of its deviating dwayaangam-like anamorph (Pls 263: 1d, 2d, 3d; 264: 1h, 3e, 4d; 265). With its usually bright orange, less translucent apothecia (due to sparse pale orange LBs in both paraphyses and excipular cells) with a crenulate margin formed by short glassy processes, the species can often already macroscopically be distinguished from *O. vinosa* which was twice found to grow in association (H.B. 5142c, 6748f). The asci and spores tend to be slightly larger: the spores are often over *2 µm wide while, in comparison, those of *O. vinosa* are usually below *2 µm.

The species was so far with certainty only found on wood of *Pinus* and once *Abies* in southern France and Spain, mainly in the orosubmediterranean humid zone. A record of the characteristic anamorph in western Anatolia (Turkey) on *Pinus brutia* is exceptional because it was made at a comparatively low altitude in the supramediterranean belt.

The very similar but angiosperm-inhabiting *O. angiosubvinosa* is described here as a separate species, because the associated conidia are slightly narrower, the spores slightly shorter and wider, and a sequence from a sample on *Corylus* distinctly deviates from sequences of typical *O. subvinosa* on coniferous substrate.

Variation. Apothecial size and colour varied somewhat among the populations, also the finely denticulate margin was not always present. Though typically light to bright orange, a distinct rose component was noted in apothecia of two collections (H.B. 5015a, 5016a). Crystalloid SCBs were usually present, but in one specimen only globose SCBs were seen (H.B. 5016a), and in the holotype they were absent in one population, while present in apothecia on a separate branch (Pl. 263: 1b). Spore length varied between 14–16 and 17–20 µm while spore width was more constant. Glassy processes were absent in a few specimens (e.g., H.B. 6729a), and varied also in length among the populations. The ascus apical dome was either around 1–1.5 µm thick or only ~0.5 µm, but more data are required to find out the predominant case.

Not included collections. Some orosubmediterranean samples on *Juniperus* and supramediterranean ones on *Abies pinsapo* might belong to *O. subvinosa* but clear evidence was lacking. Those on wood of *Abies* from three localities in the Sistema Bético of Andalucía, at first identified as *O. vinosa*, had orange-red apothecia with (2–)10–20(–25) µm long glassy processes, but conidia were not observed in any of them. The spores (†12.5–17.5 × 1.7–1.9 µm) would fit *O. vinosa*, but these samples are only assigned with hesitation to *O. subvinosa*. Three records on *Juniperus* from southern France and central Spain, with glassy processes up to 10 µm length, are also not included in the description, mainly because of the paucity of microscopic data and because conidia were not observed.

Anamorph. The characteristic dwayaangam-like conidia were observed on the natural substrate in association with apothecia of *O. subvinosa* in at least nine of our collections on *Pinus*. In 2012 we succeeded to obtain them also in pure culture from an ascospore isolate (from Grasse, Pl. 265: 1). They further developed in an isolate gained from conidia taken from the natural substrate (from Briançon, Pl. 265: 2). The same type of dwayaangam-like conidia was once observed in the submediterranean collection on *P. brutia*, but the associated apothecia belonged to *O. subaristata*, *O. pleiomicrosoma*, and *O. euonymi*.

However, in an earlier trial in 2001 to obtain the anamorph of *O. subvinosa* (from Col de Pommerol, H.B. 6748g, Pl. 258: 4), the ascospore isolate formed consistently trinacrium-like conidia typical of *O. vinosa*, although only dwayaangam-like conidia

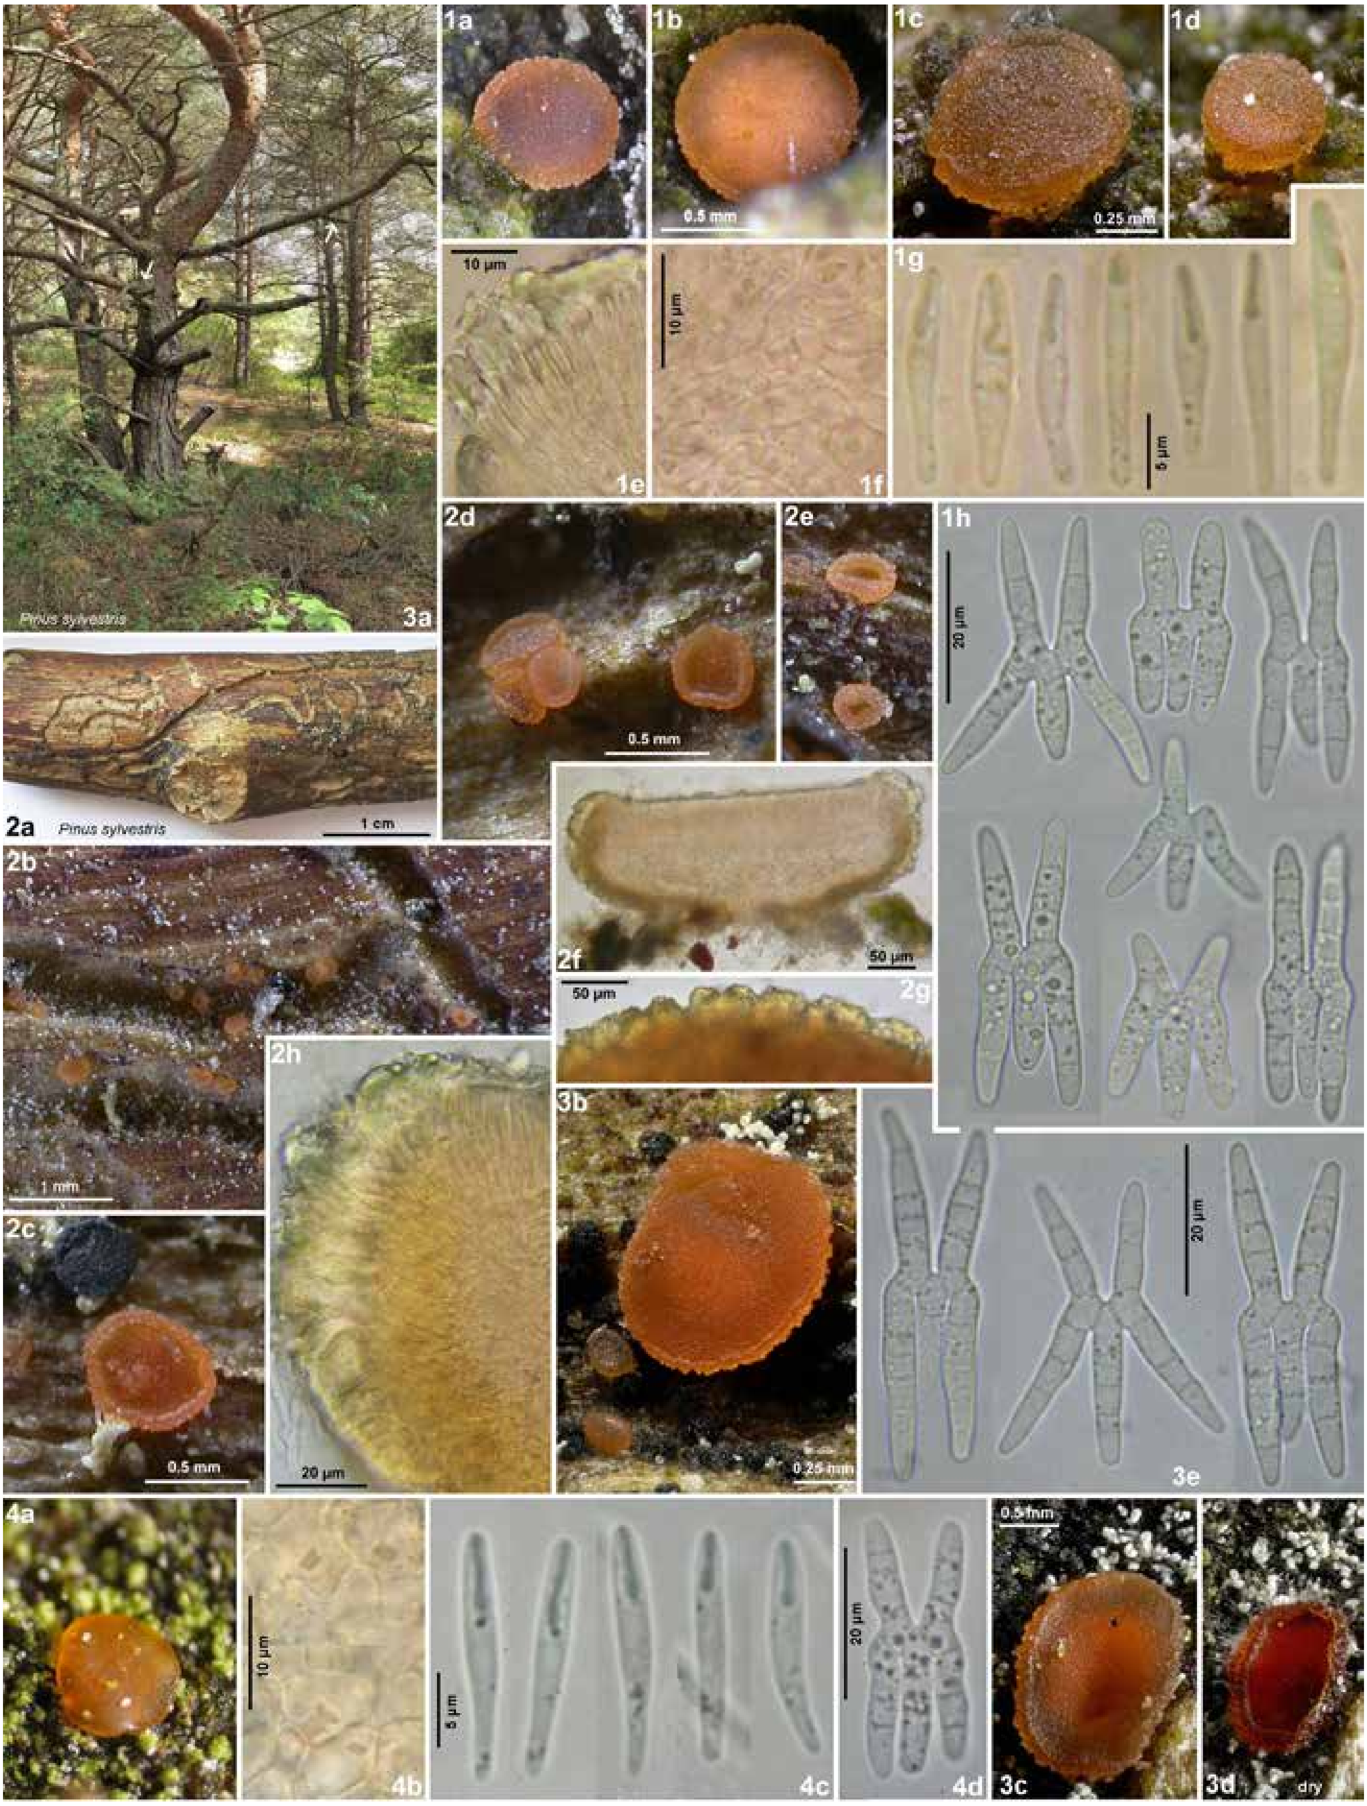

Plate 264. **1–4**: *Orbilia subvinosa*. – **1a**. orosubmediterranean *Pinus sylvestris* forest; **2a**. decorticated xeric branch of *Pinus* with old beetle galleries (rehydrated); **1a–d**, **2b–e**, **3b–c**, **4a**. rehydrated apothecia (**2c** with black apothecium of *Orbilia patellarioides*); **3d**. dry apothecium; **2f**. apothecium in median section; **1e**, **2h**. id., marginal ectal excipulum; **2g**. apothecium in top view showing marginal teeth; **1f**, **4b**. crystalloid SCBs in excipular cells of margin and flanks; **1g**, **4c**. ascospores; **1h**, **3e**, **4d**. conidia from substrate. – Living state. – **4a–d**: phot. R. Tena. — **1a–h**. H.B. 9173b: France, Mont Ventoux, on *Pinus*; **2a–h**. H.B. 6490b (holotype): Spain, Sierra de Albarracín, on *Pinus*; **3a–e**. 24.IX.2009: France, Grasse, on *Pinus*; **4a–d**. 1.IV.2012: Spain, Sierra de Javalambre, on *Pinus*.

were abundantly observed on the natural substrate (H.B. 6748f, Pl. 263: 2). Therefore, we suspected that the apothecium used for isolation belonged in the scope of *O. vinosa* rather than *O. subvinosa*. In fact, molecular data gained from this culture differ strongly from both species, but are slightly closer to *O. vinosa* (see below).

Conidia varied in total length between ~25–30 and ~35–55 µm. The arms were usually ± parallel, but sometimes they diverged and then the conidia are much wider. Also stipe length may vary between 10–13 and 13–19 µm.

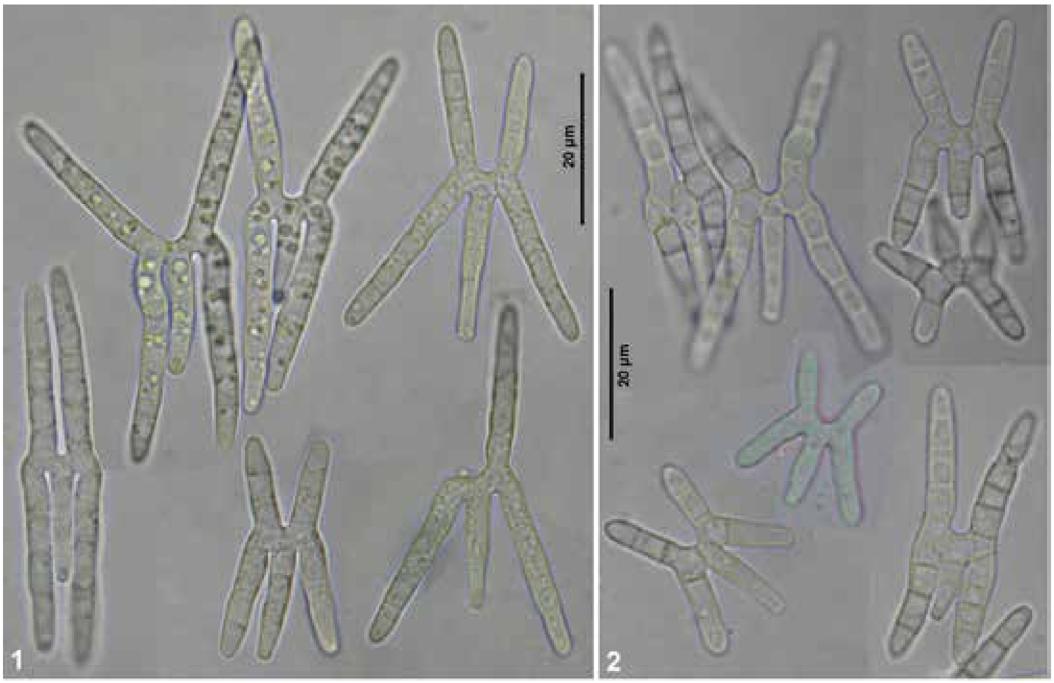

Plate 265. **1–2**: *Orbilia subvinosa*. – Conidia in pure culture (**1**. ascospore isolate, **2**. conidial isolate). – Living state. **— 1**. 18.IX.2011: France, Grasse, Col du Ferrier, on *Pinus*; **2**. 5.IX.2010: France, Briançon, Cervières, on *Pinus*.

The conidia of *O. subvinosa* resemble those of the tropical angiosperm-inhabiting *Dwayaangam yakuensis* but are certainly not conspecific (for the differences see under *O. angiosubvinosa*, p. 622).

Phylogeny. Sequences of ITS and mostly also LSU were available for seven strains of *O. subvinosa* (see Tab. 66). They differ by 0.2–1.1 % in the ITS at pos. 10 in the ITS1 and at pos. 369, 382, 406, 412, and 503 in ITS2. The six variable positions are either T or C, and in two strains 3 or all 6 positions were ambiguous (Y), which suggests that variation at these positions regularly occurs, even within a population. The seven sequences concurred at pos. 369 & 382 (4 strains T or mainly T, 3 strains C) and 406 & 412 (4 strains C or mainly C, 3 strains T). Variation at pos. 10 was only observed in the *Abies* sample (T vs. C) and at pos. 503 also in the sample from Moustiers-Ste.-Marie. No variation was observed in the two isolates from ascospores and conidia, which could mean that a single apothecium includes only 1 genotype.

To *O. angiosubvinosa* a distance of 6–7 % was found, and to *O. vinosa* 9.5–11 %. Also the intermediate sample from Col de Pommerol shows a distance of 10.5–11.5 % to *O. subvinosa*. In the LSU (D1–D2) *O. subvinosa* did not show any variation and differs from *O. vinosa* by 1.1–1.3 % (see also under *O. vinosa*, p. 609). For the phylogenetic placement see under *O. vinosa*.

Five of the seven *O. subvinosa* sequences comprise enough nucleotides of the SSU in order to verify the absence of the S1506 intron, which was also absent in the sequence of *O. angiosubvinosa* and the intermediate strain from Boston (bhi-F731), but present in all sequences of *O. vinosa*, including the intermediate strain from Col de Pommerol (Tab. 66).

Ecology. To the present knowledge, *O. subvinosa* is restricted to the altimontane to subalpine, orosubmediterranean, rarely orotemperate or suprasubmediterranean humid regions, where it was mainly found on wood of xeric branches of *Pinus*, particularly *P. sylvestris*, but also on *Abies alba*. Typical associated taxa are *O. patellarioides* and *O. sphaerospora*, which show a very similar prevalence for pine wood. However, also *O. vinosa* is not rare in these habitats, with which it was occasionally found to grow in association. The record on *Pinus brutia* was in a supramediterranean forest at 425 m altitude in western Anatolia, while all collections from Spain and France, whether included or not, derive from altitudes above 850 m.

Specimens included. **FRANCE**: **Rhône-Alpes**, **Drôme**, 20 km W of Serres, 4.3 km NNW of Rosans, Col de Pommerol, 1045 m, branches of *Pinus sylvestris*, on wood, 22.VIII.2000, G. Orbilia angiosubvinosa Baral, R. Tena & E. Weber, **sp. nov.**, MB 825630 — Pls 266–267

Etymology: referring to the growth on angiosperms and the similarity with *O. subvinosa*.

Typification: Spain, Asturias, Pola de Somiedo, Valle de Lago, branch of *Corylus avellana*, 4.VI.2013, T. Læssøe (ex H.B. 9813a, AH 52842, sq.: MK493127, holotype).

Latin diagnosis: *Similis* Orbiliae subvinosae *sed conidia angustiores, habitat ad lignum putridum ramorum siccorum angiospermarum in zona suprasub- ad orosubmediterranea Europae meridionalis et zona oceanica Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.4–0.8 mm diam., 0.16 mm high, light to deep orange, rarely rose-orange, hardly to medium translucent, ± round, very scattered to gregarious in small groups; disc flat, margin distinct, thin or thick, 8 µm protruding, smooth to distinctly crenulate; broadly sessile, superficial; dry bright to deep orange-red, with thick protruding margin. **Asci** *(50–)55–70(–79) × (5–)6–7(–7.5) µm {2}, †40–65 × 4.6–5.5 µm {2}, 8-spored, spores *3–4-seriate, 2–4 lower spores inverted {4}, pars sporifera *25–38 µm long; **apex** (†) hemispherical, dome †0.8–1.4 → 0.7–1 µm thick {2}, with small apical chamber; **base** with short to very long, thick or thin, flexuous stalk, T- to L-shaped. **Ascospores** *((11.5–))(12.5–)14–17(–19) × (1.8–)2–2.4(–2.7)((–3)) µm {7}, narrowly fusoid (to fusoid-clavate), apex rounded to obtuse, base ± attenuated, sometimes tail-like, straight to very slightly, exceptionally strongly curved near base; **SBs** *(2.7–)3.5–5.5(–7) × 0.6–1(–1.3) µm {6}, vermiform or with a ± ellipsoid basal inflation, apically not narrowed, ± broadly attached, straight; with some small LBs. **Paraphyses** apically uninflated to very slightly clavate or lageniform, terminal cells *9.5–16 × 1.8–2.8(–3.2) µm {4}, lower cells *8–11.5 × 1.5–2.6 µm {2}; unbranched at upper septum, hymenium light orange. **Medullary excipulum** pale rose to orange, 45 µm thick, of dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** subhyaline at base, light orange towards margin, of (†) not or slightly gelatinized, vertically oriented t. globulosa-angularis-prismatica from base to mid flanks, 30–35 µm thick near base, cells *8–16 × 5–10(–13) µm {3}; 35 µm thick near margin, of t. porrecta oriented at a 10–50° angle to the surface, marginal cortical cells *6–15 × 2.5–3.5 µm {2}; **glassy processes** 0–1 {4} or 5–28 {3} × 2.5–3.5(–3.8) µm {2}, ± high-refractive, stratified, coherent to form indistinct to distinct teeth. **Anchoring hyphae** medium abundant, †1.5–2.7 µm wide, walls 0.2–0.3 µm thick {1}. **SCBs** in paraphyses and ectal excipulum (at margin) globose, 1–2.5 µm diam. {6}, also crystalloid {7}, in excipulum 2–4.5 × 1–1.5 µm, hyaline to pale orange; **LBs** in lower part of paraphyses and in ectal excipular cells at mid flanks and margin minute, ± scattered, light yellowish-orange (carotenoids) {1}. **Exudate** over paraphyses, margin and flanks 1–2.5 µm thick, cloddy, hyaline to pale yellow, loosely attached. — **ANAMORPH**: dwayaangam-like (presumed, from natural substrate {4}). **Conidiophores** very short, unbranched. **Conidia** resembling clothes-pegs, total size *(26–)35–52 × 10–11 µm, 12–21 µm wide when arms diverging; stipe *11–15 × 2.7–3.3(–3.7) µm, 2-septate, usually shorter than basal arms; twice dichotomously branched: two arms pointing upwards, two downwards, arms straight, not or slightly to medium tapered near the ends, *(11–)13.5–26 × 3–3.5(–3.8) µm, 2–3-septate {2}, containing many minute LBs near septa or close to wall, sometimes also with some large LBs {2}.

Habitat: collected 1–1.5 m above the ground, partially to sometimes entirely decorticated, 7–40 mm thick branches of *Corylus avellana* {2}, *Rosa* sp. {1}, *Salix* sp. {1/1}, *S. caprea* {2}, on up to 1 mm deep medium to strongly decayed wood {7}, slightly to strongly greyed, ± covered by green algae. **Associated**: *Cryptodiscus foveolaris*

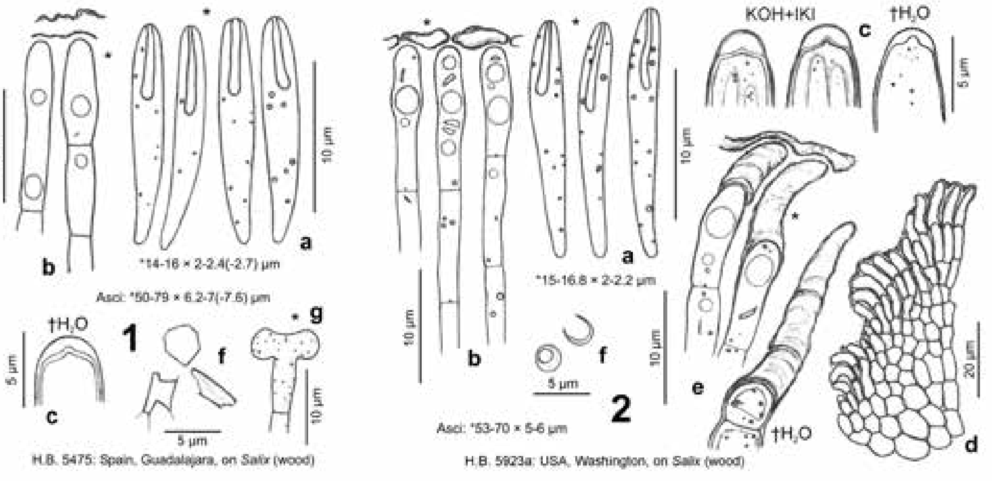

Plate 266. **1–2**: *Orbilia angiosubvinosa*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section; **e**. cortical cells with glassy process; **f**. crystalloid SCBs in excipular cells; **g**. young conidium (from substrate).

Plate 267. **1–5**: *Orbilia angiosubvinosa*. – **1a**. pond with *Salix caprea* in a *Fagus* forest; **1b–d**, **3a**, **4a**. rehydrated apothecia; **3c**. apothecium in median section; **3b**, **5**. id., marginal ectal excipulum; **1f**, **3e**. ectal excipulum with crystalloid SCBs; **1e**, **2a**, **3d**, **4b**. ascospores; **2b**, **3f**. conidia from substrate. – Living state, except for **5** (in KOH). – **1a–f**, **2a–b**, **4a–b**: phot. R. Tena. — **1a–f**. 1.VI.2013: Spain, Zaragoza, Moncayo, on *Salix*; **2a–b**. 3.VII.2011: ibid.; **3a–f**. H.B. 9813a (holotype): Spain, Asturias, Pola de Somiedo, on *Corylus*; **4**. 3.IV.2013: ibid., Teruel, on *Rosa*; **5**. H.B. 5923a: USA, Washington, on ?*Salix*.

{1}, *Deltopyxis triangulispora* {1}, *Hysterographium fraxini* {1}, *Mellitiosporiella pulchella* {1}, *Orbilia eucalypti* {1}, *O. subovoidea* {1}, *O. vinosa* {2}, *Parmelia* sp. {2}, *Physcia* sp. {1}, *Usnea* sp. {1}. **Desiccation tolerance**: fully viable for at least 2 months. **Altitude**: 1140–1548 m a.s.l. (Spain), 82 m (USA). **Geology**: Spain: slate, sand & clay, dolomite; USA: Quaternary sediment from Jurassic-Cretaceous sedimentary rock. **Phenology**: IV–VIII (possibly throughout the year, long-lived).

Taxonomic remarks. Based on the associated dwayaangam-like anamorph and the deep orange apothecia, the angiosperm-inhabiting *Orbilia angiosubvinosa* is undoubtedly closely related to the conifericolous *O. subvinosa*. Our preliminary molecular data indicate a close but distant relationship to that species. Morphologically, *O. angiosubvinosa* differs in slightly narrower conidia, also in slightly shorter and wider ascospores which resemble a bit those of *O. hesperidea*. Yet, the included SBs are longer and the crystalloid SCBs in the ectal excipulum are too small to fit *O. hesperidea*. *O. coronohesperidea* from semihumid to arid Australia mainly differs in slightly wider spores, while its anamorph is unknown.

The morphological limits in the teleomorph between *O. angiosubvinosa* and *O. vinosa* are not sharp, however, and it may well be that some collections with wider ascospores here included in *O. vinosa* belong in fact to *O. angiosubvinosa*.

Variation. The four collections from Asturias (on *Corylus*) and Zaragoza (on *Salix*) (Pl. 267) lack glassy processes, although thickened cell walls up to 1 µm were observed at the margin; therefore, the apothecia have a smooth margin. The three collections from Teruel, Guadalajara, and Washington (on *Rosa* and *Salix*) have glassy processes 5–28 µm in length (Pl. 266) which may form a crenulate margin (see also Pl. 267: 4a). Yellowish-orange LBs in paraphyses and excipular cells were only observed with certainty in the collection on *Rosa*.

Anamorph. Conidia of *O. angiosubvinosa* (Pl. 267: 2b, 3f) closely resemble those of *O. subvinosa*. However, their connection to a teleomorph was not affirmed in pure culture. Only a single dwayaangam-like conidium was seen in the specimen from Washington (IVV: H.B. 5923a), and in the sample from Guadalajara a T-shaped conidium was observed on a conidiophore emerging from the hymenium, perhaps representing a very young stage of dwayaangam-like anamorph (Pl. 266: 1g).

The similar *Dwayaangam yakuensis* (Pl. 13: a) differs from *O. subvinosa* and *O. angiosubvinosa* in conidia which never exceed 34 µm in length due to shorter arms with only (0–)1–2 septa, and in which the stipes are consistently longer than the basal arms. Therefore, we believe that this anamorph is undoubtedly not conspecific with either of these species. It was isolated from rotten angiosperm leaves in the tropics: in Japan on *Machilus thunbergii* and in Australia on *Archontophoenix alexandrae* (Matsushima 1975: 158 pl. 345, 1989: 17 fig. 517). This deviation applies also to some other records referred to *D. yakuensis*, being reported from more temperate regions: Matsushima (1981: 9 fig. 84, from bark of *Fagus crenata* in Japan), Ando & Tubaki (1984a, from rainwater from the canopy of *Quercus* spp. in Japan), and Kitz & Embree (1980, from soil and leaf mold in an oak-hickory woodland in Iowa, USA). The conidia from temperate Japan deviate from tropical *D. yakuensis* in slightly outwards curved arms, whereas those from Iowa tend to have inward curved arms. We believe that all these records are not conspecific with *O. angiosubvinosa*.

Phylogeny. A sequence of the ITS region was gained from the sample on *Corylus* from Asturias. As in *O. subvinosa* the S1506 intron is absent. *O. angiosubvinosa* clustered highly supported with *O. subvinosa* (Phyl. 11), though with a 6–7 % distance. Its distance to *O. vinosa* is 10.5–11.5 % and to the intermediate strain H.B. 6748g 11 %.

Ecology. *Orbilia angiosubvinosa* was collected in suprasub- to orosubmediterranean, (semi)humid regions of southern Europe above 1100 m altitude, repeatedly at water bodies such as ponds or streams, for instance, in a forest with *Fagus sylvatica*, *Quercus pyrenaica*, and *Betula pendula* at a pond with *Salix caprea* in the Sierra del Moncayo, or in an open vegetation along a streamlet with *Salix* and *Populus* in the northeastern part of the Sierra de Guadarrama. The holotype was found in a deciduous forest in a creek which included *Fagus sylvatica* and *Corylus avellana*. The single North American location was a deciduous lowland forest in the mild-maritime humid Pacific west at the southern end of the Coast Mountains.

Specimens included. **SPAIN**: **Asturias**, 4.1 km ESE of Pola de Somiedo, 1.2 km NE of Valle de Lago, 1165 m, branch of *Corylus avellana*, on wood, 4.VI.2013, T. Læssøe (ex H.B. 9813a, AH 52842, **holotype**, anam. substr.; sq.: MK493127). – 2.2 km SE of Pola de Somiedo, SW of Coto de Buenamadre, Hayedo de Mumián, 1155 m, branch of *C. avellana*, on wood, 2.VI.2013, T. Læssøe & J.H. Petersen (ø). – **Aragón**, **Zaragoza**, Sierra del Moncayo, 9 km SE of Ágreda, 3.8 km SW of San Martín de la Virgen de Moncayo, SW Agramonte visitor center, 1140 m, branch of *Salix caprea*, on wood, 3.VII.2011, R. Tena (ø, anam. substr., doc. vid.). – ibid., 1.VI.2013 (R.T.L. 13060101, 13060102, doc. vid.). – **Teruel**, 52 km WNW of Teruel, 2 km SW of Orihuela del Tremedal, 1548 m, branch of *Rosa*, on wood, 3.IV.2013, R. Tena (R.T.L. 03041301, doc. vid.). – **Castilla-La Mancha**, **Guadalajara**, Sierra de Guadarrama, 55 km NNW of Guadalajara, 0.7 km NW of Majaelrayo, Arroyo La Matilla, 1180 m, branch of *Salix*, on wood, 14.V.1996, H.O. Baral (H.B. 5475 ø, anam. substr.). — **USA**: **Washington**, 14 km S of Acme, 5 km S of Whatcom, railway, 82 m, branches of (?)*Salix*, on wood, 15.VIII.1997, G. Marson (H.B. 5923a, anam. substr.).

Orbilia arachnovinosa Baral & E. Weber, **sp. nov.**, MB 813560 — Pls 268–269, Map 47

?= *Orbilia rubinella* (Nyl.) P. Karst., Bidr. Känn. Finl. Nat. Folk 19: 97 (1871)

to fusoid-clavate, apex (rounded to) obtuse, base medium to mostly strongly attenuated, without or sometimes with a distinct tail *4–5 × 0.8–1.2 µm, straight to often distinctly bent near base, sometimes also towards apex; **SBs** *4–6(–7.5) × (0.6–)0.7–1(–1.2) µm {9}, vermiform (rod-shaped), sometimes ± inflated at the base, also subulate, apically narrowed to a small to wide point, rarely not narrowed, straight, with a few minute or also many small LBs; SBs in aged spores ampulliform, 2.5–4 × 0.9–1.3 µm {2}. **Paraphyses** apically uninflated to slightly clavate, terminal cells *11–25 × 2.3–3.5 µm {2}, †8–13.5(–22) × (1.5–)1.8–2.8 µm {1}, lower cells †7–11.5 × 1.4–1.7 µm {1}; unbranched at upper septum, hymenium pale or light rose to orange. **Medullary excipulum** hyaline to pale rose, 50–130 µm thick, of loose or dense textura intricata, with indistinctly inflated cells, medium to sharply delimited. **Ectal excipulum** hyaline to pale rose, of (†) thin-walled, ± vertically oriented textura globulosa(-prismatica) from base to mid flanks, 30–100 µm thick near base, cells *8–25 × 6–12(–20) µm {3}; 30–40(–50) µm thick near margin, of t. porrecta oriented at a 45–80° angle to the surface, marginal cortical cells *10–13 × 2.7–3.3 µm {1}; **glassy processes** 0–3 {4} or 3–10 {3} or 10–30 {9} × (2–)2.3–3.5(–4)((–5)) µm {12}, high-refractive, ± stratified, coherent, sometimes forming distinct teeth. **Anchoring hyphae** very abundant, *2–3 µm wide, walls 0.2–0.5 µm thick {1}. **SCBs** in paraphyses and ectal excipulum (near margin) absent {3} or globose {2}, 1–3 µm diam., also crystalloid {3}, hyaline to very pale orange, 1.5–6 µm diam.; **LBs** in basal part of paraphyses golden yellow to orange (carotenoids) {2}, minute or up to 1–1.5 µm diam. **Exudate** over paraphyses 0.5–2 µm thick, cloddy, hyaline, loosely attached, over margin and flanks 0.5–4 µm thick, rough, yellowish-chlorinaceous. — **ANAMORPH**: dwayaangam-like (presumed, from natural substrate {9}). **Conidiophores** unknown. **Conidia** resembling a spider or butterfly, total size *(30–)40–57(–65) × (25–)30–60(–77) {7} or *62–64 × 35–40 µm {1}; stipe *(11.5–)12.5–17(–19.5) × 3–3.7(–4.2) {7} or *25–29 × 5.2–5.4 µm {1}, 2–3-septate; twice dichotomously branched: two arms pointing upwards, two downwards, arms ± tapered, slightly to medium outwards curved, in situ *(12–)17–37(–41) × (2.5–)2.8–3.5(–4.2) {7} or *26–38 × 4.2–4.5 µm {1}, (2–)3–5(–6)-septate, containing some or many minute LBs, sometimes also larger ones with 1–1.5(–2) µm diam.

Habitat: collected 0.3–3 m above the ground, decorticated, also ± corticated, 6–50 mm thick branches, also in a wound of 25 cm thick standing trunk, of *Betula pubescens* {4}, *Clematis vitalba* {1}, *Erica arborea* {1}, *Fagus sylvatica* {3}, *Rhododendron dahuricum* {1}, *Salix* sp. {1}, *S. appendiculata* {1/1}, *S. aurita* {1}, *S. caprea* {1}, *Sorbus aucuparia* {2}, ?*Ulmus minor* {1}, on 0.2 mm deep strongly decayed wood {17}, rarely bark {2}, strongly greyed, sometimes covered by abundant green algae. **Associated**: *Cryptodiscus foveolaris* {1}, *Dacrymyces* sp. {1}, *Durella connivens* {1}, *Echinosphaeria strigosa* {1}, *Hyalorbilia helicospora* {1}, *H. juliae* {1}, *Hypogymnia physodes* {2}, *Hysteropatella elliptica* {1}, *Lecanora* sp. {1}, *Lecophagus vermicola* {1}, *Orbilia cejpii* {1}, *O. eucalypti* {1}, *O. filiformis* {1}, *O. flagellispora* {1}, *O. montigena* {1}, *O. subsphaerospora* {1}, *O. subtrapeziformis* {1}, *O. vinosa* {2}, *Parmelia sulcata* {2}, *Perrotia flammea* {1}, *Physconia distorta* {1}, *Propolis farinosa* {1}, *Sclerococcum* ?*epimyces* {1}, *Usnea* sp. {1}, pleurocarpous moss {1}. **Desiccation tolerance**: fully viable for at least 4 months. **Altitude**: 42–550 m a.s.l. (northern Europe), 1043–1845 m (central and southern Europe), 470 m (central Asia). **Geology**: Cambrian & Silurian shale, lime- & sandstone, Buntsandstein, Lower & Middle Jurassic and Cretaceous marl & limestone, dolomite, Eocene flysch, Pleistocene sand; granite, granodiorite, syenite, migmatite, dolerite, quartzite, gneiss, mica schist, phyllite, amphibolite. **Phenology**: III, VI–X (probably throughout the year, long-lived).

Taxonomic remarks. *Orbilia arachnovinosa* is separated from *O. vinosa* and *O. subvinosa* mainly because of its deviating anamorph and molecular data. Very similar to the mainly orosubmediterranean and mainly conifericolous *O. subvinosa*, the angiosperm-inhabiting, mainly boreal to orotemperate *O. arachnovinosa* tends to deviate from *O. vinosa* in apothecia with a bright orange-red colour and a finely denticulate margin, and in slightly larger ascospores, but these characteristics are too inconsistent to permit clear recognition of the species.

Variation. Apothecial colour was usually bright orange in various shades towards yellow, rose or red. In a population with mainly orange apothecia (Pl. 269: 1b–f), a few were light rose without an orange component (Pl. 269: 1g). In this collection, apart from large dwayaangam-like conidia also trinacrium-like conidia typical of *O. vinosa* were found on the substrate (Pl. 261: 5). Therefore, the light rose apothecia, though also with a crenulate margin and microscopically ± indistinguishable from the orange ones (the right spore in Pl. 269: 1i is from a rose apothecium), might belong to *O. vinosa*.

Despite the predominant orange colour, the presence of yellow-orange LBs was only noted in three collections (H.B. 7838a, 8248a, A.P. 19/31). They were perhaps present in the others too, but certainly in lower amounts. Also crystalloid SCBs were only seen in three collections (H.B. 7838a, 9408b, A.P. 19/31) while absent in others, and their presence is accordingly inconsistent. The length of the glassy processes varied among or sometimes even within the populations between ± absent (Pl.

268: 1d, 3d) and up to 30 µm long (Pl. 269: 2c); consequently the margin varied between smooth (holotype, Pl. 269: 4c–d) and ± distinctly crenulate (Pl. 269: 1c–g, 2a–b, 5b–c). Some variation was also noted in the size of asci, ascospores, and SBs.

In the collection from Norway (on *Betula*, H.B. 9408), apothecia of *O. arachnovinosa* grew intermingled with *O. vinosa* and were recognizable by their deeper colour and crenulate margin. Also Malençon & Llimona (1980: 54) drew attention to the difference in apothecial colour when comparing an supramediterranean collection on *Quercus pyrenaica* bark (with orange-red apothecia and slightly larger asci) with vinaceous apothecia in the literature.

In two collections from Scandinavia (Pl. 269: 2, 5) we were unable to detect conidia, but we have included them because of an intense apothecial colour and presence of marginal teeth in combination with an angiosperm host. Conidia were also not found in a specimen from Altay Republic (on *Rhododendron*) with bright red apothecia and spores of *17.5–20 × 2–2.3 µm, which might belong here, according to a drawing by E.S. Popov (pers. comm., IVV: 13.VIII.2008), in one from Austria (on *Fagus*), with light orange apothecia with prominent marginal teeth (G. Friebes pers. comm.), and in one from Pyrénées (on *Fagus*), in which the spores were unusually narrow (*15.5–16.5 × 1.7–1.9 µm).

Type studies. Based on comparatively large asci, a red apothecial colour, and occurrence in a hemiboreal region on angiosperm wood, it cannot be excluded that *O. rubinella* is conspecific with the present species. Unfortunately, the type sample was not searched for conidia. The spores were only seen inside the asci and here difficult to discern, and perhaps therefore, they are rather small. In any case, the SBs were visible as a transparent region of 3.8–6 × 1.2–1.4 µm (Pl. 268: 3). The apical dome was sometimes also to thicker than illustrated here. We refrained from adopting the name *O. rubinella*, e. g., because the apothecia were rather small and thin, and also the marginal ectal excipulum was comparatively thin.

The type material of *O. rubinella* in H consists of two convolutes which apparently belong to a single collection (on wood of *Quercus*, according to the wood anatomy). This was found to represent a double organism consisting of *O. vinosa* s.l. and the asci of an intrahymenial parasite, *Helicogonium orbiliarum* Baral & G. Marson (Baral 1999: 47). The protologue of *Peziza rubinella* includes elements of both the host (excipulum, paraphyses) and the parasite (asci, globose ascospores, ascoconidia). The taxon was lectotypified on the host element by Baral (l.c.) because the name *rubinella* refers to the colour of the host apothecia (flesh- to almost scarlet-red), hence became a later synonym of *O. vinosa* (s.l.). Nannfeldt (1932: 252) thought that the protologue of *P. rubinella* is erroneous as he happened to study just that part of the collection which contained asci of the *Orbilia* with narrowly fusiform ascospores, but not the globose spores reported by Nylander. Nannfeldt was in error when referring *P. rubinella* to synonymy with *Hyalinia rubella*.

When lectotypifying *P. rubinella*, Baral (1999) did not mention that two convolutes exist. In one of them (P.A. Karsten 3196, ‘ad lign querc.’) two apothecia were examined and found to contain many mature asci of *O. vinosa* s.l., though in one of the two also some immature asci of *Helicogonium* were seen. In the other convolute (labelled XII.1858, Fennia, regio Aboensis, Merimasku) three apothecia were examined and found to contain numerous parasitic asci among the paraphyses (Baral l.c., fig. 22), but no host asci. Also here the host obviously represents the same *Orbilia*. *P. rubinella* is **lectotypified** here on the convolute Karsten 3196, by excluding the sparsely observed immature parasitic asci.

Seaver’s (1951: 157) report of *O. rubinella* from North America (New Hampshire) with subglobose ascospores 2–3 µm diam. deserves reexamination. Possibly the ascospores belong to a small-spored *Orbilia*, but it could also refer to *Helicogonium orbiliarum* which was reported from Utah and Washington (USA) in apothecia of *O. vinosa* (Baral 1999).

Not included collections. In a specimen from Schwarzwald (southern Germany) and in the type of *O. rubinella* from Finland the anamorph was not observed, and in both the glassy processes were either absent or only up to 3 µm long. Since the spores were rather short (*14–16 × 2–2.3 µm in the German sample), we refrained from including them in the description.

Three orotemperate, (sub)alpine samples from Spain and Austria referred to as *O.* aff. *arachnovinosa* (on ?*Calluna*, E. Rubio, IVV: E.R.D. 6754, 7933; on *Rhododendron*, G. Friebes, IVV: 2.VI.2018) are microscopically indistinguishable from *O. subulivinosa*, but DNA data place them close to *O. arachnovinosa*, from which they deviate in distinctly narrower spores of *(14–)16–22 × 1.4–1.8(–2) µm.

Anamorph. The conidia observed in association with *O. arachnovinosa* belong to an undescribed species of the form genus *Dwayaangam* (Pl. 269: 1j, 4f, 6–7). With their outwards curved arms they resemble those of *O. junci* (?series *Vibrioides*) but are much larger due to their rather long and narrow arms with more septa. In addition, the two upper arms are always distantly inserted on very short primary arms, whereas in *O. junci* and in the similar ‘*Dwayaangam cornuta*’ as illustrated by Matsushima (1993) they touch each other more or less (Pl. 13: b–c). *D. cornuta* as described by Descals & Webster (1982) is similar but differs in much fewer septa, the arms being twice as wide, and in a tendency to higher-branched conidia. Pure cultures were not undertaken in any of the included samples of *O. arachnovinosa*, therefore, the connection of these remarkable conidia to the teleomorph could not be established with certainty.

Gönczöl & Révay (2006: fig. 19, as *D. cornuta*) illustrated a conidium which resembles the present ones even in arm width, but the arms show only 2–3-septa, also the 3-septate stipe is much longer and slightly exceeds the basal arms in length. Gönczöl & Révay observed this type of conidia in stemflow from living trees of *Fagus* and *Carpinus* collected by K. Vanký in Tübingen (southern Germany). In a sample from Loire (G.M. 2018-09-13.1) the conidia differ in their considerable length (*62–64 × 35–40 µm) and the extraordinarily long and wide stipe, also the arms are oriented more like a H than an X (IVV: 13.IX.2018). An ascospore isolate of this sample grew very slowly and finally failed to produce a mycelium.

Phylogeny. Sequences of *O. arachnovinosa* were gained from three samples: one from Asturias (on *Erica*, H.B. 10093) and two from southern France (on *Clematis*, G.M. 2015-09-15.8; on *Sorbus*, G.M. 2016-08-14.5), comprising S1506 intron+ITS, the latter two also LSU and the latter SSU. The sequence of *O.* aff. *arachnovinosa* on *Rhododendron*, comprises SSU, ITS, and LSU, and lacks the intron. No DNA data from the type of *O. arachnovinosa* were available. The characteristic conidia were only observed in one of these three samples (on *Sorbus*), and here also different types of trinacrium-like conidia occurred.

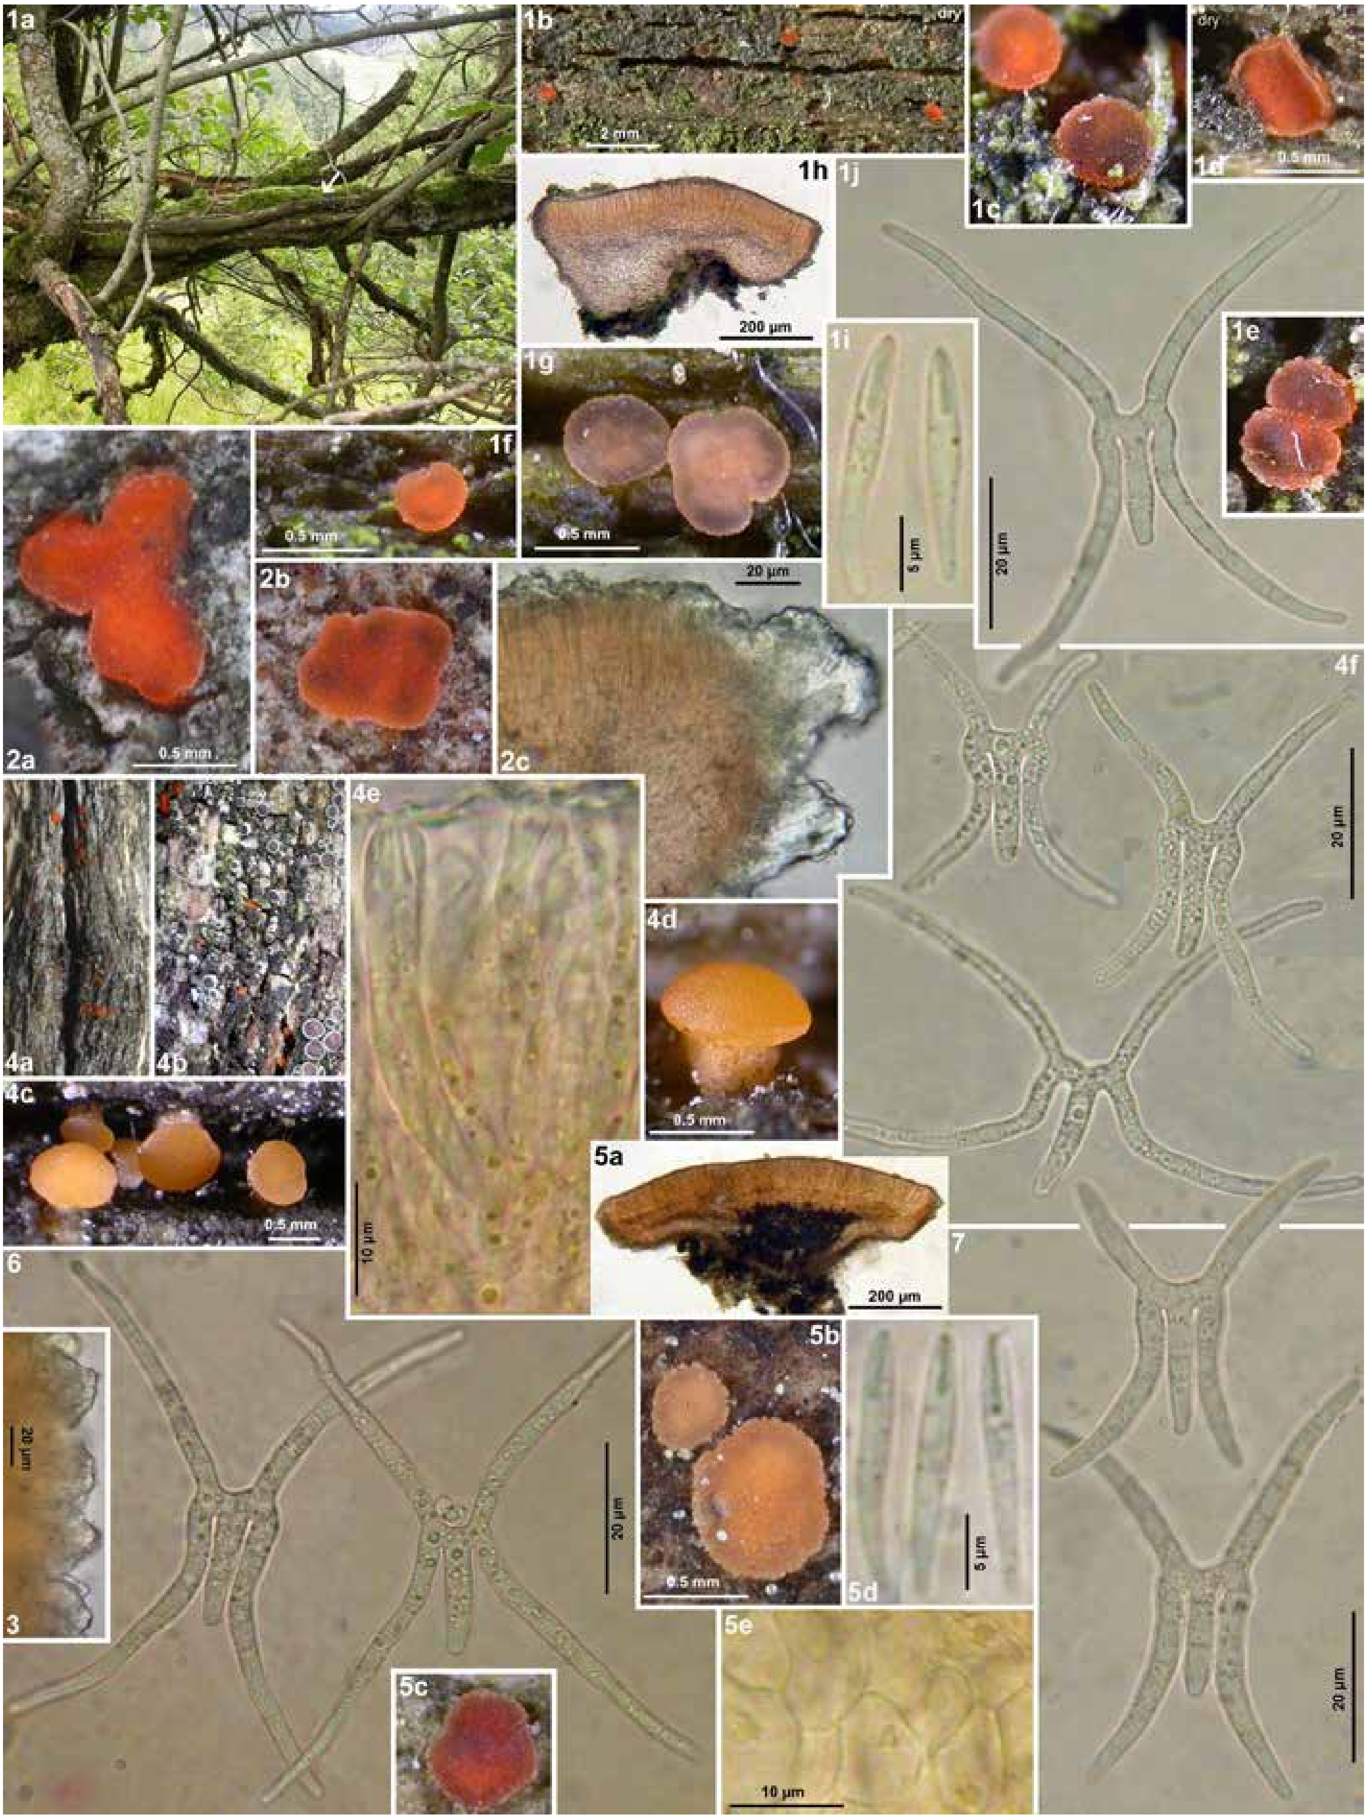

Plate 269. **1–7**: *Orbilia arachnovinosa*. – **1a**. *Salix appendiculata* in a montane pasture, dead mossy branches; **1c**, **e–g**, **2a–b**, **4a–d**, **5b–c**. fresh or rehydrated apothecia (**4b** with *Lecanora* ?*argentata*); **1b**, **d**. dry apothecia; **1h**, **5a**. apothecia in median section; **2c**. id., marginal ectal excipulum with glassy processes forming teeth; **3**. marginal teeth in top view; **5e**. crystalloid SCBs in excipular cells (lower flanks); **4e**. ascus and paraphyses (with yellow-orange LBs); **1i**, **5d**. ascospores; **1j**, **4f**, **6**, **7**. conidia from substrate. – Living state, except for **2c**, ascus in **4e** (in H_2O). — **1a–j**. H.B. 8248a: Switzerland, Luzern, on *Salix*; **2a–c**. H.B. 9360b: Sweden, Lapland, on *Betula*; **3**. H.B. 9375: ibid.; **4a–f**. H.B. 7838a (holotype): Germany, Miesbach, on *Sorbus*; **5a–e**. H.B. 9408: Norway, Gudbrandsdal, on *Betula*; **6**. H.B. 7830a: Germany, Lenggries, on *Salix*; 7. H.B. 9170b: France, Grenoble, on *Salix*.

The two strains from France have identical sequences except for 1 nt in the LSU D3 domain. They differ from the Spanish sample in the ITS1 by 1 nt, in the ITS2 by 2 nt, and in the intron by 1 nt (overlapping 403 nt). Three conspecific environmental sequences, obtained by Menkis et al. (2016) from elm bark beetles in Gotland (Sweden), comprise 5.8S+ITS2 and obviously belong to *O. arachnovinosa*. Only one of them was uploaded in GenBank (KP891980), while the other two are identical except for one of them deviating by 1 gap in the ITS2 and 1 gap in the 5'-end of LSU (A. Menkis pers. comm.). From the two above sequences these differ by 1–2 nt (1.5–2 %) and 0–1 insert in the ITS2. It is just the gap in the ITS2 that is also observed in our two strains.

O. arachnovinosa clustered in the *vinosa-subvinosa* subclade (Phyl. 11), with an ITS distance of 5 % to *O.* aff. *arachnovinosa* (not shown, mentioned under *O. subulivinosa*), 7–7.5 % to *O.* cf. *vinosa* (H.B. 6748g), 7.5–8.5 % to *O. vinosa*, and 8.5–9.5 % to *O. subvinosa*. When separately comparing ITS1 and ITS2, the distances are partly distinctly higher in the ITS2: to *O.* aff. *arachnovinosa* 7.5–8.5/5.7–6.8 %, to *O.* cf. *vinosa* 7–7.5/12.5–13.5 %, to *O. vinosa* 8–10/11–14 %, and to *O. subvinosa* 4.8–5.5/19–21 %. In the intron the distance is 6.5–8 % to *O. vinosa* and 5.5–6 % to *O.* cf. *vinosa* (H.B. 6748g), and in LSU D1–D2 only 0.5 % (3 nt deviation) to *O. subvinosa* compared to 0.8 % to *O.* cf. *vinosa*, 1.4 % to *O.* aff. *arachnovinosa* and 1.7 % to *O. vinosa*.

Ecology. *O. arachnovinosa* was recorded on ± rotten wood of xeric branches of various angiosperms. Records so far mainly derive from *Betula*, *Fagus*, and *Salix*. The species is known from a few orotemperate humid, altimontane to subalpine sites in the northern, eastern, and southern Alps, also from orotemperate to rarely orosubmediterranean Southern French Alps and Cantabrian mountains. Further records are from oroboreal Lapland and supraboreal Norway and from the orotemperate humid western Altay Mts. in central Asia. The environmental sample from cold-temperate southern Sweden (Gotland) was isolated from elm bark beetles, and the fungus probably originated from *Ulmus* bark.

Two not included collections are from montane southern Germany (Schwarzwald) and from hemiboreal southern Finland. *O.* aff. *arachnovinosa* was found in two ± alpine (orotemperate humid) European shrublands: on wood of xeric twigs and thin branches of ?*Calluna* in northern Spain and of *Rhododendron* in eastern Austria.

Map 47. Known distribution of *O. arachnovinosa* in Europe (yellow = not included collections, cyan = *O.* aff. *arachnovinosa*)

Specimens included. **NORWAY**: **Oppland**, Sel, 20 km SE of Dovre, 3 km E of Sel, Gudbrandsdal, E of Fugleskjelle, 370 m, branch of *Betula pubescens*, on wood, 30.VII.2010, H.O. Baral (H.B. 9408b). — **SWEDEN**: **Västerbotten**, Vilhelmina, 4.5 km SW of Saxnäs, Satsfjället, Pojken, 715 m, branches of *B. pubescens*, on wood & bark, 24.VII.2010, H.O. Baral (H.B. 9360b). – 0.5 km SW of Saxnäs, Fjällgarden, 550 m, trunk of *B. pubescens*, on wood, 26.VII.2010, P. Perz & H.O. Baral (H.B. 9368a, anam. substr.). – **Jämtland**, Strömsund, 57 km W of Saxnäs, E of Bjurälven, west-edge of Leipikvattnet, 475 m, branch of *B. pubescens*, on wood, 27.VII.2010, P. Perz (H.B. 9375, anam. substr.). – **Gotland**, 12.5 km S of Visby, 1.9 km N of Hogräns kyrka, 42 m, from adults of *Scolytus multistriatus* (pheromone trap, probably emerging from *Ulmus minor*), VI–VIII.2012–2014 (Menkis et al. 2016, clone 2170_1175 [921_2026 & 419_1868], mol. extr.; sq.: KP891980). — **GERMANY**: **Bayern**, **Oberbayern**, Mangfallgebirge, 16.5 km SSE of Miesbach, 2.7 km ESE of Spitzingsee, Taubenstein, 1600 m, branch of *Sorbus aucuparia*, on wood, 3.VII.2005, P. Karasch (ex H.B. 7838a, M-0281049, **holotype**, anam. substr.; MAMU 453, **isotype**). – Kocheler Berge, 6.5 km WSW of Lenggries, NW of Latschenkopfhütte, S of Vorderer Kirchstein, 1600 m, branch of *Salix caprea*, on wood, 21.VI.2005, P. Karasch & B. Fellmann (H.B. 7830a ø, anam. substr.). — **SWITZERLAND**: **Nidwalden**, 8.2 km SSW of Luzern, 3.2 km W of Hergiswil, N of Bergstation Gschwänd, 1200 m, branches of *S. appendiculata*, on wood, 18.VIII.2006, H.O. Baral (H.B. 8248a, anam. substr.). — **AUSTRIA**: **Steiermark**, 11 km NW of Deutschlandsberg, 3 km W of Rachling, E of Rosenkogel, 1150 m, branch of *Fagus sylvatica*, on wood, 24.III.2012, G. Friebes (ø, doc. vid.). — **ITALY**: **Trentino-Alto Adigo**, **Bolzano**, 3 km SSE of St. Magdalena, NNE of Seceda, 1845 m, branch of *Salix*, on wood & bark, 1.VIII.2019, A. Orbilia nothovinosa Baral, **sp. nov.**, MB 813562
— Pls 270–271, Map 48

Etymology: the epithet means 'false *O. vinosa*'.

Typification: Western Australia, Mandurah, branches of *Nuytsia floribunda*, 17.XII.2001, G. Marson (ex H.B. 7087a, MEL 2389217, holotype).

Latin diagnosis: *Similis* Orbiliae vinosae *sed asci apice in statu emortuo multo magis crassitunicati, ascosporae paulo breviores. Habitat ad lignum vel corticem putridum ramulorum vel ramorum siccorum fruticum vel arborum angiospermarum* (Fabales, Myrtales), *in zona subtropica, raro temperata semi- vel (sub)humida Australiae meridio-occidentalis et orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.8(–1.1) mm diam., 0.08–0.19 mm high, pale to bright orange, orange-rose or rose, slightly to strongly translucent, round to elongate, scattered to ± gregarious, margin even to lobate; disc slightly concave to mostly flat, margin distinct, 0–10 µm protruding, smooth; sessile or with a very indistinct broad stipe 0.04–0.05 × 0.14–0.15 mm, superficial or ± immersed in clefts; dry light to bright rose- or apricot-red. **Asci** *(36–)40–50(–56) × (5.5–)5.8–6.3 µm {3}, †30–42 × (5–)5.5–6 µm {2}, 8-spored, spores *4-seriate, 3–4 lower spores inverted {3} (not mixed); **apex** (†) hemispherical, dome †(1.8–)2–2.5(–3.5) → 1–2.2 µm thick {5} (in H_2O, in KOH not thicker), sometimes with apical chamber, inner part pale reddish in IKI (dextrinoid); **base** with short to long, medium thick, flexuous stalk, L-shaped. **Ascospores** *(10–)11–15(–16.5) × (1.7–)1.8–2.1(–2.2) µm {4}, †10–14(–15) × (1.5–)1.7–2 µm {3}, narrowly cylindric-clavate to slightly fusoid-clavate, apex obtuse, sometimes rounded, base slightly to strongly attenuated, sometimes tail-like, straight to often slightly (rarely medium) curved; **SBs** 3–4.5(–5) × (0.6–)0.8–1(–1.2) µm {5}, rod-shaped to slightly ampulliform or dumbbell-shaped, apically narrowed to a small or sometimes wide point, straight (rarely somewhat flexuous), overmature *2–3.2 × 0.8–1.2(–1.5) µm. **Paraphyses** apically uninflated to slightly (rarely medium) clavate, terminal cells *9–16 × 2.3–3 µm {2}, lower cells *(5–)9–11 × 2.3–3 µm {2}; sometimes branched at upper septum. **Medullary excipulum** subhyaline to light rose or orange, 20–25 µm thick, of medium dense textura intricata with sparse or many inflated cells, indistinctly to medium sharply delimited (mainly towards margin). **Ectal excipulum** of (†) thin- to slightly thick-walled, irregularly oriented t. globulosa-angularis(-prismatica) at base and flanks, 25–80 µm thick near base, cells *6–20 × 6–12 µm {2}, †7–12 × 6–7 µm {2}; 10–25 µm thick at mid flanks and margin, at least at margin of t. prismatica-porrecta oriented at a 30–60° angle to the surface, marginal cortical cells *10–15 × 3–4 µm {1}; **glassy processes** absent {4} or present {2}, 3–4(–10) × 4–5 µm. **Anchoring hyphae** abundant, †1.5–2.5(–3.5) µm wide, walls 0.2(–0.4) µm thick {1}, forming a 5–10 µm thick layer on substrate. **SCBs** globose, in paraphyses 1.2–2 µm diam., in ectal excipulum (near margin) 2–4 µm. Yellow-orange **LBs** (carotenoids) absent or present in cells of lower part of paraphyses and in marginal excipular cells. **Exudate** over paraphyses 1.5–4 µm thick, cloddy, rough, loosely attached, subhyaline to light yellow-chlorinaceous, over margin and flanks (2–)4–6 µm thick. — **ANAMORPH**: unknown.

Habitat: collected 0.5–3 m above the ground, corticated to almost decorticated, 3–10(–50) mm thick twigs and branches of *Acacia* sp. {3}, *Eucalyptus* sp. {1}, *Jacksonia* sp. {1}, *Melaleuca* sp. {1}, *Nuytsia floribunda* {1}, on 0.2–0.5 mm deep medium to strongly decayed wood {5} and bark (periderm & bast) {5}, sometimes on inner surface of detached bark, on petioles of *Macrozamia riedlei* {1}, ± greyed, sometimes covered by abundant green algae. **Associated**: *Amandinea* sp. {1}, *Claussenomyces* sp. {2}, *Durella* sp. {1}, *D.* aff. *connivens* {1}, *Frullania* sp. {1}, *Gloniopsis* aff. *praelonga* {1}, *G. praelonga* {2}, *Orbilia acaciae* {1}, *O. albidorosea* {1}, *O. amberina* {1}, *O. australiensis* {3/1}, *O. austroobtusispora* {2}, *O. aviceps* {1}, *O. aviflagellata* {1}, *O. cejpii* {1}, *O. curvativitalbae* {1}, *O. eucalypti* {2}, *O. helicoobliqua* {1}, *O. hesperidea* {1}, *O. kingsiana* {1}, *O. macrotrapeziformis* {1}, *O. microserpens* {3}, *O. multiserpens* {1}, *O. myriofusiclava* {2}, *O. myriolilacina* {1}, *O. myrioobliqua* {4}, *O. paraobliqua* {1}, *O. pleioaustraliensis* {1}, *O. pleioaustrocylindrica* {1}, *Ostropales* {1}, *Patellaria* ?*andina* {1}, *Proliferodiscus griseoviolaceus* {1}, ?*Triblidium* sp. {1}. **Desiccation tolerance**: fully viable for at least 25 months. **Altitude**: 11–380 m a.s.l. (western Australia), 278–1073 m (eastern Australia). **Geology**: Archean, Permian, Triassic & Cretaceous sedimentary rock, Cenozoic regolith; granite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia nothovinosa* is segregated from the very similar European and North American *O. vinosa* based on the height of ascus apical dome, being distinctly above the range of *O. vinosa*, and because of slightly shorter spores on average. Comparatively large globose SCBs were noted in those specimens studied in the living state, whereas crystalloid SCBs could not be observed, though such were frequently seen in *O. vinosa*. The Australian *O. astrovinosa* has apical domes comparable to *O. vinosa*, narrower spores and SBs, and usually very long marginal teeth. *O. nothoaprilis* differs in shorter spores and much thinner apical domes, also in the presence of crystalloid SCBs.

Beaton & Weste (1979) reported *O. vinosa* from Victoria (Australia), but did not supply collection data or a description, and no Australian specimen of *O. vinosa* can be found in the Kew Herbarium (B. Spooner pers. comm.).

Variation. Macroscopically, the collections on *Nuytsia* and *Melaleuca* differ from the others in their orange colour and often somewhat larger size, but the microscopical features were comparatively consistent in all seven specimens studied. However, in the sparse, unpreserved specimen from Queensland

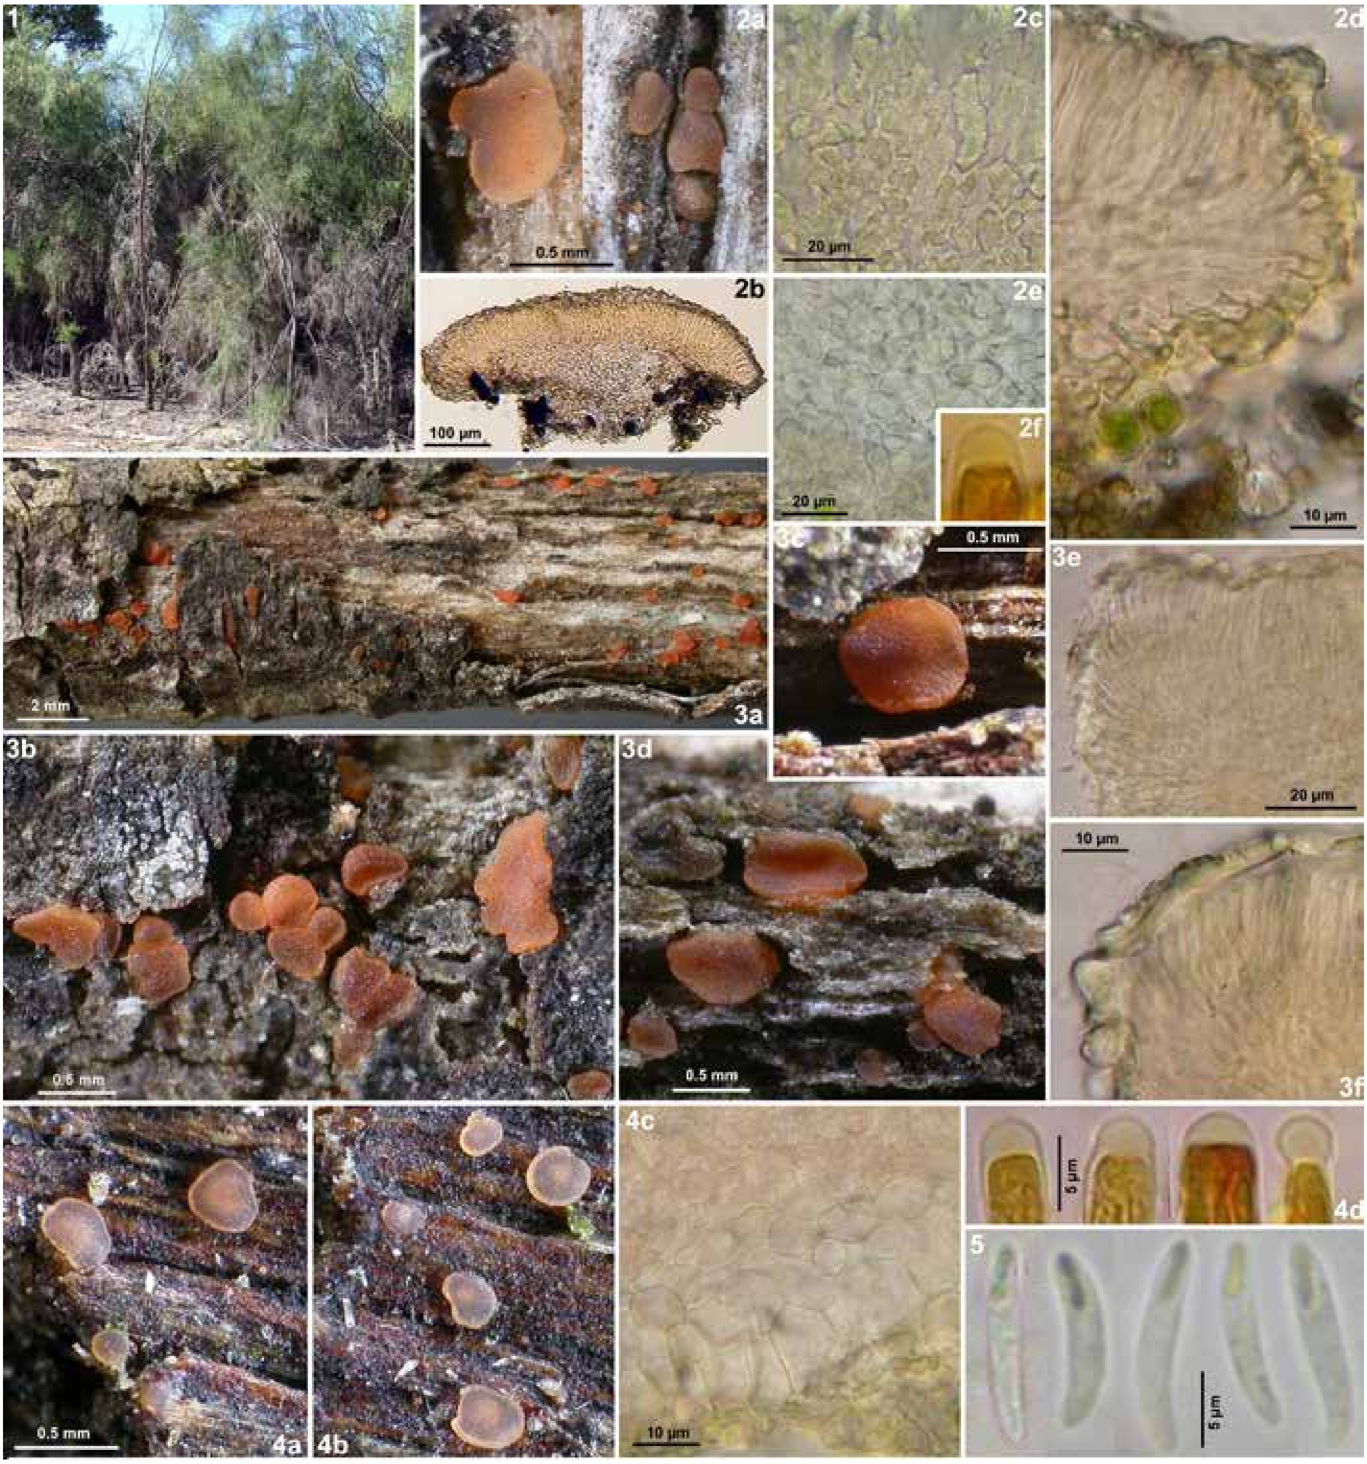

Plate 271. **1–5**: *Orbilia nothovinosa*. – **1**. semihumid Eucalypt open woodland with predominant *Jacksonia*; **2a**, **3a–d**, **4a–b**. rehydrated apothecia; **2b**. apothecium in median section; **2d**, **3e–f**. id., marginal ectal excipulum; **4c**. id., basal ectal excipulum; **2e**. id., medullary excipulum (of loose t. globulosa); **2c**. exudate on margin (external view); **2f**, **4d**. ascus apices; **5**. ascospores. – Living state: **4c**, **5**; dead state: **2c**, **e** (H_2O); **2b**, **d**, **3e–f** (in KOH); **2f**, **4d** (in IKI). — **1**. H.B. 7284b: Western Australia, Perth, on *Jacksonia*; **2a–f**. H.B. 7204r: ibid., Mt. Singleton, on *Acacia*; **3a–f**. H.B. 7087a (holotype): ibid., Perth, on *Nuytsia*; **4a–d**. H.B. 8478c: ibid., on *Acacia*; **5**. 3.IX.2006: Bindoon, on *Macrozamia*.

(on *Melaleuca*) the apical dome was only sketchily documented as about †1 µm thick, and it remains unclear whether it exceeded 2 µm in immature asci; also in that on *Macrozamia* the ascus apex was not examined. The very abundant type collection on *Nuytsia* showed the largest apothecia and, in contrast to the other samples, no associated further species of *Orbilia* could be discovered on the branches. *O. nothovinosa* varies in the glassy processes at the margin, which were found to be frequently absent, but at least in two collections present in some apothecia though rather short: in the holotype they were once seen but in all later examined apothecia they were absent, and in H.B. 7204r they were at least partly present.

Not included collections. A single apothecium on *Banksia* (2.IX.2006, unillustrated) differed in slightly shorter spores (*9.5–13.5 × 2–2.2 µm) and thinner domes (†1.5–2.2 µm). It is somewhat intermediate to *O. nothoaprilis* and, therefore, not included in either description. A similar size of spores (†8.5–12.5 × 1.8 µm) and apical domes (†1.4–1.8 µm) was noted in a sparse specimen on *Acacia*, which was only studied in the dead state (IVV: H.B. 8954c).

Map 48. Known distribution of *O. nothovinosa* in Australia (yellow = not included collections).

Ecology. *O. nothovinosa* occurs on ± rotten wood and bark of xeric twigs and branches of angiosperm trees and shrubs (*Myrtaceae*, *Fabaceae*, *Loranthaceae*) and leaves of *Cycadatae* in subtropical semihumid banksia-eucalypt woodlands (mallee) of southwestern Australia (Darling Range and Plateau) and subtropical subhumid to warm-temperate humid eucalypt open woodlands and forests in eastern and southeastern Australia (Great Dividing Range).

Specimens included. **AUSTRALIA**: **Western Australia**, Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, twig of *Acacia*, on wood, 24.XI.2001, G. Marson (H.B. 7204r). – Swan Coastal Plain, 15 km SE of Mandurah, SW of Pinjarra Road, NE of Sir Ross McLarty Park, 11 m, branches of *Nuytsia floribunda*, on wood & bark, 17.XII.2001, G. Marson (ex H.B. 7087a, MEL 2389217, **holotype**). – 30 km NE of Perth, 4 km N of Upper Swan, W of Walyunga, 37 m, twig & branch of *Jacksonia*, on wood & bark, 23.XI.2001, G. Marson (H.B. 7284b). – ibid., 76 m, branch of *Acacia*, on bark, 2.IX.2006, G. Marson (H.B. 8478c). – Jarrah Forest, 25 km NNE of Bindoon, 12 km ESE of Wannamal, 272 m, leaves of *Macrozamia riedlei*, on petioles, 3.IX.2006, G. Marson (ø). – **Queensland**, Brigalow Belt South, 80 km N of Goondiwindi, 10 km S of Moonie, 278 m, branch of *Melaleuca*, on wood, 23.X.1998, G. Marson (H.B. 6823e ø). – **New South Wales**, Sydney Basin, 95 km WNW of Sydney, 11.5 km SE of Lithgow, 1.6 km SE of Mt. York, 1073 m, branch of *Eucalyptus*, on bark & wood, 26.X.1998, G. Marson (ø).

Not included. **AUSTRALIA**: **Western Australia**, Swan Valley, 30 km NE of Perth, 4 km NE of Upper Swan, W of Walyunga, 76 m, branch of *Banksia cuneata*, on wood, 2.IX.2006, G. Marson (ø). – Geraldton Sandplains, 20 km SE of Jurien Bay, 18 km NE of Cervantes, Cervantes Rd, 65 m, branch of *Acacia*, on bark, 11.XI.2007, G. Marson (H.B. 8954c ø).

Orbilia astrovinosa Baral & G. Marson, **sp. nov.**, MB 813574 — Pls 272–273

Etymology: closely related to *O. vinosa* but with long marginal teeth that resemble sun rays.

Typification: Western Australia, Cervantes, inflorescence stems of *Xanthorrhoea preissii*, 11.XII.2001, G. Marson (ex H.B. 7192a, MEL 2389219, holotype).

Latin diagnosis: *Similis* Orbiliae vinosae *sed excipulum marginale processis vitreis perlongis praeditum, dentes magnos formantibus, ascosporae paulo minores, corpusculum refringentem vermiformem ad subulatum, partim flexuosum continentes. Habitat ad corticem putridum ramorum siccorum* Proteacearum, *ad caules putridos inflorescentiae* Xanthorrhoeae, *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.55 mm diam. (0.3–0.7 mm incl. teeth), (0.1–)0.12–0.17(–0.2) mm high, pale to bright rose (also orange-ochraceous), slightly translucent, ± round, scattered; disc flat, margin distinct, 0–5 µm protruding (up to 200 µm incl. teeth), with short to usually very long whitish teeth (40–)80–140(–200) × (20–)60–120(–160) µm; broadly sessile, ± superficial; dry with bright (brick-)orange to orange-rose disc, teeth sometimes strongly incurved. **Asci** *(40–)49–55(–65) × 5.2–5.7 µm {2}, †40–47 × 4.3–4.6 {1} or 50–65 × 4.7–5.7 µm {T}, 8-spored, spores *3–4-seriate, 3–4 lower spores inverted {2} (not mixed), pars sporifera *23–30 µm long; **apex** (†) hemispherical, dome †0.8–1 → 0.5 µm {1} or 1.2–1.6 → 0.7–1 µm {T} thick, with or without minute apical chamber; **base** with short to very long, thin or thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(10.5–)12–14.5(–15.5) × (1.5–)1.6–1.8 µm {3}, †12.5–13(–15) × 1.5–1.7(–1.9) µm {2}, narrowly subcylindric-clavate to fusoid, apex (rounded to) obtuse, base medium (rarely strongly) attenuated, straight to slightly inequilateral; **SBs** *4–6 × 0.3–0.5 µm {3}, vermiform to subulate, apically narrowed to a small to wide point, straight to slightly flexuous. **Paraphyses** apically slightly to medium clavate-capitate, rarely spathulate, terminal cells *10–15(–19) × 2.3–3.5(–4.3) µm {2}, †1.8–3 µm wide {T}, lower cells *5–13 × 1.5–2.2 µm {2}; unbranched at upper septum, hymenium and subhymenium pale rose-orange. **Medullary excipulum** hyaline, 30–100 µm thick, of loose or dense textura intricata with many inflated cells, also of t. globulosa, medium sharply delimited. **Ectal excipulum** very pale orange, of (†) slightly to medium gelatinized, vertically oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 20–50 µm thick near base, cells *10–21 × 8–14 µm {1}, †8–13 × 7–10 µm {T}; 15 µm thick near margin, inner part of t. prismatica-angularis oriented at a 70–80° angle to the surface, outer part from lower flanks up to margin of t. porrecta oriented at 20–40°, marginal cortical cells *(5–)8–13 × 2–4 µm {1}, †8–10 × 2–2.5 µm {T}; **glassy processes** 30–60 or 40–140(–200) × 2–3.3(–3.7) µm {2} (sometimes nearly absent), high-refractive, not stratified or very sparsely so, uniformly straight to distinctly inwards curved, coherent to form very compact teeth. **Anchoring hyphae** ± abundant, */†2–3.5 µm wide, walls 0.2–0.5(–1) µm thick {2}. **SCBs** in paraphyses globose (to ellipsoid), 1.3–3.3 µm diam., in marginal excipulum 1.5–2.5 µm. **Exudate** over paraphyses (0.5–)1–2 µm thick, cloddy-continuous, pale yellowish, loosely attached, over glassy processes absent. **— ANAMORPH**: unknown.

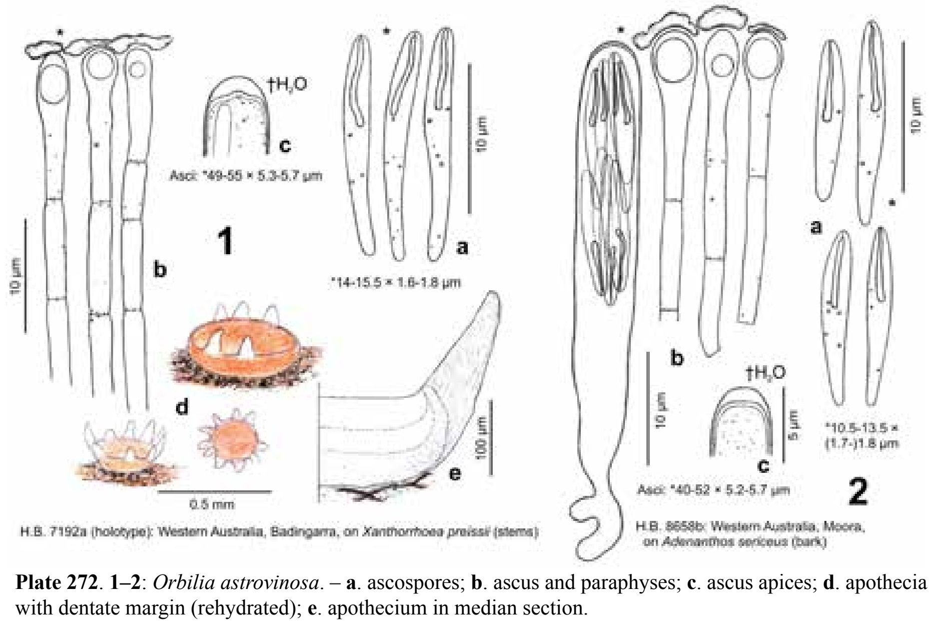

Plate 272. **1–2**: *Orbilia astrovinosa*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecia with dentate margin (rehydrated); **e**. apothecium in median section.

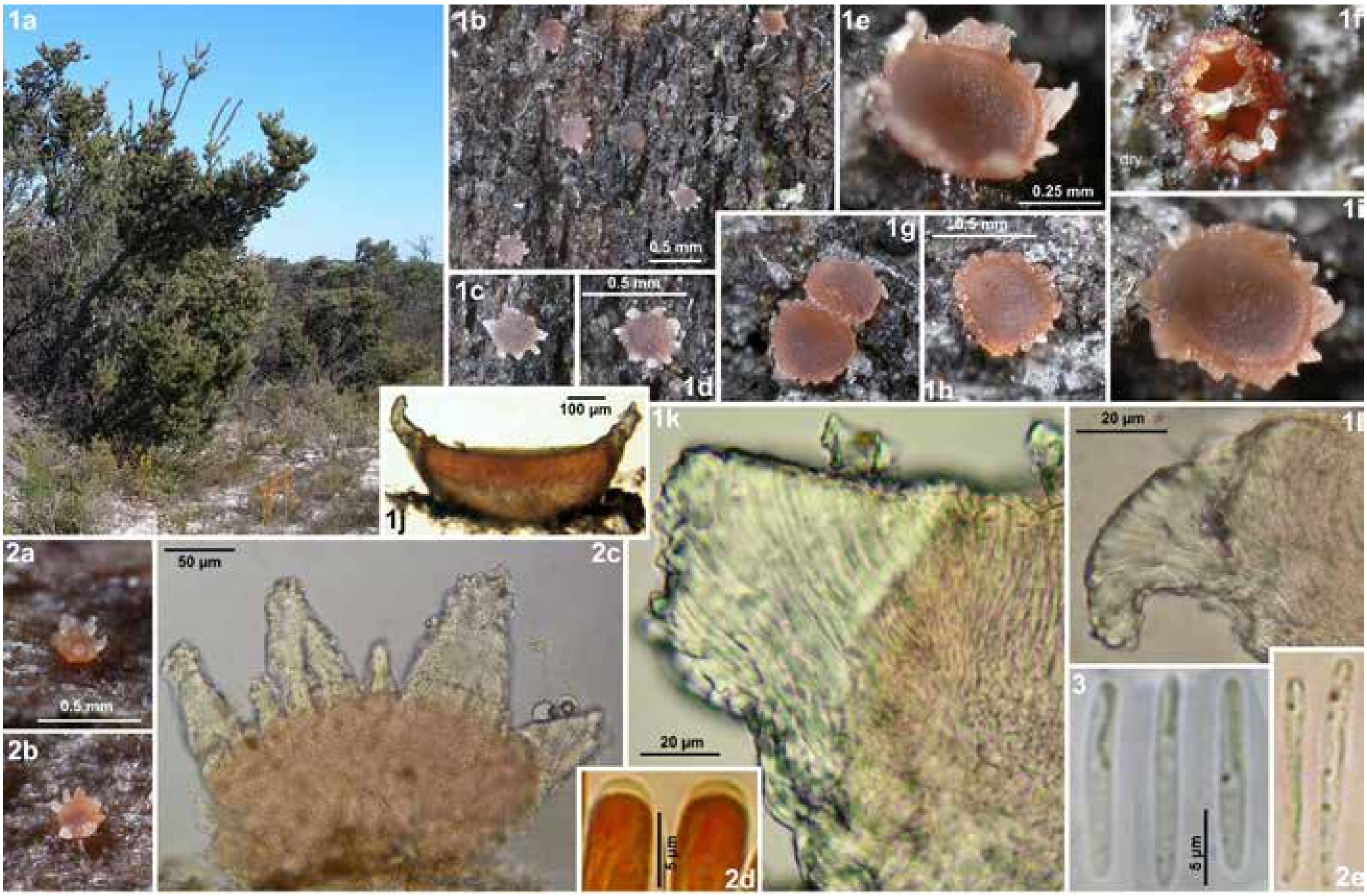

Plate 273. **1–3**: *Orbilia astrovinosa*. – **1a**. semihumid banksia-eucalypt woodland with *Adenanthos*; **1b–e**, **g–i**, **2a–b**. rehydrated apothecia; **1f**. dry apothecia; **2c**. apothecium in top view (squash mount); **1j**. apothecium in median section; **1k–l**. id., marginal ectal excipulum with teeth of conglutinated glassy processes; **2d**. ascus apices; **2e**, **3**. ascospores. – Living state, except for **2d** (in KOH+IKI), **2e** (in H_2O). — **1a–l**. H.B. 8658b: Western Australia, Moora, on *Adenanthos*; **2a–e**. H.B. 7192a (holotype): ibid., Badingarra, on *Xanthorrhoea*; **3**. 7.IX.2006: ibid., Perth, on *Banksia*.

Habitat: collected 1–2 m above the ground, corticated to decorticated, 5–21 mm thick twigs and branches of *Adenanthos sericeus* {1}, *Banksia grandis* {1}, on strongly decayed bark {2} (bast & periderm), bark partially detached, on outer surface; on woody, decorticated inflorescence stems of *Xanthorrhoea preissii* {1}, greyed, no algae. **Associated**: *Gloniopsis praelonga* {1}, *Mellitiosporiella* sp. {1}, *Orbilia austrocylindrica* {1}, *O. eucalypti* {1}. **Desiccation tolerance**: fully viable for at least 8.5 months, many mature asci still viable after 13.5 months. **Altitude**: 48–92 m a.s.l. **Geology**: Triassic to Cretaceous sedimentary rock, Cenozoic regolith (whitish sandy soil). **Phenology**: long-lived.

Taxonomic remarks. Apart from the large teeth, *O. astrovinosa* closely resembles European *O. vinosa*. Since large teeth have never been seen in European collections of *O. vinosa*, we prefer to assign the present specimens to a distinct species. A further characteristic that permits distinction from *O. vinosa* is seen in the somewhat shorter and narrower ascospores containing vermiform, slightly flexuous SBs. The triangular teeth are formed by glassy processes which all end up at about the same level by gradually decreasing in length from mid flanks to upper margin.

Variation. The rather abundant type collection mainly consists of apothecia with very short teeth or a nearly smooth margin, while only some possessed large teeth (Pl. 272: 1). However, the teeth easily break near their base, therefore, especially the older apothecia have evidently lost some or all of them. Whether those nearly smooth apothecia always have lost their large teeth is not certain. Apothecia with long teeth are predominant in the collections on bark of *Adenanthos* and *Banksia.* These differ from the type merely in slightly shorter spores.

Ecology. **–** *O. astrovinosa* was collected on wood of xeric inflorescence stems of the grass tree *Xanthorrhoea* and on bark of xeric twigs and branches of different *Proteaceae* in subtropical semihumid banksia-eucalypt open wood- and shrublands on sand dunes of southwestern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Geraldton Sandplains, 23 km SE of Jurien Bay, 19 km NE of Cervantes, Munbinea Road, 92 m, inflorescence stem of *Xanthorrhoea preissii*, 11.XII.2001, G. Marson (ex H.B. 7192a, MEL 2389219, **holotype**). – Swan Coastal Plain, 59 km SW of Moora, 8 km NE of Cowalla, Moore River, Orange Springs Rd, 77 m, branch of *Adenanthos sericeus*, on bark, 5.IX.2006, G. Marson (H.B. 8658b). – Perth, Kings Park, 48 m, branch of *Banksia grandis*, on bark, 7.IX.2006, G. Marson (ø).

Orbilia helicovinosa Baral, **sp**. **nov**., MB 813586 — Pls 274–275

Etymology: named after the helicoid ascospores and the similarity to *O. vinosa*. **Typification**: Western Australia, Toolonga, branch of *Acacia*, 8.XI.2007, G. Marson (ex H.B. 9050b, MEL 2389278B, holotype).

Latin diagnosis: *Similis* Orbiliae vinosae *sed ascosporae distincte helicoideae in statu vivo, corpuscula refringentia breviora, apothecia hydratata roseo-lilacina. Habitat ad corticem putridum truncorum siccorum* Acaciae *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.22–0.5 mm diam., 0.13–0.16 mm high, light rose- to cream-lilaceous, hardly translucent, round to somewhat lobate, scattered to subgregarious; disc flat, margin distinct, 3–10 µm protruding, smooth; sessile, slightly to strongly immersed in cracks or wood fibres; dry bright cream-orange to orange-red, slightly contracted. **Asci** *37–57 × 5.5–6.4 µm, †34–46 × 4.7–5(–5.3) µm, 8-spored, spores *8-seriate in a bundle, ~4 lower spores inverted, pars sporifera *19–23 µm long;

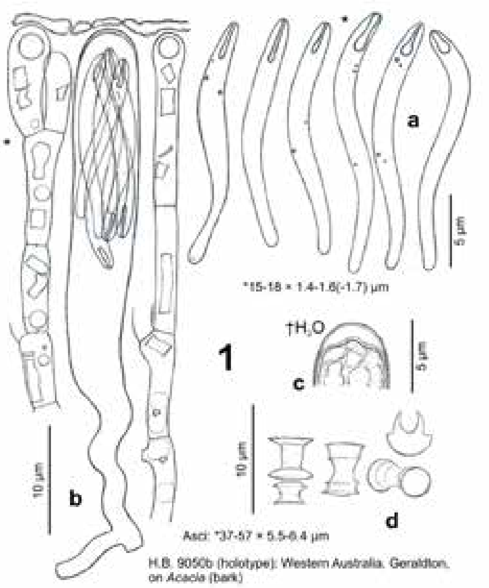

Plate 274. **1**: *Orbilia helicovinosa*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. crystalloid SCBs in ectal excipular cells.

apex (†) hemispherical, dome in KOH 1–1.4 → 0.8–1.2 µm thick, with or without small apical chamber; **base** with short to long, ± thin, flexuous stalk, L- or T-shaped. **Ascospores** *15–18 × 1.4–1.6(–1.7) µm, †(12–)14–16.5(–18) × 1.3–1.6 µm, cylindrical to narrowly subfusoid-clavate, apex obtuse to almost rounded, base not or usually slightly (rarely medium) attenuated, medium curved (helicoid, like a left-hand thread), (†) almost straight to distinctly falcate or helicoid; **SBs** *2.5–3 × 0.3–0.7 µm, vermiform to subulate or elongate tear-shaped, apically narrowed to a small or wide point, straight, overmature *1.5–2 × 1 µm. **Paraphyses** apically uninflated to slightly or medium (rarely strongly) clavate(-capitate), sometimes moniliform, terminal cells *(7–)10–16(–20) × (2–)2.5–3.8(–4.5) µm, lower cells *7–11.5 × 2–2.5(–3) µm; rarely branched at upper septum, hymenium very pale rose-lilaceous. **Medullary excipulum** hyaline to very pale rose-lilaceous, 20–40 µm thick, of dense textura intricata with many inflated cells, medium to sharply delimited. **Ectal excipulum** ± hyaline, of (†) not or slightly gelatinized, indistinctly vertically oriented t. globulosa(-prismatica) from base to mid flanks, 60–90 µm thick near base, cells *(8–)10–20(–23) × (7–)10–14(–17) µm; 20–30 µm thick near margin, inner part of t. prismatica oriented at a 60–80° angle to the surface, outer part of t. porrecta oriented at 20–40°, marginal cortical cells *6–11.5 × (2.5–)3–4(–4.5) µm; **glassy processes** absent. **Anchoring hyphae** ± abundant, *2–3.2 µm wide, walls 0.2–0.3 µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.5–3.5 µm diam., and very distinct (low- to high-refractive) crystalloid SCBs, hyaline to very pale rose. **Exudate** over paraphyses 1–1.5(–2.5) µm thick, cloddy, hyaline, loosely attached, over margin and flanks 1.5–3 µm thick, rough-cloddy. — **ANAMORPH**: unknown (but see below).

Habitat: collected 0.5–1.5 m above the ground, corticated, ~5–6 cm thick trunk of *Acacia* sp., on exterior of detached, strongly decayed bark (bast), slightly to strongly greyed, no algae. **Associated**: *Orbilia anguliobliqua*, *O. angustoobliqua*, *O.* ?*atriplicis*, *O. myriella*, *O.* ?*saguarina*, ?*Triblidium* sp. **Desiccation tolerance**: fully viable for at least 18 months. **Altitude**: 190 m a.s.l. **Geology**: Cretaceous sedimentary rock (red-brown sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia helicovinosa* resembles a North American collection mentioned under *O. vinosa* (on wood of *Arctostaphylos*, Pl. 259: 4) in the narrow ascospores with short SBs; it differs in a distinctly helicoid spore shape, the abundant presence of crystalloid SCBs, and in the colour of the hydrated apothecia (rose-lilaceous).

Anamorph. Some dwayaangam-like conidia were found on the substrate in the type collection near apothecia of both *O. helicovinosa* (IVV: H.B. 9050b) and the associated *O. angustoobliqua*, resembling those of *O. subvinosa* but with longer stipes [in total */†33–42 µm high, stipe 18–24 × 4–4.5 µm, 4–5-septate, arms 6–18 × 3.5–4 µm, (1–)2–4-septate].

Ecology. *O. helicovinosa* was found on rotten xeric bark detaching from the main trunk of a ~3 m tall *Acacia* tree in a subtropical semiarid acacia open shrubland of western Australia (Yalgoo ecoregion).

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, branch of *Acacia*, on bark, 8.XI.2007, G. Marson (ex H.B. 9050b, MEL 2389278B, **holotype**).

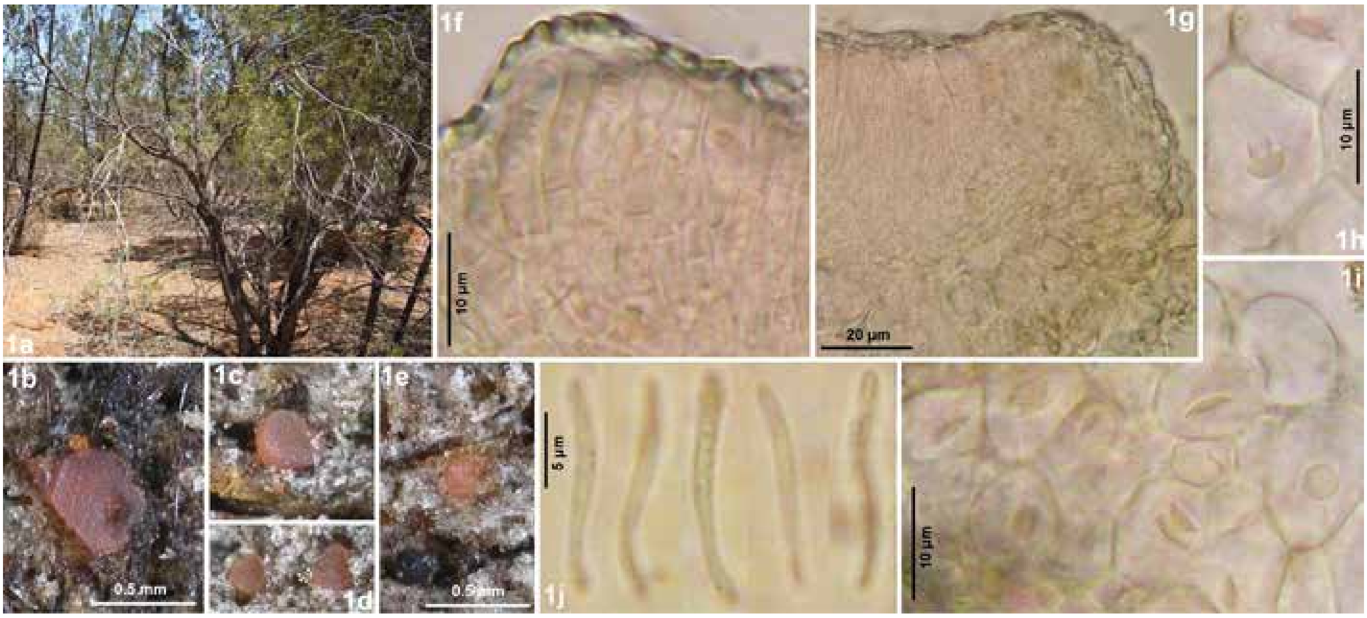

Plate 275. **1**: *Orbilia helicovinosa*. – **1a**. semiarid acacia shrubland; **1b–e**. rehydrated apothecia; **1f–g**. marginal ectal excipulum in median section; **1h–i**. crystalloid SCBs in excipular cells (mid flanks); **1j**. ascospores. – Living state, except for **1j** (in KOH). — **1a–i**. H.B. 9050b (holotype): Western Australia, Yalgoo, on *Acacia*.

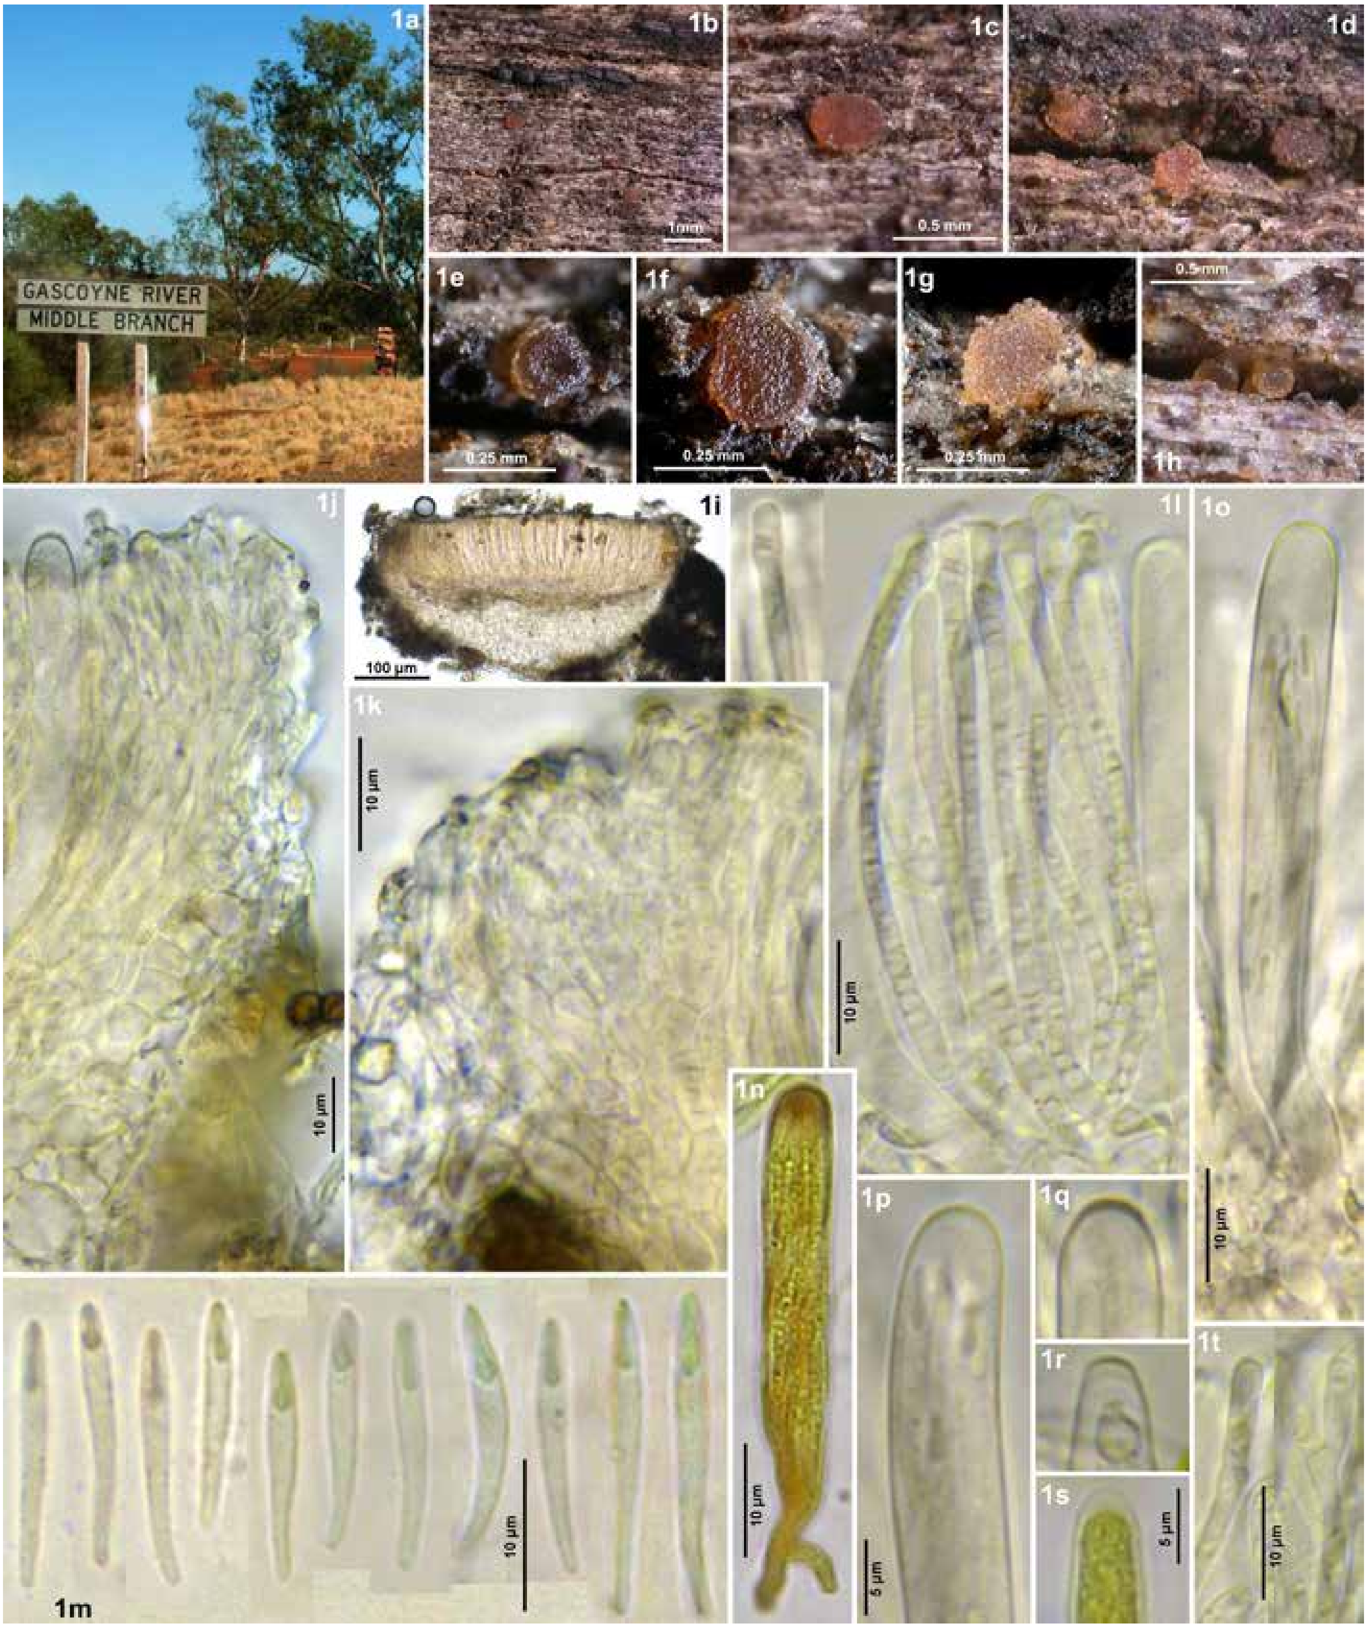

Plate 276. **1**: *Orbilia pleiovinosa*. – **1a**. bridge over Gascoyne river, arid acacia open woodland with *Eucalyptus*; **1b–h**. rehydrated apothecia; **1i**. apothecium in median section; **1j–k**. id., marginal ectal excipulum (**1k** with crystalloid SCBs); **1l**, **t**. paraphyses (with crystalloid SCBs); **1n–o**. mature asci; **1p–s**. ascus apices; **1m**. ascospores. – Living state, except for **1n**, **r–s** (**1r** in H_2O, **1n**, **s** in IKI). — **1a–t**. H.B. 9695a (holotype): Western Australia, Gascoyne, on *Acacia*.

Orbilia pleiovinosa Baral & G. Marson, **sp. nov.**, MB 813595 — Pl. 276

Etymology: named after the 16-spored asci and the similarity to *O. vinosa*.
Typification: Western Australia, Kumarina Roadhouse, branch of *Acacia cyperophylla*, 28.X.2007, G. Marson (ex H.B. 9695a, MEL 2389279B, holotype).

Latin diagnosis: *Similis* Orbiliae vinosae *sed asci 16-spori, apothecia minora. Habitat ad lignum putridum ramuli sicci* Acaciae *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.17–0.36(–0.4) mm diam., 0.15–0.22 mm high, light to bright dirty orange-red, non-translucent, round, scattered or in small groups; disc flat, margin indistinct, 0–10 µm protruding, smooth or indistinctly rough to crenulated and whitish; broadly sessile, slightly immersed; dry strongly contracted and almost invisible. **Asci** *(67–)70–85(–90) × (6.2–)6.7–7.5(–8) µm, †(47–)55–65 × 5.7–6.2 µm, 16-spored, spores *~5–6-biseriate, 7–9 of lower spores inverted (mixed in middle part), pars sporifera *41–52 µm long; **apex** (†) hemispherical, dome †1.2–1.5(–1.8) → 0.7–1 µm thick, without apical chamber; **base** with short to medium long, thick, flexuous stalk, L- to h-shaped. **Ascospores** *(11.5–)13–19(–21.5) × (1.6–)1.7–2 µm, †(12–)14–17(–19) × 1.5–1.8(–2) µm, narrowly fusoid-clavate, apex obtuse to subacute, base gradually attenuated, straight to sometimes slightly curved near base; **SBs** *3–5 × 0.7–1.3 µm, rod-shaped or often dumbbell-shaped, with a narrower middle part and a ± strongly inflated globose base, apically narrowed to a wide point, straight. **Paraphyses** apically uninflated to slightly clavate-capitate or spathulate to moniliform, terminal cells *5–15(–20) × 1.8–3.5 µm, lower cells *8–14 × 1.7–2.3(–3) µm; unbranched or frequently branched at upper septum. **Medullary excipulum** pale rose-orange, 20–60 µm thick, of dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** subhyaline, of (†) thin-walled, irregularly or vertically oriented textura globulosa-angularis(-prismatica) from base to mid flanks, 40–80 µm thick near base, cells *(7–)10–20 × (5–)8–12(–15) µm; 15–40 µm thick near (sub) margin, of t. prismatica(-angularis) oriented at a 10–50° angle to the surface, upper margin of t. prismatica-porrecta, marginal cortical cells *5–9 × (2–)3–4(–5) µm, sometimes covered by a 10 µm thick layer of dead hyphae; **glassy processes** absent. **Anchoring hyphae** sparse to medium abundant, †2–3 µm wide, walls 0.2–0.5 µm thick, sometimes extending to the margin as a covering layer. **SCBs** in paraphyses and marginal ectal excipulum globose, 1.5–2.2 µm diam., but mainly crystalloid, hyaline to pale yellowish-rose; with or without light yellow **LBs** (carotenoids) in lower half of paraphyses. **Exudate** over paraphyses and margin 0.3–2 µm thick, ± smooth or cloddy, hyaline, loosely or firmly attached on cell each tip. **— ANAMORPH**: unknown.

Habitat: collected 2.5–3 m above the ground, decorticated, 16–20 mm thick branch *Acacia cyperophylla*, on 0.2 mm deep very decayed wood, strongly greyed, no algae. **Associated**: *Coccomycetella* spp. {2}, *Hysterobrevium mori*, *Orbilia allantoobliqua*, *O. australiensis, O. multiaustraliensis*, *O. pleioaustraliensis*, *O. ?pleiocoronohesperidea, Ostropales*. **Desiccation tolerance**: fully viable for 34 months (57 months including singular rehydration). **Altitude**: 540 m a.s.l. **Geology**: Mesoproterozoic sedimentary rock (red-brown sandstone). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia pleiovinosa* appears to be closely related to *O. multivinosa*, *O. helicovinosa*, and *O. vinosa*, from which it differs in 16-spored asci, from *O. helicovinosa* also in less curved ascospores. Except for *O. vinosa*, these species share also a subtropical (semi)arid habitat and comparatively small apothecia.

O. pleiovinosa grew intermingled with the very similar *O.* aff. *pleiocoronohesperidea*, which differs in shorter and particularly wider spores which are more distinctly divided into an elongated upper part and an often ± curved tail, also in shorter SBs and larger apothecia. Nine mature apothecia of *O. pleiovinosa* and five of *O.* aff. *pleiocoronohesperidea* were examined and found to be fairly consistent and sharply separated in their microfeatures.

Ecology. *O. pleiovinosa* was found on rotten wood of a decorticated xeric branch of *Acacia* in an (almost tropical) semiarid (almost arid) acacia open woodland with *Eucalyptus* in a most of the time dry riverbed in the Gascoyne ecoregion of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Gascoyne, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *Acacia cyperophylla*, on wood, 28.X.2007, G. Marson (ex H.B. 9695a, MEL 2389279B, **holotype**; MEL 2389280, **isotype**).

Orbilia multivinosa Baral & G. Marson, **sp. nov.**, MB 828906 — Pl. 277

Etymology: named after the 32-spored asci and the similarity to *O. vinosa*. **Typification**: Australia, Ayers Rock, branch of *Allocasuarina decaisneana*, 12.X.1998, G. Marson (H.B. 6617j, unpreserved, holotype: illustration Pl. 73 Fig. 1).

Latin diagnosis: *Similis* Orbiliae pleiovinosae *sed asci 32-spori, ascosporae breviores. Habitat ad lignum putridum rami sicci* Allocasuarinae decaisneanae *in zona subtropica arida Australiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated ?0.3 mm diam., light (dirty) orange-reddish, round, scattered; disc flat, margin thin, smooth; sessile. **Asci** *70–82 × 7.5–8.2 µm, 32 spored (25–28 spores counted), spores *~4–5-seriate, min. 9–10 lower spores inverted (slightly to strongly mixed), pars sporifera *55 µm long; **apex** (†) hemispherical to slightly truncate, dome †0.8–1 µm thick (immature and mature), with or without small apical chamber; **base** with short, thick, flexuous stalk, T-shaped. **Ascospores** *12–14.5 × 1.8–2 µm, narrowly fusoid-clavate, apex obtuse to subacute, base slightly to often ± strongly attenuated (sometimes tail-like), mostly slightly curved towards base; **SBs** *3–4.3 × 0.5–0.8 or 1–1.5 µm, subulate to ampulliform, apically narrowed to a small to wide point, straight. **Paraphyses** apically uninflated to medium clavate-capitate, terminal cells *5–14 × 2.5–4 µm; unbranched near apex. **Medullary excipulum** not examined. **Ectal excipulum** of textura globulosa at base and flanks, marginal cortical cells ± elongate, (†) slightly thick-walled; **glassy processes** absent. **Anchoring hyphae** no examined. **SCBs** in paraphyses and ectal excipulum crystalloid, also globose. **Exudate** over paraphyses 0.5 µm thick, granular-cloddy, ± loosely attached. **— ANAMORPH**: unknown.

Habitat: lying on ground, decorticated, 10 mm thick xeric branch of *Allocasuarina decaisneana*, on 0.1 mm deep very decayed wood, strongly greyed, no algae. **Associated**: *Orbilia macrotrapeziformis*, *O. phanosoma*, *O. pleiolentiformis*, *O. pleioobtusispora*, *O. pleiovitalbae*, *O. pluristomachia*, *O. serpentina*, *Symbiotaphrina desertorum*, *Teichosporella dura*. **Desiccation tolerance**: many mature asci still viable after 19 months. **Altitude**: 500 m a.s.l. **Geology**: Cenozoic regolith (red-brown sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multivinosa* is characterized by 32-spored asci, while in the other features (ascospores, SBs, crystalloid SCBs) the species much resembles European *O. vinosa*. The collection contained only two apothecia which were used up during examination. *O. pleiocoronohesperidea* differs in 16-spored asci, larger spores, and glassy processes at the margin.

Since no apothecia remained and the inhabited branch fragment was not preserved, the illustration of the fungus is designated as holotype. Art. 40.5 ICN permits illustrations as

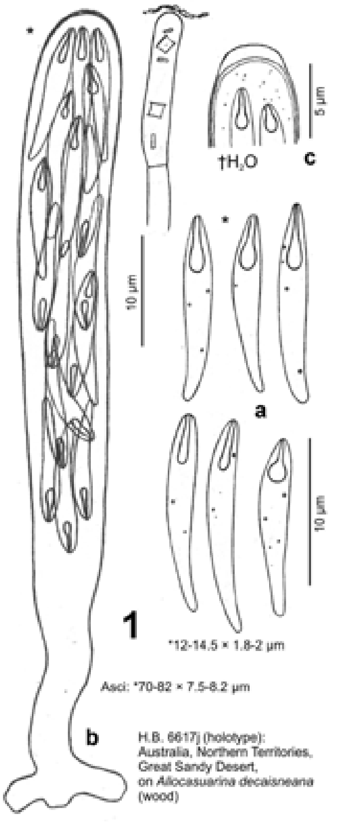

Plate 277. **1**: *Orbilia multivinosa*. – **a**. ascospores; **b**. ascus and paraphysis; **c**. dead ascus apex containing living spores.

type, if it is impossible to preserve a specimen that would show the important features. We here rely on this article, because the taxonomically relevant spore bodies (SBs) and soluble cytoplasmic bodies (SCBs) cannot be preserved by conventional methods.

Ecology. The two detected apothecia grew on rotten wood of a xeric branch of *Allocasuarina decaisneana* in a subtropical arid acacia open shrubland northeast of Ayers Rock at the southeastern end of the Great Sandy Desert of central Australia.

Specimens included. **AUSTRALIA**: **Northern Territories**, Great Sandy Desert, 11.5 km ENE of Yulara, 14 km NNE of Ayers Rock, 500 m, branch of *Allocasuarina decaisneana*, on wood, 12.X.1998, G. Marson (H.B. 6617j ø, **holotype** [illustration]).

Orbilia subulivinosa G. Marson, Baral & E. Weber, **sp. nov.**, MB 828908 — Pls 278–279

Etymology: named after the long and narrow, subulate spores.

Typification: France, Var, Cogolin, branches of *Erica arborea*, 4.IX.2017, G. Marson (ex G.M. 2017-09-04.1 & ex H.B. 10140a, M-0291757, holotype; sq.: MH221056).

Latin diagnosis: *Similis* Orbiliae vinosae *sed ascosporae longiores, excipulum et paraphyses absque corpusculis crystalloideis. Habitat ad lignum putridum ramorum siccorum* Ericae arboreae *in zona mesomediterranea Europae meridionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.28–)0.33–0.8(–0.9) mm diam., 0.13–0.32 mm thick (receptacle 0.11–0.15 mm), pale to bright orange-rose, translucent, round to somewhat elongate or undulating, scattered to subgregarious, sometimes in small dense groups; disc flat, margin distinct, thin, hardly protruding, smooth to finely rough; broadly sessile or with an abrupt stipe up to 0.15 × 0.35 mm, superficial; dry light to deep brick-red, with thick protruding margin. **Asci** *~55–67 × 5.5–6.5 µm, †~53–65 × 5.2–6.2 µm, 8-spored, spores *4–8-seriate, 3–4 lower spores inverted (not mixed); apex (†) hemispherical, dome in IKI †1–1.4(–1.8) → 0.5–1 µm thick, with small apical chamber; base with short to long, ± thin, flexuous stalk, T- to L-shaped. **Ascospores** *(16–)20–22 × 1.6–1.8 µm, †17.5–22(–25) × 1.6–2 µm, narrowly subulate to acicular, apex rounded to obtuse gradually slightly to medium attenuated towards base, straight or very slightly curved in lower part; **SBs** *4.7–5.7 × 0.6–0.9 µm, narrowly subulate-vermiform, not inflated at base, straight or very slightly flexuous. **Paraphyses** apically uninflated or slightly clavate, terminal cells *8–13 × 1.8–3(–3.2) µm, lower cells *7–18 × 1.5–2.3 µm; unbranched at upper septum. **Medullary excipulum** hyaline 40–60 µm thick, of dense textura intricata with inflated cells, medium to sharply delimited. **Ectal excipulum** hyaline, of thin-walled, vertically oriented t. globulosa-prismatica from base to mid flanks, 30–100 µm thick at base, cells *(6–)8–18(–22) × 5–13 µm; 20–65 µm thick at flanks, 20–30 µm near margin, of t. prismatica-porrecta oriented at a 60–90° angle to the surface, marginal cortical cells †5–12 × 2.5–4.5 µm; **glassy processes** absent. **Anchoring hyphae** sparse, †1.5–2.7 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses and ectal excipulum at base and margin sparse, globose, 1 µm diam., crystalloid SCBs absent. **Exudate** over paraphyses 0.8–1.5(–2) µm thick, cloddy, hyaline pale yellow, loosely attached, over margin and flanks 1.5–3.5(–6) µm thick, rough-cloddy, light to bright yellow. — **ANAMORPH**: unknown.

Habitat: collected 0.5–4 m above the ground, almost entirely decorticated, 11–13 mm thick branches of *Erica arborea*, on 0.1–1 mm deep very rotten wood or remnants of bark (bast), strongly greyed or sometimes blackened, green algae sparse to abundant. **Associated**: *Claussenomyces* sp. {1}, ?*Hysterobrevium smilacis* {1}, *Mollisia* sp. {1}, *Orbilia aprilis* {1}, *O. hesperidea* {1}, *Propolis viridis* {1}. **Desiccation tolerance**: excipular cells and some mature asci and ascospores viable after 6 months. **Altitude**: 380 m a.s.l. **Geology**: gneiss & mica schist. **Phenology**: IX (probably long-lived).

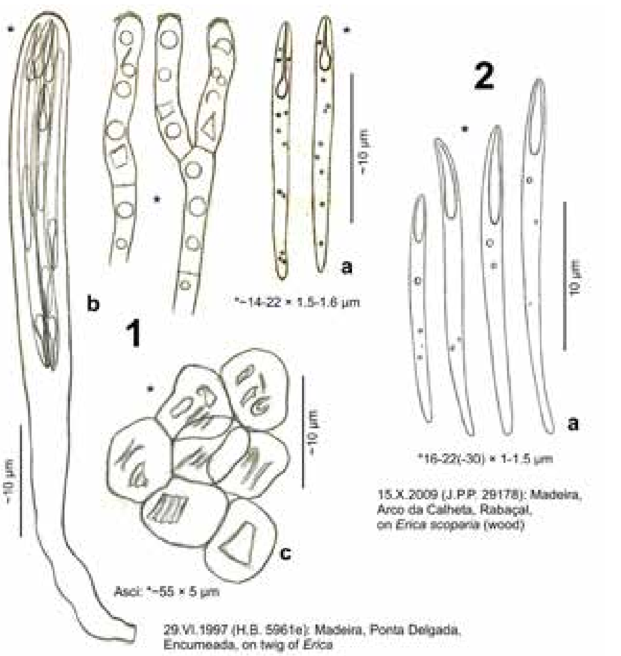

Plate 278. **1–2**: *Orbilia* cf. *subulivinosa*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ectal excipulum, with crystalloid SCBs.

Taxonomic remarks. *Orbilia subulivinosa* resembles *O. vinosa* except for its distinctly longer ascospores. It is also recognized as a species of its own based on strongly deviating DNA data. However, a morphologically similar species was not included in the description because its molecular data refer it instead in vicinity of *O. arachnovinosa* and it is thereafter here treated as *O.* aff. *arachnovinosa* (Pl. 279: 2; IVV: 2.VI.2018). Because of this genetic distance we have not included all morphologically similar collections for which no molecular data were available.

Not included collections. Most of the samples without a sequence originate from Macaronesia. Two very sparse collections on *Erica* from Madeira could not adequately be studied (Pl. 278): their acicular spores are with *(14–)16–22(–30) × 1.1–1.6 µm narrower than in *O. subulivinosa* but concur in length. Their SBs differ between the two collections (broadly subulate-vermiform vs. narrowly subulate with an abrupt tear-shaped basal inflation). The pale orange(-rose), apothecia measured 0.2–0.6 mm diam., the marginal excipulum showed 2–3 µm long marginal glassy processes, and the paraphyses contained both globose and crystalloid SCBs. Two collections on *Erica* and *Ilex* from the laurel forest in Tenerife studied by L. Quijada (IVV: TFC Mic. 23493) have similar narrow but shorter spores of *(12–)14–16(–17) × 1.3–1.5(–1.6 µm).

Various mesomediterranean collections with a comparable spore length mentioned under *O. vinosa* were not included in *O. subulivinosa* because they possess glassy processes (Pl. 262). A sample on *Picea* from Slovakia (A. Polhorský, IVV: 30.VII.2018) closely resembles *O. vinosa* (spores *14.5–19 × 1.8–2 µm); it is called *O.* aff. *subulivinosa* because its sequence clustered in a clade with *O. subulivinosa*; associated tridentaria-like conidia with mainly 4 arms support its distance to *O. vinosa* but are doubtfully connected to it.

Phylogeny. A sequence was taken from apothecia of the holotype of *O. subulivinosa*, comprising SSU, S1506 intron, ITS, and LSU. The Slovakian sample on *Picea* includes intron and ITS and two of *O.* aff. *arachnovinosa* (from Austria and Spain) ITS, one also SSU and LSU (in both the intron is absent).

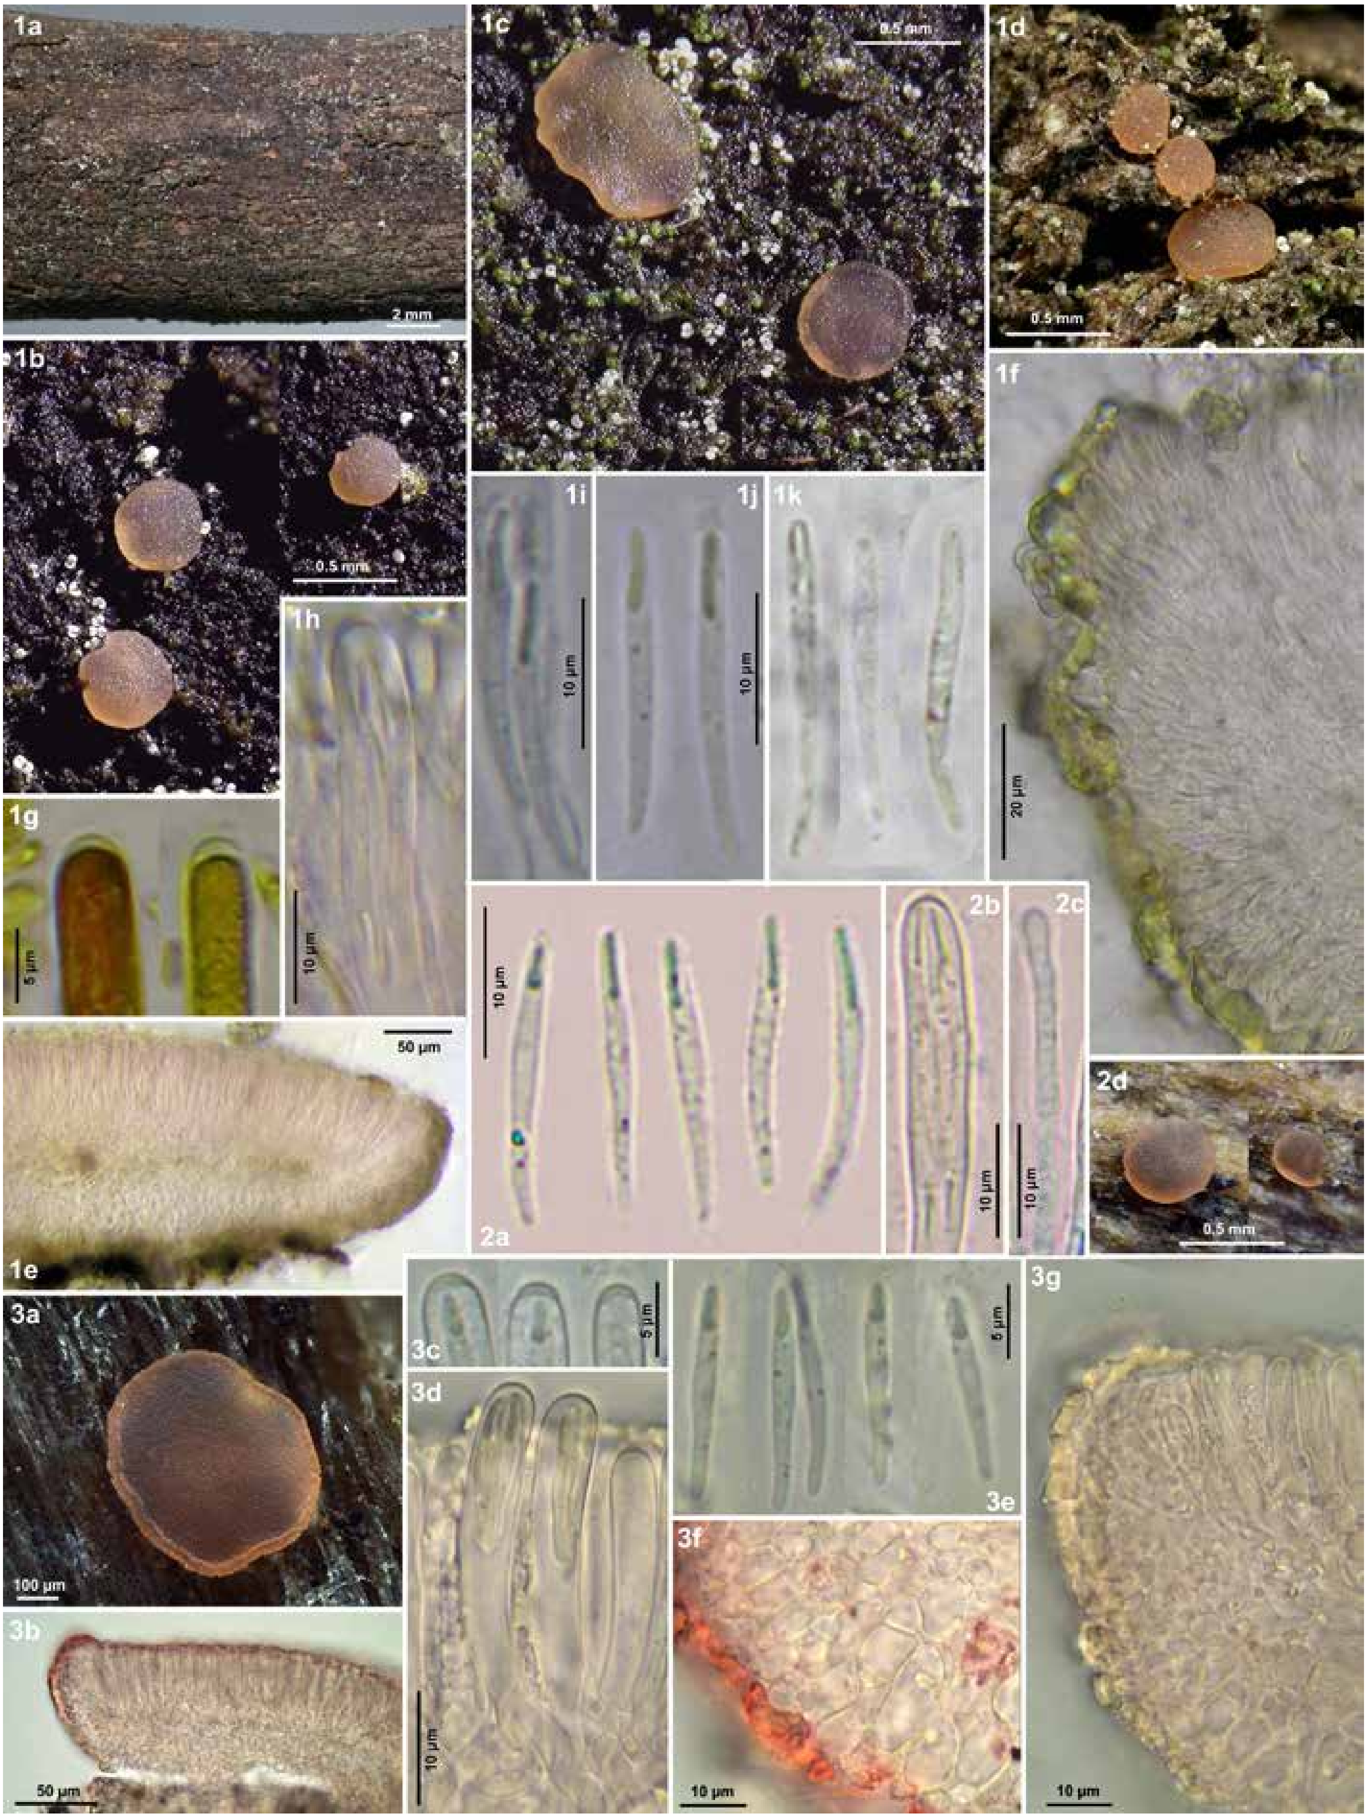

Plate 279. **1**: *Orbilia subulivinosa*; **2**: *O.* aff. *arachnovinosa*; **3**: *O.* cf. *subulivinosa*. – **1a**. ± decorticated branch of *Erica arborea* with apothecia (rehydrated); **1b–d**, **2d**, **3a**. rehydrated apothecia; **1e**, **3b**. apothecia in median section; **1f**, **3g**. id., ectal excipulum at margin; **3f**. id., at flanks; **1g**, **3c**. ascus apices; **1h**, **2b**. mature asci at normal turgescence; **3d**. mature asci at full turgescence; **2c**. paraphysis; **1i–k**, **2a**, **3e**. ascospores. – Living state (**3b** & **f** in CR), except for **1g** (in IKI), **1f**, **1k**, asci in **3c** (in H_2O). – **2**: phot. E. Rubio, **3**: phot. L. Quijada. — **1a–k**. H.B. 10140a: France, Cogolin, on *Erica*; **2a–d**. E.R.D. 6754: Spain, Villablino, on ?*Calluna* (see under *O. arachnovinosa*); **3a–g**. TFC Mic. 23493: Tenerife, on *Ilex*.

When analysing ITS, LSU, or ITS+LSU, *O. subulivinosa* clustered with medium (ITS+LSU), weak (ITS), or no support (LSU) with *O. multicurvula* (Phyls 9, 11, S13), showing an LSU D1–D2 minimum distance of 1.3 % to *O. multicurvula* and *O. nothoaprilis* (ITS 12.5–14 %). *O. vinosa* and *O. subvinosa* differ in the ITS by ~16–17 %. In the intron *O. subulivinosa* clustered with high support but high distance with *O. paramontigena* (Phyl. S13). Similarly unexplainable is the position of the Slovakian sample on *Picea*, which resembles *O. vinosa* but clustered strongly supported with the type of *O. subulivinosa* (Phyl. 11), with an ITS distance of 4.8 %.

When analysing the intron, *O. subulivinosa* clustered strongly supported with *O. paramontigena* (Phyl. S13), though with a 13.5 % distance, whereas the Slovakian *O.* aff. *subulivinosa* clustered unresolved and with high distance near the *vinosa-velutina* clade (not shown).

The two *O.* aff. *arachnovinosa* sequences are fully identical in the ITS, except for 2 gaps. They clustered in a medium supported clade with *O. arachnovinosa* when analysing ITS (not shown), to which it shows a distance of 4.5 % (ITS) and 1.4 % (LSU D1–D2). In comparison, its distance to *O. vinosa*/*O. subvinosa*/*O. subulivinosa* ranges at 8–9/9.5–10.5/17 % (ITS) and 1.7–1.9/1.3/7 % (LSU D1–D2).

Ecology. *O. subulivinosa* grew on strongly decayed wood and bark of xeric thin branches of *Erica arborea* in a mesomediterranean semihumid woodland in southeastern France. The not included collections from Macaronesia were on xeric twigs and branches of *Erica* and *Ilex* at two distant sites in the suprasubmediterranean subhumid ridge-crest laurel forest (*Ilici canariensis-Ericetum platycodonis*) on volcanic soil in Madeira, and in infra- to thermomediterranean semihumid shrublands on (trachy)basaltic flow in Tenerife. The not included sample from the High Tatras (Slovakia) was in a humid altimontane forest with *Picea abies* and *Pinus cembra* on acidic bedrock.

Specimens included. **FRANCE**: **Provence-Alpes-Côte d'Azur**, **Var**, 10 km W of Cogolin, 5 km NW of Gorbière, SW of Capelude, 380 m, branches of *Erica arborea*, on wood & bark, 4.IX.2017, G. Marson (ex G.M. 2017-09-04.1, ex H.B. 10140a, M-0291757, **holotype**; sq.: MH221056).

Not included. **MACARONESIA**: **Madeira**, 4.5 km NNE of Arco da Calheta, SE of Rabaçal, 1305 m, branch of *Erica platycodon*, on wood, 15.X.2009, J.P. Priou (J.P.P. 29178, doc. vid.). – 8 km SSW of Ponta Delgada, 1.8 km N of Lombo do Moleiro, W of Boca da Encumeada, 990 m, twig of *Erica*, on wood (?), 29.VI.1997, R. Reuter (H.B. 5961e ø). – **Canary Islands**, **Tenerife**, Güímar, 3.5 km W of Güímar, Higueras Salvajes, 927 m, branch of *Erica arborea*, 23.III.2013, L. Quijada, I. Pérez-Vargas & J. Díaz-Armas (TFC Mic. 23976). – Los Silos, 5 km SE of Buenavista del Norte, 3.5 km SSW of Los Silos, 740 m, 4.V.2012, branch of *Ilex canariensis,* 4.V.2012, L. Quijada (TFC Mic. 23493, doc. vid.). — **SLOVAKIA**: **Prešov**, Carpathian Mts., Vysoké Tatry, 9.5 km SSW of Tatranská Javorina, Bielovodská valley, 1408 m, branch of *Picea abies*, on wood, 30.VII.2018, A. Polhorský (A.P. 18/97, doc. vid.; sq.: MK651741).

Orbilia multicurvula Baral & G. Marson, **sp. nov.**,

MB 813596 — Pls 280–281

Etymology: named after the 32-spored asci and strongly curved ascospores.

Typification: Western Australia, Cowalla, branches of *Eremaea pauciflora*, 5.IX.2006, G. Marson (ex H.B. 8643a, MEL 2389245, holotype; sq.: KT222427).

Latin diagnosis: *Apothecia rehydratata 0.25–0.75 mm diam., aurantiaca, sessilia vel subsessilia, margine valde albido-denticulata. Asci 32-spori. Ascosporae *6.8–10 × 1.3–1.6 µm, anguste subcylindrico- ad fusoideo-clavatae, apice obtusae, ad basim attenuatae, fortiter arcuatae, in statu vivo corpusculum refringens brevem, vermiformem ad subulatum, ad apicem affixum continentes. Cellulae vivae excipuli et paraphysium corpuscula globosa continentes, excipulum marginale processis vitreis longis praeditum, dentes magnos formantibus. Habitat ad corticem putridum ramorum siccorum fruticum* Eremaeae *et* Hibbertiae *etc. in zona subtropica semihumida Australiae meridio-occidentalis.*

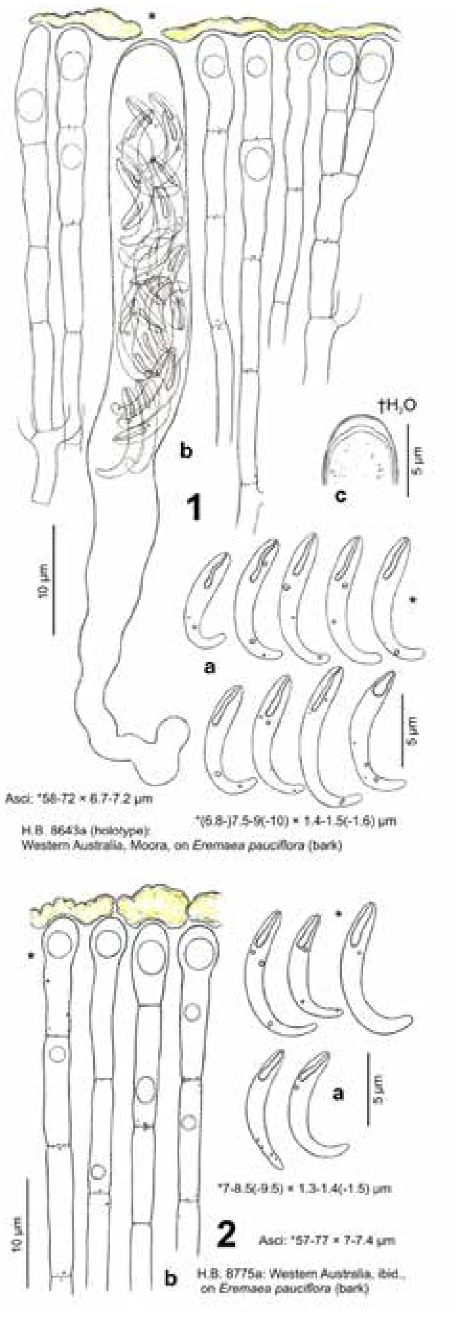

Plate 280. **1–2**: *Orbilia multicurvula*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.25–)0.3–0.5(–0.75) mm diam. [(0.2–)0.28–0.4(–0.6) mm excluding teeth], (0.11–)0.13–0.15(–0.2) mm high, (pale to) light to bright orange(-rose), slightly translucent, round (to broadly elliptical), scattered (to subgregarious); disc flat, margin thin or thick, mostly with prominent whitish teeth (30–)50–85(–100) × 30–60 µm, protruding 10–50 µm beyond disc (0–10 µm excluding glassy processes); sessile on an obconical base or distinct stipe 0.05 × 0.13 mm, ± superficial; dry bright orange-red, disc ± closed by the incurved teeth. **Asci** *57–72 × 6.7–7.4 µm {2}, †51–68 × 5.5–6.5 µm {2}, 32-spored (28–30 spores counted), spores ~4-seriate, lower spores inverted but very strongly mixed, pars sporifera *30–39 µm long; **apex** (†) hemispherical, dome †1–1.2(–1.4) → 0.8–1 µm thick {1}, with or without very indistinct apical chamber; **base** with short to long, ± thick, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *6.8–9.5(–10) × 1.3–1.5(–1.6) µm {2} (actual length ~9–12 µm), †6.8–8.5(–9.5) × (1.2–)1.3–1.5 µm {1}, narrowly

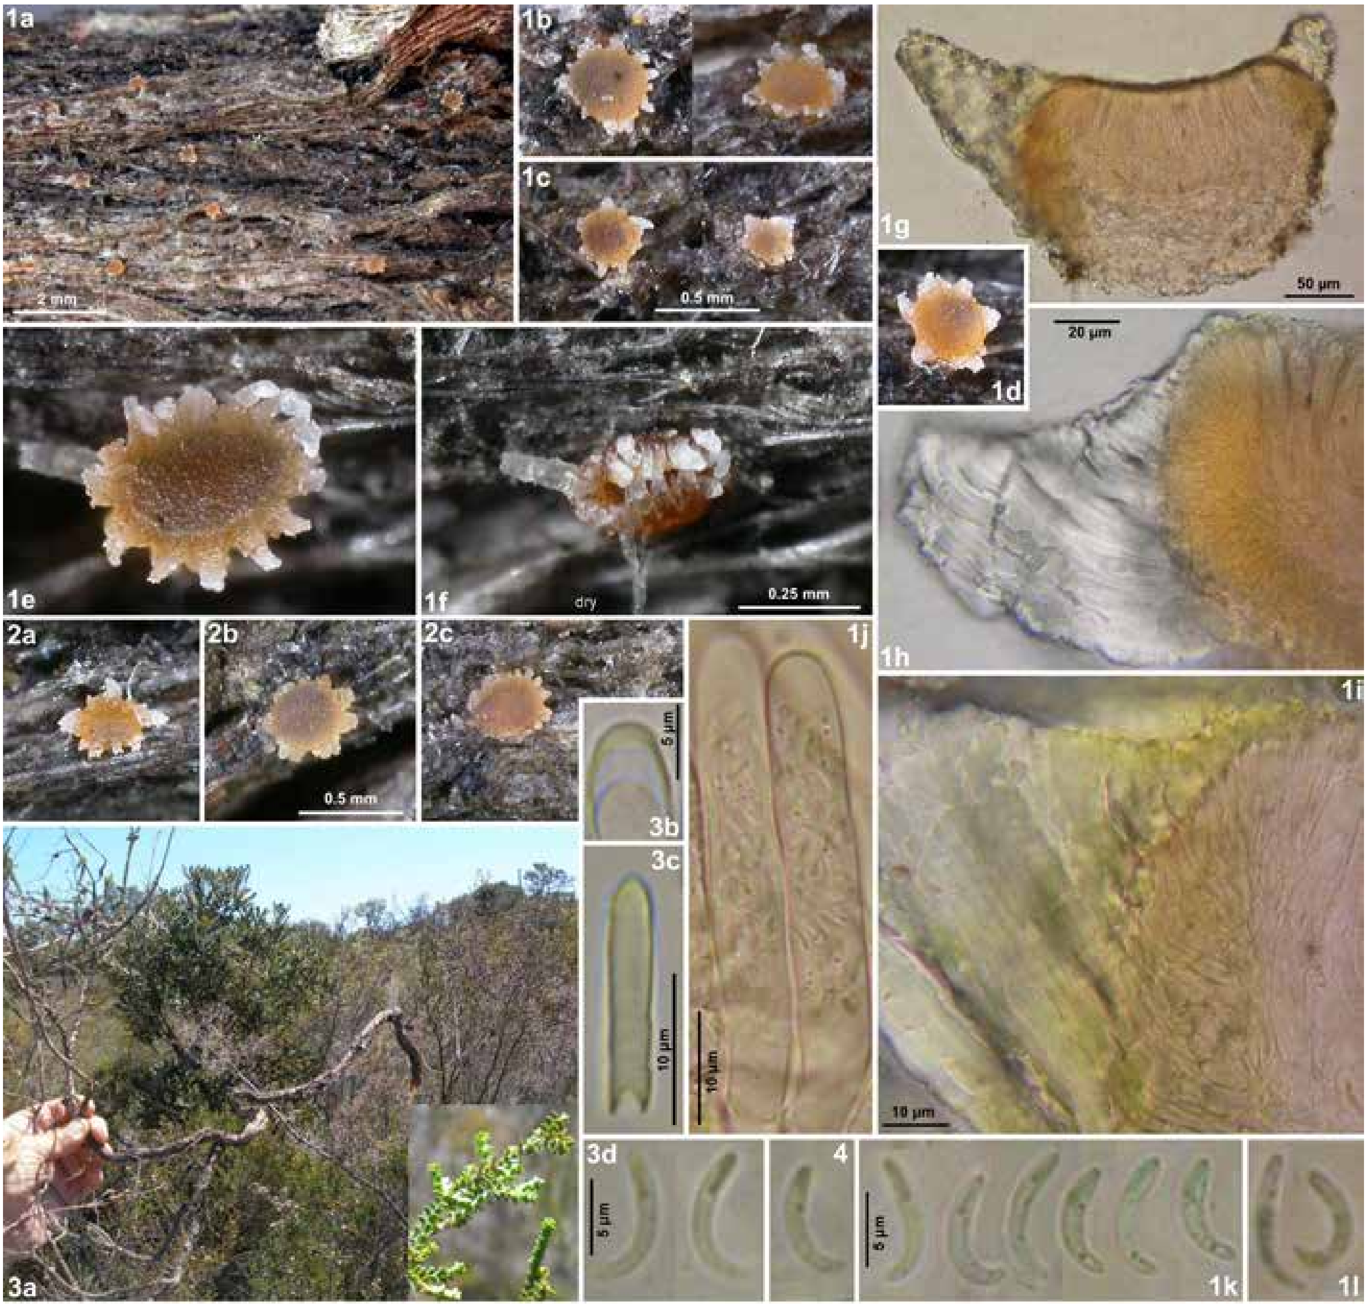

Plate 281. **1–4**: *Orbilia multicurvula*. – **3a**. semihumid banksia-eucalypt woodland with ?*Myrtaceae*; **1a–e**, **2a–c**. rehydrated apothecia; **1f**. dry apothecium; **1g**. apothecium in median section; **1h–i**. id., marginal ectal excipulum; **3c**. glassy process; **3b**. ascus apex; **1j**. mature asci; **1k–l**, **3d**, **4**. ascospores. – Living state, except for **3b**, **1l** (in H_2O). — **1a–l**. H.B. 8643a (holotype): Western Australia, Moora, on *Eremaea*; **2a–c**. H.B. 8775a: ibid., on *Eremaea*; **3a–d**. 11.XI.2007: ibid., on indet. ?*Myrtaceae*; **4**. 24.X.2007: ibid., on *Hibbertia*.

subcylindric-fusoid-clavate, apex obtuse (to subacute), base slightly to strongly attenuated, mostly very strongly curved in lower part (slightly in upper part); **SBs** *2.5–3.5 × 0.3–0.6 µm {2}, vermiform to subulate, apically narrowed to a small point, straight to slightly flexuous; in aged spores 2–3 × 0.7–1 µm, tear-shaped. **Paraphyses** apically uninflated to slightly (rarely medium) clavate-capitate, sometimes sublageniform, terminal cells *(6–)8–15(–18) × (2–)2.5–3.2(–3.7) µm {2}, lower cells *(6–)8–12 × 1.6–2.8 µm {2}; sometimes branched at upper septum, hymenium pale rose. **Medullary excipulum** hyaline to pale rose, (30–)50–100 µm thick, of medium dense textura intricata with many inflated cells, sharply delimited from ectal excipulum (at flanks by a thin t. porrecta), subhymenium light rose. **Ectal excipulum** hyaline, at margin pale honey-yellow to light orange, of (†) slightly gelatinized, indistinctly oriented t. angularis-globulosa from base to mid flanks, (20–)25–30 µm thick near base, cells *6–17 × 5–12 µm {1}; 15–30 → 10–20 µm thick near margin, inner part of t. prismatica-angularis oriented at a 30–40 up to 70–80° angle to the surface, outer part of t. (prismatica-) porrecta oriented at 10–20 up to 40–70°, marginal cortical cells *7–13 × 2.5–3.5 µm {2}; **glassy processes** 10–150 × (2–)2.5–3(–3.8) µm {3}, high-refractive, stratified or not, straight to slightly inwards curved, sometimes strongly hooked at the end, coherent to form compact, white or sometimes light yellow-chlorinaceous teeth. **Anchoring hyphae** medium abundant, †1.7–4 µm wide, walls (0.2–)0.3–0.8(–1.2) µm thick {1}. **SCBs** in paraphyses and ectal excipulum globose (to ellipsoid), 1.5–2.6 µm diam. **Exudate** over paraphyses 0.8–3 µm thick, cloddy-continuous, light to bright sulphur-yellow, loosely attached, over teeth absent (except for uppermost margin). **— ANAMORPH**: unknown.

Habitat: collected 0–1 m above the ground, corticated, 6–18 mm thick branches of *Eremaea pauciflora* {2}, *Hibbertia aurea* {1}, ?*Myrtaceae* {1}, on 0.3–0.5 mm deep strongly decayed bark {4} (periderm & bast), sometimes detaching, greyed, with some green algae. **Associated**: *Capronia* sp. {1}, *Durella* aff. *connivens* {1}, ?*Eutypa* sp. {1}, *Gloniopsis praelonga* {2}, *Hyalorbilia juliae* {1}, *Orbilia amberina* {1}, *O. austrocylindrica* {3}, *O. curvativitalbae* {1}, *O. eremaeae*

{1}, *O. eucalypti* {1}, *O. microserpens* {1}, *O. pleistovitalbae* {2}, *O. plurililacina* {1}, *Proliferodiscus olivaceoviridis* {2}, *Rhizodiscina lignyota* {1}. **Desiccation tolerance**: fully viable for at least 13 months. **Altitude**: 77–83 m a.s.l. **Geology**: Cretaceous sedimentary rock (whitish sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia multicurvula* is easily recognized by its strongly falcate (boomerang-shaped) ascospores, 32-spored asci, and apothecia with prominent marginal teeth, also by a sulphur-yellow colour of the exudate over the hymenium. Very similar in spore shape is *O. curvatinavajoana*, a species with 8-spored asci, tear-shaped SBs in the spores, and smooth apothecia without glassy processes.

Variation. The species appears to be quite constant in its peculiar characteristics, judging from the four known records which were, however, made within an area of only about 5 km diam. Only the length of the glassy processes varied, which did not exceed ~30 µm in the samples on *Hibbertia* and ?*Myrtaceae*.

Phylogeny. A sequence that includes SSU, ITS, and LSU (S1506 intron absent) was gained from apothecia of the holotype. In analyses of ITS+LSU, ITS, or LSU, *O. multicurvula* clustered with high support in the *vinosa*-*velutina* clade (Phyls 9, 11, S13), where it formed with *O. subulivinosa* a medium, low, or unsupported clade respectively. The ITS distance is 9% to *O.* aff. *subulivinosa* (Slovakia), 11.5% to *O. subulivinosa* (1.3% in LSU), and 13–17% to *O. vinosa*, *O. subvinosa*, and *O. nothoaprilis* (3–3.7% in LSU).

Ecology. *O. multicurvula* was found on rotten clefty bark of xeric twigs and branches of *Myrtaceae* and *Dilleniaceae* in subtropical semihumid banksia-eucalypt open wood- and shrublands of southwestern Australia. The wood core of the branches is very undecayed, and possibly the apothecia also occur on dead bark of still-living branches.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 55 km SSW of Moora, 30 km NNE of Gin Gin, Moore River, 83 m, branch of ?*Myrtaceae*, on bark, 11.XI.2007, G. Marson (G.M. 2007-11-11.1 ø). – 60 km SW of Moora, 8 km NE of Cowalla, Moore River, Orange Springs Road, 77 m, twigs & branches of *Eremaea pauciflora*, on bark, 5.IX.2006, G. Marson (ex H.B. 8643a, MEL 2389245, **holotype**; sq.: KT222427). – ibid., branches of *E. pauciflora*, on bark, 23.X.2007, G. Marson (H.B. 8775a). – 58 km SW of Moora, 10 km NE of Cowalla, Orange Springs Road, 83 m, branch of *Hibbertia aurea*, on bark, 24.X.2007, G. Marson (ø).

Orbilia velutina Baral & G. Marson, **sp. nov.**, MB 813599 — Pls 282–283

Etymology: named after the velvety exterior of the apothecia.

Typification: Western Australia, Kumarina Roadhouse, branch of *Eucalyptus*, 28.X.2007, G. Marson (ex H.B. 9772a, MEL 2389281, holotype; sq.: KT380093).

Latin diagnosis: *Apothecia rehydratata 0.2–0.75 mm diam., obscure lateritio-aurantia, sessilia, margine aspera vel distincte velutina. Asci 128-spori, apice in statu emortuo hemisphaerico, crassitunicato. Ascosporae *5.5–8 × 1.7–2.5 µm, ellipsoideo-fusoideae, rectae, corpusculum refringens cylindricum, brevem, basi leniter inflatum, ad apicem affixum continentes. Habitat ad lignum putridum rami sicci* Eucalypti *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.75 × 0.2–0.55 mm diam., 0.17–0.32 mm high, light to bright ± dirty dull orange-red, non-translucent, round (to elliptical), scattered to subgregarious; disc flat, margin usually distinct and ± thick, rough or mostly with whitish, short or sometimes long, erect or appressed hairs which protrude 30–50(–90) µm beyond disc; broadly sessile, superficial to slightly immersed; dry contracted and inconspicuous. **Asci** *(88–)108–120(–135) × (10–)11–12.5(–13) µm, †85–120 × (8.5–)9–10(–10.8) µm, 128-spored (~75–90 spores counted, ~100–130 spores evaluated from volume), in some apothecia only 64-spored (~60 spores counted), spores multiseriate, part of spores inverted (strongly mixed), pars sporifera *60–80 µm long; **apex** (†) hemispherical, dome †1.5–1.7 → 0.7–1.3 µm thick, with apical chamber, inner delimitation staining light purplish-red in $\mathrm{CR}_{\mathrm{SDS}}$; **base** with short to very long, thin or thick, straight or flexuous stalk, T, L- or h-shaped. **Ascospores** *(5.5–)6–7.5(–8)((–9)) × (1.7–)1.9–2.3(–2.5) µm, †6–7.2 × 1.7–2.1 µm, ellipsoid-fusoid (to ellipsoid-clavate), apex obtuse, base often medium to strongly attenuated, obtuse to mostly (sub)acute, straight to slightly inequilateral; **SBs** *(2–)2.5–3(–3.2) × (0.5–)0.6–0.8(–0.9) µm, elongate tear-shaped or cylindrical with a distinct small basal inflation, apically narrowed to a ± wide point, also slightly widened (dumbbell-shaped), straight. **Paraphyses** apically uninflated or slightly to medium, rarely strongly clavate-capitate or somewhat spathulate, terminal cells *8.5–20 × 2.5–4(–5) µm, sometimes ± flexuous, lower cells *(7–)9–17 × 1.7–2.8(–3.2) µm; rarely branched at apex. **Medullary excipulum** hyaline to pale yellowish-orange, 40–100 µm thick, of dense (below also loose) textura intricata with many inflated cells, sharply delimited (sometimes by an 8–15 µm thick layer of t. porrecta). **Ectal excipulum** pale rose, of (†) slightly (to medium) gelatinized, indistinctly to vertically oriented t. globulosa-angularis-prismatica, 30–80 µm thick near base, cells *(9–)11–20(–26) × (5–)8–16(–18) µm; 15–40 µm thick near margin, at mid flanks of t. globulosa-angularis or t. prismatica oriented at a 30–70° angle, cells *5–12 × 4.5–6 µm, at upper margin of t. prismatica oriented at a 10–30° angle, marginal cortical cells *6–12 × 3–5 µm, terminating in ± flexuous, septate **hairs** */†25–95 × 3–4.2 µm, wall 0.2–0.4(–1) µm thick, ± smooth, septate, individual cells 8–12 µm long; **glassy processes** absent. **Anchoring hyphae** sparse, *(1.8–)2.2–4 µm wide, walls 0.2–0.3(–0.5) µm thick. **SCBs** in paraphyses, ectal excipulum (near margin) and hairs globose, 1.5–2 µm diam., mixed with rod-shaped to angular ones, hyaline to pale yellow-orange, strongly refractive crystalloid SCBs 1–4 × 0.3–0.8 µm. **LBs** in lower half of paraphyses pale yellow (carotenoids), minute. **Exudate** over paraphyses 0.2–1 µm thick, granular-continuous, hyaline, loosely attached over ample gel, over marginal hairs as scattered low warts. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1}). **Colonies** pale to light orange. **Conidiophores** reduced. **Conidia** Y-shaped, total size *(18–)22–35(–42) × (17–)30–75(–92) µm, stipe *11.5–16(–18) × 3.5–4.6 µm, 1–2(–3)-septate, arms somewhat tapering, *(7–)20–50(–63) × (3.8–)4.2–4.7(–5.5) µm, ((1–))(2–)3–6(–7)-septate, also some unbranched conidia present: straight to slightly curved, *(28–)38–41 × 5–6.2 µm, (3–)4–6-septate {1}, both without constrictions.

Habitat: collected ~3 m above the ground, dead, decorticated, 10–18 mm thick branch of a large, fallen but living *Eucalyptus* sp., on 0.1–0.2 mm deep very decayed wood, strongly greyed, no algae. **Associated**: *Orbilia austropleiomicrosoma*, *O.* ?*multiserpens*, *O.* ?*pleioaustraliensis*. **Desiccation tolerance**: fully viable after 40 months. **Altitude**: 540 m a.s.l. **Geology**: Mesoproterozoic sedimentary rock (red-brown sand and gravel). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia velutina* is easily recognized by its large, 128-spored asci and small, ellipsoid-fusoid ascospores containing rod-shaped SBs with a slight basal bulb, also by an apothecial margin covered with short to long, flexuous, septate hairs without glassy processes. Especially because of its hairs, *O. velutina* might occupy a rather isolated position within series *Hesperideae*. However, in spore and SB shape the species resembles *O. aprilis*.

Anamorph. The trinacrium-like conidia obtained in pure culture vary strongly in arm length. They resemble those large trinacrium-like conidia that frequently occur in series *Hemiorbilia*, but when shorter-armed they are very similar to those of *O. vinosa*.

Phylogeny. A sequence comprising S1506 intron, ITS, and LSU was gained from the holotype culture. In analyses of ITS+LSU, ITS, or LSU (Phyls 9, 11, S13), *O. velutina* clustered with high support in the *vinosa*-*velutina* clade, with a distance of

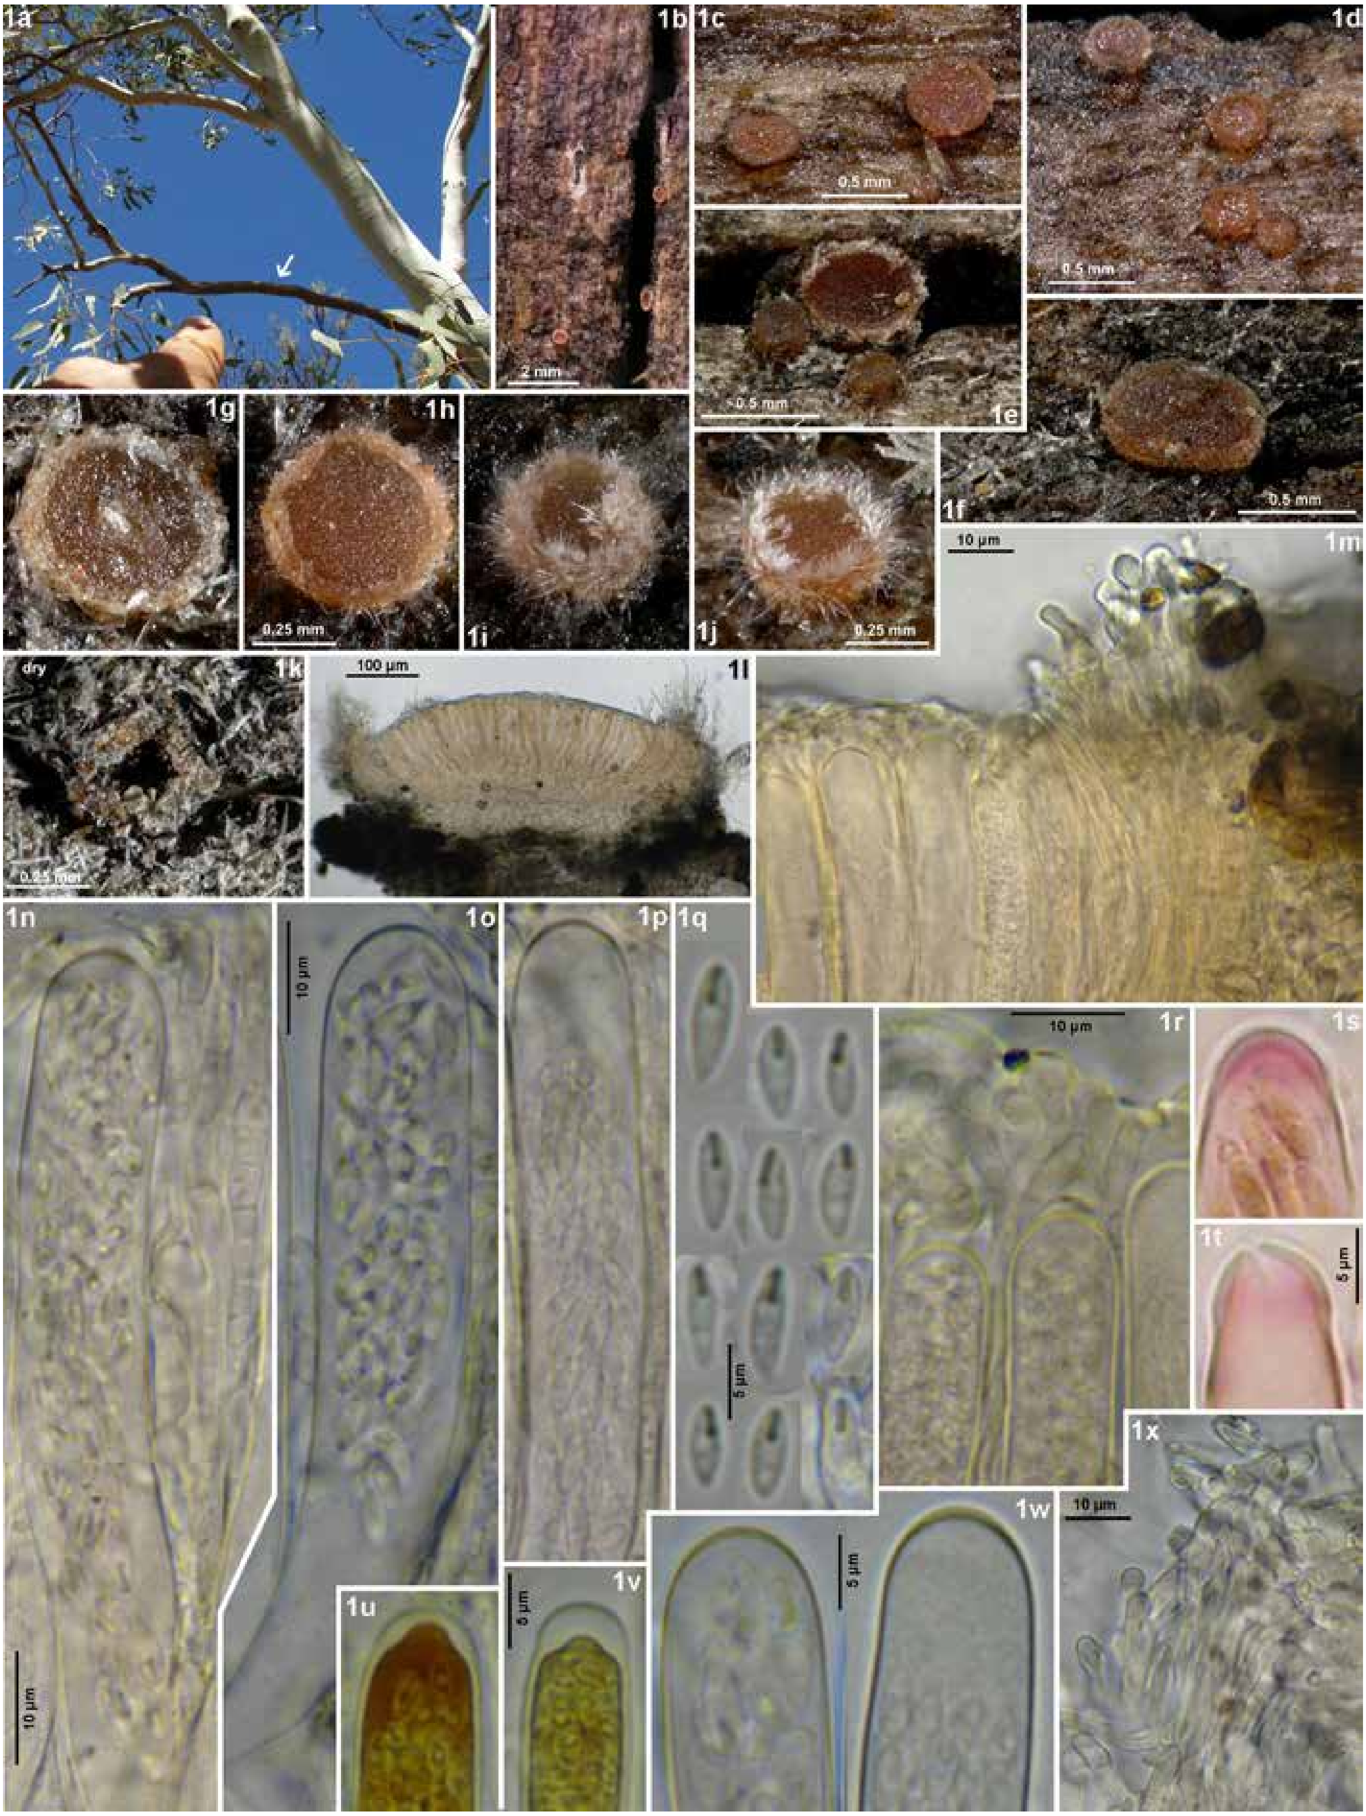

Plate 282. **1**: *Orbilia velutina*. – **1a**. 1–2 cm thick decorticated branch attached to living *Eucalyptus* tree; **1b**. surface of decorticated branch with rehydrated apothecia; **1c–j**. rehydrated apothecia; **1k**. dry apothecium; **1l**. apothecium in median section; **1m**. id., upper margin with short hairs; **1x**. ± projecting marginal hairs; **1n–o**. mature asci and paraphyses; **1p**. immature ascus; **1r**. apices of paraphyses between asci; **1.s–w**. ascus apices. – Living state, except for **1s–t** (in CR_{SDS}), **1u–v** (in KOH+IKI), **1x** (in H_2O). — **1a–w**. H.B. 9772a (holo/isotype): Western Australia, Gascoyne, on *Eucalyptus*.

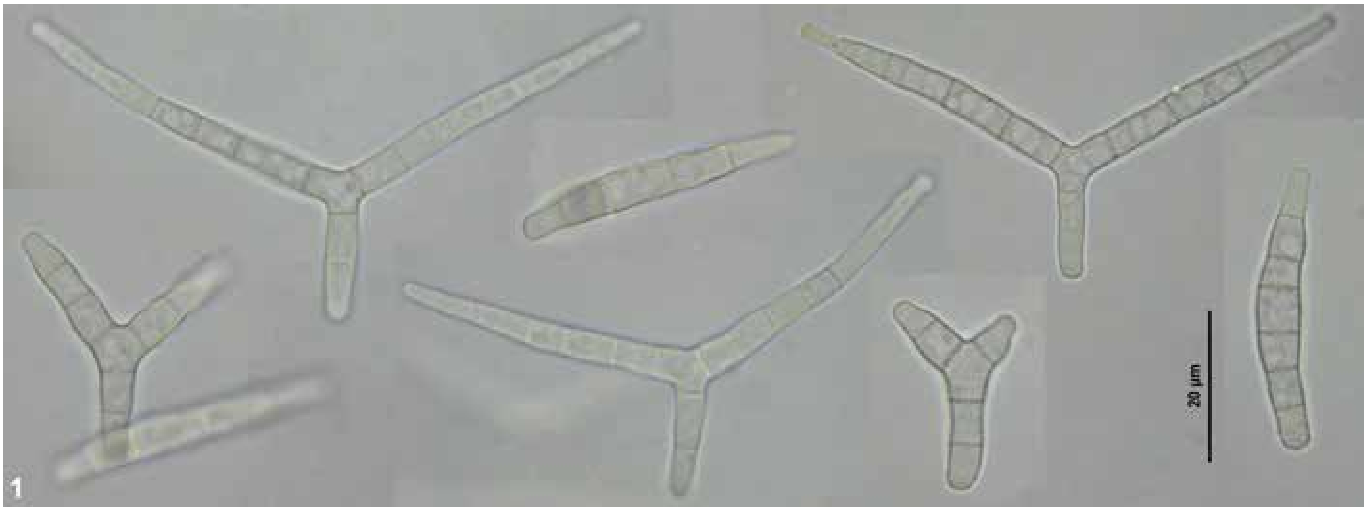

Plate 283. **1**: *Orbilia velutina*. – **1**. conidia (living state, H.B. 9772a, holotype).

11.5–20% in the ITS region to other members of the clade, the lowest percentage being to *O.* cf. *angustoaristata*, with which it formed a moderately supported clade when using ITS+LSU or LSU. Also when analysing the intron the two species clustered weakly supported together In the LSU (D1–D2) the lowest distance was 1.5% to *O.* cf. *angustoaristata*, 3% to *O. multicurvula*, and 4% to *O. vinosa*. In the intron *O. velutina* shows a distance of 7.5% to *O.* cf. *angustoaristata*, 13–14% to *O. aprilis*, and 15–16.5% to *O. vinosa*.

Ecology. *O. velutina* was found on rotten wood of a decorticated xeric branch of *Eucalyptus*, in a subtropical semiarid acacia open woodland with *Eucalyptus* in a most of the time dry riverbed in the Gascoyne ecoregion of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Gascoyne, 171 km NE of Meekatharra, 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *Eucalyptus*, on wood, 28.X.2007, G. Marson (MEL 2389281, **holotype**; H.B. 9772a, **isotype**, anam. cult.; sq.: KT380093).

Orbilia nothoaprilis Baral, **sp. nov.**, MB 813598 — Pls 284–285

Etymology: the epithet means 'false *Orbilia aprilis*'.

Typification: Australia, Queensland, Craiglie, branch of *Acacia*, 31.VIII.2006, G. Marson (ex H.B. 8588, BRI AQ799196, holotype; sq.: KT380091).

Latin diagnosis: *Similis* Orbiliae aprili *sed cellulae vivae excipuli marginalis et paraphysium corpuscula crystalloidea continentes*, *ascosporae paulo longiores*, *corpuscula refringentia longiora*, *asci apice in statu emortuo leniter crassitunicati. Habitat ad lignum putridum rami sicci* Acaciae *in zona tropica (sub)humida Australiae septentrio-orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.4 mm diam., 0.1 mm high (receptacle 0.08–0.09 mm), pale to light orange-rose, somewhat translucent, round (to elliptical), (very) scattered; disc flat, margin distinct, thin, 10 µm protruding, finely rough to crenulate; broadly sessile, superficial; dry light to bright orange. **Asci** *35–42 × 5.2–5.5 µm, †31–40 × 4.5–5.2 µm, 8-spored, spores *3–4-seriate, 3–5 lower spores inverted (not mixed); **apex** (†) ± hemispherical, dome in KOH 0.7–0.8 → 0.5–0.6 µm thick, with slight apical chamber; **base** with short to medium long, ± thin, flexuous stalk, L-shaped. **Ascospores** *8–11 × 1.7–1.8(–1.9) µm, †8–11 × 1.6–1.7 µm, fusoid, apex obtuse, base strongly attenuated, straight to slightly inequilateral; **SBs** *2–3 × 0.3–0.5 µm, subulate to vermiform, apically narrowed to a wide or small point, straight, overmature *1.6–1.8 × 0.6–0.8 µm. **Paraphyses** apically uninflated to slightly clavate or spathulate, terminal cells *(7–)10–13.5 × 2.2–3 µm, lower cells *(5–)7–8.5 × 1.5–2.2 µm; unbranched at upper septum, hymenium pale rose. **Medullary excipulum** hyaline, 25 µm thick, of dense textura intricata with many inflated cells, rather sharply delimited. **Ectal excipulum** hyaline to pale rose, of (†) thin-walled, indistinctly vertically oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 35 µm thick near base, cells *9–17 × 7–11(–14) µm; 15–20 µm thick near margin, of t. porrecta

H.B. 8588 (holotype): Australia, Queensland, Port Douglas, on *Acacia*; *O.* aff. *nothoaprilis*: **2a–b**. H.B. 8495: ibid., Cape Tribulation, on *Bambusa*; **3a–b**. H.B. 8303c: Western Australia, Perth, on *Anigozanthos*; **4a–b**. 7.IX.2006: ibid., on ?*Ptilotus*; **5a–g**. H.B. 8609a: Australia, Queensland, Mossman, on indet. angiosperm.

oriented at a 10–40° angle to the surface, marginal cortical cells */†6–10 × 2–2.5(–3) µm; **glassy processes** 2–5 × 2.5–3 µm, high-refractive, not stratified. **Anchoring hyphae** sparse, †1.5–2.5 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) globose to ellipsoid, 2–2.8 µm diam., distinct hyaline crystalloid SCBs present in ectal excipulum from base to margin, 2–4.5 × 1.7–2.8 µm. **Exudate** over paraphyses 1–1.5 µm thick, cloddy-continuous, ± loosely attached, over glassy processes 1–3 µm thick, rough-cloddy, pale yellowish-chlorinaceous. **— ANAMORPH**: unknown.

Habitat: collected 6 m above the ground, decorticated, 45 mm thick branch of *Acacia* sp., heavily perforated by ants, on 0.1 mm deep slightly to medium decayed wood in outer galleries (especially on thin walls between galleries), not or slightly greyed, with a few green algae. **Associated**: *Hypoxylon* ?*rubiginosum*, on much thinner separate branch *Hyalorbilia inflatula* (1 m above the ground). **Desiccation tolerance**: fully viable for at least 3 months, after 11 months many excipular cells and a few immature asci still alive. **Altitude**: 15 m a.s.l. **Geology**: Devonian sedimentary rock (whitish soil). **Phenology**: VIII (but rather long-lived).

Taxonomic remarks. The Australian *Orbilia nothoaprilis* is very similar to the European (and North American) *O. aprilis*, from which it differs in the presence of crystalloid SCBs in the ectal excipulum, slightly longer ascospores with distinctly longer SBs, also in slightly wider asci with thinner apical domes.

Although the taxon is so far only known from a single collection, it is described here as a separate species, based mainly on the presence of crystalloid SCBs which have never been seen in the many collections of *O. aprilis* studied in the living state.

The North American *O. georgiana* was predominantly studied in the dead state and differs from *O. nothoaprilis* only slightly in the available morphological features.

Not included collections. A lignicolous specimen from northeastern Australia (on indet. angiosperm, Pls 284: 2; 285: 5) might be conspecific with *O. nothoaprilis* on account of its very thin apical domes (†0.8 → 0.3 µm) and the presence of crystalloid SCBs. It differs in slightly longer and narrower spores, longer SBs (3–4 × 0.4–0.5 µm), shorter asci, and smaller, very thin apothecia (60 µm) and is, therefore, not included in the description. From *O. nothovinosa* this sharply differs in the thin apical domes and the presence of crystalloid SCBs.

A sparse collection from southwestern Australia (on herbaceous stem of *Anigozanthos*, Pl. 284: 3) differs from *O. nothoaprilis* in its unusual host, but also in the absence of crystalloid SCBs in paraphyses and excipulum, more fusiform spores, and a distinctly thicker apical dome (†1.5 µm). It was collected together with a similar taxon with more subcylindric-fusoid spores with obtuse ends, which grew on dicot stems (?*Ptilotus*, Pls 284: 4; 285: 4). From European *O. aprilis* both taxa differ mainly in the herbaceous substrate, the latter also in larger SBs (*2.3–2.7 × 0.6–0.9 µm). A single apothecium from northeastern Australia (on stem of *Bambusa*, Pl. 285: 2) was only studied in the dead state. It might belong to one of these taxa because of thicker ascus domes (†1.5 → 1 µm), also because of rather short asci [†20–24(–28) × 4.7–5.7 µm] and spores (†6–8.5 × 1.5–1.8 µm). We conclude that these samples on herbaceous substrates belong to 1 or more species different from *O. nothoaprilis.*

An Australian collection on *Eremaea* was only studied in the dead state (IVV: H.B. 9132a). It differs in smaller spores (†6–8 × 1.3–1.4) and sometimes strongly truncate and thin-walled ascus apices, therefore, it is not included.

Phylogeny. A sequence taken from apothecia of the isotype of *O. nothoaprilis* comprises ITS and LSU (S1506 intron absent). Surprisingly, it clustered in the highly supported *vinosa-velutina* clade (Phyls 9, 11, S13), though unresolved by showing a high distance in the ITS/LSU region: 12.5/3.7% to *O.* cf. *angustoaristata*, 13/3.7% to *O. multicurvula*, 14/3.7% to *O. velutina*, and 15–16/4.5–5% to *O. vinosa*/*O. subvinosa* (19.5/7.3% to *O. aprilis*). A sample from Georgia (USA), described as *O. georgiana* in Shao et al. 2018 based on its deviating rDNA data, clustered highly supported with *O. nothoaprilis* (for the distance see p. 643).

Ecology. *O. nothoaprilis* was found on ± rotten wood of dead, xeric branches of *Acacia* in tropical (sub)humid northeastern Australia. *O.* aff. *nothoaprilis* on *Bambusa* and bark of an indet. angiosperm (with *Carallia brachiata* close to it) are from a similar area and climate, whereas those on *Anigozanthos*, ?*Ptilotus* and *Eremaea* are from subtropical semihumid southwestern Australia.

Specimens included. **AUSTRALIA**: **Queensland**, Wet Tropics, 7 km S of Port Douglas, SSE of Craiglie, 15 m, branch of *Acacia*, on wood, 31.VIII.2006, G. Marson (ex H.B. 8588, BRI AQ799196, **holotype**; MEL 2389243, **isotype**; sq.: KT380091).

Not included. **AUSTRALIA**: **Queensland**, Wet Tropics, 43 km N of Port Douglas, Cape Tribulation, 14 m, stem of *Bambusa*, 30.VIII.2006, G. Marson (H.B. 8495). – Einasleigh Uplands, 3 km SW of Mossman, 1 km ESE of Mossman Gorge Camping, Tara Hills Road, 32 m, branch of indet. angiosperm, on wood & bark, 29.VIII.2006, G. Marson (H.B. 8609a). – **Western Australia**, Swan Coastal Plain, Perth, Kings Park, 50 m, stem of *Anigozanthos manglesii*, 7.IX.2006, G. Marson (H.B. 8303c); – ibid., stem of ?*Ptilotus polystachyus*, 7.IX.2006, G. Marson (ø). – 20 km SW of Jurien Bay, 19.5 km NE of Cervantes, Cervantes Rd, 80 m, branch of *Eremaea*, on bark, 11.XI.2007, G. Marson (H.B. 9132a ø).

Orbilia georgiana Y.Y. Shao, Baral & Bin Liu, in Shao et al., Mycol. Res. 17(11): 1228 (2018) — Pl. 286

Etymology: from the state of Georgia where the species was collected.

Typification: USA, Georgia, Albany, Chehaw Park, branch of *Quercus*, 3.IX.2015, Y.Y. Shao, P.S. Ji & H.F. Zheng (GXU 1472, holotype; ex-type culture: ga006; sq.: MG742408, MG742396).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.25–0.65(–0.8) mm in diam., 0.08 mm thick, pale to light yellow-orange or cream-reddish or orange-rose when fresh, slightly to strongly translucent, round, scattered to subgregarious; disc flat to slightly convex, translucent, margin distinct, not protruding, smooth to very finely rough; sessile on a broad base, superficial or somewhat erumpent between fibres; dry rose-red, slightly contracted. **Asci** †28–38 × 4–5 µm, 8-spored, spores †2–3-seriate, spores inversion unclear; **apex** (†) rounded to slightly truncate, dome ~0.9 µm thick, with small apical chamber; **base** with short to medium long, flexuous stalk, L- to Y-shaped. **Ascospores** *7.5–11 × 1.4–1.5 µm, †9–10.5(–11.5) × 1.3–1.6(–1.8) µm, fusoid to very slightly clavate, apex obtuse, base ± strongly attenuated, straight or sometimes slightly inequilateral; **SBs** *1.5–1.8 × 0.8 µm, elongated tear-shaped, straight. **Paraphyses** apically uninflated to slightly

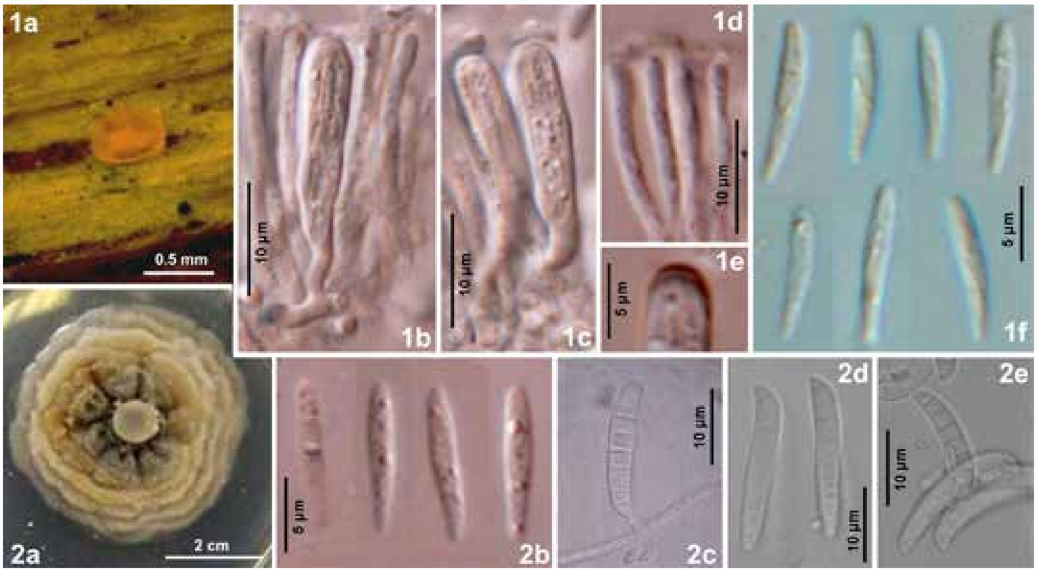

Plate 286. **1–2**: *Orbilia georgiana*. – **1a**. rehydrated apothecium; **1b–d**. asci and paraphyses; **1e**. ascus apex; **1f**, **2b**. ascospores; **2c–e**. conidia (from culture); **2a**. pure culture on PDA. – Dead state (in H_2O), except for **2c–e**. – **1–2**: phot. Y.Y. Shao. — **1a–f**. GXU 1488: USA, Georgia, Albany, on indet. angiosperm; **2a–e**. GXU 1472: ibid.

clavate-capitate, terminal cells †~11–13 × 1.5–3 µm, lower cells †1.8–2.3 µm wide; sometimes branched in middle part. **Medullary excipulum** 25 µm thick, rather sharply delimited. **Ectal excipulum** of (†) thin-walled, indistinctly vertically oriented t. angularis(-prismatica) from base to mid flanks, 25 µm thick near base, cells †6–13 × 5–9 µm; marginal cortical cells elongate, †3–6.7 µm wide; **glassy processes** not observed. **Anchoring hyphae** not examined. **SCBs** no data available. **Exudate** over paraphyses 0.3–1.5 µm thick, granular to cloddy, ± loosely attached, hyaline to pale orange-yellowish-chlorinaceous. — **ANAMORPH**: vermispora-like (from ascospore isolate {1}). **Conidiophores** integrated, sympodial, *1.5–2 × 0.8–1 µm. **Conidia** unbranched, slightly to strongly curved towards the ends, more straight in middle part, cylindrical but tapering at the ends, apex obtuse, base indistinctly truncate, *(12–)13.5–19(–22.5) × 2.5–3.2 µm, 6–7(–8) septate.

Habitat: collected on the ground, decorticated, 20–80 mm thick branches of *Acer* sp. {2}, *Quercus* sp. {2}, on decayed wood {4}, slightly to strongly greyed. **Associated**: none observed. **Desiccation tolerance**: not tested (probably tolerant). **Altitude**: 40–60 m a.s.l. **Geology**: Pennsylvanian, Eocene and Quaternary (carbonate) sedimentary rock. **Phenology**: IX (but probably long-lived).

Taxonomic remarks. The North American *Orbilia georgiana* appears to differ from the mainly European *O. aprilis* in slightly longer and narrower ascospores and from Australian *O. nothoaprilis* in narrower spores and particularly in shorter and wider SBs. Except for the spores the species was only studied in the dead state, therefore, data on the SCBs are missing.

A collection from Texas mentioned under *O. aprilis* differs from *O. georgiana* in thin-walled ascus apices and distinct glassy processes. Two collections from Massachusetts were here included in the description of *O. aprilis* although their relationship to *O. georgiana* remains uncertain.

Not included collection. One of the five samples from the type locality had distinctly smaller spores (*5.5–6.7 × 1–1.2 µm) and was, therefore, not included in the description (see also Shao et al. 2018).

Anamorph. In one of the specimens a pure culture was gained by Y.Y. Shao which produced a vermispora-like anamorph (Pl. 286: 2c–e). The conidia resemble those observed in *O. crenatovinosa*, but this species clusters in the *aprilis-crenatovinosa* clade, unlike *O. georgiana* which clusters in the *vinosa-velutina* clade. Regrettably, the anamorph of *O. nothoaprilis* is unknown.

Phylogeny. A sequence taken from pure cultures of ga006 (holotype) and ga040 comprise ITS (S1506 intron absent) and LSU D1–D3. The two ITS sequences have only in part a good signal but complement one another to permit assembling a complete (chimeric) sequence. The two LSU sequences are identical, except for 1 nt in the D1 domain. *O. georgiana* clustered in a highly supported clade with *O. nothoaprilis* when analysing ITS+LSU, ITS, or LSU, Phyls 9, 11, S13). The two species show an ITS distance of 4.5 % to each other, and 2 % in the LSU (D1–D2), or 1.3 % when including the D3 domain in which no differences were noted between the two species.

Ecology. *O. georgiana* was collected on wood of *Quercus* and *Acer* branches in the warm-temperate humid southern Appalachian Mts. and especially in the subtropical humid lowlands of Georgia (southeastern North America).

Specimens included. **USA**: **Georgia**, ~47 km WNW of Dalton, ~27 km SW of Chattanooga, Canyon State Park, 310 m, branch of *Acer* sp., on wood, 30.IX.2015, Y.Y. Shao (ga055, GXU 1497, doc. vid.). – 5 km NNE of Albany, Chehaw Park, 60 m, branch of *Quercus*, on wood, 3.IX.2015, Y.Y. Shao, P.S. Ji & H.F. Zheng (GA006, GXU 1472, **holotype**, anam. cult., doc. vid.; sq.: MG742408, MG742396). – 88 km NW of Jacksonville, ~25 km NE of Fargo, Stephen C. Foster Park, 40 m, branch of *Quercus*, on wood, 24.IX.2015, Y.Y. Shao (GA040, GXU 1488, doc. vid.; sq.: MG742394, MG742395). – ibid., branch of *Acer*, on wood, 24.IX.2015, Y.Y. Shao (ga026a, GXU 1493, doc. vid.).

Not included. **USA**: **Georgia**, 5 km NNE of Albany, Chehaw Park, 60 m, branch of indet. angiosperm, on wood, 3.IX.2015, Y.Y. Shao, P.S. Ji & H.F. Zheng (ga013, GXU 1478, doc. vid.).

Orbilia crenatovinosa Baral & Friebes, **sp. nov.**, MB 813597 — Pls 287–288

Etymology: named after the toothed margin and similarity with *O. vinosa*.
Typification: Austria, St. Ilgen, branch of *Pinus sylvestris*, 24.X.2009, G. Friebes (ex H.B. 9247, M-0276463, holotype).

Latin diagnosis: *Similis* Orbiliae vinosae *sed ascosporae paulo minores, corpuscula refringentia multo breviora, excipulum marginale processis vitreis multo longioribus praeditum. Habitat ad lignum putridum ramorum siccorum* Pini sylvestris *in zona orotemperata humida in Alpibus orientalibus Europae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.4–0.7(–0.8) mm diam., 0.15–0.2 mm high (receptacle 0.1 → 0.08 mm), light rose-orange, hardly translucent, round to angular, scattered to gregarious in small groups; disc slightly to medium concave, margin with prominent, whitish to pale cream teeth protruding 40–60 µm; sessile on a narrow or broad base, slightly to strongly immersed in furrows and biofilm; disc dry bright orange-brown, half to entirely closed. **Asci** *45–57 × 4.2–4.5 µm {2}, †(40–)45–55(–60) × 4–4.3 µm {1}, 8-spored, spores 3–4-seriate, 2–3 lower spores inverted {1} (not mixed), pars sporifera *19–26 µm long; **apex** (†) hemispherical to slightly (rarely medium) truncate, dome †0.7–1 → 0.5–0.7 µm thick {1}, apical chamber absent or indistinct; **base** with short to long, ± thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(8.7–)9.5–12(–13) × (1.3–)1.4–1.6 µm {3}, †10–12(–13) × 1.4(–1.5) µm {1}, narrowly fusoid(-clavate), apex obtuse, base slightly to often strongly attenuated, with or without an indistinct tail, straight to slightly inequilateral; **SBs** *1.8–2.2 × 0.5–0.8 µm {1}, tear-shaped, apically narrowed to a short filum. **Paraphyses** apically uninflated, rarely clavate-spathulate, terminal cells *8–21 {1} × 1.8–2.3(–2.8) µm {3}, lower cells *10–14 × 1.6–2.2(–2.5) µm {1}; unbranched at upper septum. **Medullary excipulum** pale orange, 50–80 µm thick, of dense textura intricata with many inflated cells, indistinctly to sharply delimited from ectal excipulum by a t. porrecta. **Ectal excipulum** pale orange, of (†) thin-walled to slightly gelatinized, irregularly oriented t. angularis-globulosa from base to mid flanks, 25–50 µm thick near base, cells *8–18 × 6–11(–14) µm {1}; 20–30 µm thick near margin, of t. porrecta oriented at a 10–30° angle to the surface, marginal cortical cells †10–18 × 2.3–3 µm {1}; **glassy processes** 10–40 × 2.3–3.5(–4) µm {2}, high-refractive, stratified, coherent to form distinct teeth, predominantly outwards curved.

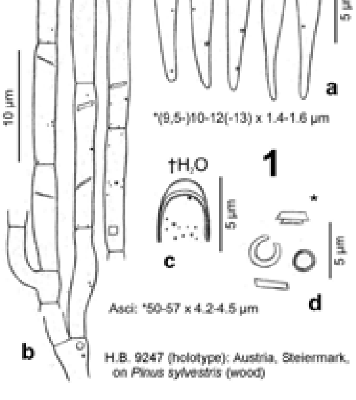

Plate 287. **1–2**: *Orbilia crenatovinosa*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex; **d**. crystalloid SCBs in ectal excipular cells at flanks.

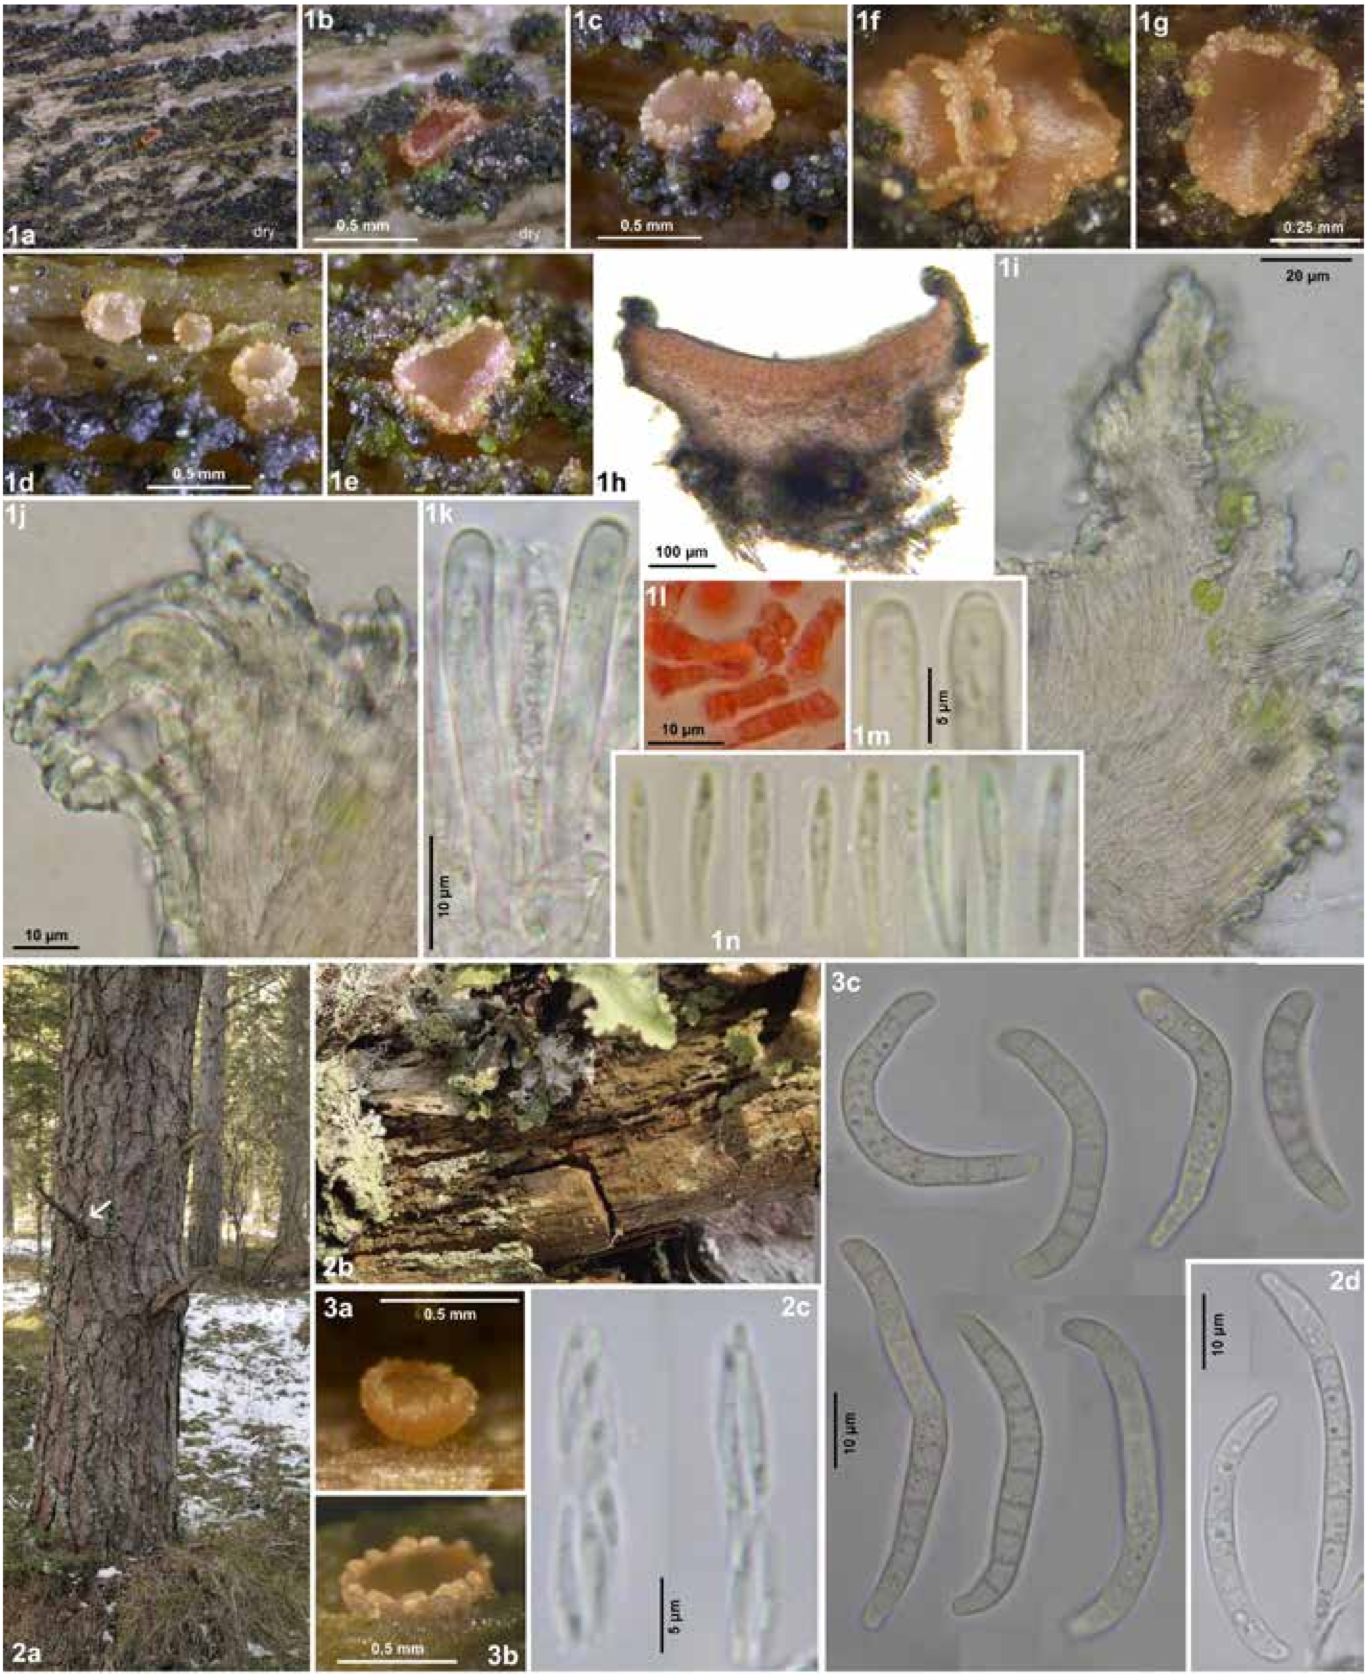

Plate 288. **1–3**: *Orbilia crenatovinosa*. – **2a**. G. Friebes. — **1a–n**. H.B. 9247 (holotype): Austria, Steiermark, on *Pinus*; **2a–c**. G.F. 20160008, ibid.; **3a–d**. G.M. 2014-05-10.1: ibid.

Anchoring hyphae ± abundant, †2–3 µm wide, walls 0.2–0.3(–0.5) µm thick {1}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.3–2.5 µm diam. {2}, also rod- to ring-shaped, hyaline, 1.5–3 µm diam. {2}; **Exudate** over paraphyses (0.3–)1–2(–3) µm thick, cloddy, hyaline, loosely attached, over glassy processes and elongate marginal cells 0.2–0.3 µm thick, finely granular. — **ANAMORPH**: vermispora-like (presumed, from natural substrate {2}). **Conidiophores** not observed. **Conidia** unbranched, multiseptate, irregularly medium to strongly curved in upper and lower part or entirely, cylindrical, slightly tapering at the ends, apex obtuse, base slightly truncate, with many small LBs near septa and a few larger ones; *36–50 × 3.3–4 µm (~42–52 µm actual length), ~4–7-septate {20.II.2016}; *30–42(–57) × 4.2–4.7 µm (~33–59 actual length), 7–11-septate {10.V.2014}.

Habitat: lying close to ground or attached 1.5–2 m above the ground, partially or entirely decorticated, 12–30 mm thick branches of *Picea abies* {1}, *Pinus sylvestris* {4}, on 0.5 mm deep very decayed wood {5}, slightly to strongly greyed, with or without many green algae. **Associated**: *Mellitiosporium propolidoides* {2}, *Platismatia glauca* {1}, on separate branch *Chrysodisca peziculoides* {1}. **Desiccation tolerance**: fully viable for at least 1 week. **Altitude**: 890–950 m a.s.l. **Geology**: Mesozoic dolomite. **Phenology**: II, IV–V, X (probably throughout the year, long-lived).

Taxonomic remarks. *Orbilia crenatovinosa* is characterized by apothecia with a concave disc and distinctly dentate-crenulate margin, in combination with a spore shape similar to *O. vinosa*, and tear-shaped SBs as in *O. aprilis*. Spore length is between these two common species, and spore width somewhat below, while the glassy processes of *O. vinosa*, *O. aprilis* and the Australian *O. nothoaprilis* are never as long as in *O. crenatovinosa* and, therefore, the apothecia never so prominently dentate. The Australian *O. astrovinosa* differs in more vermiform SBs of double or triple length, and usually much longer glassy processes being inwards curved by forming more discrete teeth. *O. aprilis* and *O. astrovinosa* differ also in always lacking crystalloid SCBs.

Anamorph. More or less strongly curved phragmoconidia were observed on the natural substrate in two collections (Pl. 288: 2d, 3c). However, the two collections differ in conidial width and number of septa. Regrettably, in the culture of G.F. 20160008 no conidia developed.

Phylogeny. Sequences were gained from apothecia and an ascospore isolate of two topotypes which comprise S1506 intron, ITS, and LSU. In the intron 1 nt differs between the two strains, while the ITS and overlapping part of LSU (D1–D4) are identical, except for 3 gaps in the ITS2. In analyses of ITS and ITS+LSU, *O. crenatovinosa* clustered in a highly supported clade with *O. aprilis* (Phyls 9, 11), while in the intron and LSU only with medium support (S12, S13). To *O. aprilis* it shows a distance of 9.7 % (ITS), 3.8–4 % (LSU), and 10 % (intron), while to *O. vinosa*/*O. subvinosa* the distance is 19–22 %, 7–7.3 % and 18–19 %, respectively.

Ecology. *O. crenatovinosa* was several times found on rotten wood of xeric or semihygric branches and stubs of *Pinus* and *Picea* in montane, ± mixed forests (*Pinus sylvestris*, *Picea abies*, *Fagus sylvatica*, *Abies alba*, *Juniperus communis* etc.), see Friebes (2017: 36, fig. 27a–c, as *Orbilia* sp.). The two localities are on very calcareous soil in the subcontinental, orotemperate humid eastern Alps of central Europe. The type locality is a west-exposed slope of a valley with abundant *Cypripedium*, the other place is at the top of a crest.

Specimens included. **AUSTRIA**: **Steiermark**, 20 km NNW of Bruck an der Mur, 3 km NNW of St. Ilgen, Karlschütt, 890 m, branch of *Pinus sylvestris*, on wood, 24.X.2009, G. Friebes (ex H.B. 9247, M-0276463, **holotype**). – ibid., 10.V.2014, G. Friebes (G.M. 2014-05-10.1, anam. substr., doc. vid.; sq.: KT380085). – ibid., branches of *P. sylvestris*, on wood, 20.II.2016, G. Friebes (G.F. 20160008, anam. substr., doc. vid.; sq.: KY419189). – **Kärnten**, 15 km S of Klagenfurt, 5.5 km SE of Ferlach, Waidisch, 950 m, branch of *P. sylvestris*, on wood, 9.IV.2016, G. Friebes (G.F. 20160092, doc. vid.). – ibid., branch of *Picea abies*, on wood, 9.IV.2016, G. Friebes (G.F. 20160093, doc. vid.).

Orbilia aprilis Velen., Opera Bot. Čech. 4: 102 (1947) — Pls 289–291, Map 49

= *Trinacrium tothii* Magyar, in Magyar & Révay, Nova Hedwigia 87: 514, figs 1–57 (2008)

Etymology: *aprilis*: named after the month when the holotype was collected; *tothii*: in honour of the Hungarian mycologist Sándor Tóth.

Typification: Czechia, Mnichovice, branch of *Corylus avellana*, 28.IV.1941, J. Velenovský (PRM 152434, holotype of ***O. aprilis***); Luxembourg, Bettembourg, branch of ?*Rhamnus*, 20.X.2000, G. Marson (ex H.B. 6801, M-0291762, epitype, designated here, MBT385114, CBS 116278; sq.: KT215268). — Hungary, Tolnau, Szekszárd, *Elaeagnus angustifolia*, 12.XI.2007, D. Magyar (BP 99770, holotype of ***Trinacrium tothii***).

Misapplied names: Rehm (1891: 455, p.p. ?*O. aprilis*), as *O. luteorubella*; Svrček (1954: 9), as *O. vinosa*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.8(–1)((–1.4)) mm diam., 0.1–0.2(–0.23) mm high (receptacle 0.07–0.12 mm), (pale to) light (to bright) (orange-)rose to rose-red or rose-pink, also yellowish-ochraceous to orange, medium translucent, round, scattered to mostly ± gregarious; disc slightly concave to flat, margin ± thin, 0–15 µm protruding, smooth or mostly finely rough to crenulate; broadly sessile, sometimes with a ± distinct hidden stipe 0.02–0.09 × 0.15–0.4 mm, superficial or immersed in algal layer; dry light to bright orange-rose to apricot, slightly contracted. **Asci** *(35–)38–58(–61) × (4–)4.3–5.2(–5.5) µm {15}, †(28–)33–50(–56) × (3.5–)4–4.5(–5)((–5.8)) µm {11}, 8-spored, spores 3–4-seriate, (1–)2–4(–5) lower spores inversely oriented {27} (not or sometimes strongly mixed), pars sporifera *14–23 → 13–16 µm long; **apex** (†) hemispherical to slightly (rarely medium) truncate, dome †0.8–1.8 → 0.4–1.3 µm thick {6}, with or without apical chamber; **base** with short to very long, ± thin, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *((5.5–))(6–)6.5–9.5(–10.5) × (1.5–)1.6–2(–2.2)((–2.4)) µm {72}, †6.2–9 × (1.2–)1.4–1.7(–2) µm {4}, fusoid-clavate, rarely subcylindrical, apex rounded to obtuse, sometimes subacute, base mostly slightly to strongly attenuated (rarely tail-like), straight, sometimes slightly curved near base; **SBs** *((1.2–))1.5–2.2(–2.5)((–2.7)) × (0.3–)0.4–0.8(–0.9) µm {67}, tear-shaped, pyriform-ampulliform, or subulate to rod-shaped, apically narrowed to a small to wide point, with or without a very short filum. **Paraphyses** apically uninflated, sometimes slightly (rarely medium) clavate-capitate, exceptionally spathulate, terminal cells *(5–)7–16 × (1.7–)2–2.7(–3) µm {7}, †8–16 × 2–3 µm {T}, lower cells *(2–)4–10(–12) × 1.8–2.6 µm {5}, †5–7 × 1.7–2.2 µm {T}; never branched near apex; hymenium pale rose. **Medullary excipulum**, 30–80(–100) µm thick, of medium loose or dense textura intricata with many inflated cells, medium to sharply delimited. **Ectal excipulum** pale rose, of ± thin-walled, vertically (or irregularly) oriented t. globulosa-angularis(-prismatica) from base to submargin, 20–60(–110) µm thick near base, cells *(6–)9–20(–25) × (4–)6–13(–17) µm {9}; 10–30(–40) µm thick at flanks and margin, inner part of t. prismatica-angularis oriented at a 45–80° angle to the surface, cells *6–8 × (2–)3–5(–7) µm {2}, outer part of t. porrecta oriented at 10–40(–80)°, marginal cortical cells *6–15 × 2–4(–5) µm {8}, †6–12 × 2–3 µm {2}, **glassy processes** ± absent {8} or present {48}, (0–)1–10(–12) × (2–)2.5–3.5(–4.5) µm {23}, refractive, slightly to strongly stratified, cortical cells somewhat protruding to form 0–1-septate hairs up to 12–18 µm long, agglutinated to form small teeth (8–18 × 15–30 µm) or radial ribs at the margin. **Anchoring hyphae** sparse to medium abundant, *1.5–3 µm wide, walls 0.2–0.3 µm thick {4}, sometimes forming a dense t. intricata up to 20 µm thick. **SCBs** globose to ellipsoid {35}, in paraphyses 1.5–2.5 µm diam., in excipular cells 1–2.5 µm. **Exudate** over paraphyses (0.5–)1–2(–3) µm thick, pale yellowish-chlorinaceous, broken into clods, loosely attached; over margin and flanks (1–)2–6(–10) µm thick, coarsely rough, pale to light golden- or honey-yellow, ± firmly attached to glassy processes, also covering them as a thin layer. — **ANAMORPH**: trinacrium-like (from ascospore isolate {2} and natural substrate {17}). **Conidiophores** *~(2–)14–18 × (1.2–)1.8–2.2 µm. **Conidiogenous cells** monoblastic or sympodial. **Conidia** Y-shaped, total size *19–33 × (12.5–)15–24(–26) µm, stipe *12–21 × 4–5.2 µm, 2–4-septate, arms cylindrical with rounded to obtuse ends, not or only slightly tapered, *7–13 × (3–)3.5–

4.7 µm, 1–3(–4)-septate {7}; unbranched conidia rarely seen (both in pure culture and on natural substrate), straight, *25.5–35 × 3.3–4.8 µm, 5–7-septate {2}.

Habitat: collected (0–)1–3(–8)((–20)) m above the ground, ± corticated or often decorticated, (4–)10–65(–100) mm thick branches (rarely up to 35 cm thick trunks) of *Acer* sp. {2}, *A. campestre* {1}, *A. platanoides* {1}, *Alnus glutinosa* {3}, *Betula* sp. {1}, *B. pubescens* {1}, *Buxus sempervirens* {2}, *Calicotome villosa* {1}, *Carpinus betulus* {5}, *Castanea sativa* {10}, *Ceratonia siliqua* {1}, *Clematis vitalba* {6}, *Cornus mas* {1}, *Corylus avellana* {10}, *Crataegus* sp. {1}, *C. laevigata* {2}, *C. monogyna* {2}, *Elaeagnus angustifolia* {1}, *Erica arborea* {1}, *E. scoparia* {3}, *Fagus orientalis* {1}, *F. sylvatica* {8}, *Frangula alnus* {4}, *Ilex aquifolium* {4}, *Juglans regia* {1}, *Laburnum anagyroides* {1}, *Ligustrum vulgare* {2}, *Malus domestica* {1}, *Picea abies* {10}, *P. orientalis* {1}, *Pinus pinaster* {1}, *P. radiata* {1}, *P. sylvestris* {6}, *Pistacia lentiscus* {1}, *Populus tremula* {1}, *Prunus* sp. {1}, *P. avium* {4}, *P. domestica* {1}, *P. spinosa* {3}, *Pseudotsuga menziesii* {1}, ?*Pyrus communis* {1}, *Quercus* sp. {24}, *Q. cerris* {1}, *Q. petraea* {2}, *Q.* ?*pubescens* {1}, *Q. robur* {27/1}, *Q. rubra* {1}, *Rhamnus* sp. {1}, *R. cathartica* {1}, *Rhododendron ponticum* {1}, *Robinia pseudoacacia* {10}, *Rosaceae* {1}, *Rubus grandifolius* {1}, *Salix* sp. {7/1}, *S. caprea* {7}, *S. cinerea* × *aurita* {1}, *S. cinerea* {3/1}, *S. fragilis* {1}, *Sambucus nigra* {5}, *S. racemosa* {2}, *Sequoiadendron giganteum* {1}, *Sorbus aucuparia* {3}, *S. torminalis* {1}, *Spartium junceum* {1}, *Syringa reticulata* {1}, *S. vulgaris* {1}, *Tamarix anglica* {3}, *Taxus baccata* {1}, *Thuja occidentalis* {1}, *T. plicata* {1}, *Tilia* sp. {2}, *Ulex europaeus* {3}, *U. minor* {1}, *Ulmus* sp. {3}, on 0.1–3 mm deep (or even deeper) strongly (rarely slightly to medium) decayed wood {202}, sometimes on bark (bast) {30}, sapwood sometimes strongly eroded or removed, heartwood then either undecayed or white-rotten, sometimes in old beetle galleries or on inner surface or edges of detached bark, slightly to strongly greyed, very sparsely to often densely covered by green algae. **Associated**: *Agyrium roseum* {1}, *Amandinea punctata* {1}, *Arachnopeziza aurata* {1}, *Arthonia crozalsiana* {1}, *Capitotricha bicolor* {1}, *Capronia* sp. {1}, ?*Ceratosphaeria* sp. {1}, ?*Chaetosphaeria* sp. {1}, *C. myriocarpa* {2}, *Chalara inflatipes* {1}, ?*Ciliolarina* sp. {1}, *Coenogonium pineti* {1}, *Cryptodiscus foveolaris* {6}, *C. pallidus* {1}, *Dacrymyces* sp. {6}, ?*Durella* sp. {1}, *D. atrocyanea* {5}, *D. connivens* {19}, *Evernia prunastri* {1}, *Exarmidium inclusum* {1}, *Helicogonium orbiliarum* (parasitic in *O. aprilis*) {1}, '*Helotium*' *uvidulum* {3}, *Hyalorbilia fusispora* {1}, *H. juliae* {2}, *H. subfusispora* {3/1}, *Hyaloscypha minuta*/*intacta* {7}, *H. quercicola* {1}, *Hyphodontia* sp. {3}, *Hysterium pulicare* {2}, *Hysterobrevium smilacis* {2/1}, ?*Hysteropatella* sp. {1}, *Lecanora conizaeoides* {1}, *Minimelanolocus hughesii* {1}, *Mollisia* sp. {2}, *M. ligni* {13}, *M.* ?*melaleuca* {3}, *Nemania confluens* {2}, *Neodasyscypha cerina* {1}, *Orbilia alpigena* {1}, *O. aristata* {1}, *O. cylindrospora* {1}, *O. eucalypti* {7}, *O. euonymi* {7}, *O. hesperidea* {3}, *O. microsoma* {1}, *O. montigena* {1}, *O. pleiomicrosoma* {1}, *O. pleistoeuonymi* {3}, *O, polyspora* {1}, *O. subclavuliformis* {1}, *O. subulivinosa* {1}, *O. trapeziformis* {1}, *O.* ?*tremulae* {1}, *O. vibrioides* {1}, *O. vinosa* {22}, *Parmelia sulcata* {2}, ?*Phoma* sp. {1}, *Phragmiticola* sp. {1}, *Physcia* sp. {1}, *Polydesmia pruinosa* {1}, *Proliferodiscus pulveraceus* {3}, *Propolis farinosa* {4}, *P. viridis* {2}, *Pyrenopeziza* ?*coriariae* {1}, *Resupinatus applicatus* {3}, *Rhamphoria pyriformis* {1}, *Rhizodiscina lignyota* {1}, *Strossmayeria basitricha* {1}, *Symbiotaphrina microtheca* {1}, *Trichonectria* sp. {1}, *T. hirta* {1}, '*Tympanis*' *xylophila* {1/2}, *Unguiculariopsis* sp. {1}, crustose lichens, indet pyrenomycetes {2}. **Desiccation tolerance**: fully viable for at least 3 weeks, some mature asci still alive after 2 months, excipular cells and ascospores even after 22 months, conidia and conidiophores after 1.5 months (see also Magyar & Révay 2008). **Altitude**: 1–1083 m (northern and central Europe), 8–1400 m (southern Europe), -8–1415 m a.s.l. (eastern Europe). **Geology**: Ordovician-Devonian-Carboniferous lime-, sand-, silt- & mudstone, shale, quartz, greywacke, Permian (Rotliegend, Zechstein), Buntsandstein, Muschelkalk, Keuper-Jurassic -Cretaceous marl, clay, sand- & limestone, flysch, Tertiary molasse & limestone, Quaternary loess, moraine, till & sand; granite, migmatite, quartz diorite, porphyry, andesite, diabase, biotite-amphibole, gneiss, mica schist. **Phenology**: throughout the year (long-lived).

Phenology of *O. aprilis*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
11	11	15	31	35	26	10	23	19	15	15	18

Taxonomic remarks. *Orbilia aprilis* is characterized by rather small and narrow, fusoid-clavate ascospores with small, tear- to rod-shaped SBs. The closely related *O. vinosa*, with which *O. aprilis* might have been confused in the past, is sharply delimited by much longer spores and SBs, with (9.5–)10 µm and (3–)3.5 µm as minimum length, respectively. The measurements do not even overlap in almost all of the many collections studied. Further differences exist in the anamorph (see below). For the similar Australian *O. nothoaprilis* (p. 640) and *O. crenatovinosa* (p. 643) see there.

O. aprilis may also have been confused with species of section *Helicoon* because of a similar spore size and shape, e.g., by Rehm (1891). Section *Helicoon* differs in truncate thin-walled ascus apices, often capitate paraphyses, and a hygric to semiaquatic habitat. The European *O. luteorubella*, *O. rosea*, and *O. sarraziniana* have a similar spore size and shape as *O. aprilis* but differ in much longer, ± filiform spore bodies. Many members of section *Helicoon* have long, filiform SBs, but others from that section (*O. hoana*, *O. juruensis*, *O. yuanensis*), or *O. bannaensis* from section *Aurantiorubrae*, have rather short and thick SBs similar to *O. aprilis*.

Variation. *O. aprilis* is an easily recognizable species that shows little micromorphological variability. Ascus and spore measurements but also SB size varied to some extent among the collections [e.g., spore width between *1.5–1.7 and *1.8–1.2(–2.4) µm). Especially spore and SB length shows much less variation compared to *O. vinosa*. The short glassy processes on the cortical excipular cells, which provoke a crenulate appearance to the apothecial margin, are quite characteristic though not always present. A mediterranean collection (on *Spartium*, Pl. 291: 1) was only studied in the dead state; it deviates in a thick apothecial margin and in spores with ± distinct tails (†7–9 × 1.7–1.9 µm). However, tails were rarely also seen in some spores of other collections, e.g., Pl. 289: 8.

Type studies. The holotype of *O. aprilis* contains a corticated branch with five minute apothecia seated on very rotten, greyed, algae-covered xeric wood at the cross-cut end. The protologue says 'ad truncum sectum *Carpini betuli*', but the microanatomy of the wood clearly refers to *Corylus*. The inhabited substrate was apparently a young trunk which has been cut near the bottom some years before the apothecia developed.

Svrček (1954: 9) observed in the scanty type material only immature asci without spores. He assumed that Velenovský's report of 3–5 µm long, ellipsoid, eguttulate spores was erroneous, and that *O. aprilis* was a not fully developed *O. vinosa.* In the present examination of the largest apothecium a single nearly mature ascus with 6 visible spores (7–8 × 1.7 µm) was found. Though the ascus was apparently not fully mature, these spores appeared to have already attained their final size which would exclude *O. vinosa*. The asci showed an extraordinary width (4.5–5.5 µm), perhaps due to slight artificial flattening. Based on the mentioned ascospore size we here adopt Velenovský's taxon for this overlooked though very common and distinctive species.

In order to emphasize this interpretation, we here designate a collection from Luxembourg on *Rhamnus* (ex

H.B. 6801, CBS 116278; sq.: KT215268) as **epitype** of *O. aprilis* (Pl. 289: 12).

Not included collections. Two samples from Massachusetts (on *Pinus*, Pl. 289: 9; on indet angiosperm, IVV: bhi-F628a) match perfectly European *O. aprilis*. Because available sequence data of the angiosperm sample markedly differ from typical *O. aprilis* and suggest a deviating cryptic taxon (see below), we refrained from including any North American records in the description. A sample from Texas on *Quercus* (IVV: H.B. 6202) was only studied in the dead state; it deviates in a thin-walled, sometimes slightly truncate ascus apex, therefore, its resemblance with *O. aprilis* is perhaps only superficial.

Anamorph. The conidia of *O. aprilis* closely resemble those of *O. vinosa*, differing only in shorter arms and stipes with fewer septa. This anamorph concurs very well with the protologue of *Trinacrium tothii* (see Pl. 22: a), a taxon being recently described from a conidial isolate derived from colonies between layers of detaching xeric bark of *Elaeagnus angustifolia* in Hungary (Magyar & Révay 2008). Previous records were reported from stemflow samples from different tree species in Hungary (Gönczöl & Révay 2004, fig. 5; 2006, figs 49–50).

In the ex-type cultures of *T. tothii* (on CMA) apart from the Y-shaped conidia also unbranched conidia were formed, especially when permanently flooded with water. The conidia from culture were identical with those on the natural substrate, according to Magyar & Révay (l.c.). The size of the Y-shaped conidia were given as (12–)17–22(–31) × 8.7–16.7(–20) µm, with a 2.7–3.6(–5) µm wide stipe [10–20(–29) × (2.3–)2.7–4(–4.5) µm according to scale], and arms of 2.5–7.5 × (2–)2.3–2.7(–4) µm [(2.5–)4–8.5 × 2.3–3.8 µm according to scale]. This is distinctly smaller compared to our measurements of living conidia: the width of the stipe and the size of the arms overlaps only slightly. However, these measurements were made in CB_L (D. Magyar pers. comm.), which explains the smaller size to a certain degree. The phragmoconidia better fit, their smaller size in the protologue being easily be explained by the shrinking effect in CB_L.

Phylogeny. Sequences were gained from pure cultures of two samples (H.B. 6801 from Bettembourg, epitype; H.B. 6715a from Stuttgart), comprising SSU (V7–V8), S1506 intron, ITS, and LSU (D1–D2). They are of equal length (1901 nt) while a sequence from apothecia (G.M. 2017-07-30.1, Hovelange) covers S943 intron and V6 of SSU until D5 of LSU. In the SSU they are identical while 1–2 nt differ in the S1506 intron as well as in the ITS, and 0–1 nt differ in the LSU.

In spite of a strong morphological similarity, the distance between *O. aprilis* and *O. vinosa* is very high: ITS 21–22.5%, intron 18.5–19.5%, and LSU (D1–D2) 7.5% (0.3% in SSU). In phylogenetic analyses of SSU+ITS+LSU, ITS+LSU, ITS, intron, or LSU, (Phyls 7, 9–11, S12, S13), *O. aprilis* rarely clustered near *O. vinosa* (e.g., in Baral et al. 2017b) but is usually found unresolved within section *Hemiorbilia* in a clade of its own (here called *aprilis-crenatovinosa* clade). *O. aprilis* and *O. crenatovinosa* are always associated with medium or strong support (see under the latter species, p. 645). The also very similar *O. nothoaprilis* clustered in the *vinosa-velutina* clade.

From one of the North American collections from Massachusetts referable to *O. aprilis* (IVV: bhi-F628a) a sequence was gained (S1506 intron and ITS) which deviates from *O. aprilis* by 1.6–1.9% in the ITS and 3.3–3.8% in the intron, therefore, it might belong to a separate cryptic species without obvious morphological differences in the available teleomorph.

There exists an apparently confused or contaminated culture from South Africa (CBS 12521, allotype of *Metschnikowia proteae*, *Saccharomycetales*), the unofficial ITS sequence of which shows a 1.8–2% distance to *O. aprilis* (2.5% in the intron), whereas LSU sequences of the holotype culture (CBS 12522, type) in GenBank concur with those of CBS 12521 in the CBS database and cluster with *Saccharomycetales*.

Our trials to gain a sequence from the type culture of *Trinacrium tothii* failed, as it turned out to be contaminated by a *Cordycipitaceae*.

Ecology. Like *O. vinosa*, *O. aprilis* belongs to the most frequently collected species of *Orbilia* on xeric woody substrates in temperate regions of Europe. A total of 228 samples have been recorded, 153 of them examined by the first author and 79 by others. The species occurs widespread throughout atlantic, central, eastern, and southern Europe. It was also recorded in western Russia, the Caucasus mountain range, and western Anatolia. Although frequently investigated by mycologists, records from Spain and boreal parts of Scandinavia are so far wanting, and only one for Switzerland and Italy, and two for Croatia are known. Missing records in various other countries are probably only a matter of sparse collecting.

O. aprilis was mainly collected in atlantic to continental, cold- to warm-temperate humid regions of western and central Europe in thermophilous or more shady forests and shrubs. The ecological preferences are very similar to *O. vinosa*, including both calcareous and acidic geology, but *O. aprilis* appear to avoid altimontane (orotemperate) regions of central Europe. Its presence in the hemi- to thermoboreal zone is only known at present for northwestern Russia. Further records include mesosub- and mesomediterranean semihumid (more rarely orosub- to suprasubmediterranean) areas in southern Europe, the warm-continental subhumid steppic Caspian Volga floodplain, and supramediterranean semihumid western Anatolia. The few not included extra-European samples that came to our notice were from cold-temperate humid forests in northeastern North America and from a warm-temperate subhumid shrubland of *Quercus virginiana* and *Juniperus occidentalis* in the south of Northern America.

O. aprilis inhabits rotten, periodically dry wood, sometimes bark, of xeric branches of a very wide range of angiosperm but also gymnosperm trees and shrubs. The most favoured host genus in our collections was *Quercus* {57}, followed by *Salix* {21}, *Picea* (11), *Castanea* {10}, *Corylus* {10}, *Robinia* {10}, *Pinus* {8}, *Fagus* {9}, and *Prunus* {9}. The fact that *O. aprilis* could not be found in the consulted herbaria, apart from the sparse immature holotype, illustrates how seriously xeric substrate was neglected by collectors.

In concordance with the epithet, our phenological data suggest a maximum in April–June, but this is merely a result of more intense collecting activities during annual ascomycete

Not included. **USA**: **Massachusetts**, 30 km WNW of Boston, 4.5 km SSW of West Concord, Maynard-Sudbury, 61 m, twig of *Pinus strobus*, on wood, 8.VIII.2011, U. Graf (H.B. 9591). – 16 km SE of Boston, 3.5 km NNE of Hingham, Slate Island, 2 m, branch of indet. angiosperm, on wood, 21.III.2017, A.C. Dirks & L.A. Kappler, vid. L. Quijada (bhi-F628a; sq.: MF161307). – **Texas**, Oaks and Prairies, 65 km W of Austin, ~2 km WSW of Johnson City, 378 m, branch of *Quercus virginiana*, on wood, 18.VI.1996, G. Marson (H.B. 6202).

Orbilia myriofusiclava Baral & G. Marson, **sp. nov.**, MB 813533 — Pls 292–293, Map 50

Etymology: referring to the 64-spored asci and the fusoid-clavate spores.

Typification: Western Australia, Northampton, branches of *Acacia*, 9.XII.2001, G. Marson (ex H.B. 7237a, MEL 2389232, holotype; CBS 116224; sq.: KT215274).

Latin diagnosis: *Apothecia rehydratata 0.3–1.3 mm diam., vivide aurantiaca, sessilia vel substipitata, margine subaspera vel minute crenulata. Asci 64-spori, apice in statu emortuo hemisphaerico, crassitunicato. Ascosporae *5–10.5 × 2–2.7 µm, fusoideo-clavatae, apice obtusae ad acutae, basi plerumque valde attenuatae, leniter ad valde curvatae, corpusculum refringens pyriformem, ad apicem affixum continentes. Cellulae vivae excipuli marginalis et paraphysium corpuscula crystalloidea hyalina vel pallide aurantiaca, et globosa continentes. Habitat ad corticem leniter vel valde putridum ramorum* Acaciae *et* Jacksoniae *in zona subtropica semihumida ad arida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–1(–1.3) mm diam., 0.15–0.25(–0.45) mm high, light to bright (sometimes dirty) orange, non-translucent, round to irregularly elongate, scattered to densely gregarious in ± small groups; disc slightly concave to flat, margin distinct, thin, 5–30 µm protruding, ± smooth to finely rough or crenulate; broadly sessile, sometimes with a broad stipe up to 0.2 × 0.5 mm, superficial if on inner surface of bark, often partially to completely immersed in clefts of outer surface; dry ± closed (sometimes hysterioid), bright to deep orange-red or rose-carmine. **Asci** *((71–))(80–)85–110(–120) {4} × (7.5–)8–9(–10) µm {5}, †(73–)80–98(–108) × (6.7–)7–8(–8.5) µm {3}, 64-spored (46–52 spores counted), spores *4–5-seriate, many spores inverted (strongly mixed), pars sporifera *60–75 µm long; **apex** (†) hemispherical to very slightly truncate, dome †0.8–1.2 → 0.5–0.8 µm thick {3, in H_2O or KOH}, with distinct apical chamber; **base** with short, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(5–)6–8.5(–10.5) × (2–)2.2–2.5(–2.7) µm {5}, †(6–)7–8(–9) × 2–2.6(–2.8) µm {2}, fusoid-clavate, apex rounded to obtuse or usually subacute to acute, base mostly strongly attenuated (often tail-like), slightly to very strongly curved, especially near base; **SBs** apically attached to spore wall, *(1.8–)2–2.8(–3) × 0.8–1.3 µm {3}, pear-shaped, apically narrowed to a small to wide point. **Paraphyses** apically uninflated or mostly slightly to medium clavate(-capitate), sometimes sublageniform, terminal cells *8.5–25 × (2.3–)3–4.5(–5) µm {3}, projecting 5–25 µm beyond dead asci, lower cells *8.5–23 × 1.8–3 µm {2} (towards upper septum sometimes up to 4.5 µm wide); sometimes or rather frequently branched near apex, hymenium pale orange-rose. **Medullary excipulum** hyaline to pale orange, 25–45(–60) µm thick, of medium loose or dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a parallel 10 µm thick layer of t. porrecta. **Ectal excipulum** hyaline to pale orange-rose, of (†) thin-walled to slightly gelatinized, indistinctly to vertically oriented t. angularis(-prismatica) from base to submargin, 25–100(–270) µm thick near base, cells *(5–)10–20(–28) × (6–)8–14(–20) µm {4}, †6–11 × 6–9 µm {1}; 15–30 µm thick near margin, upper part of t. prismatica-porrecta oriented at a 20–50° angle to the surface, marginal cortical cells *7–17 × 3–5(–6) µm {4}, cylindric-clavate; **glassy processes** absent. **Anchoring hyphae** sparse to quite abundant, †1.5–2.5 µm wide, walls 0.2–0.4 µm thick {3}. Globose **SCBs** in paraphyses (1.8–3 µm diam) and marginal ectal excipulum (2.5–4 µm), crystalloid SCBs in upper part of paraphyses and from basal to marginal ectal excipulum {4}, hyaline to light yellow-orange. Light yellow-orange **LBs** 0.2–1 µm diam. (carotenoids) abundant in ectal excipulum (especially towards margin) and paraphyses (except for apex). **Exudate** over paraphyses (0.5–)1–4(–6) µm thick, coarsely continuous to cloddy, hyaline to pale yellowish, loosely attached; over margin and flanks (0.5–)1–5(–15) µm thick, cloddy, light yellow (to ochre-orange). — **ANAMORPH**: vermispora-like (from ascospore isolate {1} and natural substrate {1}). **Conidiophores** absent. **Conidiogenous cells** integrated, with short pegs *1.5–3 × 2.2–2.5 µm. **Conidia** unbranched, curved in upper part, rarely straight, narrowly fusoid, tapering especially at the tip, truncate at the base, *(26–)31–42 × (3.7–)4–4.5(–4.8) µm, (3–)6–8-septate {1}.

Habitat: collected ~0.2–2.5 m above the ground, corticated, 8–50 mm thick branches of *Acacia* sp. {6}, *Jacksonia* sp. {2}, on mostly slightly to entirely detached, slightly to strongly decayed bark {8}, on periderm or bast (especially on outer surface in cracks of periderm, also often on inner surface), slightly to strongly greyed, green algae very sparse to abundant. **Associated**: *Baggea* sp. {1}, *Caloplaca* sp. {2}, *Claussenomyces* sp. {3}, *Durella* sp. {1}, *D.* aff. *connivens* {1}, *Gloniopsis praelonga* {3}, *Hyalorbilia* ?*erythrostigma* {1}, *Hypoxylon* sp. {1}, ?*Hysteropatella* sp. {1}, *Muellerella lichenicola* {1}, *Orbilia albidorosea* {1}, *O. anguliobliqua* {1}, *O. australiensis* {5}, *O. commarosa* {2}, *O. curvativitalbae* {2}, *O. curvatiobliqua*

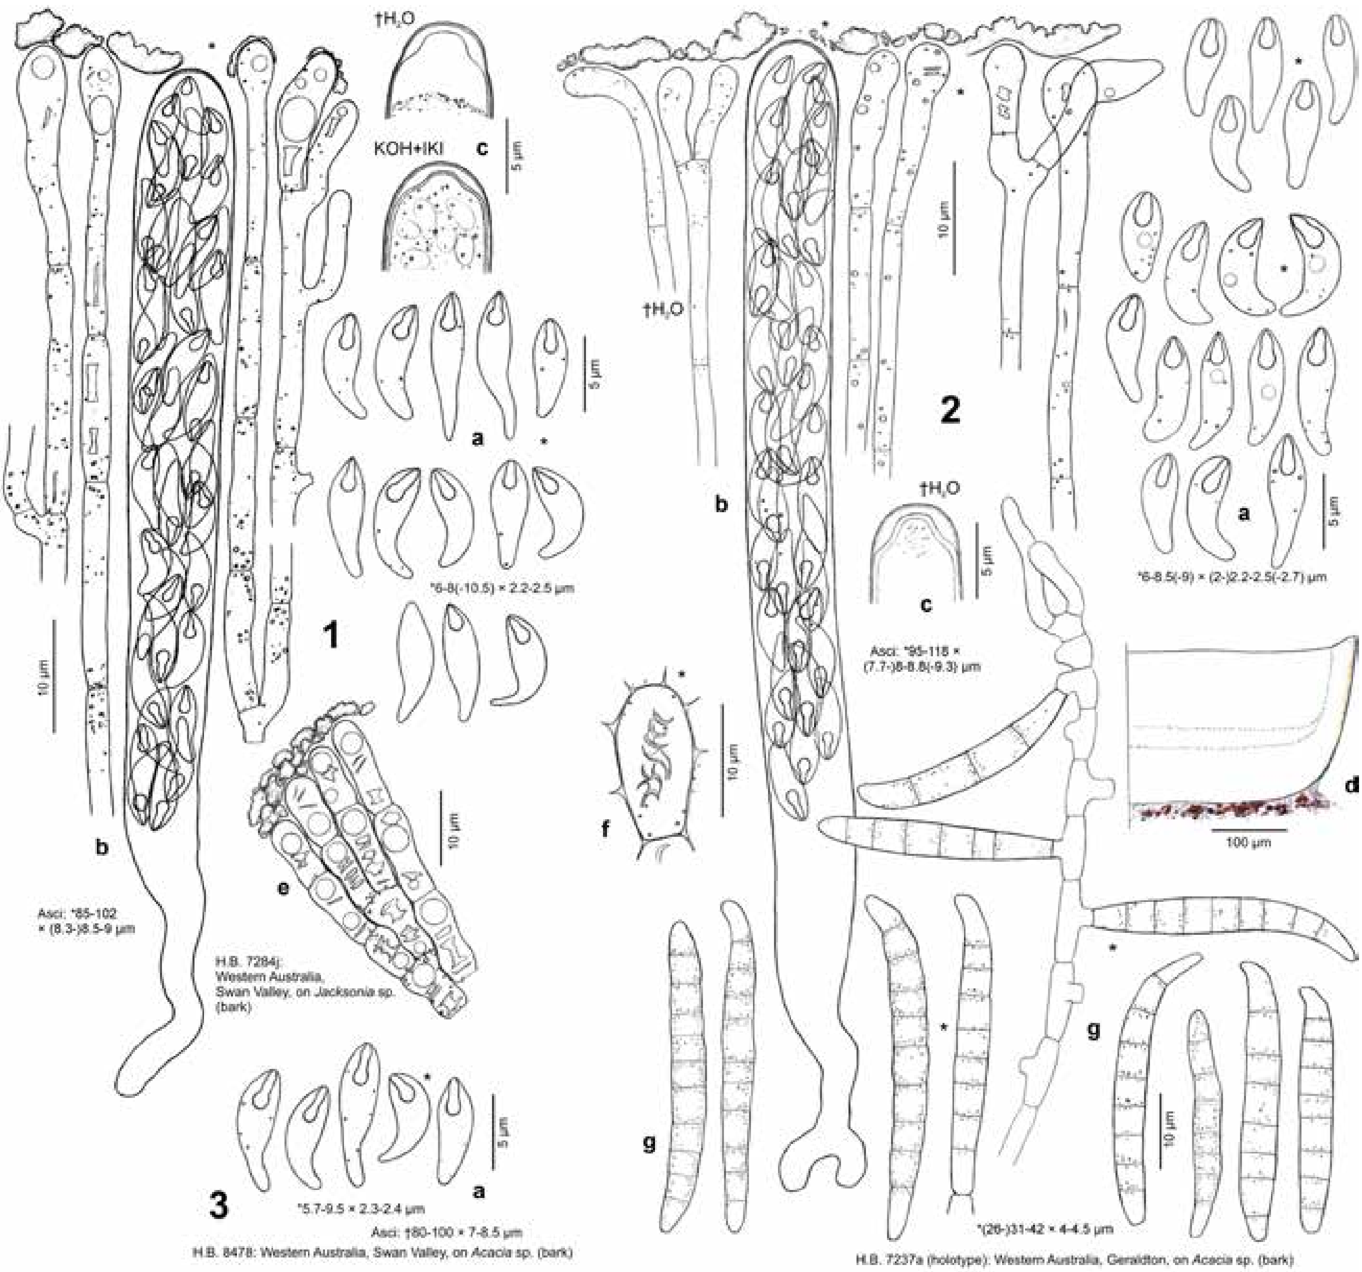

Plate 292. **1–3**: *Orbilia myriofusiclava*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum; **f**. ectal excipular cell at flanks containing crystalloid SCBs; **g**. conidia and integrated conidiogenous cells from culture.

{1}, *O. eucalypti* {4/1}, *O. helicoobliqua* {1}, *O. hesperidea* {1}, *O. kingsiana* {1}, *O. macrotrapeziformis* {2}, *O. microserpens* {2}, *O. ?multiserpens* {1}, *O. myrioeuonymi* {1}, *O. myriolilacina* {1}, *O. myriomuscula* {1}, *O. myrionanosoma* {1}, *O. myrioobliqua* {5}, *O. myriopseudoregalis* {1}, *O. nothovinosa* {2}, *O. paraobliqua* {1}, *O. pleioaustraliensis* {2}, *O. pleioquaestiformis* {1}, *O. ?pleioserpens* {1}, *O. pluristomachia* {1}, *O. ?serpentina* {1}, *O. wannerooensis* {1}, *Patellaria atrata* {1}, *Schizoxylon* sp. {1}, ?*Triblidium* sp. {1}, indet. coelomycete {1}. **Desiccation tolerance**: many mature asci still viable after 12 months, some still after 14.5 months. **Altitude**: 37–278 m a.s.l. **Geology**: Archean and Cretaceous sedimentary rock, Cenozoic regolith (whitish sand); granite, granitic gneiss. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myriofusiclava* is characterized by 64-spored asci and fusoid-clavate, often strongly curved ascospores. The species resembles *O. cryptogena*, from which it differs in smaller spores with usually acute apices, and in the presence of crystalloid SCBs. Two species of series *Hesperideae*, *O. palmicola* and *O. multiaustraliensis*, differ in 32-spored asci and in having wider and scarcely curved spores. For the similar *O. myriohesperidea* see Pl. 247.

Variation. *O. myriofusiclava* seems to be a rather constant species. Remarkable variation was only observed in the spore apices, which varied between rounded-obtuse and subacute-acute: more or less acute spore apices were seen in most of the collections examined, but in some of them spores with rounded to obtuse apices also occurred. In the holotype, one apothecium showed only spores with rounded to obtuse apices (Pl. 292: 2a, above 5 spores), and also in the sparse collection H.B. 7215d only rounded spore apices were seen (dead state, see IVV). The living asci varied between 71–83 and 100–120 µm in length (within H.B. 8745e), and between 8–8.3 and 8.5–10 µm in width (between different collections). Extraordinarily small apothecia were noted in H.B. 7215d (0.15–0.17 mm diam).

Anamorph. The anamorph obtained in pure culture resembles *Vermispora spermatophaga* in conidial morphology. However,

Plate 293. **1–6**: *Orbilia myriofusiclava*. – **3a**. semihumid Eucalypt open forest (Jarrah Forest); **2a–b**. ± corticated xeric branches of *Acacia*; **1a–c**, **2a**, **d**, **3b**, **5a–c**, **6a**. rehydrated apothecia; **2c**. dry apothecia; **3c**, **5d**. apothecia in median section; **5e**. id., marginal ectal excipulum; **5f–h**, **6c**. crystalloid SCBs in ectal excipular cells; **2f–g**, **3d–e**. ascus apices; **2i**, **4a**. asci; **2j**, **h**, **4b**, **6b**. ascospores. – Living state, except for **2f–g** (in H$_2$O), **3d–e**, **4a** (in KOH+IKI), **4b** (in KOH). — **1a–c**. H.B. 7215d: Carnarvon, on *Acacia*; **5a–h**. H.B. 8611d: Swan Valley, on *Jacksonia*; **6a–c**. H.B. 8745e: Swan Coastal Plain, on *Acacia*.

Map 50. Known distribution of *O. myriofusiclava* in (south) western Australia.

in *V. spermatophaga* the conidiophores are 35–75 µm long whereas in *O. myriofusiclava* they are strongly reduced pegs of 1.5–3 µm length. Consistently phragmosporous (unbranched) conidia are quite exceptional in section *Hemiorbilia*, being otherwise only seen in the neighbourhood of *O. crenatovinosa* and possibly representing its anamorph.

Phylogeny. Sequences from three collections of *O. myriofusiclava* were gained: from pure culture of the holotype (SSU+ITS+LSU) and from apothecia of H.B. 8923b and G.M. 2007-10-26 (ITS). In all of them the S1506 intron is absent at the 3'-end of SSU. The three strains are identical except for 1 nt differing in the ITS2 region of the holotype.

In our analyses, *O. myriofusiclava* clustered with medium (ITS+LSU) or no support (ITS, LSU) with *O. adenocarpi*, *O. concoloris*, and *O. sarothamni* in a subclade of the *cryptogena-sarothamni* clade (Phyls 9–10, S13). In the ITS region *O. adenocarpi* and *O. sarothamni* show a distance of ~ 15–17 % to *O. myriofusiclava* (1.3 % and 2.8 % in the LSU, respectively), and also *O. octocorculispora*, *O. corculispora*, and *O. cyptogena* differ by 17–18.5 % from that species (2.8–3.2 % in the LSU). The ITS1 of *O. myriofusiclava* is distinctly longer than in other sequences of section *Hemiorbilia* with which it partly badly aligns, while this is not the case in the ITS2.

Ecology. *O. myriofusiclava* was collected on ± rotten bark of xeric branches of different *Fabales*. It is known from several sites in western and southwestern Australia not far from the coastline, where it occurs in subtropical semiarid to arid open acacia shrublands or semihumid open eucalypt woodlands (mallee) or open forests (jarrah forest), e.g., with *Acacia*, *Jacksonia* and *Nuytsia floribunda*.

Specimens included. **AUSTRALIA**: **Western Australia**, Carnarvon, 183 km SSE of Carnarvon, 10 km W of Overlander Roadhouse, 12 km NE of Hamelin Pool, Denham-Hamelin Road, 67 m, branch of *Acacia*, on bark, 7.XII.2001, G. Marson (H.B. 7215d ø). – Geraldton Sandplains, 60 km N of Geraldton, 12 km N of Northampton, 278 m, branches of *Acacia*, on bark, 9.XII.2001, G. Marson (ex H.B. 7237a, MEL 2389232, **holotype**, CBS 116224, anam. cult., anam. substr.; sq.: KT215274). – Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, twig of *Acacia*, on bark, 24.XI.2001, G. Marson (G.M. 2001-11-24.1, non vid.). – ibid., 26.X.2007 (G.M. 2007-10-26.1, H.B. 8883l ø; sq.: MK473436). – Swan Coastal Plain, 150 km N of Perth, 13 km WNW of Moora, Dandaragan Road, 235 m, branch of *Acacia*, on bark, 24.X.2007, G. Marson (H.B. 8923b ø; sq.: KT380062). – 30 km NNW of Perth, 1 km NW of Kinross, Tamala Park, 38 m, branch of *Acacia*, on bark, 23.X.2007, G. Marson (H.B. 8745e). – Jarrah Forest, 30 km NE of Perth, 4 km N of Upper Swan, W of Walyunga, 37 m, branches of *Jacksonia*, on bark, 23.XI.2001, G. Marson (H.B. 7284j). – ibid., 76 m, branch of *Acacia*, on bark, 2.IX.2006, G. Marson (H.B. 8478d). – ibid., branch of *Jacksonia*, on bark, 2.IX.2006, G. Marson (H.B. 8611f).

Orbilia corculispora Baral & G. Marson, in Karasch et al., Österr. Z. Pilzk. 14: 285 (2005) — Pls 294–295, Map 51

Etymology: referring to the heart-shaped ascospores.
Typification: France, Séderon, branches of *Spartium junceum*, 17.VIII.2001, G. Marson (ex H.B. 7039a, M-0140892, holotype).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.7(–0.8) × 0.25–0.5 mm, 0.14–0.24(–0.32) mm high (receptacle 0.14–0.18 mm), pale to bright (brick-)orange(-red) to (orange-)rose, rarely whitish, round to ± elliptical, scattered to (sub)gregarious in smaller or larger groups; disc slightly concave then flat, margin distinct, rising 0–25 µm above disc, smooth or distinctly scurfy, exterior finely whitish-powdered; sessile or with broad obconical stipe-like base, slightly to strongly erumpent from cracks or immersed in biofilm, rarely nearly superficial; dry light to bright orange-ochre. **Asci** *(60–)65–95 × (6.5–)7–9(–9.6) µm {7}, †55–80(–94)((–120)) × (5.7–)6–7.3(–7.7) µm {4}, 16-spored (rarely only 12), spores 1(–2)-seriate, with SBs ± laterally oriented but also up- or downwards, pars sporifera *38–70 → 26–37 µm long; **apex** (†) hemispherical, dome †0.8–1.5 → 0.8–1 µm thick {5}, with distinct apical chamber; **base** with short to medium long stalk, L-, Y- or h-shaped. **Ascospores** *(5–)6–8(–9.5) × 3–4.2(–4.5) µm {13}, †5.3–7 × 3–3.5 µm {2}, medium to strongly heart- or kidney-shaped, with a lateral, either distinct and subacute, or indistinct and obtuse protrusion, sometimes subglobose to ellipsoid or only slightly inequilateral to kidney-shaped, *(4–)4.5–6(–7) × (3.5–)3.8–4.5(–5) µm {5}; both ends rounded; **SBs** attached at the lateral protrusion (in ellipsoid spores also at subapical to apical end), *(2–)2.5–3.5(–4.5) × (0.8–)1.2–1.7(–2) µm {8}, broadly tear- to pear-shaped, terminally narrowed to a small point, sometimes with a very short filum; germinating spores with 1 eccentrical septum, multiguttulate. **Paraphyses** apically uninflated to medium clavate-capitate (rarely spathulate), terminal cells *6–15 × (1.5–)2–3(–4) µm {6}, lower cells *7–13 × (1.2–)1.5–2(–2.5) µm {4}; rarely or frequently branched near apex. **Medullary excipulum** hyaline to very pale orange, 25–50 µm thick, of medium dense textura intricata with many inflated cells, indistinctly to medium sharply delimited. **Ectal excipulum** hyaline, near margin partly pale orange, of thin-walled, vertically oriented t. (globulosa-)angularis(-prismatica) from base to margin, (40–)60–100(–200) µm thick near base, cells from base to mid flanks *(6–)9–17(–26) × (6–)8–12(–17) µm {5}; 20–35 µm thick at flanks and margin, outer part of margin of ± thick t. prismatica oriented at a 20–80° angle to the surface, marginal cortical cells *5–11 × (2.5–)3–4.5(–5.5) µm {6}, †2.7–4 µm wide {2}, **glassy processes** absent. **SCBs** in paraphyses and marginal excipulum globose (in excipulum 1.8–2.5 µm wide), also crystalloid {14}, hyaline or pale to light orange, in excipulum 3–8(–13) × 2–5.5 µm, in basal excipulum smaller, hyaline. **Exudate** over paraphyses 1–4 µm thick, ± hyaline, clod-shaped, loosely attached; over excipulum ~(0.5–)1.5–3(–6) µm thick, large-cloddy, hyaline to light golden yellow. **Anchoring hyphae** sparse, *2–3.5 µm wide, walls 0.2–0.3 µm thick {3}. — **ANAMORPH**: trinacrium-like (from ascospore isolate {2} and natural substrate {3}). **Conidiophores** ~30–40 × 2.2–3.5 µm, simple, straight {1}. **Conidia** 2-armed (T-shaped), total size *29–55 × 24–46 µm, stipe *22–41.5 × 4–5.5 µm, (2–)3–5(–7)-septate, arms tapering, bent out- or downwards, *12–29 × 2.5–4.3(–5) µm (in situ, actual length ~12.5–30 µm), 2–3-septate {2}.

Habitat: collected 0–8 m above the ground, ± corticated, 3–25 mm thick twigs and branches of *Acacia* sp. {2}, *Anagyris foetida* {1}, *Chamaecytisus proliferus* {2}, *Cistus monspeliensis* {1}, *Cytisus scoparius* {1}, *Geijera parviflora* {1}, *Laburnum anagyroides* {1}, *Magnolia denudata* {1}, *Olea europaea* {1}, *Spartium junceum* {6}, *Syringa vulgaris* {1}, *Tipuana tipu* {1}, *Ulex europaeus* {24}, *U. parviflorus* {1}, *U. minor* {1}, ?*Vachellia* sp. {1}, *V. farnesiana* {2}, on slightly to strongly decayed bark {41} (on periderm {6} and bast {10}), rarely wood {8}, sometimes in cracks or cross-fissures of periderm, sometimes on inner surface of detached bark, medium to strongly greyed, green algae very sparse to abundant, sometimes close to or on pyrenomycetes (e.g., *Diaporthe eres* {4}). **Further associated**:

Phenology of *O. corculispora* in Europe											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
11	3	2	0	0	3	0	1	4	5	10	3

Taxonomic remarks. Typical *O. corculispora* is easily recognized by its heart-shaped ascospores containing a large tear-shaped spore body inserted in the ± acute end of the heart, and 16-spored asci. The reniform spores of *O. cryptogena* resemble somewhat those of *O. corculispora*, but the spore body is here consistently attached to one of the spore ends.

Shape of apical dome and spore body indicate relationship of *O. corculispora* near species such as *O. cryptogena* or *O. arizonensis*. The lateral insertion of the spore body is probably an apomorphy that developed from an ancestor with terminal insertion. This view is supported by the below-mentioned variant of *O. corculispora* with ellipsoid to kidney-shaped spores (see also Fig. 65).

Variation. The collections from Europe well correspond to those from Macaronesia, Australia, southeastern Asia, and southeastern Africa. However, great variability in spore shape was noted. In the more mediterranean material (Australia, Asia, Macaronesia, southern Europe) the ascospores are distinctly heart-shaped, with a more or less pronounced lateral protrusion. In the more temperate, atlantic collections the spores tend to be kidney-shaped, and especially in Great Britain nearly ellipsoid or even subglobose in almost every collection studied. However, kidney-shaped spores occurred in some of these British records (E.B. 4660: mainly kidney-shaped, H.B. 8045: both ellipsoid and kidney-shaped), and also the African sample and one of the Australian samples also showed some or many kidney-shaped to sometimes nearly ellipsoid spores. In those northwestern European collections all intermediate spore types from subglobose to strongly kidney-shaped were observed, even within a single apothecium.

Anamorph. Trinacrium-like conidia grew in pure culture of a Chinese (Ren et al. 2014b who also observed conidiophores) and an Australian sample (Pl. 294: 1h). The two arms of the conidia are mostly distinctly bent downwards, similar as in the type of *Trinacrium incurvum*, which has slightly smaller conidia. *Amphosoma resinicola*, *Hyalorbilia erythrostigma*/*H. orbiliicola* (with *T. ?angamosense*), and particularly *O. spermoides* have similar conidia, but all these species are phylogenetically not closely related to each other, while DNA data of *T. incurvum* were unavailable.

Phylogeny. Sequences were available from pure culture of an eastern Australian sample on *Geijera* and from apothecia of three French samples on the type substrate *Spartium* from the type locality and 27–80 km remote from it. All comprise SSU, ITS, and LSU, but the S1506 intron is present in the Australian sample and absent in the French ones. The latter are identical in the ITS region except for 1 nt in the 5.8S in the sample from Montelimar, whereas the former differs by 3% (15–16 nt, 2 gap). In the SSU V8–V9 all four sequences are identical, and in the LSU D1–D2 the Australian sample differs by 1.1% (7 nt) from the three identical French ones.

Our phylogenetic analyses of different regions of rDNA support a close relationship between *O. corculispora*, *O. octocorculispora*, and *O. cryptogena*, with which it formed a medium (ITS+LSU) or weakly (ITS, LSU) supported subclade within the *cryptogena-sarothamni* clade (Phyls 9, 10, S13). The lowest distance in the ITS region within the clade is 10–10.5% to *O. cryptogena* (LSU 2.8–3.5%) and 11–12% to *O. octocorculispora* (LSU 3.5–4.5%). The S1506 intron shows a high distance to other members of section *Hemiorbilia*, with a minimum of 20% to *O. octocorculispora* and *O. crenatovinosa*. An unavailable ITS+LSU sequence from the culture of the Chinese collection (Ren et al. 2014b) shows a distance of 3% (ITS) or 1.7% (LSU D1–D2) to the Australian sequence and 4% or 1.9% to that from France (B. Liu pers. comm.).

Ecology. *O. corculispora* inhabits slightly to strongly decayed bark (rarely wood) of xeric twigs and branches of predominantly *Fabales*. *Ulex* is probably overrepresented in the above host listing because gorse-rich areas of atlantic, meso- to supratemperate humid western Europe were often visited by J.P. Priou in France (Bretagne) and E. Batten & S. Francis in England (Suffolk). In central Europe the species was once recorded in a thermophilous forest strip at the cold-temperate humid lac Léman. In southern Europe (Aquitaine, Provence, Dalmatia) it occurred in suprasub- to mesomediterranean semihumid shrublands (maquis), and in Macaronesia in the thermomediterranean semihumid zone of La Palma on *Chamaecytisus proliferus* (tagasaste) planted there as fodder crop (Karasch et al. 2005), and in Tenerife on *Cistus* and *Chamaecytisus* in the Canary pine forest (*Sideritido solutae-Pinetum canariensis cistetosum monspeliensis*). In eastern and northeastern Australia *O. corculispora* was found at the northern Great Dividing Range in subtropical semiarid to tropical subhumid open eucalypt woodlands, while records from western Australia were made in subtropical (almost tropical) arid open acacia wood- and shrublands (mulga) at the southern border of the Pilbara desert. The site in southeastern Africa is a subtropical humid (winter-dry) savannah-like shrubland with *Acacia*, and that in southeastern Asia a planted tree in a park at a subtropical humid (winter-dry) monsoon-influenced climate.

Specimens included. **GREAT BRITAIN**: **East England**, **Suffolk**, 12 km WSW of Lowestoft, NE of Beccles, Beccles Common, 5 m, branch of *Ulex europaeus*, on bark, 15.VI.2005, E. Batten (E.B. 4612, K(M) 145645, doc. vid.). – 4 km ESE of Halesworth, NNW of Wenhaston, Bicker's Heath, 15 m, branch of *U. europaeus*, on bark, 3.II.2004, S.M. Francis & E. Batten (E.B. 4478 ø, H.B. 7476b ø, doc. vid.). – ibid., branch of *U. europaeus*, on bark and pyrenomycete, 3.III.2004, S.M. Francis & E. Batten (E.B. 4495, K(M) 227397, E.B. 4496, K(M) 145644, H.B. 7494). – ibid., branch of *U. europaeus*, on bark,

Orbilia octocorculispora R. Tena, Baral & E. Weber, **sp. nov.**, MB 813534 — Pl. 296

Etymology: referring to the 8-spored asci and resemblance to *O. corculispora*.
Typification: Spain, Valencia, Serra, branch of *Gleditsia triacanthos*, 23.III.2014, R. Tena (M-0276541, holotype; KT222382).

Latin diagnosis: Orbiliae corculisporae *similis, sed asci octospori, ascosporae plus minusve triangulares, corpuscula crystalloidea absentia. Habitat ad lignum vel corticem putridum ramorum siccorum* Fabacearum *vel* Pini *in zona mediterranea semihumida Europae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.65 mm diam., 0.19–0.21 mm high, bright orange to brick- or carmine-red, round (to broadly elliptical), scattered to subgregarious in small groups;

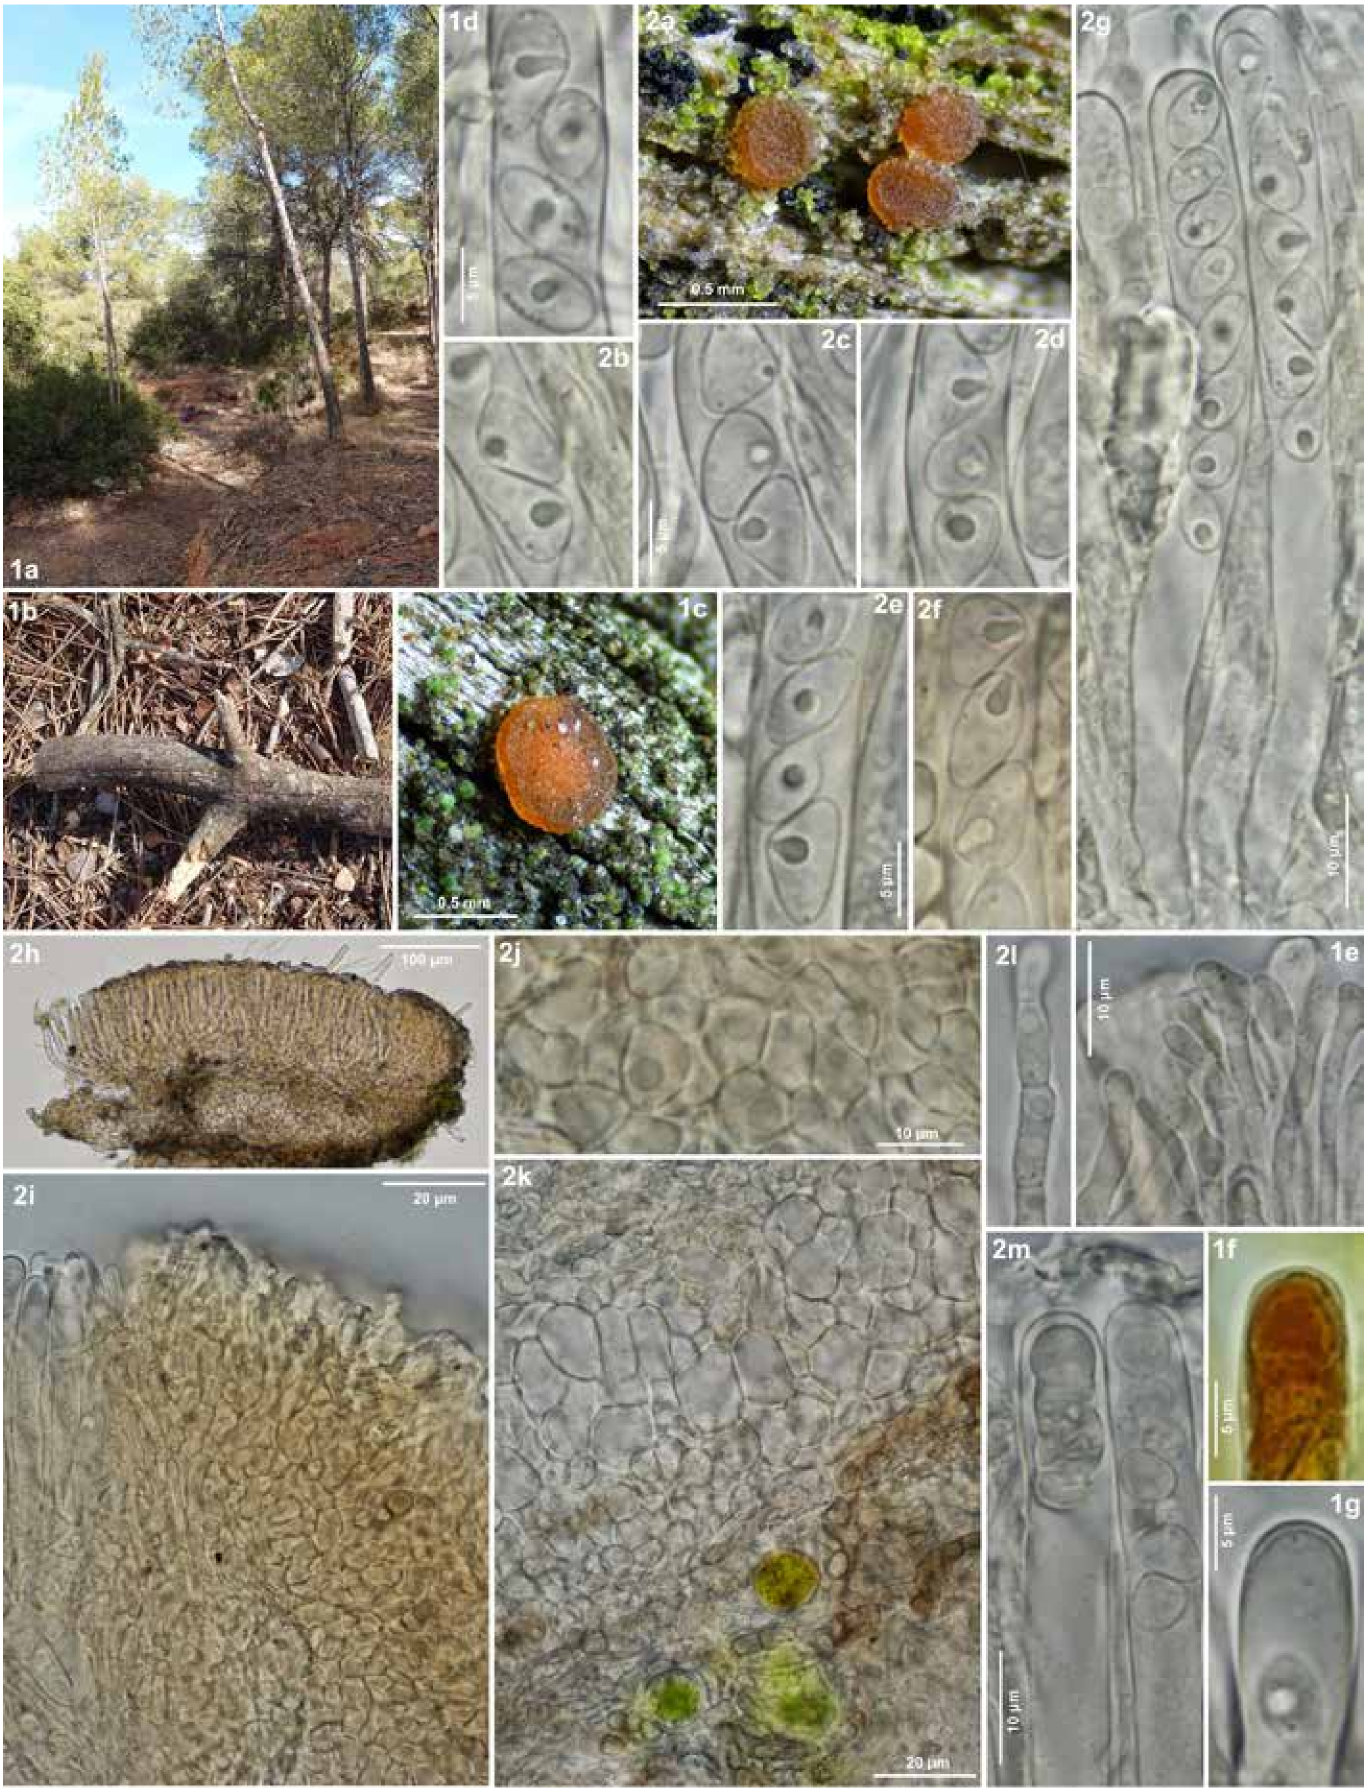

Plate 296. **1–2**: *Orbilia octocorculispora*. – **1a**. type locality with thermomediterranean open pine woodland; **1b**. decorticated xeric branch of *Pinus* in situ; **1c**, **2a**. rehydrated apothecia; **2h**. apothecium in median section; **2g**, m. mature asci with ascospores (normal turgescence in **2g** and **2m** right; full turgescence in **2m** left); **2i**. marginal ectal excipulum in median section; **2k**. id., at lower flanks; **2j**. globose SCBs at mid flanks; **1e**, **2l**. paraphyses; **1d**, **2b–f**. ascospores inside living asci; **1f–g**. ascus apices. – Living state, except for asci in **1f–g** (**1f** in IKI). — **1a–g**. phot. R. Tena, R.T.L. 14012601: Spain, Valencia, on *Pinus*; **2a–m**. phot. R. Tena, R.T.L. 14032301 (holotype): ibid., on *Gleditsia*.

disc flat, margin thick, rising 0–10 µm above disc, slightly rough; broadly sessile, ± erumpent from fibres and biofilm; dry cupulate, bright brick-red. **Asci** *~(56–)75–85(–115) × 7–8.2(–9) µm {2}, †~6.5–7.5 µm wide {1}, 8-spored, spores 1-seriate, or 2-seriate above, with SBs ± laterally oriented, rarely the upper upwards and/or the lower downwards, pars sporifera *30–43 → 17–21 µm long; **apex** (†) hemispherical to slightly truncate, dome †0.4–0.7 → 0.4–0.5 µm thick {2}, also subapically thickened; **base** with short to long, thick stalk, ± L- to Y-shaped. **Ascospores** *(6–)7–9(–10.5) × 4.2–5.5 × 4–4.5(–4.8) µm {3}, triangular, 1 side obtusely conical, opposite side ± straight; **SBs** attached at the conical side, *(2.5–)2.8–3.6(–4) × (1.2–)1.4–1.6(–1.7) µm {2}, tear- to pear-shaped, terminally narrowed to a small or sometimes rather wide point. **Paraphyses** apically slightly to medium clavate-capitate, terminal cells *(4–)6–13(–16) × (2.5–)3–4(–4.8) µm {2}, lower cells *7–17 × 1.6–2.5(–3) µm {2}; sometimes branched near apex. **Medullary excipulum** pale orange, 30 µm thick, of dense, small-celled textura angularis-intricata, medium sharply delimited. **Ectal excipulum** very pale orange, of thin-walled († slightly gelatinized), indistinctly oriented t. angularis from base to submargin, 45–60 up to 90–100 µm thick near base, cells from base to mid flanks *(8–)12–18(–22) × (7–)8–12.5 µm {2}; 25–35 µm thick at flanks and margin, outer part of margin of t. prismatica oriented at a ~50–80° angle to the surface, marginal cortical cells *~6–10 × 2.5–3.5 µm {1}, sometimes forming dead, thick-walled, protruding hyphoid elements, **glassy processes** absent. **SCBs** in paraphyses and marginal excipulum globose, hyaline, in paraphyses 1.4–2.4 µm wide, in ectal excipulum 1.8–3.3 µm {2}. Minute hyaline **LBs** very scattered in paraphyses and excipulum. **Exudate** over paraphyses and marginal excipulum 0.5–1 µm thick, hyaline, clod-shaped, loosely attached; pale yellowish-orange extracellular granules very scattered between paraphyses and cells of medullary excipulum. **Anchoring hyphae** sparse, *~1.7–3.5 µm wide, walls 0.2 µm thick {1}. **— ANAMORPH**: unknown.

Habitat: collected 0–2 m above the ground, decorticated, 6–18 mm thick twigs and branches of *Gleditsia triacanthos* {1}, *Pinus halepensis* {1}, *Ulex* sp. {1}, on 0.3–0.5 mm deep very decayed wood {2} and bark {1}, rather strongly greyed and with sparse or often abundant green algae. **Associated**: *Lophiostoma ?quadrinucleatum* {1}, *Orbilia microserpens* {1}, *Caloplaca* sp. and other crustose lichens {1}. **Desiccation tolerance**: fully viable after 14 months. **Altitude**: 185–430 m a.s.l. **Geology**: Tertiary clay & gypsum, Quaternary limestone, sandstone, marl & clay. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia octocorculispora* was collected and studied from the type locality by R. Tena (pers. comm., Pl. 296), and from a third sample by J.P. Priou (pers. comm., IVV: 16.V.2015). The above description is almost exclusively based on Tena's numerous photos. The species resembles *O. corculispora* in spore shape and lateral attachment of SBs, though the spores never show an indentation at the opposite side as in typical *O. corculispora*. The main difference lies in the 8-spored asci, but also in the complete absence of crystalloid SCBs in paraphyses and excipular cells. Spore shape is also reminiscent of *O. triangulispora* and *O. aviceps*, but these species differ in long glassy processes, the latter also in spores with a basal tail.

Variation. The two collections from the type locality closely concur in spite of the different hosts, and no morphological differences worth mentioning were found. The attachment of the SBs varies within an apothecia on both hosts between a narrow and rather broad point. The sparse collection studied by J.P. Priou also concurs with them except for a spore length at the lower end of the range [*6–6.5 × 4–5 µm, holotype: *(6–)7–9(–9.5) × 4.2–5.5 µm].

Phylogeny. A sequence taken from the holotype comprises S1506 intron, ITS, and LSU. In the ITS region the lowest distance is 11 % to *O. corculispora*, followed by 12.5 % to *O. cryptogena* and min. 16 % to *O. spermoides* and other taxa, whereas in the LSU (D1–D2) the lowest distance is 2.7 % to *O. cryptogena* and 3 % to *O. adenocarpi* (3.5 % to *O. corculispora*). In the intron the distance to other species, including *O. corculispora*, is consistently min. 20 %. For the phylogenetic placement see under *O. corculispora* (p. 658).

Ecology. *O. octocorculispora* was collected on rotten wood of xeric branches of *Pinus* and *Gleditsia* at the type locality, a thermomediterranean semihumid open pine woodland near a hospital in southeastern Spain. The branch of *Pinus* was lying on the ground when collected, but it has been cut perhaps not long ago by local people in order to prevent fires. The third collection was on bark of *Ulex* not far from this place in a mesomediterranean maquis and consisted of only one apothecium.

Specimens included. **SPAIN**: **Com**. **Valenciana**, **Valencia**, 22 km NNW of Valencia, 5.2 km SW of Serra, Porta Çoeli, 500 m SE of Hospital Doctor Moliner, 185 m, branch of *Pinus halepensis*, on wood, 26.I.2014, R. Tena (R.T.L. 14012601, doc. vid.). – ibid., 100 m ENE of Hospital, 203 m, branch of *Gleditsia triacanthos*, on wood, 23.III.2014, R. Tena (ex R.T.L. 14032301, M-0276541, **holotype**, doc. vid.; sq.: KT222382). – 65 km WSW of Valencia, 7.5 km N of Jalance, 3 km NNW of Cofrentes, 430 m, branch of *Ulex*, on bark, 16.V.2015, J.P. Priou (ø, doc. vid.).

Orbilia cryptogena Baral & G. Marson, sp. nov., MB 813538 — Pls 297–298, Map 52

Etymology: named after the apothecia being deeply immersed in the substrate and almost invisible when dry.

Typification: USA, Arizona, New River, branch of *Larrea tridentata*, 19.VI.2003, G. Marson (ex H.B. 7397a, M-0276464, holotype; CBS 140819; sq.: KT215272, MH878189).

Latin diagnosis: *Apothecia rehydratata 0.25–0.6 mm diam., vivide aurantiorubra, sessilia, margine sublaevi, erumpentia, in statu sicco retracta. Asci 32-spori. Ascosporae *8–16 × 3–4.5 µm, valde curvatae (botuliformes), apice rotundatae vel obtusae, basi saepe leniter attenuatae, in statu vivo corpusculum refringens magnum, lacrimiformem, ad apicem affixum continentes. Cellulae vivae paraphysium corpuscula globosa minuta continentes. Habitat ad lignum putridum ramorum siccorum* Larreae tridentatae *in zona subtropica semiarida ad arida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.25–0.5(–0.6)((–0.8)) × 0.2–0.3(–0.4) mm diam., 0.14–0.23 mm high, light to bright (dirty) orange(-brick-red), round or often (narrowly) elliptical, subgregarious in smaller or larger groups; disc flat, margin distinct, 0–10 µm rising above disc, ± smooth; broadly sessile or with indistinct obconical base, slightly to nearly completely immersed between fibres; dry strongly retracted and immersed in substrate, deep orange-red, elongate apothecia becoming slit-like. **Asci** *(83–)90–110(–130) × (10.5–)12–13.5(–16) µm {5}, †(73–)80–100(–120) × (10.5–)11–13(–15.5) {4}, 32-spored (rarely very few asci 16-spored), spores *3–4-seriate, about half of spores inversely oriented (strongly mixed), pars sporifera *65–80(–90) µm long, †52–66 µm; **apex** (†) hemispherical to slightly truncate, dome †0.7–1.7 → 0.3–0.8(–1.2) µm thick {5}, rarely with small apical chamber; **base** with or without short to long, thin or thick, ± flexuous stalk, L- or Y-shaped, with short legs. **Ascospores** *(8–)9.5–13(–16)((–17.5)) × (3–)3.5–4.5((–5.5)) µm {5}, †9–11.5(–13) × (2.5–)2.8–4(–4.3) µm {4}, ± subcylindrical, apex rounded to obtuse, base not or often slightly attenuated, slightly to (very) strongly curved [mainly in lower part (L-shaped), also reniform to cashew-shaped]; **SBs** apically attached to spore wall, *2.5–3.5(–4.2) × (1–)1.2–1.6(–1.8) µm {3}, tear- to pear-shaped, apically narrowed to a ± small point, overmature *2–2.5 × 1.7–1.9 µm; with a few minute LBs. **Paraphyses** apically uninflated to medium clavate-capitate, sometimes sublageniform, terminal cells *(4.5–)8–15(–17) × 2.5–3.5(–4) µm {1}, †5–18 × 1.8–3(–4) µm {3}, lower cells *8–20 × 1.8–2.5 µm {1}, †(8–)12–16 × (1–)1.4–1.8(–3) µm {1}; rather frequently branched near apex {6}, often flexuous. **Medullary excipulum** pale rose, 10–50 µm thick, of dense horizontally oriented textura intricata with many inflated cells, sharply delimited.

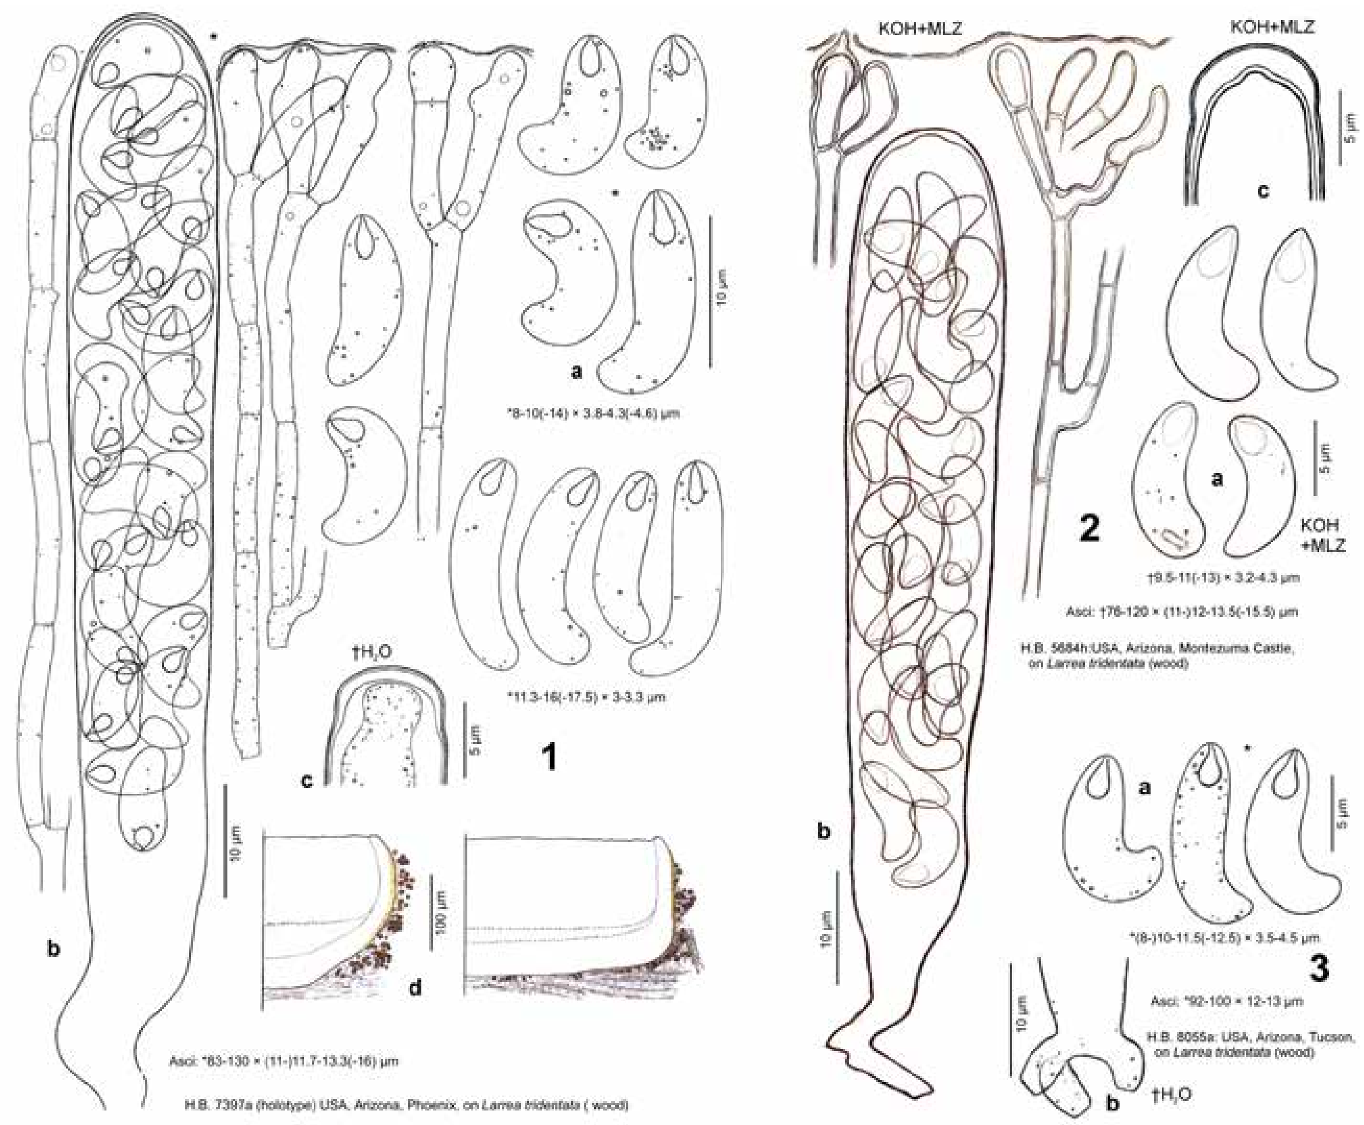

Plate 297. **1–3**: *Orbilia cryptogena*. – **a**. ascospores; **b**. asci and paraphyses (**3b** ascus base); **c**. ascus apices; **d**. apothecia in median section.

Ectal excipulum pale rose, outer layer light to bright golden- or honey-yellow (especially at mid flanks), of (†) not or slightly gelatinized, vertically or indistinctly oriented t. angularis(-prismatica) from base to mid flanks, 25–50 µm thick near base, cells *8–16(–20) × 6–11 µm {1}, †6–12 × (4–)5–8(–10) µm {3}; 15–20 µm thick near margin, of t. prismatica-porrecta oriented at a 10–45° angle to the surface, marginal cortical cells †5–12 × 3–5 µm {2}; **glassy processes** absent. **Anchoring hyphae** medium abundant, †1.8–3 µm wide, walls †0.2–0.4(–0.8) µm thick {3}, sometimes covering mid flanks and margin as a t. porrecta-intricata 10–20 µm thick. **SCBs** in terminal cells of paraphyses globose, 0.5–1.3 µm diam. **Exudate** over paraphyses 0.2–0.5(–1) µm thick, ± continuous or as scattered granules, loosely attached; over excipulum as very scattered granules. — **ANAMORPH**: unknown (an ascospore isolate did not produce conidia and finally died off, therefore it could not be deposited in a culture collection).

Habitat: collected 0.2–2.5 m above the ground, decorticated, 6–14 mm thick branches of *Larrea tridentata* {6}, on 0.2–0.5 mm deep medium to very decayed wood {6}, strongly greyed, no algae. **Associated**: *Carestiella schizoxyloides* {1/1}, *Coniochaeta* sp. {1}, *Hysterobrevium mori* {1}, *Melaspilea emergens* {1}, ?*Muellerella* sp. {1}, *Odontotremataceae* sp. {1}, *Orbilia arizonensis* {1}, *O.* ?*breviclava* {1}, *O. calyptrata* {2}, *O. lacrimispora* {1}, *O. macrodelphinus* {1}, *O. multicercocarpi* {1}, *O. multigambelii* {1}, *O. multiurosperma* {3}, *O.* ?*navajoana* {1}, *O. pluristomachia* {3}, *O. sedonensis* {1}, *O. sonorensis* {1}, *O.* ?*vitalbae* {1}, *Patellaria atrata* {1}, *Symbiotaphrina larreae* {2}. **Desiccation tolerance**: fully tolerant for at least 11 months, after 32 months still many spores viable. **Altitude**: 500–1030 m a.s.l. **Geology**: Neogene sand- & limestone, silt, clay; granite, diorite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia cryptogena* is characterized by 32-spored asci and medium to strongly curved, ± cashew-shaped, comparatively large ascospores with tear-shaped spore bodies in the apex. For the closely related *O. subcryptogena* (p. 665) and *O. myriofusiclava* (p. 653) see there.

Variation. Some variation is observed in spore size and curvature, but such also occurs within a population. Typically the apothecia are elongate when rehydrated and turn slit-like when dry, but some are ± round and remain so when dry and contracted.

Phylogeny. A sequence from pure culture of the holotype of *O. cryptogena* comprises SSU, ITS, and LSU (the S1506 intron is absent). Phylogenetic analyses support a relationship to *O. corculispora* and *O. octocorculispora* (see there, Phyls 9–10, S13), the distances being 10/2.8% and 12.5/ 2.7% in the ITS/ LSU region, respectively.

Ecology. *O. cryptogena* appears to be restricted to ± rotten wood of xeric branches of *Larrea tridentata* (creosotebush). It was collected in the southwest of Northern America in the deserts

Plate 298. **1–4**: *Orbilia cryptogena*. – **1a**. *Larrea tridentata* in dry riverbed of subtropical arid Sonoran Desert; **2a–b**, **3**, **4a–b**, **e**. rehydrated apothecia (**4e** with *Symbiotaphrina desertorum*); **2b**, **d**, **4c**. dry apothecia; **4g**. apothecium in median section; **4f**. id., marginal ectal excipulum; **2f**, **4i**. mature asci and paraphyses; **2e**, **3b**. ascus apices; **1b**, **2g**, **4h**. ascospores. – Living state: ascospores in **1b**, **4h–i**; dead state: **2g**, **4f–g** (in KOH), **2e–f**, **3b** (in KOH+IKI). — **1a–b**. Orbilia subcryptogena Baral & G. Marson, **sp. nov.**, MB 813539 — Pls 299–300

Etymology: closely related to *O. cryptogena.*

Typification: USA, Texas, Hempstead, branch of *Baccharis salicifolia*, 19.VI.1996, G. Marson (ex H.B. 5681a, M-0276593, holotype).

Latin diagnosis: *Differt ab* Orbilia cryptogena *ascis 16-sporis, ascosporis minoribus, corpusculum refringens subglobosum continentibus, cellulis vivis excipuli et paraphysium corpuscula crystalloidea pallide aurantiaca continentibus. Habitat ad lignum vel corticem putridum ramorum siccorum* Baccharidis salicifoliae *in zona subtropica subhumida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.55 mm diam., 0.13–0.23 mm high, deep orange-apricot, round to broadly elliptical, scattered; disc slightly concave to flat, margin thick, rising ~10 µm above disc, ± smooth; broadly sessile, ± erumpent, young completely immersed, mature ± half so or nearly superficial; dry dirty orange-red, somewhat retracted but not deeply sunken. **Asci** *67–82 × (6.8–)7.6–8.5 µm, †70–83(–90) × 6.5–7.8 µm, 16-spored, spores 2–3-seriate, min. ~4 spores inversely oriented (strongly mixed), pars sporifera *49 µm long (†40–50 µm); **apex** (†) hemispherical to slightly (conico-)truncate, dome †1–1.3 → 0.5–1 thick, with broad apical chamber; **base** with short to long, thick stalk, Y-, T- to h-shaped. **Ascospores** *(6–)6.5–8(–8.5) × 2.8–3.6 µm, †5–7 × 2.6–3.2 µm, reniform to cashew-shaped, apex rounded to obtuse, base not or slightly tapered, slightly to mostly medium to very strongly curved; **SBs** apically attached to spore wall, *1.3–2 × 1–1.5 µm, broadly tear-shaped to globose, apically narrowed to a small point, with some minute and larger LBs. **Paraphyses** apically uninflated or slightly to medium clavate-capitate, rarely sublageniform, terminal cells *4.5–13 × 2.2–4(–4.5) µm, lower cells *(6–)8–13 × 1.5–2.5 µm; sometimes branched at upper septum. **Medullary excipulum** pale orange, 20–40 µm thick, of dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** hyaline, mid flanks and margin light orange-rose, of (†) slightly to medium gelatinized, vertically oriented t. angularis(-prismatica) from base to margin, 30–80 µm thick near base, cells *10–15 × 8–12 µm, †7–13 × 5–8 µm; 25–40 µm thick at flanks and margin, at margin oriented at a 30–50° angle to the surface, upper margin or outer hyaline layer of t. porrecta oriented at 20°, marginal cortical cells *10–14 × 2.5–3.2 µm, thin-walled, **glassy processes** absent. **Anchoring hyphae** very abundant, †1.7–2.5 µm wide, walls 0.2(–0.3) µm thick, forming a dense 40–70 µm thick, distinctly gelatinized t. intricata. **SCBs** in paraphyses and marginal excipulum globose, 1–1.5 vs. 2–2.8 µm diam., and light orange-rose crystalloid SCBs (in excipular cells 2.5–5 µm diam). **Exudate** over paraphyses (0.5–)1–3(–4) µm thick, continuous, warted, loosely attached; over margin 1–5 µm thick. **— ANAMORPH**: unknown.

Habitat: collected 0.2–1 m above the ground, partially decorticated, 10–12 mm thick branches of *Baccharis salicifolia*, on 0.3 mm deep strongly decayed wood and bark (bast), greyed, with some green algae. **Associated**: *Haematomma* sp., *Hysterobrevium smilacis*, *Lecanora* sp., *Orbilia brachychitonis*, *Parmelia* sp., other crustose and foliose lichens. **Desiccation tolerance**: immature asci still alive after 6.5 months. **Altitude**: 70 m a.s.l. **Geology**: Miocene-Oligocene clay and mud, Quaternary fluviatile sediments. **Phenology**: long-lived.

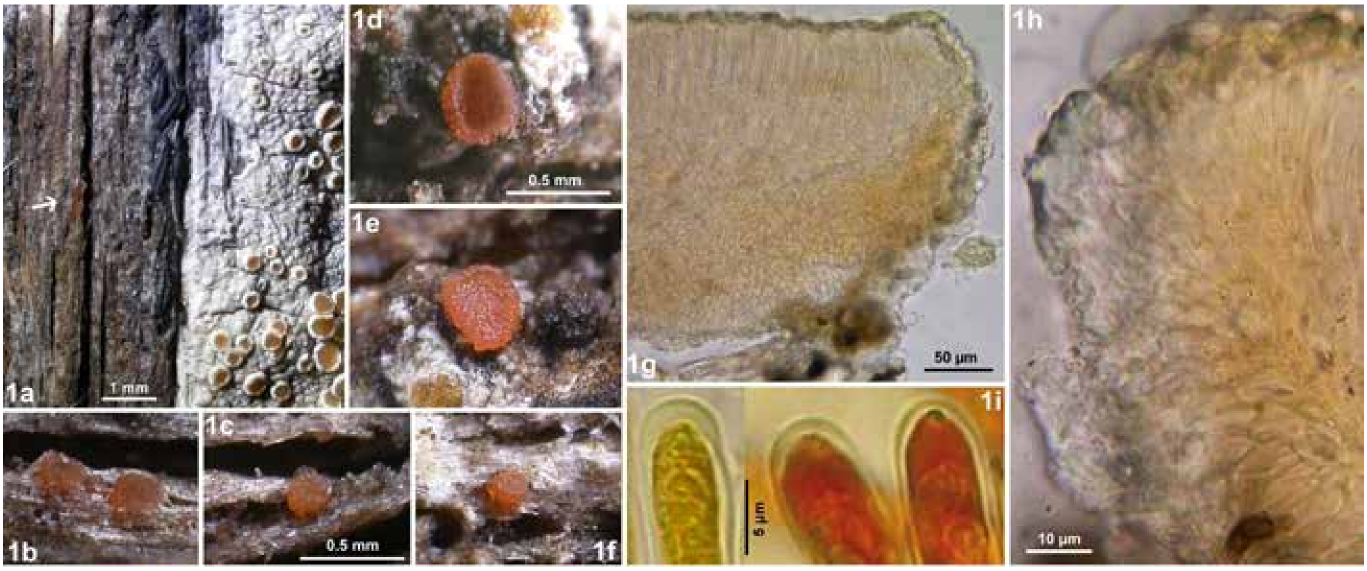

Plate 300. **1**: *Orbilia subcryptogena*. – **1a**. sector of partially decorticated xeric branch of *Baccharis salicifolia*, with *Lecanora* sp. (on bark) and *Hysterobrevium smilacis*; **1b–f**. rehydrated apothecia; **1g**. apothecium in median section; **1h**. id., marginal ectal excipulum; **1i**. ascus apices. – Dead state (**1g–h** in KOH, **1i** in KOH+IKI). — **1a–i**. H.B. 5681a (holotype): USA, Texas, on *Baccharis*.

Taxonomic remarks. *Orbilia subcryptogena* differs from *O. cryptogena* in 16-spored asci, distinctly smaller ascospores, presence of crystalloid SCBs, finally in growing on *Baccharis* instead of *Larrea*. *O. subcryptogena* also resembles *O. vibrioides* of series *Vibrioides* which differs in 8-spored asci, smaller spores, and absence of crystalloid SCBs. The somewhat variable 16-spored *O. corculispora* differs in laterally attached SBs, but may be confused in the dead state if the spores are kidney-shaped.

Ecology. *O. subcryptogena* was found on rotten wood and bark of xeric branches of *Baccharis salicifolia* in a subtropical subhumid woodland at a dry rivulet in the Coastal Prairies of the south of Northern America.

Specimens included. **USA**: **Texas**, Coastal Prairies, 100 km WNW of Houston, 13 km WNW of Hempstead, W of bridge over Brazos river, 70 m, branch of *Baccharis salicifolia*, on wood & bark, 19.VI.1996, G. Marson (ex H.B. 5681a, M-0276593, **holotype**).

Orbilia myriomuscula Baral & G. Marson, **sp. nov.**, MB 813540 — Pls 301–302, Map 53

Etymology: named after the spores resembling little mice.

Typification: Western Australia, Kumarina Roadhouse, branch of *Acacia*, 26.XI.2001, G. Marson (ex H.B. 8697c, MEL 2389248, holotype).

Latin diagnosis: *Apothecia rehydratata 0.22–0.75 mm diam.*, *vivide aurantiaca*, *sessilia*, *erumpentia*, *margine subaspera. Asci 64-spori. Singleton, on *Acacia*.

(60–62 spores counted), spores (*) 4–5-seriate, orientation irregular, pars sporifera *65–80 µm long (†65–88 µm); **apex** (†) hemispherical to very slightly truncate, dome †0.8–1.3 → 0.4(–0.8) µm thick {3}, with broad, indistinct apical chamber; **base** with short to long, thin or thick, ± flexuous stalk, L- or Y-shaped. **Ascospores** *(5.7–)6.3–7(–8) × (3–)3.3–3.6 µm {2} in situ (actual length ~9–10 µm), †5–7(–7.5) × (2.8–)3–3.4 µm {1}, with ellipsoid head and a distinct, gradually to abruptly attenuated tail *(2–)2.5–4(–6) × 0.3–0.5 µm, †(2–)3–4(–5) × 0.25–0.4(–0.7) µm, head slightly to medium curved (lunate, especially in dead state), apex obtuse (to subacute), tail straight to strongly curved, end projecting at a ~90–150(–250)° angle to the ventral side of the head; **SBs** apically to subapically attached to spore wall, 1.8–2 × 1.2–1.6 µm {2}, globose to broadly tear-shaped or ampulliform, apically narrowed to a small point. **Paraphyses** apically (not or) slightly (rarely medium) clavate, rarely sublageniform, terminal cells *7–21 × 2.5–3.5 µm {2}, †5–15 × 2.5–4 µm {1}, lower cells *9–20 × 1.6–3(–3.5) µm {2}, †10–17 × 1.5–2 µm {1}; sometimes or frequently branched near apex. **Medullary excipulum** subhyaline, 20–50 µm thick, of dense textura intricata with many inflated cells, medium to sharply delimited. **Ectal excipulum** (very) pale yellowish-orange-rose, of (†) slightly gelatinized, vertically oriented t. angularis-prismatica at base, 25–90 µm thick, cells *7–16(–20) × 5–10(–12) µm {3}, †6–13 × 5–9 µm {1}, sometimes containing very pale yellowish **LBs** (carotenoids) 0.2–1.5 µm diam.; 25–40 µm thick at flanks, of. t. angularis(-prismatica), 30–50 µm thick near margin, of t. prismatica-porrecta oriented at a 0–30(–50)° angle to the surface, marginal cells *6–14 × 3–5 µm {2}, sometimes terminated in hyaline appressed hyphae with †10–12 × 2.5–3(–4) µm large cells; **glassy processes** absent. **Anchoring hyphae** abundant, †2–3(–4) µm wide, walls 0.2(–0.3) µm thick {2}. **SCBs** in paraphyses angular, low-refractive, 1–1.7 × 0.7–1.5 µm, in ectal excipulum crystalloid to keyhole-shaped, light yellow-orange, 2–5 × 1.5–3 µm, here also globose, 2–3 µm diam. **Exudate** over paraphyses and margin (0.3–)1–1.5(–2) µm thick, cloddy(-continuous), hyaline, loosely to firmly attached. — **ANAMORPH**: unknown.

Habitat: collected 0.5–3 m above the ground, corticated, 5–15 mm thick branches of *Acacia* sp. {5}, on medium decayed bark {4} (bast, on or in cracks of periderm, or on small periderm-free areas), rarely wood {1}, strongly greyed, no algae. **Associated**: *Amandinea* sp. {1}, *Caloplaca* sp. {1}, *Orbilia anguliobliqua* {1}, *O. australiensis* {1}, *O. corculispora* {1}, *O. curvatiobliqua* {1}, *O. helicoobliqua* {1}, *O. hesperidea* {1}, *O. macrocarpa* {1}, *O. ?mirabilis* {1}, *O. ?multivirgula*

Map 53. Known distribution of *O. myriomuscula* in southwestern Australia.

{1}, *O. myriella* {1}, *O. myrioaustraliensis* {1}, *O. myriofusiclava* {1}, *O. myriolilacina* {1}, *O. myrionanosoma* {1}, *O. myrioobliqua* {1}, *O. paraobliqua* {1}, *O. phanosoma* {2}, *O. pleioaustraliensis* {1}, *O. pleioserpens* {2}, *O. pleioungulata* {1}, *O. ?pseudeuphorbiae* {1}, *Ostropales* {1}, *Rhizodiscina* sp. {1}, ?*Triblidium* sp. {1}. **Desiccation tolerance**: asci and ascospores viable even after 38 months. **Altitude**: 379–690 m a.s.l. **Geology**: Precambrian sedimentary rock (ochre to red-brown sand and gravel). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia myriomuscula* is very remarkable on account of its ascospore tails projecting laterally or even upwards, due to a strong curvature of the spores at the base, in combination with 64-spored asci. The closest relative appears to be *O. myriofusiclava*, which differs in narrower spores with more tapered apices and thicker, much less differentiated tails which are rarely strongly curved. The North American *O. cryptogena* differs in 32-spored asci and much longer spores without tails

Variation. Within a population, considerable variation is noted in the spore tails: they vary in length, thickness, and curvature, as well as between gradually and abruptly attenuated at their insertion. For the other features, *O. myriomuscula* seems to be a very constant species, judging from the few available records.

Ecology. The four rather sparse collections of *O. myriomuscula* were made on bark (rarely wood) of xeric branches of *Acacia* sp. in subtropical semiarid open acacia wood- and shrublands (mulga) inside and south of the Pilbara desert and in the Avon Wheatbelt of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Pilbara, 49 km NW of Newman, northern border of Ophthalmia Range, 690 m, branch of *Acacia*, on bark, 28.X.2007, G. Marson (ex H.B. 8940b, mixture in MEL 2389267 [type of *O. pleioserpens*]; H.B. 8879a). – Gascoyne, south-border of Collier Range, 175 km NE of Meekatharra, 41 km SW of Kumarina Roadhouse, 560 m, branch of *Acacia*, on bark, 26.XI.2001, G. Marson (ex H.B. 8697c, MEL 2389248, **holotype**). - 62 km SSW of Kumarina Roadhouse, 16 km NW Plutonic Gold Mine, 540 m, branch of *Acacia*, on bark, 28.X.2007, G. Marson (ø). – Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, 380 m, branch of *Acacia*, on bark, 26.X.2007, G. Marson (H.B. 8883h ø).

from base to mid flanks, 25–40 µm thick near base, cells *7–16 × 6–13 µm {T}, common walls 0.5–1.5 µm thick; 15–25 µm thick at mid flanks, 15–20 µm near margin, of t. prismatica-porrecta oriented at a 10–30(–40)° angle to the surface, marginal cortical cells *8–16 × 3–4.3 µm {T}, †2.5–3.5 µm wide {T}, thin-walled (walls †0.2 µm thick); **glassy processes** absent {2}. **Anchoring hyphae** very sparse, †2–3 µm wide, walls 0.2–0.3(–0.4) µm thick {T}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.5–2.5 µm diam. {2}; with minute pale orange **LBs** (carotenoids) especially near septa. **Exudate** over paraphyses 1–2 µm thick, cloddy-bizarre, hyaline, rather loosely attached; over margin and flanks 1–4 µm thick, pale chlorinaceous. — **ANAMORPH**: unknown.

Habitat: collected 0.1–1 m above the ground, ± corticated, 1–6 mm thick twigs of *Cytisus scoparius* {T}, *Erinacea anthyllis* {1}, on strongly decayed bark {2} (periderm & bast), also sometimes in beetle galleries on wood {T}, slightly to medium greyed, with some or many green algae. **Associated**: *Caloplaca* sp. {1}, *Claussenomyces* sp. {1}, *Orbilia gambelii* {1}, *O. pleiogambelii* {1}, *O. polyspora* {1}, *O. subclavuliformis* {1}. **Desiccation tolerance**: fully viable for at least 6 weeks, some spores still alive after 2 years. **Altitude**: 880–1690 m a.s.l. **Geology**: Cretaceous marl & gravel, dolomite. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia sarothamni* is characterized by 32-spored asci and ± tear-shaped to fusoid ascospores. It resembles the Australian *O. palmicola*, from which it differs in the absence of crystalloid SCBs, more acute spore apices, never tail-like spore bases, and a narrower attachment of the SBs. *O. sarothamni* also resembles *O. polyspora* (section *Ovoideae*), which differs in narrower, ellipsoid ascospores with rounded apices and smaller SBs, in the total absence of an apical dome, finally in the presence of thick-walled hair-like marginal hyphae.

Variation. The sample on *Erinacea* differs from the holotype in longer and narrower spores and SBs, narrower asci, and in apically less narrowed SBs. Whether these differences represent variation of a single species as assumed here remains uncertain, until further collections are available.

Phylogeny. A sequence taken from pure culture of the Spanish paratype comprises S1506 intron, ITS, and LSU. *O. sarothamni* clustered with strong or medium support (ITS+LSU, ITS) in a subclade of the *cryptogena-sarothamni* clade, together with *O. adenocarpi* and *O. concoloris* with an ITS distance of 9.3 %, to which *O. myriofusiclava* is associated with medium support and a 16 % distance (Phyls 9, S13). The undocumented Australian collection on *Acacia aneura* with 8-spored asci (G.M. 2007-11-02.1; ITS, S1506 intron absent) clustered with a 9.2 % ITS distance strongly supported with *O. sarothamni* (Phyl. 10).

Ecology. *O. sarothamni* was found on rotten bark and wood of xeric twigs of *Cytisus* and *Erinacea* shrubs (*Faboideae*) in a thermophilous (south-exposed) suprasubmediterranean semihumid shrubland with *Juniperus*, *Sorbus*, *Acer*, *Quercus*, and different members of *Fabaceae* in the Southern French Prealps, and in a supramediterranean (semihumid) dwarf shrub vegetation of max. 30 cm height on limestone rock in the Sistema Bético of southern Europe. In the paratype the inhabited twig was only 1 mm thick.

Specimens included. **FRANCE**: **Rhône-Alpes**, **Drôme**, 16.3 km E of Nyons, 1.5 km NNW of Bellecombe, 1 km SW of Col de Soubeyrand, 880 m, twig of *Cytisus scoparius*, on bark & wood, 10.X.2002, G. Marson (ex H.B. 7251c, M-0276583, **holotype**). — **SPAIN**: **Andalucía**, **Jaén**, Sierra de La Pandera, 15 km S of Jaén, 5 km NNE of Valdepeñas de Jaén, 1690 m, twig of *Erinacea anthyllis*, on bark, 19.IV.2014, S. Tello (H.B. 9880; sq.: KT380083).

Orbilia myrioauris Baral & G. Marson, sp. nov.,
MB 813535 — Pls 305–306

Etymology: named after the 64-spored asci and the somewhat ear-shaped ascospores.

Typification: Western Australia, Hamelin Pool, twig of *Acacia*, 6.XI.2007, G. Marson (ex H.B. 8727b, MEL 2389251, holotype).

Latin diagnosis: *Apothecia rehydratata 0.18–0.32 mm diam., lateritio-rubra, sessilia, margine subtiliter aspera. Asci 64-spori. Ascosporae *6.8–11.5 × 2.2–3 µm, cylindrico-clavatae, apice obtusae, ad basim leniter vel valde curvatae, in statu vivo corpusculum refringens globosum, ad tunicam lateralem vel interdum (sub)apicalem cuspide brevi affixum continentes. Cellulae vivae excipuli marginalis et paraphysium corpuscula globosa et crystalloidea continentes. Habitat ad corticem putridum ramuli sicci* Acaciae *in zona subtropica arida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.18–0.32 mm diam., 0.15 mm high (receptacle 0.11 mm), light brick-red(-orange), somewhat translucent, round, scattered; disc flat, margin distinct, thin or thick, 0–10 µm protruding, finely rough; broadly sessile, with hidden stipe-like base 0.05 × 0.1 mm, partially to entirely immersed in biofilm; dry ± invisible. **Asci** *(67–)75–109 × (10–)10.5–12 µm {2} → 13.5 µm wide, †58–76 × 8.5–10.7 µm {1}, 64-spored (~60 spores counted), spores *multiseriate, lower spores inverted (strongly mixed), pars sporifera *48–63 → 46 µm long; **apex** (†) hemispherical to medium truncate, dome †1–1.5 → 0.8–1 µm thick {1}, with broad apical chamber; **base** with (very) short, thick stalk, Y- to h-shaped. **Ascospores** *(6.8–)7.5–9.5(–11.5) × (2.2–)2.4–2.8(–3) µm {2}, cylindric-clavate, both ends rounded to obtuse, base not or usually slightly attenuated (almost homopolar), very slightly to rather strongly curved (entirely or near base); **SBs** laterally attached at the convex side at or somewhat below the middle of the spore, rarely ± subapically, *1.5–2 × 1.1–1.3(–1.5) µm {2}, broadly tear-shaped to ampulliform or subglobose, apically narrowed to a small or rather wide point. **Paraphyses** apically uninflated to slightly (rarely strongly) clavate, terminal cells *(6–)7.5–11.5 × 2.3–3.5 µm {1}, lower cells *(8–)10–19(–23) × 1.6–2.5(–3.3) µm {1}; sometimes branched at upper septum. **Medullary excipulum** hyaline, 25 µm thick, of dense textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** subhyaline near base, pale rose at margin, of (†) thin-walled to slightly gelatinized, vertically oriented t. angularis-prismatica at base, 45 µm thick, cells *7–12 × 5–8 µm {1}, t. angularis at flanks, 15–20 µm thick near margin, submargin of t. prismatica-angularis oriented at a 10–20° angle to the surface, cells *8–12 × 4–6 µm {1}, upper margin of t. porrecta oriented at 10°, marginal cortical cells */†6–12.5 × 3–7 µm {1}; **glassy processes** absent. **Anchoring hyphae** sparse, †1.7–2.3 µm wide, walls 0.2–0.3 µm thick {1}. **SCBs** globose, in paraphyses 1–2 µm diam., in marginal ectal excipulum 2–3.5 µm; also crystalloid SCBs frequent in paraphyses and ectal excipulum (margin and flanks), hyaline to pale orange. **Exudate** over paraphyses (0.5–)1–2 µm thick, cloddy, hyaline, ± loosely attached, over margin and flanks 0.3–2(–5) µm thick. **— ANAMORPH**: unknown.

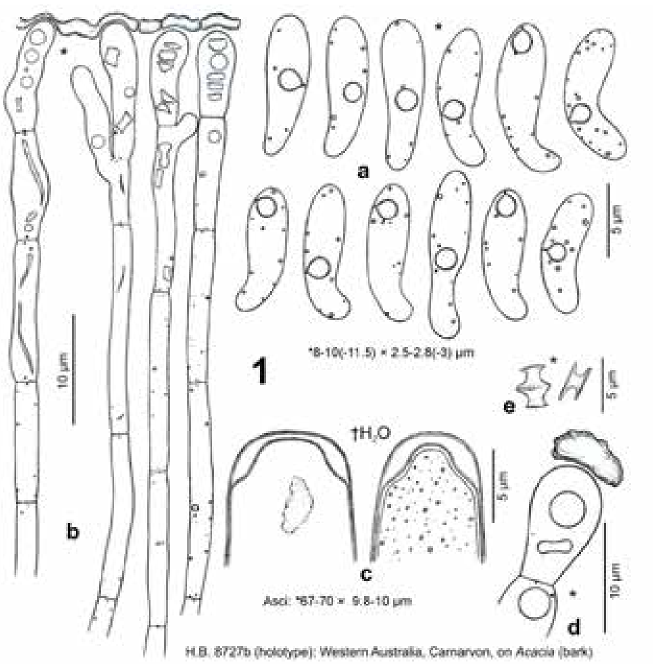

Plate 305. **1**: *Orbilia myrioauris*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices; **d**. marginal cells of ectal excipulum, tipped by exudate; **e**. crystalloid SCBs in ectal excipular cells (flanks and margin).

Habitat: collected 0.5–2 m above the ground, corticated, 4–6 mm thick twigs and thicker branches of *Acacia* sp. {2}, on strongly decayed bark (bast) {2}, in cross-clefts of periderm, strongly greyed, with some green algae. **Associated**: *Coccomycetella* sp. {1}, *Hyalorbilia ?erythrostigma* {1}, *Hysterobrevium mori* {1}, *Orbilia commarosa* {1}, *O. curvatimyriella* {1}, *O. microserpens* {1}, *O. multigambelii* {1}, *O. myriella* {1}, *O. ?myrionamibica* {1}, *O. pleioaustraliensis* {1}, *O.*

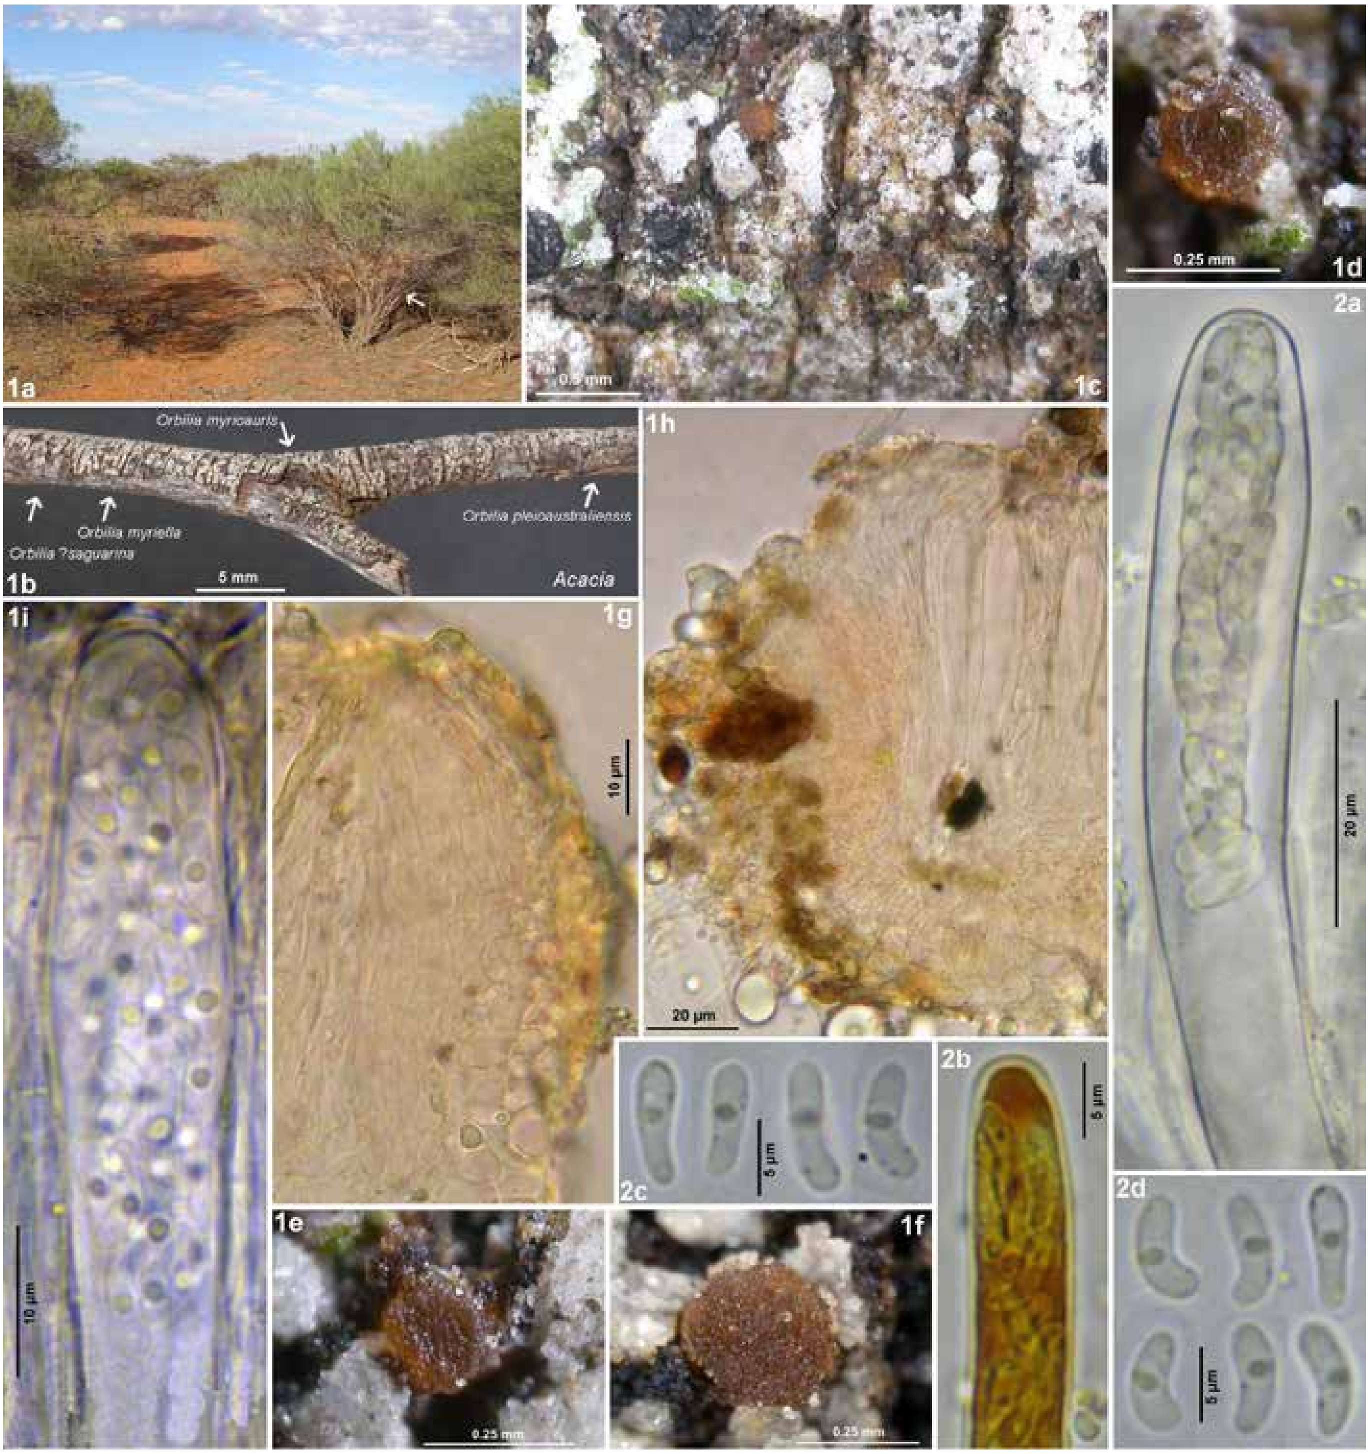

Plate 306. **1–2**: *Orbilia myrioauris*. – **1a**. semiarid acacia shrubland; **1b**. dead corticated xeric branch of *Acacia*; **1c–f**. rehydrated apothecia; **1g–h**. marginal ectal excipulum in median section; **1i**, **2a**. asci with ascospores (**2a** fully turgescent); **2b**. ascus apex. **2c–d**. ascospores. – Living state, except for **2b** (in IKI). — **1a–i**. H.B. 8727b (holotype): Western Australia, Carnarvon, on *Acacia*; **2**. 4.XI.2007: ibid., Pilbara, on *Acacia*.

pleistoobliqua {1}, *O. ?saguarina* {1}, *Ostropales* {1}, *Tryblidaria* sp. {1}. **Desiccation tolerance**: fully viable for 40 months. **Altitude**: 67–300 m a.s.l. **Geology**: Cretaceous sedimentary rock, Cenozoic regolith (red-brown sandy soil). **Phenology**: long-lived.

Taxonomic remarks. In addition to its 64-spored asci, *O. myrioauris* is easily recognized in the living state by cylindric-clavate ascospores which are more or less curved towards their base, and particularly by the subglobose to ampulliform spore body at the convex side of the spore, often a bit below the middle. However, because of their approximate homopolarity the upper spore end is not always clearly recognizable. In a few spores of an ascus the SBs were attached at the spore apex or close to it, but this peculiarity was seen only in the holotype. The lateral attachment of SBs in *O. myrioauris* somewhat resembles the situation in the 16-spored *O. corculispora*.

Ecology. The very sparse and scattered apothecia of *O. myrioauris* occurred on rotten bark of thin xeric branches of *Acacia* in subtropical semiarid to almost tropical arid acacia open shrublands (at the latter site in a tussock grassland with *Livistona alfredii*) in dry riverbeds of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Pilbara, 96 km S of Roebourne, 42 km SSW of Python Pool, SW Millstream-Chichester, Road crossing the Fortescue River, 300 m, branch of *Acacia*, on bark, 4.XI.2007, G. Marson (ø). – Carnarvon, 183 km SSE of Carnarvon, 10 km

W of Overlander Roadhouse, 12 km NE of Hamelin Pool, Denham-Hamelin Road, 67 m, twigs of *Acacia*, on bark, 6.XI.2007, G. Marson (ex H.B. 8727b, MEL 2389251, **holotype**).

Orbilia concoloris Baral & G. Marson, **sp. nov.**, MB 813758 — Pls 307–309

Etymology: named after the host plant in the holotype, *Abies concolor*.
Typification: USA, Utah, Panguitch, branch of *Abies concolor*, 20.VI.2000, G. Marson (ex H.B. 6998b, M-0276460, holotype).

Latin diagnosis: *Apothecia rehydratata 0.18–0.7 mm diam., roseo-aurantiaca, sessilia, suberumpentia, margine glabro vel saepe subtiliter crenulato. Ascosporae *6.5–11.5 × 1.5–2 µm, subcylindricae, apice rotundatae vel obtusae, basi non vel leniter attenuatae, leniter vel modice curvatae, in statu vivo corpusculum refringens ampulliformem continentes. Paraphyses ad apicem leniter inflatae, spathulatae ad lageniformes. Margo excipuli subpilosa, absque processis vitreis. Habitat ad lignum putridum ramorum siccorum* Abietis *vel* Lonicerae *in zona boreali ad temperata humida ad subhumida continentali Americae septentrionalis et Asiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.18–)0.25–0.6(–0.7) mm diam., 0.11–0.21 mm high (receptacle 0.1–0.13 mm), light to bright rose to rose-orange, semitranslucent, round (to elliptical), very scattered to subgregarious; disc medium concave to flat, margin 5–40 µm protruding, smooth to often finely pubescent or crenulate; sessile on an obconical base, or with obconical stipe 0.06 × 0.15 mm, slightly erumpent from wood fibres. **Asci** *40–61 × 4.5–5.3 µm {2}, †39–56 × 4.2–4.7 µm {1}, 8-spored, spores *2–3-seriate, (2–)3–4 lower spores inverted (often strongly mixed) {3}, pars sporifera *23–30 µm long; **apex** (†) slightly to medium truncate (never indented or laterally inflated), hemispherical in profile view, thin-walled {3}; **base** with or without short to medium long, ± thick, flexuous stalk, L- to Y-shaped. **Ascospores** *(6.5–)8–11.5(–12.3) × (1.5–)1.6–2 µm {3}, subcylindric(-clavate), rarely fusoid-clavate, apex rounded to obtuse, base not or often slightly narrowed, sometimes in a thick tail-like end, slightly to medium curved or geniculate, especially near base; **SBs** *1.5–2.7 × 0.7–1 µm {3}, ampulliform, rarely tear-shaped, apically narrowed to a wide or narrow point. **Paraphyses** apically slightly (to medium) spathulate to lageniform, terminal cells *(6.5–)9–19(–23) × 2.5–3.3(–3.6) µm {3}, exceeding the living asci by 0–5 µm, the dead asci by 3–7 µm, lower cells *8–13(–17) × 1.8–2.8 µm {2} (5–9 µm long near base); never branched at upper septum. **Medullary excipulum** pale rose-orange, 20–80 µm thick, of dense or loose textura intricata with many inflated cells, indistinctly or sharply delimited. **Ectal excipulum** very pale rose, of thin-walled († slightly gelatinized), irregularly vertically oriented t. globulosa-angularis from base to submargin, 20–100 µm thick near base, cells *7–21 × 6–12(–15) µm {3}; 15–20 µm thick near margin, uppermost margin of t. prismatica-porrecta oriented at a 10–30° angle to the surface, marginal cortical cells *7–13(–19) {3} × 2.5–4.5 {1} or 5–6 {1} µm, often terminating as free short **hairs** (7–20 µm long) or conglutinate to form small teeth; **glassy processes** absent. **Anchoring hyphae** ± sparse to medium abundant, */†2–4 µm wide, walls 0.2–0.7(–1) µm thick {3}. **SCBs** globose, in paraphyses 1–2 µm diam.; in marginal excipulum 1.5–3.2 µm diam. **Exudate** 0.1–0.2(–0.4) µm thick, ± firmly attached, over paraphyses covering apex and lateral sides; over margin more granular. **— ANAMORPH**: vermispora-like (presumed, from natural substrate {1}). **Conidiophores** not observed. A single **conidium** found, curved at the ends, straight in middle part, *42.5 × 5 µm, 11-septate.

Habitat: collected 0.2–3 m above the ground, decorticated, 5–22 mm thick twigs and branches of *Abies concolor* {1}, *Lonicera altaica* {1}, *L. microphylla* {1}, on 0.2–0.5 mm deep strongly decayed wood {3}, at edge of longitudinal cleft, or in old beetle galleries, strongly greyed, with many green algae. **Associated**: *Amandinea* sp. {1}, *Claussenomyces* sp. {1}, *Durella atrocyanea* {1/1}, *Glyphium corrugatum* {1}, *Lachnellula* sp. {1}, *Lecanora* sp. {1}, *Orbilia basiflexa* {1}, *O. delphinus* {2}, *O. euonymi* {1}, *O. maeandrina* {1}, *O. phanosoma* {1}, *O. pileosoma* {1}, *Parmelia* sp. {1}, *Stenocybe* sp. {1}, ?*Teichospora* sp. {1}. **Desiccation tolerance**: fully viable for at least 17 months. **Altitude**: 2095–2778 m a.s.l. **Geology**: USA: Upper Cretaceous calcareous sandstone; Mongolia: Paleozoic sediment. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia concoloris* is characterized by medium-sized, subcylindrical, basally ± geniculate ascospores having rounded to obtuse apices with ± ampulliform SBs, only slightly tapered bases, the absence of an ascus apical wall thickening, apically spathulate to lageniform, though hardly

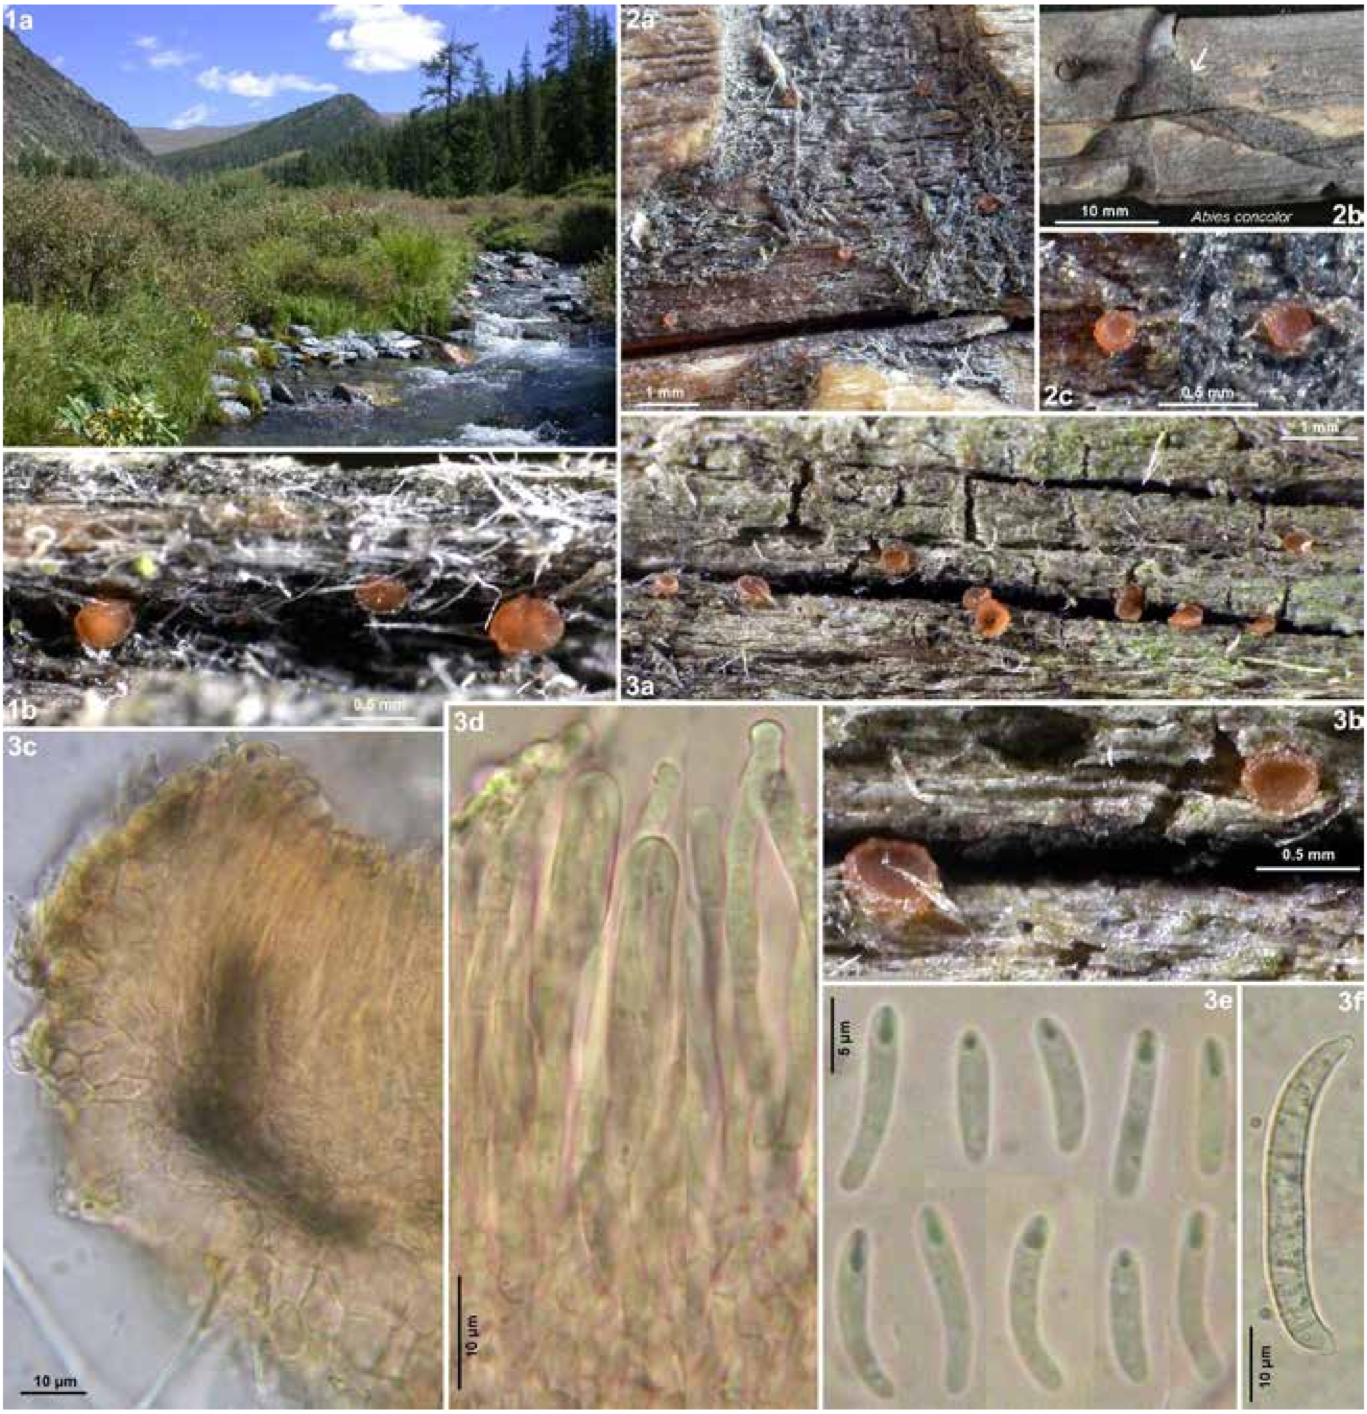

Plate 308. **1–3**: *Orbilia concoloris*. – **1a**. mountainous humid taiga with *Larix sibirica*, *Picea obovata*; **1c**. xeric decorticated branch with beetle gallery; **1b**, **2a**, **c**, **3a–b**. rehydrated apothecia; **3d**. apothecium in median section (margin and flanks); **3d**. asci and paraphyses; **3e**. ascospores; **3f**. conidium from substrate. – Living state. – **1a**: phot. P. Karasch. — **1a–b**. H.B. 7887a: Mongolia, Altay Mts., on *Lonicera altaica*; **2a–c**. H.B. 6998b (holotype): USA, Utah, on *Abies*; **3a–f**. H.B. 7897a: Mongolia, Altay Mts., on *Lonicera microphylla*.

inflated paraphyses with a thin cap-like exudate that covers their apices also laterally, and hair-like marginal cells without glassy processes. The spores resemble those of *O. denticulata* (series *Regales* of section *Aurantiorubrae*), which differs, e.g., in smaller SBs, more strongly inflated paraphysis apices with thick exudate caps, and in having glassy processes forming small to large teeth at the margin.

In spore morphology *O. concoloris* s.l. resembles also a North American specimen on *Larrea* with 16-spored asci and crystalloid SCBs mentioned under *O. pleionavajoana* (H.B. 5687g).

Unusual within series *Hesperideae* are the paraphyses and hair-like elements of *O. concoloris* with their thin layer of exudate, and particularly the thin-walled ascus apex. Placement in series *Hesperideae* is supported by ascospore and SB morphology, and particularly by the presence of an apical thickening in the very similar sample from Poland.

Variation. The Mongolian samples have longer SBs (2–2.7 µm) and very slightly larger spores, but otherwise well concur with the North American type specimen (SBs 1.5–2.2 µm). In all three collections the SBs vary in their apical attachment between narrowly and rather broadly attached.

Not included collection. On a coniferous fence in southern Poland a single apothecium was observed, which closely resembles *O. concoloris* in the spathulate paraphyses with a

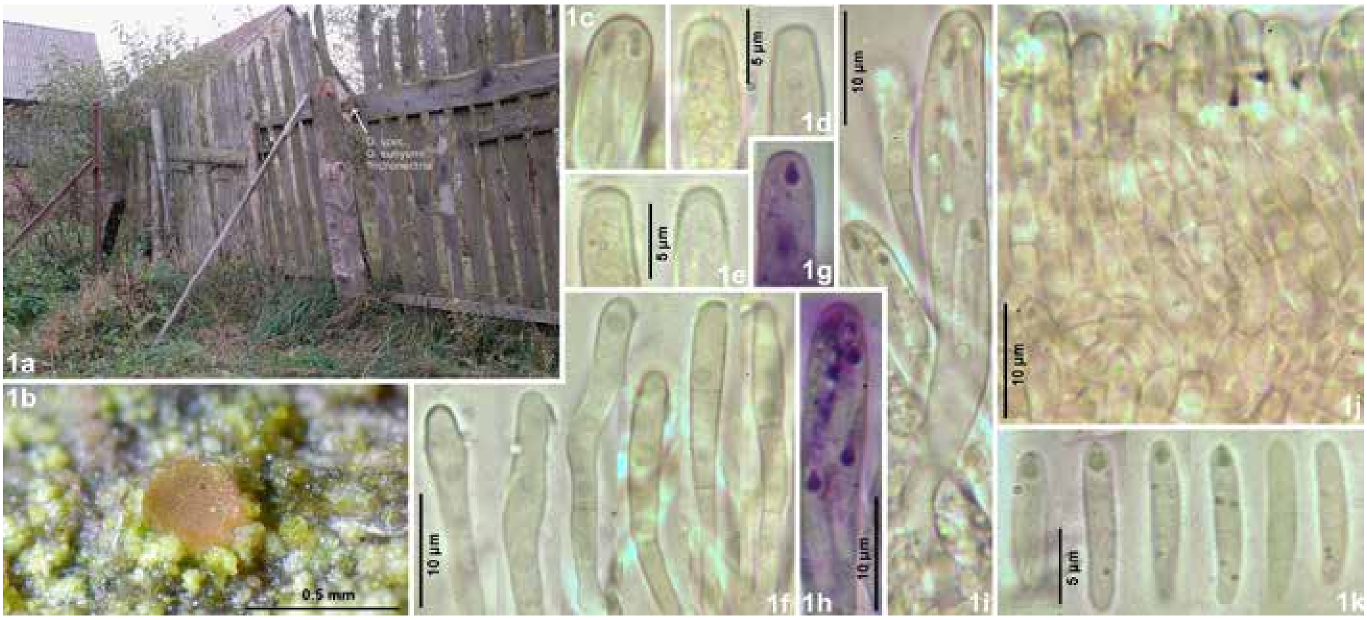

Plate 309. **1**: *Orbilia* aff. *concoloris*. – **1a**. old *Picea* fence; **1b**. rehydrated apothecium; **1c–e**, **g–h**. ascus apices; **1f**, **i**. asci and paraphyses; **1j**. marginal ectal excipulum (external view); **1k**. ascospores. – Living state, except for **1d–e** (in KOH); asci in **1g–h** (in CRB); 2 right spores in **1k** (in H_2O). — **1a–k**: phot. P. Perz, H.B. 9234b: Poland, Kłodzko, on *Picea*.

thin exudate and in the spores (*9–11.2 × 1.7–2 µm) and SBs (1.4–2 × 0.7–0.9 µm). It merely differs in a distinct ascus apical thickening of 0.7 µm and never distinctly curved spores (Pl. 309).

Phylogeny. From apothecia of one of the Mongolian specimens an ITS sequence was gained, in which the S1506 intron is absent. *O. concoloris* was first thought to belong to series *Regales* of section *Aurantiorubrae*. However, the species clustered unresolved when analysing a dataset restricted to that section by showing a distance of 20–21 % to members of series *Regales*, whereas in phylogenetic analyses of section *Hemiorbilia* (Phyls 9–10) it clustered with high (ITS+LSU) or medium (ITS) support in a subclade of the *cryptogena*-*sarothamni* clade, together with *O. adenocarpi* and *O. sarothamni*, with an ITS distance of 8.3 % and 9.3 %, respectively. Indeed, BLAST search for *O. concoloris* in GenBank yielded these two species of series *Hesperideae* as closest match, besides various other members of section *Hemiorbilia*. *O. concoloris* is indeed very different from series *Regales* in both the ITS1 and ITS2 region.

Ecology. *O. concoloris* was found on rotten wood of xeric twigs and branches of both gymno- and angiosperms. In western North America it occurred on *Abies* in the boreal humid Douglas fir mixed conifer forest at the southern end of the Utah Mountains, and in central Asia on *Lonicera* in an orotemperate (sub)humid (winter-dry), subalpine, continental, north-exposed mountain taiga (with *Larix sibirica* and *Picea obovata*) and adjacent south-exposed shrub vegetation (with *Spiraea alpina*, *Ribes nigrum*, *Juniperus sabina*). The not included collection from Poland was on a standing *Picea* fence on calcareous (Cretaceous) clay soil in temperate humid central Europe.

Specimens included. **USA**: **Utah**, Utah Mts., Bryce Canyon, 42 km SSE of Panguitch, Rainbow Point, 2778 m, branch of *Abies concolor*, on wood, 20.VI.2000, G. Marson (M-0276460, **holotype**; **isotype** in H.B. 6998b). — **MONGOLIA**: **Bayan Ölgii**, Sagsai, Altay Mts., S-part of Tavan Bogd, 25 km SE of Dayan lake, 8 km NE of Chinese border, Songino Gol river valley, 2100 m, twig & branch of *Lonicera altaica*, on wood, 15.VIII.2005, P. Etymology: named after the substrate of the type, *Adenocarpus viscosus*.
Typification: Macaronesia, Tenerife, El Portillo, branch of *Adenocarpus viscosus*, 25.III.2009, L. Quijada, E.V. Rodríguez & R. Castro (ex H.B. 9056, TFC Mic. 21741, holotype; sq.: KT222366).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.25–0.7(–0.9) mm diam., (0.12–)0.15–0.23(–0.3) mm high, light orange to rose(-orange), not or slightly translucent, round, scattered to subgregarious; disc flat (to slightly convex), margin distinct, ± thick, 5–10 µm protruding, smooth to very finely rough; broadly sessile or on a narrowed base, superficial or somewhat erumpent between fibres; dry slightly contracted, deep orange. **Asci** *(61–)71–108(–116) × (5.3–)5.8–7(–7.6) µm {2}, †(55–)65–90(–110) × 5–6(–6.3) µm {2} (up to 6.8 µm if flattened), 8-spored, spores *~4-seriate, 3–5(–7) lower spores inverted {3} (often strongly mixed), pars sporifera *(34–)38–48(–55) µm long; **apex** (†) hemispherical (to slightly truncate), dome †0.8–1.3 → 0.5–0.7 µm thick {2}, with distinct apical chamber; **base** with short to long, thin or thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(13.2–)18–27(–30) × ((1.7–))(2–)2.2–2.7(–3) µm {3}, †(13.7–)16–22(–24) × 2–2.5 µm {1} (up to 2.7–3.3 µm if flattened), fusoid to mostly fusoid-clavate, apex obtuse to subacute, base medium to mostly strongly attenuated in a tail or tail-like end *(3–)5–8(–10) × 0.9–1.2 µm, straight or slightly flexuous, sometimes slightly curved near base; **SBs** *(2.5–)3–3.5(–3.8) × (0.8–)1–1.2(–1.3) µm {2}, †3–3.5 × 0.8–1.2 µm {1}, elongate tear-shaped to subulate, apically narrowed to a narrow point, straight. **Paraphyses** apically uninflated or often slightly (to medium) clavate(-capitate), terminal cells *(8–)12–25 × (2–)2.5–3.2(–4) µm {3}, †2–2.5(–3.8) µm wide {1}, lower cells *10–18.5 × 1.7–2.3(–3) µm {2}; unbranched at upper septum. **Medullary excipulum** 40–60 µm thick, of dense textura intricata with many slightly inflated cells, indistinctly to sharply delimited from ectal excipulum by a ± distinct t. porrecta. **Ectal excipulum** of (†) not or slightly gelatinized, vertically oriented t. angularis(-prismatica) from base to mid flanks, 25–50 µm thick near base, cells *9–15(–19) × 6–9(–10) µm {1}, †4–8 µm wide; 20–30 µm thick near margin, of t. porrecta oriented at a 20–

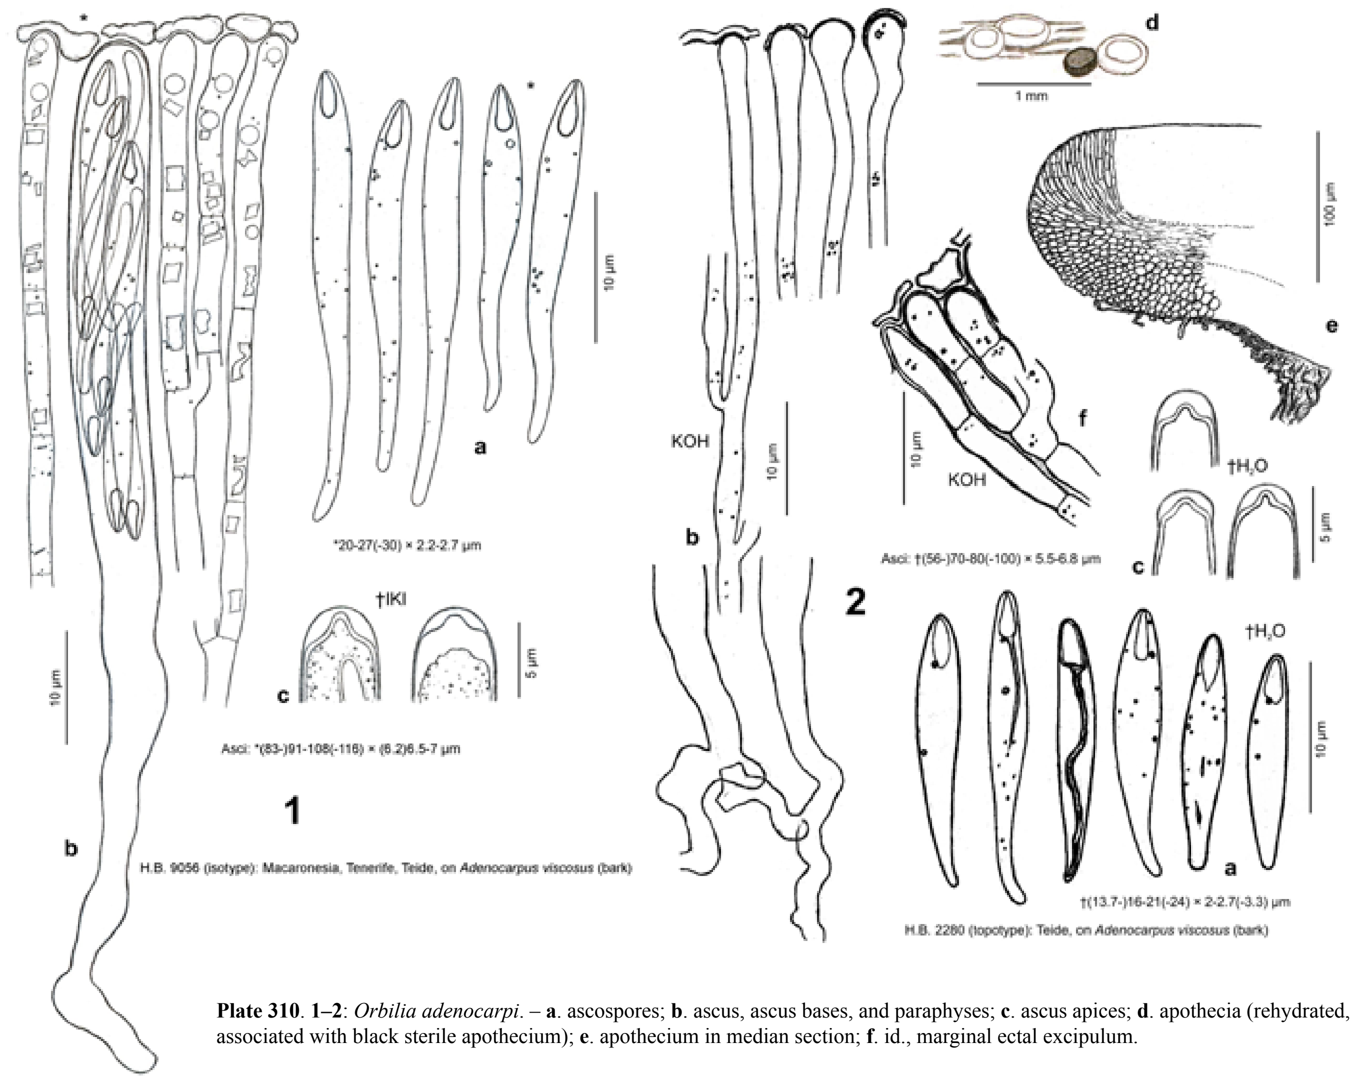

Plate 310. **1–2**: *Orbilia adenocarpi*. – **a**. ascospores; **b**. ascus, ascus bases, and paraphyses; **c**. ascus apices; **d**. apothecia (rehydrated, associated with black sterile apothecium); **e**. apothecium in median section; **f**. id., marginal ectal excipulum.

45° angle to the surface, marginal cortical cells *8–13 × 3–4.5 µm {3}, 7–10 × 2–3 µm {1}; **glassy processes** absent, at submargin sometimes with scattered, straight to flexuous, thick-walled, protruding hair-like hyphae 10–25 × 3–5 µm {2}. **Anchoring hyphae** abundant, */†2–3 µm wide, walls 0.2(–0.3) µm thick {2}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1.2–2 µm diam., mixed with many hyaline crystalloid ones of 1.2–3.5 × 0.3–1.7 µm. **Exudate** hyaline to very pale yellowish, over paraphyses (0.5–)1–2(–3) µm thick, (granular-)cloddy, ± firmly attached, over margin and flanks 1–3(–5) µm thick, cloddy. **— ANAMORPH**: unknown.

Habitat: lying on dry ground or still attached but close to the ground, corticated, 10–30 mm thick dead or living branches and stumps of *Adenocarpus viscosus* subsp. *viscosus* {10}, on medium to very decayed bark {10} (on uneven periderm), hardly to strongly greyed, algae absent or very sparse. **Associated**: *Coniochaeta* sp. {1}, *Helotiales* {1}, *Orbilia pleiogambelii* {1}, *Peniophora* sp. {1}, *Teichosporella dura* {1}. **Desiccation tolerance**: fully viable for at least 8 weeks. **Altitude**: [1300–1450] 1920–2660 m a.s.l. **Geology**: trachyte, phonolite, basalt. **Phenology**: X–XII, II–VI (probably throughout the year, long-lived).

Taxonomic remarks. *Orbilia adenocarpi* differs from *O. vinosa* in distinctly longer and wider ascospores, shorter and wider SBs with a narrower attachment, and distinctly larger asci. It also resembles the North American *O. navajoana* (series *Hesperideae*), from which it differs in the presence of crystalloid SCBs, also in longer and narrower spores with longer SBs. *O. hesperidea* corresponds to *O. adenocarpi* in many respects, including SB size and shape, but likewise differs in distinctly shorter spores.

Variation. Ascospore length varies strongly within populations, but also between them. In the first and some later records spores longer than 24 µm could not be found, while in the holotype some attained 30 µm because of a rather long tail. The above description is mainly based on the two here studied specimens (isotype and H.B. 2280), while not all data from other samples studied by L. Quijada were available.

Phylogeny. A sequence taken from apothecia of the isotype comprises ITS (with incomplete 5'-end) and LSU. A DNA isolate (partial 5.8S and entire ITS2) from *Pinus heldreichii* needles in Montenegro differs by only 1 nt in the ITS2. In our analyses, *O. adenocarpi* clustered strongly (ITS+LSU, Phyl. 9), medium (ITS, Phyl. 10), or weakly (LSU, S13) supported with *O. concoloris* and *O. sarothamni*, to which also *O. myriofusiclava* is associated. However, the ITS distance to *O. adenocarpi* is rather high (8.3–9.3%, to the latter 13%). In the LSU (D1–D2, 522 nt) the lowest distance is 1.3% to *O. myriofusiclava* and 1.7% *O. sarothamni*. The four species formed a medium supported subclade of the *cryptogena-sarothamni* clade (Phyl. 9). An environmental sequence from savannah soil in Texas (ITS+LSU) clustered with *O. adenocarpi* (Phyls 9–10, S13; ITS distance 7.5%, LSU 1%).

Ecology. *O. adenocarpi* grows in the upper meso- to supra-mediterranean semihumid high plateau (caldera) and on the south and west-exposed slopes outside the rim around the volcano Teide (Tenerife, Macaronesia). The species was recorded on bark of xeric branches of the dwarf shrub *Adenocarpus viscosus* (codeso del Teide), either dead or sometimes internally still alive (Quijada

et al. 2012), lying on the ground or attached. The first collection was made in 1978 on '*Spartocytisus supranubius*' (retama del Teide), but a revision of the bark structure by L. Quijada (pers. comm.) revealed that it is *A. viscosus*, in coincidence with all later samples of L. Quijada between 2008–2009. The eight collection sites lie mainly in the dry summit broom scrub (retamar-codesar, *Spartocytisetum supranubii,* facies with *A. visosus*), twice in adjacent plant communities (*Sideritido solutae-Pinetum canariensis spartocytisetosum subranubii* and *Erysimo scoparii-Pterocephaletum lasiospermi*), including almost vegetation-less lava areas. The host plant is endemic to the Canary islands and occurs in Tenerife mainly in the caldera, but also on La Palma and Gomera at similar altitudes. It is known to act as condensator of the air humidity and thus experiences a (sub)humid microclimate in spite of the dry climatic conditions there (Brullo et al. 2008).

Specimens included. **MACARONESIA** (all on bark of branches of *Adenocarpus viscosus*: **Canary Islands**, **Tenerife**, **La Orotava**, las Cañadas del Teide, 8 km ENE of Teide, NW of El Portillo, 2098 m, 18.II.1978, R. Series *Hemiorbilia*

Orbilia subgenus ***Orbilia*** section ***Hemiorbilia*** series ***Hemiorbilia*** – Type species: *Orbilia occulta* (Rehm) Sacc.

(?)= *Trinacrium* Riess in Fresenius, Beitr. Mykol. 2: 42 (1852) – Type species: *T. subtile* Riess

(?)= *Radotinea* Velen., Monogr. Discomyc. Bohem.: 298 (1934) – Type species: *R. caudata* Velen. [(?)= *Orbilia aristata* (Velen.) Velen.]

= *Orbilia* subgroup V *Aristula* Velen., Monogr. Discomyc. Bohem.: 102 (1934, unranked, in 1947 as '*Aristulae*') – Type species: not designated

?= *Descalsia* A. Roldán & Honrubia, Mycol. Res. 92: 494 (1989) – Type species: *D. cruciata* A. Roldán & Honrubia, *Mycol. Res.* 92: 495 (1989)

Etymology: *Aristula*: referring to the ascospores with long tails; *Descalsia*: named after the Spanish mycologist Enrique Descals; *Hemiorbilia*: named after the ± hemispherical shape of the ascus apex (in both living and dead state); *Radotinea*: after the village Radotín near Praha (Czechia); *Trinacrium*: according to the triradiate (Y-shaped) conidia with 1 main axis and 2 divergent arms.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–0.7(–1.5) mm diam. (incl. teeth), pale to bright orange to rose, margin smooth or often finely to strongly crenulated or toothed, rarely with long hyaline hairs, sessile or with a ± distinct short stipe. **Asci** *(35–)40–75(–90)((–103)) × (5–)5.5–8.5(–10) µm, rarely *22–32 × 3.6–4.5 µm, 8-spored, 0–4(–6) lower spores inverted; **apex** (†) hemispherical to slightly (rarely medium) truncate, with (0.6–)1–2(–3) µm thick dome, often with apical chamber; **base** L-, T-, Y- or h-, exceptionally H-shaped. **Ascospores** *3.5–9 or mostly (9–)11–20(–29.5) × (1.6–)2.2–4(–4.8) µm, usually divided into an inflated head and a distinct tail, head cylindrical or narrowly to broadly ellipsoid to fusiform, rarely strongly inequilateral to triangular, SB-containing end rounded to mostly obtuse to subacute, rarely acute to acuminate, tail ± abruptly delimited from head, short to very long, *0.2–1.2 µm thick, basally sometimes swollen, rarely absent, straight to slightly curved, sometimes strongly geniculate near base or below head. **SBs** apically affixed to spore wall (except for *O. aviceps* and *O. triangulispora* with laterally attached SBs), (1.6–)2–5(–6.5) × (0.4–)0.6–1.5(–1.7) µm, rarely only 1.3–1.5 µm long or 2–2.2 µm wide, rod-shaped (vermiform) to subulate or tear-, pear- to dumbbell-shaped or ampulliform, straight, apically narrowed to a small to wide point, with or without a very short filum. **Paraphyses** uninflated or slightly to medium, rarely strongly clavate-capitate, in *O. fimbriata* predominantly slightly lageniform, terminal cells (1–)1.5–2(–2.5)× as long as the lower cells, sometimes of equal length. **Ectal excipulum** cells near base *(5–)8–20(–30) × (4–)8–15(–20) µm, near margin of t. angularis to t. prismatica or t. porrecta, outer part oriented at a high to often medium or low angle, with **glassy processes** of 1–5 up to 30–100 µm length, rarely without, in *O. fimbriata* instead with 60–300 µm long septate hairs. **SCBs** globose (rarely absent), in some species also crystalloid. **Exudate** 0.2–0.5 up to 1–3(–5) µm thick, continuous-cloddy or granular, loosely attached, hyaline or pale yellowish, rarely absent. — **ANAMORPH**: trinacrium-like, descalsia-like, dwayaangam-like. **Conidiophores** not observed. **Conidia** staurosporous, of 3 types: 2-armed (Y- or rarely T-shaped), *20.5–80 × 18–100 µm, arms straight or somewhat curved downwards; 3-armed (descalsia-like), *18–73 × 25–85 µm; 4-armed (dwayaangam-like): *27–95 × 29–115 µm, arms straight; exceptionally a few conidia unbranched (phragmosporous), straight.

Habitat: on wood and bark of both gymno- & angiosperms, rarely on leaves or bryophytes, all species desiccation-tolerant, in humid to semiarid, boreal to subtropical climates.

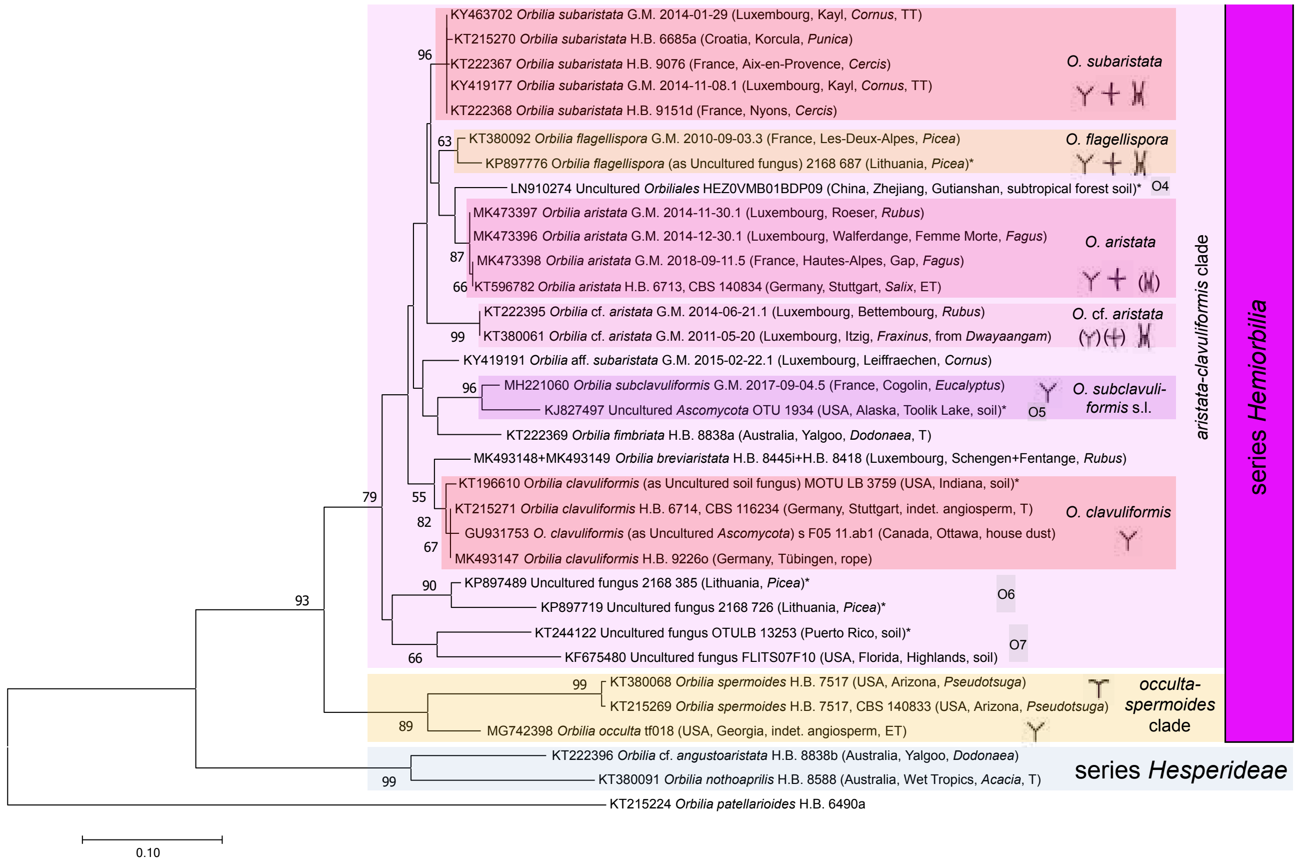
Recognized species: 24, plus 3 unnamed species ('affinis').

Taxonomic remarks. Within section *Hemiorbilia* series *Hemiorbilia* is characterized by ascospores with mostly distinct basal tails, also by the frequent presence of glassy processes that are agglutinated to form minute to large marginal teeth. The spore tails are not wider than 1.2 µm in their middle part, but may be swollen to 1.5–2 µm at the base. As a further peculiarity, all included species are 8-spored, and mostly only a few of the lower spores are inverted. In many of the species the terminal cells of paraphyses tend to be 1.5–2 × as long as the lower cells, while those of series *Hesperideae* range mainly around 0.5–1.5 ×. The variously branched conidia of the so far known anamorphs of series *Hemiorbilia* tend to have longer and narrower arms than those of series *Hesperideae*.

O. aviceps and *O. triangulispora* are exceptional in their strongly asymmetrical (triangular) ascospores with laterally attached SBs and short or even absent tails. They somewhat resemble *O. corculispora* in spore shape, but are retained in series *Hemiorbilia* because of their prominent glassy processes and 8-spored asci with only a few inverted lower spores. These features point to a relationship with *O. aviflagellata* and *O. aviaristata*, which have similar asymmetrical spore heads, although their SBs point in subapical direction and the spores have long tails. Also *O. colombiana* lacks a spore tail but is compared with *O. clavuliformis* for similar reasons.

O. nanosperma deviates from the other members of this series in remarkably small asci and spores, short SBs, and very long marginal teeth. *O. megaocculta* and *O. fimbriata* deviate by spores being distinctly wider than the average, the former species also by very wide SBs and short tails, and the latter by very long, septate hairs that are not agglutinated. In *O. fimbriata* the paraphysis apices are predominantly slightly lageniform. Here and in *O. spermoides* no exudate could be observed over the paraphyses. As an exception within series *Hemiorbilia*, *O. brevicauda* was collected in a humid subtropical forest on bark lying on the moist ground, nevertheless, we assume that also this species tolerates desiccation, as do all the others of section *Hemiorbilia*.

Velenovský (1934) included in his subgroup 'V *Aristula*' three species: *O. occulta*, *O. herbarum*, and *O. carpathica*. His *O. occulta* corresponds to *O. aristata* in the present study, while



Phylogenetic analysis 12. Phylogram of series *Hemiorbilia* inferred from ML analysis of ITS1-5.8S-ITS2 rDNA dataset (29 sequences, 610 positions, aligned with MUSCLE) using the K2+G model in MEGA6 (500 replicates). 9 environmental strains from GenBank are included, 4 of them representing unidentified species (O4–O7). The tree is rooted with *O. patellarioides*. Asci 8-spored in all taxa; T = type, ET = epitype, TT = topotype. * = without ITS1 and partial 5.8S.

the latter two taxa resemble *O. flagellispora* but are of uncertain identity. *O. carpathica* resembles also some members of section *Arthrobotrys*, see p. 1664). Later (Velenovský 1947), the author changed the name of this subgroup to *Aristulae*, again without stating its taxonomic rank.

Species delimitation. Series *Hemiorbilia* contains a rather large aggregate of species, which includes the type species *O. occulta* and which is quite problematic in regard to species delimitation. Its members are characterized mainly by spore shape and size, and by presence and length of glassy processes. Some of them, e.g., *O. aristata*, *O. subaristata*, *O. flagellispora*, and *O. clavuliformis*, were quite frequently collected within Europe in the present study, and could not clearly be identified in every case. They are rather variable in their spore characters, such as length of inflated apical part, length of tail, and strength of basal inflation of the tail. It is also impossible to recognize different subgroups of species, because quite a few intermediate species exist, e.g., *O. clavuliaristata* as a link between *O. aristata*/*O. subaristata* and *O. clavuliformis*/*O. subclavuliformis*.

Anamorph. Members of series *Hemiorbilia* produce a variety of staurosporous conidial types. Often several types were observed within a species or single strain: (1) trinacrium-like (Y-shaped) conidia were observed in 11 species, in four of them also or only in ascospore isolates (*O. clavuliformis*, *O. occulta*, *O. spermoides*, *O. subaristata*); (2) descalsia-like (┼-shaped) conidia occurred in six species, in two of them also in ascospore isolates (*O. aristata*, *O. subaristata*); (3) dwayaangam-like conidia were observed in three species in which also trinacrium- and descalsia-like conidia occurred, in one also in a conidial isolate that was sequenced (*O. aristata*).

Descalsia cruciata was described with almost exclusively tetraradiate (┼-shaped), apparently plane conidia, besides Y-shaped and unbranched ones. It was isolated from foam in a stream in the mountainous supramediterranean region of Calar del Mundo in Albacete, southern Castilla-La Mancha (Spain) and could possibly provide an older name for *O. subaristata* or *O. flagellispora*, or be a synonym of *O. aristata*. A living culture was not preserved (A. Roldán & L. Marvanová pers. comm.). Efforts by one of us (G.M.) to gain DNA from a permanent slide failed. Descalsia-like conidia observed by us in series *Hemiorbilia* have a spatial, tetraradiate shape when floating in thicker water films. They appear as plane cross-like structures only when exposed to pressure in the narrow water film under the cover slip. Possibly the 4-armed conidia of *D. cruciata* were also tetraradiate in three dimensions when floating in water.

Although conidial branching varied on the natural substrate within a given population between trinacrium-, descalsia- and dwayaangam-like, we obtained in four ascospore isolates only one type of conidia: trinacrium-like in *O. clavuliformis* and *O. spermoides*, descalsia- or dwayaangam-like in *O. aristata*, whereby the isolates of *O. aristata* showed a distinct molecular distance between descalsia- and dwayaangam-like (Phyl. 12). On the other hand, trinacrium- and descalsia-like conidia developed in our isolate of *O. subaristata* (H.B. 6685a, CBS 116217, unillustrated). Likewise Ando (1992) figured a very similar conidial state which he identified as *T. subtile* (without teleomorph). In addition to the Y-shaped trinacrium-like conidia, he observed four further conidial forms: *Sigmoidea* (unbranched), *Lambdasporium* (2-armed, sometimes with 1 arm again branched), *Articulospora* (┼-shaped), and *Dwayaangam*

(4-armed). The author concluded that the current system of conidial shapes is artificial. Quite probably, Ando was dealing with the anamorph of a species of series *Hemiorbilia*. Since the morphology of a given conidial type within this series is rather uniform, we are unable to decide to which species Ando's isolate belongs. Possibly it represents a species of the *O. aristata* aggregate. The same uncertainty applies to the type of *Trinacrium subtile*, which is very probably the anamorph of a species of series *Hemiorbilia* and resembles particularly those of *O. clavuliformis*, *O. subclavuliformis*, and *O. clavuliaristata*.

At the present state of knowledge we may conclude that some species of series *Hemiorbilia* are able to produce two or three types of conidia whereas others produce only one type.

Phylogeny. Molecular data were available for nine of the 24 species included here in series *Hemiorbilia*. Seven of them form in our analyses a strongly (ITS+LSU, Phyl. 9) or medium supported (ITS, Phyl. 12; LSU, S13) monophyletic clade which is called *aristata-clavuliformis* clade here. It includes *O. aristata*, *O. breviaristata* (not shown in analyses), *O. subaristata*, *O. flagellispora*, *O. clavuliformis*, *O. subclavuliformis*, and *O. fimbriata*. Another strongly (ITS) or medium (ITS+LSU) supported clade includes *O. spermoides* and *O. occulta* and is called *occulta-spermoides* clade here. Both clades show a remarkable distance between each other, despite a close morphological similarity between *O. occulta* and *O. aristata*/*O. breviaristata*. They clustered with strong (ITS) or medium support (ITS+LSU) as sister groups in a clade which represents series *Hemiorbilia*. However, the sequence of a tenth taxon, *O.* cf. *angustoaristata*, is even more surprising: it shows a strong distance to those nine species of series *Hemiorbilia* and clustered instead in the *vinosa-velutina* clade. The distance in the ITS region among the seven species of the *aristata-clavuliformis* clade ranges at 3.5–8% and between *O. spermoides* and *O. occulta* at 9%, while the distance between both clades lies at 10–17%. All these species show a distance of 16–22% to *O.* cf. *angustoaristata*.

Specific nucleotide positions. In the LSU D1–D2, pos. 153 is unique and consistent within series *Hemiorbilia* (excluding *O.* cf. *angustoaristata*) in having TTTG**T**AGA vs. TTTG**A**AGA in all remaining taxa of *Orbiliomycetes*, except for the *Hyalorbilia*-*Vermispora* clade which has TCTG**G**AGA or TCTG**C**AGA or rarely TCTG**A**AGA. In the ITS1 occurs a long, highly conservative motif with only 2 variable positions (ACCAAACTTGTTATTTCTG*DW*CAGTCTGAAAAACATTTTTTG), which is unique for the six species of the *aristata-clavuliformis* clade. *O. spermoides* and *O. occulta* deviate hereof by various nucleotides and indels, but differ also strongly between each other. This region is very different in other members of section *Hemiorbilia*, including *O.* cf. *angustoaristata*.

Ecology. Many species of series *Hemiorbilia* were found in temperate to boreal-subalpine, more or less humid regions, but many others predominantly or exclusively occur in subtropical semihumid to semiarid regions. The apothecia often grew on wood and more often bark of xeric branches and trunks of gymno- and predominantly angiosperms, but various species were occasionally or exclusively found on more or less herbaceous substrates: *O. aristata* on stems of *Heracleum* and *Humulus*, also on *Pinus* leaves, *O. breviaristata* on stems of *Euphorbia* and *Rubus*, *O.* cf. *angustoaristata* on *Dryas* leaves, *O. parviclava* on *Livistona* petiole, *O.* cf. *clavuliaristata* on *Phragmites* culm, and *O. subclavuliformis* on *Melilotus* stem. Several species were recorded on stems of *Rubus*, and *O. frullaniae* grew on leaves of *Frullania*. Members of series *Hemiorbilia* occur worldwide: records are known from Europe, Northern, Middle and South America, Africa, Asia, and Australia.

Orbilia colombiana Baral & Priou, **sp. nov.**, MB 813600 — Pls 312–313

Etymology: named according to the geographical origin of the holotype, Colombia (South America).

Typification: Colombia, Bogotá, branch of *Eucalyptus*, 30.X.1994, W. Jaklitsch (ex H.B. 5187, M-0276459, holotype).

Latin diagnosis: *Apothecia 0.3–1 mm diam. in statu umido, sessilia, superficialia, aurantio-rosea, margine valde albido-denticulata. Asci 8-spori. Ascosporae *6–9.8 × 2.1–2.5 µm, ellipsoideo- vel fusoideo-clavatae, apice rotundatae vel subacutae, subrectae, in statu vivo corpusculum refringens pyriformem, ad apicem affixum continentes Cellulae vivae excipuli et paraphysium corpuscula globosa continentes, excipulum marginale processis vitreis longis praeditum. Habitat ad corticem putridum ramulorum subsiccorum* Eucalypti *et* Polylepidis *in zona subtropica (sub)humida montana Americae australis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–1 mm diam., 0.14–0.23 mm high, pale rose or light to bright orange-rose, round, scattered to gregarious in small groups; disc flat, margin and exterior with ± prominent whitish or pale orange teeth projecting 30–60 µm beyond disc; sessile, superficial. **Asci** *42–50 × 5.3–6 µm {T}, †(35–)40–48(–53)((–60)) × (4–)4.5–5(–5.3) µm {2}, 8-spored, spores biseriate, (1–)2(–3) lower spores inversely oriented {2}, pars sporifera *18–27 µm long; **apex** (†) hemispherical (to slightly truncate), dome (†) 0.7–1.3 → 0.5–1 µm thick {2}, with very slight apical chamber; **base** with short to long, thin or thick, flexuous stalk, L-, T- or Y-shaped. **Ascospores** *(6–)7–9(–9.8) × 2.1–2.5((–2.7)) µm {2}, †6.5–8 × (1.8–)2–2.3 µm {T}, subcylindric- or ellipsoid-clavate with rounded apex {T}, or fusoid to fusoid-clavate with (obtuse to) subacute apex {1}, base slightly to strongly attenuated, straight to very slightly curved below; **SBs** *(1.8–)2.3–2.8(–3.2) × 0.7–1.3 µm {2}, pyriform to dumbbell-shaped or slightly ampulliform, rarely tear-shaped, apically narrowed to a small to wide point {T} or to a very short filum {1}. **Paraphyses** apically uninflated to slightly clavate-capitate, terminal cells *(8–)11–18 × 1.8–3 µm {2}, lower cells *7–13.5 × 1.6–2.5(–3.2) µm {2}; never branched at upper septum; hymenium very pale reddish. **Medullary excipulum** hyaline, 40–100 µm thick, of dense to loose textura intricata with many inflated cells, sharply delimited. **Ectal excipulum** hyaline, of (†) thin-walled, indistinctly oriented t. globulosa-angularis from base to margin, 40–60 µm thick near base, cells *11–21(–30) × 10–15 µm {1}, †7–20 × 6–12 µm {T}; 20–25 µm thick at mid flanks and margin, of t. angularis oriented at a 60–90° angle, cells *7–11 × 6–9 µm {T}, outer marginal layer of t. porrecta oriented at 20–30°, marginal cortical cells *6–13 × 1.5–3.4 µm {2}, giving rise to **glassy processes** of 18–80 × 1.8–3.5 µm {2}, stratified, low- to medium-refractive, curved in- {2} or outwards {1}, coherent to form 30–100 × 50–90 µm large teeth. **Anchoring hyphae** (very) abundant, *2–3(–4)((–5)) µm wide, walls 0.2(–0.3) µm thick {2}, forming strands, near base gradually emerging from ectal excipulum as thick moniliform hyphae, intergrading at flanks into glassy hairs. **SCBs** in paraphyses and excipular cells (sub)globose, 1.2–2.3 µm diam. {2}. **Exudate** over paraphyses (0.5–)1–2.5(–3.5) µm thick, broken in clods, very pale yellowish, loosely attached; on teeth sparse or abundant. — **ANAMORPH**: descalsia-like (presumed, from natural substrate {1}). **Conidiophores** not seen. **Conidia** 3–4-armed (by repeated dichotomous branching), total size *~18–28 × 25–30 µm {1}, stipe *10–18 × 2.8–3.5 µm, 1–2-septate, arms tapering, *11–17 × 2.5–3 µm, 1–3(–4)-septate.

Habitat: lying on somewhat moist ground {2}, corticated, 4–8 mm thick semixeric twigs and branches of *Eucalyptus* sp. {1}, *Polylepis* sp. {1}, on medium decayed bark {2} (in deep cross-cracks, on bast), somewhat greyed, sometimes blackened, green algae very sparse. **Associated**: brown ?conidiomata. **Desiccation tolerance**: fully viable for at least

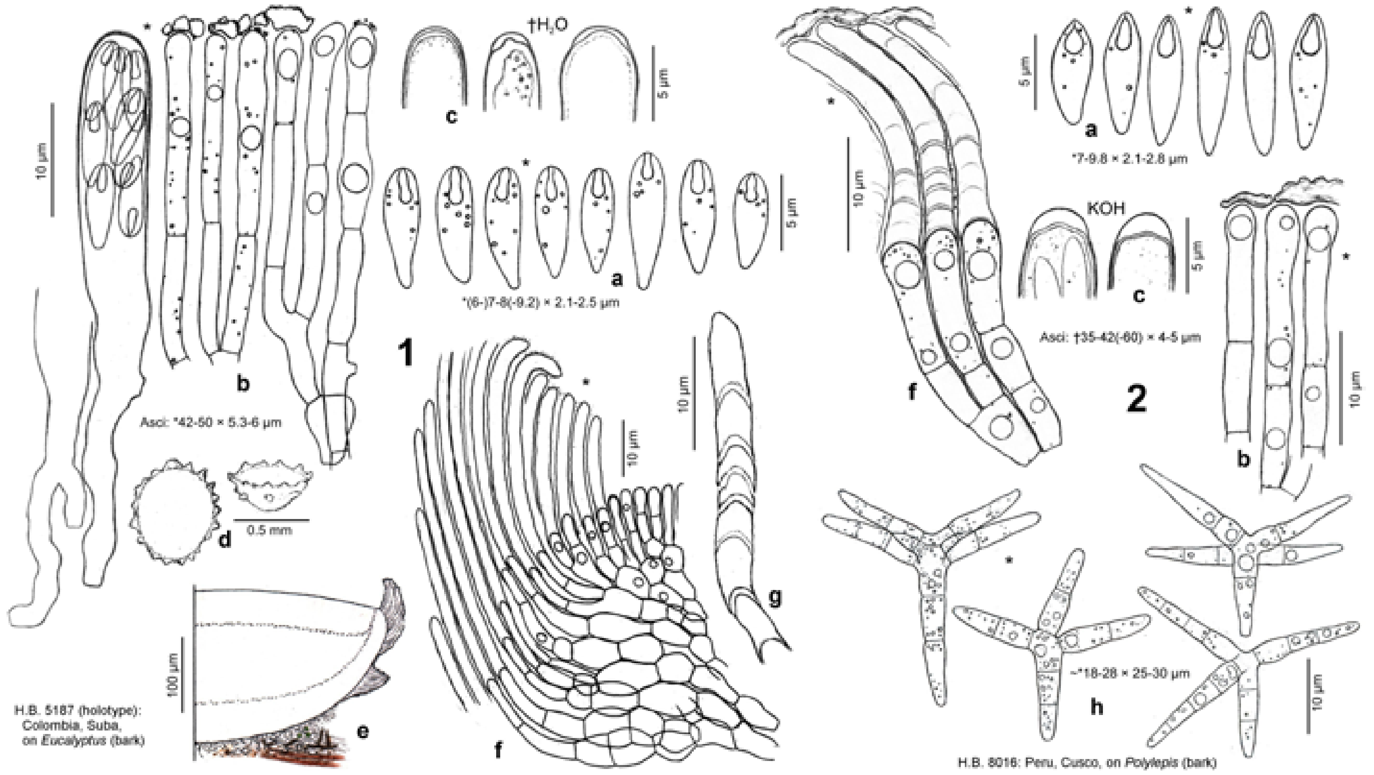


Plate 312. **1–2**: *Orbilia colombiana*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecia with dentate margin (rehydrated); **e**. apothecium in median section; **f**. id., marginal ectal excipulum with long glassy processes; **g**. glassy process; **h**. conidia from substrate.

3 weeks, paraphyses, excipular cells, ascospores and conidia after 2 months. **Altitude**: 2620–3820 m a.s.l. **Phenology**: X (tropical belt).

Taxonomic remarks. *Orbilia colombiana* resembles *O. montigena*, *O. alpigena*, and *O. hesperidea* (series *Hesperideae*) in the shape of ascospores and SBs. It differs in long glassy processes and shorter spores, from *O. hesperidea* also in the absence of crystalloid SCBs. *O. colombiana* is tentatively placed in series *Hemiorbilia* because of showing only a few inverted spores in the asci and the presumed descalsia-like anamorph. *O. colombiana* resembles particularly *O. clavuliformis*, in which the spore tails are sometimes rather short or even absent (Pls 314: 6; 315: 9). From this species it differs in smaller spores being consistently without a tail, and in longer glassy processes which form distinct teeth.

Variation. The holotype differs in cylindric-clavate spores with rounded apices from the collection on *Polylepis* with fusoid spores with obtuse to subacute apices, also shape and attachment of the SBs are slightly different. The glassy processes are curved inwards in the holotype but outwards in the *Polylepis* specimen, though here teeth with slightly inwards curved processes also occur. It cannot be excluded that the two collections belong to two different taxa. Yet, similar variation in spore morphology was noted, e.g., in *O. hesperidea*.

Anamorph. The conidia found in the paratype of *O. colombiana* resemble descalsia-like conidia of some typical members of series *Hemiorbilia*, e.g., *O. aristata*. They are also similar to trinacrium-like conidia typical of series *Hesperideae*, but differ in 1 or 2 more branches.

Ecology. *O. colombiana* grew on medium decayed bark of semixeric twigs and branches of *Eucalyptus* and *Polylepis* at two subtropical highland areas in the mountain range of northwestern and western South America. That on *Eucalyptus* was in the humid high basin of Colombian Andes, that on *Polylepis* in a subhumid highland in the Peruvian Andes. Although collected on rather moist ground, *O. colombiana* is desiccation-tolerant and possibly survives drought for a much longer period of time than evaluated at present.

Specimens included. **COLOMBIA**: **Cundinamarca**, Cordillera oriental, 16 km N of Bogotá, Suba, 2620 m, branch of *Eucalyptus*, on bark, 30.X.1994, W. Jaklitsch (ex H.B. 5187, M-0276459, **holotype**). — **PERU**: **Cusco**, 5 km N of Cusco, 2.6 km NW of Yuncaypata, Tambo Machay, 3820 m, twig of *Polylepis*, on bark, 18.X.2005, J.P. Priou (H.B. 8016, anam. substr.).

Orbilia clavuliformis Baral & G. Marson, **sp. nov.**, MB 814366 — Pls 314–317, Map 55

Etymology: referring to the club-shaped ascospores.

Typification: Germany, Stuttgart, branch of indet. angiosperm, 23.VI.2000, H.O. Baral (ex H.B. 6714, M-0276457, holotype; CBS 116234; sq.: KT215271).

Latin diagnosis: *Apothecia rehydratata 0.15–0.7 mm diam., roseo-aurantiaca, (sub)sessilia, margine subtiliter vel distincte crenulata. Asci 8-spori. Ascosporae *13–21.5 × 2.8–3.7 µm, ellipsoideae, cauda basali 3–10 × 0.8–1.5 µm, basi non inflata praeditae, in statu vivo corpusculum refringens bacilliformem, ad apicem affixum continentes. Cellulae vivae excipuli marginalis et paraphysium corpuscula globosa continentes, excipulum marginale processis vitreis dentes minutos formantibus praeditum. Habitat ad corticem putridum, etiam lignum, ramulorum vel ramorum siccorum fruticum vel arborum angiospermarum, raro coniferarum, in zona temperata ad submediterranea (semi)humida atlantica ad continentale Europae et hemiboreale humida Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.5(–0.9) mm diam., 0.12–0.2 mm high (receptacle 0.08–0.13 mm), pale to bright orange-rose, medium translucent, round, scattered to (sub) gregarious; disc ± flat, margin thin, 0–12 µm protruding, finely rough to distinctly crenulate; sessile or with a very indistinct stipe up to 50 × 250 µm; superficial but sometimes immersed in biofilm; dry bright orange-red to dark brick-red. **Asci** *(47–)50–70(–85) × 6.8–8.5(–10) µm {12}, †42–68 × 5.5–7.3 µm {6}, 8-spored, spores 2–4-seriate, 1–3(–4)((–6)) lower spores inversely oriented {12} (mostly not mixed), pars sporifera *26–47 µm long; **apex** (†) hemispherical to slightly truncate, dome

Rubus fruticosus {3}, on medium to strongly decayed bark {37}, on periderm {9} or bast {13} (in small cracks or larger periderm-free areas), sometimes on inner surface of detaching bark, rarely on wood {9}, on a thorn of *Rosa* {1}, on textile {1}, slightly to strongly greyed, green algae sparse or abundant. **Associated**: ?*Calloria* sp. {1}, ?*Ciliolarina* sp. {1}, *Dacrymyces* sp. {1}, *Diatrype* sp. {1}, *Hyalorbilia latispora* {1}, *H. multiguttulata* {1}, *H. subfusispora* {3}, *Karstenia rhopaloides* {2}, *Lasiosphaeria* sp. {1}, *Lecophagus ellipsoideus* {1}, *Lophiostoma compressum* {1}, *Melanelia glabratula* {1}, *Melaspileella* ?*proximella* {1}, *Merismodes* sp. {2}, *Micropeziza* sp. {1}, *Mollisia* sp. {2}, *M. ligni* {1}, *Neodasyscypha cerina* {1}, *Nitschkia cupularis* {1}, *Orbilia aristata* {11}, *O. aurantiorubra* {2}, *O. breviaristata* {3}, *O. eucalypti* {1}, *O. flavida* {1}, *O. gambelii* {1}, *O. mali* {1}, *O. pseudoaristata* {1}, *O. quaestiformis* {1/1}, *O. septispora* {1}, *O. subaristata* {1}, *O. subclavuliformis* {1}, *O. trapeziformis* {1}, *O. vinosa* {1}, *O. vitalbae* {2/1}, *Orthotrichum* sp. {1}, *Olla scrupulosa* {1}, *Parmelia sulcata* {1}, *Patellaria atrata* {2}, *Phaeophyscia orbicularis* {1}, *Physcia* sp. {1}, *P. tenella* {1}, *Phyllactinia guttata* {1}, *Pseudolachnea hispidula* {1}, *Pyrenopeziza rubi* {1}, *Rutstroemia punicae* {1}, *Sporidesmium* sp {1}, *Trimmatostroma salicis* {1}, *Tympanis ligustri* {1}, *Xanthoria parietina* {1}. **Desiccation tolerance**: fully viable for at least 2 weeks, many spores and some paraphyses still alive after 5 months. **Altitude**: 10–480 m a.s.l. **Geology**: Cambrian-Ordovician shale, silt, greywacke, Muschelkalk, Keuper (Gipskeuper, Stubensandstein, Knollenmergel), Cretaceous lime-, clay- & marlstone, flysch, Tertiary molasse, sand & clay, Pleistocene loess & sand; rhyolite, dacite, mica schist, gneiss; USA: Carboniferous calcareous sediment. **Phenology**: throughout the year (long-lived).

Phenology of *O. clavuliformis*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
2	2	4	1	5	14	5	2	1	5	5	3

Taxonomic remarks. *Orbilia clavuliformis* is characterized by rather broad, ellipsoid-clavate ascospores with a well-defined thick tail, and by the presence of glassy processes. Similar spores as in *O. clavuliformis* are found in several more or less closely related species, such as *O. subclavuliformis*, *O. breviclava*, *O. parviclava*, and *O. clavuliaristata* (for the differences see there). *O. aristata* and *O. flagellispora* are readily distinguished by much thinner spore tails. *O. clavuliformis* resembles also the mediterranean *O. hesperidea*, from which it differs in the presence of glassy processes and rather distinct spore tails, further in the consistent absence of crystalloid SCBs. However, our molecular data suggests placement of *O. clavuliformis* in the *aristata-clavuliformis* clade.

Variation. *O. clavuliformis* is a rather constant species. Variability is mainly observed in spore length, especially due to variation in tail length. In one collection the tails were often very short or rarely even absent (Pls 314: 6; 315: 9). Also the glassy processes varied strongly in length among the collections. In only one specimen (1.X.2000, Stuttgart) a single free mature spore with a fully developed SB possessed an eccentrical septum near the tail.

Not included collections. The only known two collections from North America (Arizona, on bark of *Pinus edulis*, soc. *O. spermoides*, 17.V.1995, unillustrated; North Carolina, on *Cornus*, soc. *O. occulta*, Pl. 317) each consisted of a single apothecium. Both are tentatively referred to *O. clavuliformis* but are not included in the description. The former was only studied in the dead state. The glassy processes were short or absent and the spores had a short, rather thin tail. In that on *Cornus* the rehydrated apothecium measured 0.8 mm diam., the glassy processes were exceptionally long (20–40 µm), the asci comparatively large (*8.5–9.7 µm wide, †60–70 × 6.8–8 µm), and the spores had often subacute apices and somewhat shorter and thicker SBs. Further records are needed to clarify whether populations from North America are specifically distinct.

Anamorph. Trinacrium-like conidia in pure culture of the holotype (Pl. 314: 5f) were only obtained after flooding with water. They closely resemble those observed on the natural substrate and are very similar to the type of *Trinacrium subtile*. In four collections of *O. clavuliformis* we found together with triradiate also tetraradiate conidia near apothecia, which strongly resemble the descalsia-like anamorph obtained in pure culture of *O. aristata* and *O. subaristata*. Since *O. aristata* was sometimes found growing in association with *O. clavuliformis*, they might in fact belong to this species. In the North American collection on *Cornus* (IVV: H.B. 7402b) two trinacrium-like conidia were observed (†30–35 × 42 µm, arms 2.5–2.8 µm wide).

Phylogeny. A sequence from the ex-type culture of *O. clavuliformis* (H.B. 6714) comprises SSU (without S1506 intron), ITS and LSU (D1–D2), and one taken from apothecia of H.B. 9226o (as H.B. 9226a = *O. aristata*) likewise lacks the intron and fully coincides in the ITS and LSU. Obviously, collection H.B. 9226 included, besides abundant *O. aristata* and one apothecium of *O. subclavuliformis*, also *O. clavuliformis* which was overlooked during microscopic examination.

In our phylogenetic analyses *O. clavuliformis* clustered in the *aristata-clavuliformis* clade (Phyls 9, 12, S13). In the ITS region *O. clavuliformis* shows a distance of 4.5–6% to *O. subaristata*, *O. aristata*, and *O. flagellispora*, 6.5% to *O. subclavuliformis*, 7% to *O. fimbriata*, 16% to *O. spermoides*, and 19% to *O. angustoaristata*. When analysing LSU (D1–D2), *O. clavuliformis* clustered with medium support and a 0.8% distance with *O. subclavuliformis* in a clade (S13), the next close taxon being *O.* aff. *subaristata* (KY419191) with 1%, whereas in the ITS analysis *O. clavuliformis* clustered distant from *O. subclavuliformis* (Phyl. 12).

Two environmental ITS sequences from North America are undoubtedly conspecific with *O. clavuliformis* (see Phyl. 12). One from Ottawa (GU931753) differs by 3 nt and 1 gap (0.6%) in the ITS region (2 nt in ITS2), and that from Indiana (KT196610), comprising only partial 5.8S and entire ITS2, deviates from *O. clavuliformis* in the ITS2 by 5 nt and 2 gaps (in 2 of these 5 nt it concurs with the Ottawa strain).

Ecology. *O. clavuliformis* grows on ± rotten bark and also wood of xeric twigs and branches of various trees and shrubs of angiosperms, sometimes gymnosperms, also on stems of *Rubus*, in thermophilous (sun-exposed) but also shady forests and scrubs, including a swampy *Salicetum* with *Filipendula*. The rather numerous collections and environmental DNA data suggest that the species is restricted to more or less temperate humid, oceanic to continental areas of Europe and North America. In Europe it was repeatedly found growing in association with *O. aristata*. In samples from western France the climate is mesotemperate humid (oceanic), in those from Montenegro mesosubmediterranean (semi)humid, and in the two DNA-extracts from North America hemiboreal humid (Ottawa) and warm-continental humid (Indiana). Records from montane, boreal, and eumediterranean areas are so far absent. The not included samples from North America are from the cold-temperate (sub)humid southern Appalachian Mountains and Colorado Plateau (pinyon-juniper woodland).

Specimens included. **GREAT BRITAIN**: **East Midlands**, **Nottinghamshire**, 5 km NW of Retford, 2 km NE of Barnby Moor, Daneshill Energy Forest, 15 m, trunk *Eucalyptus gunnii*, on bark, 26.V.2011, C. Hobart (ø, doc. vid.).

Orbilia asturiensis Baral, E. Rubio & J. Linde, **sp. nov.**, MB 813601 — Pls 318–319

Etymology: named after the geographical origin (Asturias, northwestern Spain)
Typification: Spain, Villablino, branch of *Salix caprea*, 17.VIII.2008, J.L. Cheype (ex H.B. 8901, M-0276435, holotype).

Latin diagnosis: *Similis* Orbiliae clavuliformi *sed cauda ascosporarum distincte inflata, corpusculum refringens brevius, ab* O. flagellispora *cauda breviore, leniter constricta differt. Habitat ad lignum et corticem putridum ramorum siccorum* Salicis *in zona orotemperata humida Europae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.25–)0.5–1.2(–1.5) mm diam. (without teeth), 0.15–0.18(–0.3) mm high (receptacle 0.14 mm), light to bright yellowish-orange, slightly translucent, round to slightly lobate, scattered to ± gregarious in small groups; disc flat, margin not protruding but with prominent, 20 µm protruding white teeth of 40–70(–100) × 50–130(–200) µm; broadly sessile or with a stalk up to 0.15 × 0.25 mm, superficial; dry bright orange-red. **Asci** *65–80 × 7–8 µm {2}, †60–70 × 5.5–6.5 µm {T}, 8-spored, spores (*) biseriate, 2–4(–5) lower spores inverted {2} (not mixed), pars sporifera *~40–50 µm long; **apex** (†) hemispherical, dome †1.2–1.4 → 0.7–1 µm thick {T}, with distinct apical chamber; **base** with short to medium long, ± thick, flexuous stalk, T- to L-shaped. **Ascospores** *(13.7–)15–19(–21) × 3.3–3.8 µm {2}, †13.5–18 × 3.2–3.5 µm {T}, with ellipsoid head of *(8.5–)9–11(–12) µm length and a distinct *(3.5–)5–7(–8) µm long tail with a basal *1.5–2 µm wide inflation (rarely ± uninflated and *1.2–1.4 µm wide), above inflation *0.8–1.3 µm wide, apex obtuse to subacute, straight or somewhat inequilateral, rarely slightly to medium geniculate between head and tail; **SBs** *3–4 × 1–1.2(–1.4) µm {2}, cylindrical to pear- or dumbbell-shaped, apically abruptly narrowed to a very short filum (not visible on photographs), straight. **Paraphyses** apically uninflated to medium capitate, terminal cells *(12–)18–26(–32) × 2.5–3.3 µm {T}, lower cells *12–17 × 1.5–2.5 µm {T}; unbranched at upper septum, hymenium pale orange. **Medullary excipulum** pale orange, 40–70 µm thick, of loose to dense textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** pale orange, of (†) ± thin-walled, vertically oriented t. angularis-prismatica from base to margin, 40–75 µm thick near base, cells *9–25 × 6–12 µm {2}; 20–30 µm thick near margin, oriented at a 40–70° angle to the surface, outermost cells elongate, oriented at 20–40°, marginal cortical cells *6–9 × 2.5–3.5(–4.5) µm {T}; **glassy processes** (10–)20–70 × 2.5–3.5(–4.5) µm {2}, refractive, unstratified, curved outwards, coherent to form distinct teeth. **Anchoring hyphae** abundant, †2–3 µm wide, walls 0.2–0.7 µm thick {T}. **SCBs** in paraphyses and ectal excipulum absent {T} or globose, 1.8–2.1 µm diam. {1}; ectal excipular cells at flanks with some light yellow-orange **LBs** 1–2.5 µm diam. that contain carotenoids {2}. **Exudate** over paraphyses and teeth 1–3 µm thick, cloddy-continuous, pale yellowish-orange, loosely attached. **— ANAMORPH**: unknown.

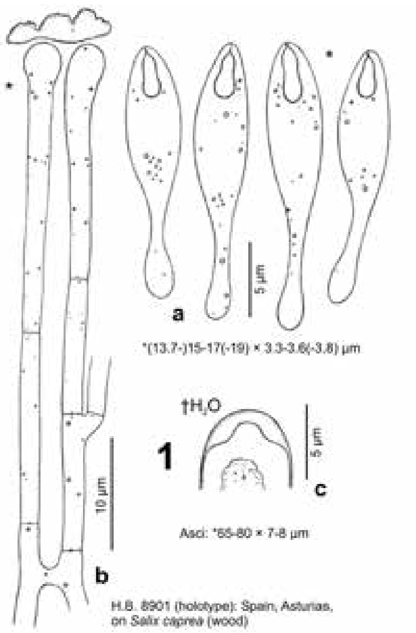

Plate 318. **1**: *Orbilia asturiensis*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex.

Habitat: collected 1.5–3 m above the ground, decorticated, 13–15 mm thick branch of *Salix cantabrica* {1}, *S. caprea* {1}, on 0.2–0.3 mm deep strongly decayed wood {1} or on medium decayed bark {1}, slightly greyed, no algae. **Associated**: *Lindgomyces griseosporus* {1}, *Orbilia subtrapeziformis* {1} (both on another xeric branch of the same tree of paratype). **Desiccation tolerance**: mature asci still viable after 3 weeks. **Altitude**: 1365–1505 m a.s.l. **Geology**: acidic glacial deposits from Silurian-Devonian-Carboniferous quartzite, clay and slate. **Phenology**: VII–VIII (but probably long-lived).

Taxonomic remarks. *Orbilia asturiensis* resembles *O. clavuliformis*, from which it differs in the spore tails being consistently inflated at the base, also in shorter SBs with a very short filum, and larger marginal teeth made up of longer glassy processes. However, the filum is invisible on photographs and perhaps not always present. *O. asturiensis* differs from *O. flagellispora* in shorter spore tails which are much thicker above the basal inflation. In some collections here referred to *O. flagellispora* (e.g., Pl. 327: 3–4) the spore tails approach those of *O. asturiensis* in thickness, but here the spore heads are narrower and the SBs exceed 4 µm in length. An illustration of the paratype of *O. asturiensis* is also found in Rubio & Zapico (2018: 52).

Variation. In the paratype the spores tend to be slightly longer than in the holotype due to longer spore tails, otherwise the two samples concur very well.

Plate 319. **1–2**: *Orbilia asturiensis*. – **1a–c**, **e–g**, **2a–b**. rehydrated apothecia; **1d**. dry apothecium; **1h**. apothecium in median section; **1i**. id., marginal ectal excipulum with glassy processes that form teeth; **1k**. id., basal ectal excipulum; **1j**, **2c–e**. ascus and paraphysis apices; **1l**, **2f**. ascospores. – Living state (**2c–f** in CRB), except for **1j** (ascus and paraphyses), ascus in **2e**. – **1c**, **f–g**, **j**, **l**, **2a–f**: phot. E. Rubio. — **1a–l**. H.B. 8901 (holotype): Spain, Asturias, Monasterio de Hermo, on *Salix*; **2a–f**. id., El Puerto, on *Salix*.

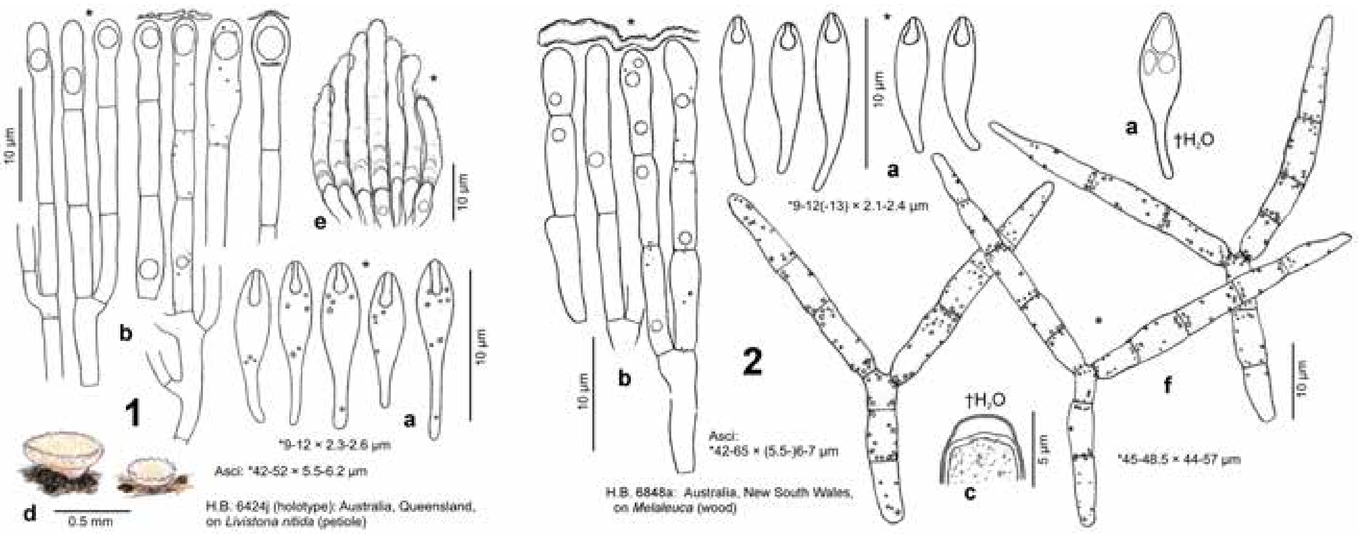

Plate 320. **1**: *Orbilia parviclava*; **2**: *O*. aff. *parviclava*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex; **d**. apothecia with dentate margin (rehydrated); **e**. marginal cortical cells with glassy processes (external view); **f**. conidia from substrate.

Ecology. *Orbilia asturiensis* was found on rotten wood and bark of xeric branches of *Salix* spp. in the orotemperate humid atlantic Cantabrian Mountains of Asturias (southwestern Europe). Despite repeated search at the type locality, apothecia could only be observed on the original tree individual. The vegetation was a *Fagus sylvatica* dominated forest on acidic soil, with *Betula pubescens*, *Corylus avellana* and *Salix caprea*, at a medium shaded forest edge. The paratype locality lies in a heath- and shrubland with, e. g., *Erica* spp., *Cytisus scoparius*, *Genista florida*, *Juniperus alpina*, *Thymelaea cordifolia*, and *Vaccinium myrtillus*, where *O. asturiensis* grew on an attached branch 1.5–2 m above the water of a streamlet bordered by shrubs of *Salix cantabrica*. The associated *Lindgomyces griseosporus* was considered to be an aquatic fungus but is obviously able to form perithecia also on xeric branches (here with *O. subtrapeziformis* about 2 m above the water, E. Rubio pers. comm.).

Specimens included. **SPAIN**: **Asturias**, 7 km S of Pola de Somiedo, 1.6 km W of El Puerto, N of Vega Cimera, 1505 m, branch of *Salix cantabrica*, on bark, 7.VII.2017, E. Rubio (E.R.D. 7104, doc. vid.). – 23 km SW of Pola de Somiedo, 4 km E of Monasterio de Hermo, 1365 m, branch of *S. caprea*, on wood, 17.VIII.2008, J.L. Cheype, vid. E. Rubio (ex H.B. 8901, M-0276435, **holotype**; E.R.D. 4549, **isotype**).

Orbilia parviclava Baral, **sp. nov.**, MB 813602 — Pls 320–321

Etymology: referring to the rather small clavate ascospores.

Typification: Australia, Queensland, Taroom, leaf of *Livistona nitida*, 22.X.1998, G. Marson (ex H.B. 6424j, BRI AQ799183, holotype).

Latin diagnosis: *Similis* Orbiliae clavuliformi *sed ascosporae multo minores, corpusculum refringens brevius differt. Habitat ad petiolum putridum siccum* Livistonae nitidae *in zona subtropica subhumida Australiae orientalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.22–0.55 mm diam., 0.07–0.15 mm high (receptacle 0.06–0.09 mm), pale cream-orange, translucent, round, ± scattered; disc flat (to slightly convex), margin thin,

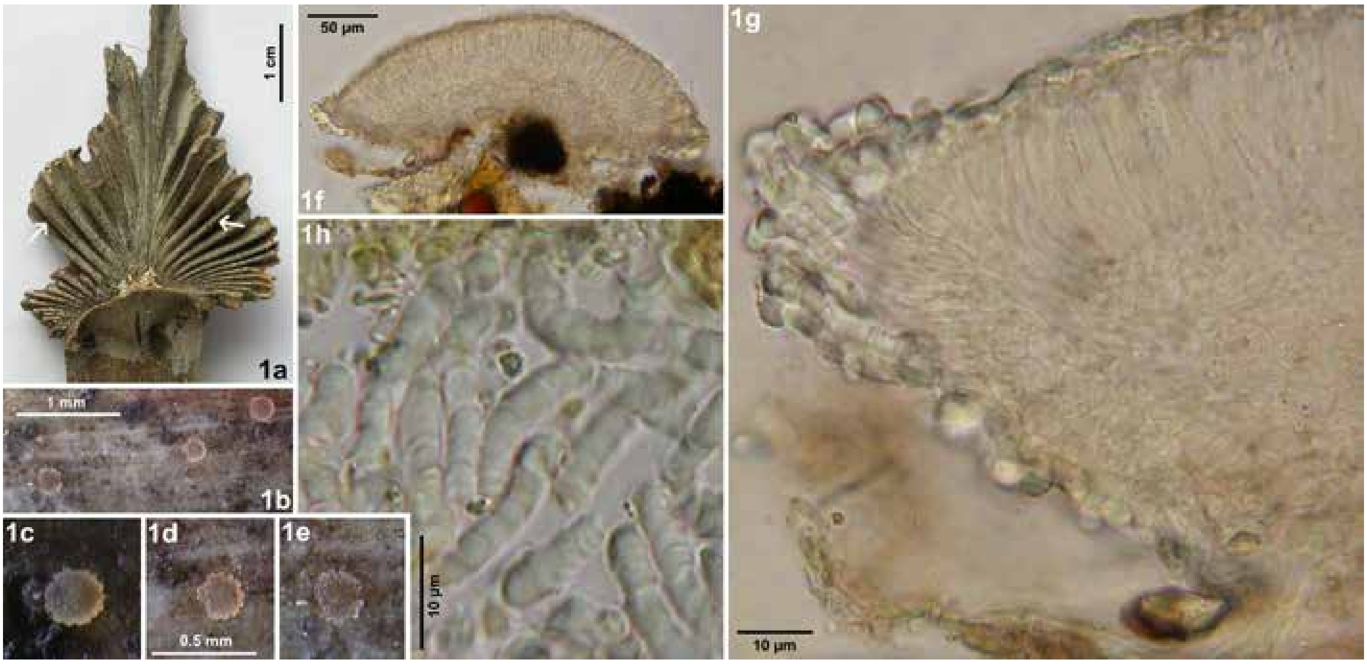

Plate 321. **1**: *Orbilia parviclava*. – **1a**. dead fan-shaped part of leaf of *Livistona nitida*; **1b–e**. rehydrated apothecia; **1f**. apothecium in median section; **1g**. id., marginal region; **1f**. marginal glassy processes (squash mount). – Dead state (in KOH). — **1a–g**. H.B. 6424j (holotype): Australia, Queensland, Taroom, on *Livistona*.

smooth or more often distinctly crenulate or toothed, teeth 30–50 × 15–30 µm; sessile or with a short, broad stipe, superficial. **Asci** *42–52 × 5.5–6.2 µm, †34–43 × 4–5 µm, 8-spored, 2–3 lower spores inversely oriented, pars sporifera *22–24 µm long; **apex** (†) ± hemispherical, dome immature †1–1.3 µm thick, without apical chamber, **base** with medium to long, thin, ± flexuous stalk, L-shaped. **Ascospores** *9–12 × 2.3–2.6 µm, ± clavate, with ellipsoid-fusoid head *6.2–7 µm long and a distinct, straight (to slightly curved) basal tail *2–5 × 0.6–0.9 µm; **SBs** *2.2–2.5 × 0.7–0.9 µm, rod-shaped to ampulliform, apically attached by a ± wide point. **Paraphyses** apically uninflated to slightly capitate, terminal cells *7–12(–17) × 2–3.3 µm, lower cells *6–11 × 1.3–2.7 µm; never branched near apex. **Medullary excipulum** 20 µm thick, of dense textura intricata with some inflated cells, medium sharply delimited. **Ectal excipulum** of (†) thin-walled, indistinctly oriented t. angularis from base to mid flanks, 30–40 µm thick near base, cells *10–17 × 8–13 µm, †8–13 × 5–7 µm; 15–20 µm thick near margin, of t. prismatica-porrecta oriented at a 20–40° angle to the surface, marginal cortical cells *8–13 × 2.5–4 µm. †5–7 × 2.8–3.2 µm, **glassy processes** 4–30 × 3–4 µm, refractive, stratified, slightly outwards curved, coherent to form 20–30 × 15–30 µm large teeth. **Anchoring hyphae** abundant, †1.5–2.5 µm wide, walls 0.2(–0.3) µm thick. **SCBs** globose, in paraphyses 1.5–2.5 µm diam., rarely with a needle-shaped (crystalloid) SCB. **Exudate** over paraphyses 0.3–1.5 µm thick, cloddy, loosely attached; over glassy processes scattered, granular, 0.2–0.5 µm thick. **— ANAMORPH**: unknown (but see below).

Habitat: collected ~1 m above the ground, upper end of dead petiole of *Livistona nitida*, on ridges and deep in clefts at the base of the leaf blade (upperside), medium decayed, strongly greyed, with or without many green algae. **Associated**: remotely (on different leaves) with *Gloniopsis* sp., *Mellitiosporiella* sp., *Orbilia acaciae*, *O. ?australiensis*, *O. ?commarosa*, *O. coronohesperidea*, *O. ?dixiensis*, *O. livistonae*, *O. multiserpens*, *O. myrioeuonymi*, *O. palmicola*, *O. pleiohesperidea*. **Desiccation tolerance**: fully viable for at least 9 months. **Altitude**: 200 m a.s.l. **Geology**: Jurassic sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia parviclava* is characterized by clavate ascospores similar as in the European *O. clavuliformis*, and glassy processes that form distinct teeth. It deviates in much smaller spores with shorter spore bodies. The European *O. breviclava* differs in longer spores with more cylindrical heads, longer SBs, larger apothecia without glassy processes, also in more abundant crystalloid SCBs.

Not included collections. Two very sparse Australian collections on wood of *Melaleuca* (Pl. 318: 2, also mentioned under *O. australiensis*) and bark of *Eucalyptus* (IVV: H.B. 6764b) differ in slightly longer and narrower spore heads and in the absence of glassy processes. Moreover, in that on *Melaleuca* the SBs are shorter and wider (no SBs were seen in H.B. 6764b which was only studied in the dead state).

Anamorph. No anamorph was observed in *O. parviclava*. However, in the *Melaleuca* collection trinacrium subtile-like conidia were found on the natural substrate (Y-shaped, total size *45–48.5 × 44–57 µm, stipe *18–21 × 3.5–4 µm, 2-septate, arms slightly tapering, *31–38.5 × 3.5–4 µm, 3–5-septate, Pl. 318: 2f).

Ecology. *O. parviclava* was found on a medium decayed xeric (attached) leaf of *Livistona nitida* in the Palm-Tree Creek in a subtropical subhumid (winter-dry savannah) eucalypt woodland (Great Dividing Range, eastern Australia). One of the two mentioned deviating collections grew on wood of *Melaleuca* under a similar climate, that on *Eucalyptus* in a warm-temperate humid mountainous eucalypt open forest in southeastern Australia (Great Dividing Range).

Specimens included. **AUSTRALIA**: **Queensland**, Brigalow Belt South, 69 km SSW of Theodore, 15 km N of Taroom, Palm-Tree Creek, Roy Staines Bridge, 200 m, leaf of *Livistona nitida*, 22.X.1998, G. Marson (ex H.B. 6424j, BRI AQ799183, **holotype**).

Not included. **AUSTRALIA**: **New South Wales**, Brigalow Belt South, 38 km SSW of Goondiwindi, 34 km SSW of Boggabilla, 230 m, branch of *Melaleuca*, on wood, 23.X.1998, G. Marson (H.B. 6848a ø). – Sydney Basin, 95 km WNW of Sydney, 11.5 km SE of Lithgow, 1.6 km SE of Mt. York, 1073 m, branch of *Eucalyptus*, on bark, 26.X.1998, G. Marson (ex H.B. 6764b, mixture in MEL 2389215 [type of *O. plurililacina*]).

Orbilia breviclava Baral, **sp. nov.**, MB 813603 — Pls 322–323

Etymology: named according to the clavate ascospores which are shorter than in *O. subclavuliformis* and *O. clavuliformis*.

Typification: Austria, Gmunden, trunk of *Frangula alnus*, 19.IV.1994, W. Dämon (ex H.B. 5072, M-0276445, holotype).

Latin diagnosis: *Similis* Orbiliae clavuliformi *sed ascosporae breviores, subcylindricae, excipulum marginale absque processis vitreis, cellulae vivae excipuli marginalis et paraphysium corpuscula crystalloidea continentes. Habitat ad lignum putridum trunci sicci* Frangulae alnus *in zona temperata humida Europae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.6 mm diam., 0.12–0.15 mm high (receptacle 0.11–0.13 µm), light orange-rose, semitranslucent, ± round, (densely) gregarious; disc flat to medium convex, margin thin, not protruding, smooth; sessile, superficial; dry bright orange. **Asci** *42–60 × 5.7–6.3 µm, †39–53 × 5–5.7 µm, 8-spored, spores *3–4-seriate, 2–6 lower spores inverted (scarcely mixed), pars sporifera *26–30 → 18 µm long; **apex** (†) hemispherical, dome mature 0.5–1 µm thick, with apical chamber; **base** with short to medium long, thin, flexuous stalk, L- to Y-shaped. **Ascospores** *(9–)11–14(–15) × 2.4–2.6(–2.7) µm, †9.5–12.5 × 2–2.5 µm, with cylindric to ellipsoid head *7.5–9 µm long, with rounded apex, and a medium sharply differentiated tail *(2–)3–5(–6) × 0.7–1(–1.2) µm, straight to slightly curved near base, sometimes slightly swollen at base;

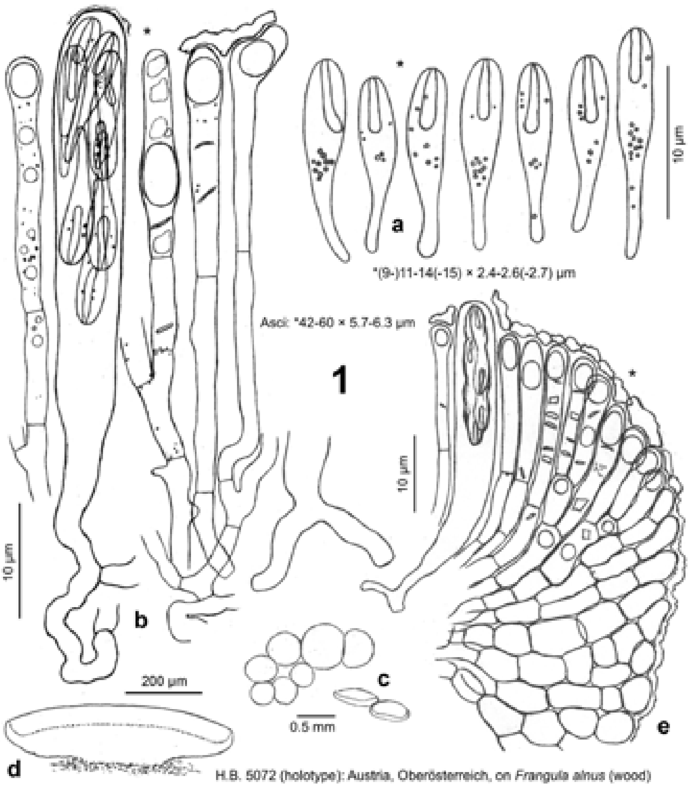

Plate 322. **1**: *Orbilia breviclava*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. apothecia (fresh); **d**. apothecium in median section; **e**. id., ectal excipulum (margin and mid flanks), with high-turgescent ascus.

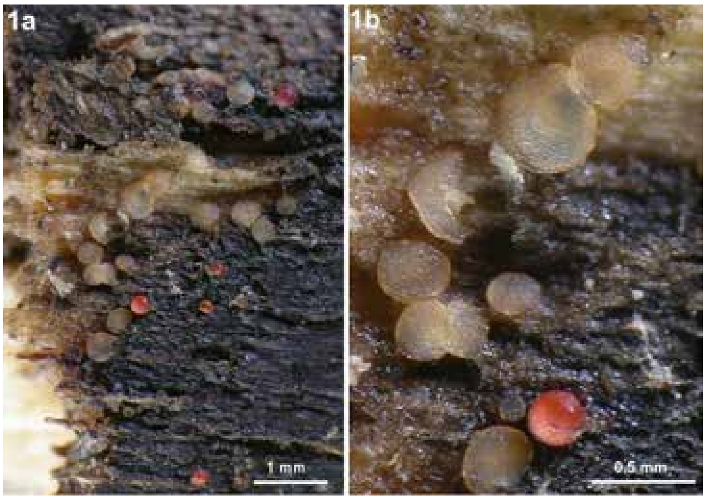

Plate 323. **1**: *Orbilia breviclava*. – **1a–b**. rehydrated apothecia (with *Neonectria coccinea*) (phot. after 12 years). — **1a–b**. H.B. 5072 (holotype): Austria, Oberösterreich, Gmunden, on *Frangula*.

SBs *(3–)4–5(–5.5) × (0.7–)0.8–1(–1.2) µm, rod-shaped to subulate, apically narrowed to a small to wide point, ± straight; with a number of small, often aggregated LBs. **Paraphyses** apically uninflated to slightly clavate-capitate, terminal cells *17–30 × 2.2–3.5 µm, lower cells *8–20 × 1.5–2(–3) µm; unbranched at upper septum, hymenium pale rose. **Medullary excipulum** 30 µm thick, of dense textura globulosa(-intricata), indistinctly delimited. **Ectal excipulum** pale rose, of thin-walled, indistinctly vertically oriented t. globulosa-angularis from base mid flanks, 60–80 µm thick near base, cells *8–18 × 8–15 µm; 30–40 µm thick at flanks, 20 µm near margin, of t. prismatica-porrecta oriented at a 45° angle to the surface, marginal cortical cells *(5–)9–18 × 3–4.5 µm; **glassy processes** absent. **Anchoring hyphae** rather abundant, *2–4 µm wide, walls 0.2–0.5 µm thick, somewhat gelatinized. **SCBs** in paraphyses and ectal excipulum (near margin) globose to ellipsoid, 2–3 µm wide, and rod-shaped to angular. **Exudate** over paraphyses 1–2 µm thick, cloddy, loosely attached; over margin and flanks 1–3 µm thick. **— ANAMORPH**: unknown.

Habitat: collected 1.5 m above the ground, on a partially decorticated, 5 cm thick standing trunk of a dead shrub of *Frangula alnus*, on medium decayed wood, sometimes blackened, without algae. **Associated**: *Neonectria coccinea*. **Desiccation tolerance**: not tested, probably at least slightly tolerant. **Altitude**: 470 m a.s.l. **Geology**: peat bog over Cretaceous-Paleogene flysch. **Phenology**: IV.

Taxonomic remarks. The ascospore characters of *O. breviclava* are very similar as in *O. subclavuliformis* and *O. clavuliformis*, from which this species differs in shorter spores and the presence of crystalloid SCBs, also in a tendency to more inverted spores within the asci. *O. clavuliformis* differs in wider, more ellipsoid spore heads, and in the presence of glassy processes. For the similar Australian *O. parviclava* see p. 688.

Not included collection. A very sparse collection from southwestern North America (on wood of *Larrea*, IVV: H.B. 5658c) shows a similar spore size (*10.5–13 × 2.4–3 µm) and shape, but the SBs are too short (~2.5–3.5 µm) and more ampulliform, and the tails rather thick. The sample was not studied thoroughly and the material is now without mature apothecia. The marginal excipulum was without devoid of glassy processes, and only globose SCBs were seen in the paraphyses.

Ecology. *O. breviclava* was collected on medium rotten wood of a xeric young trunk of *Frangula alnus* in a cold-temperate humid, subcontinental, submontane, *Sphagnum*-rich *Betula-Pinus* bog with *Alnus glutinosa* at the northern foothills of the Alps (central Europe). The not included collection was on very rotten wood of a xeric *Larrea tridentata* branch in the subtropical semiarid Sonoran paloverde-mixed cacti desert scrub with, e. g., *Cylindropuntia versicolor* and *Parkinsonia microphylla* on Cenozoic mixed sand- & mudstone and volcanic rock in Arizona (southwest of Northern America).

Specimens included. **AUSTRIA**: **Oberösterreich**, Salzkammergut Mts., 55 km SW of Linz, 1 km NE of Gmunden, SE of Schloss Cumberland, Krottensee, 470 m, trunk of *Frangula alnus*, on wood, 19.IV.1994, W. Dämon (ex H.B. 5072, M-0276445, **holotype**).

Not included. **USA**: **Arizona**, Sonoran Desert, 82 km NW of Phoenix, ~1.5 km SE of Wickenburg, 615 m, branch of *Larrea tridentata*, on wood, 4.V.1995, G. Marson (H.B. 5658c).

Orbilia subclavuliformis Baral, E. Weber & Priou, **sp. nov.**, MB 813605 — Pls 324–326, Map 56

Etymology: closely related to *O. clavuliformis*.

Typification: France, La Tranche-sur-Mer, branch of *Quercus ilex*, 2.VI.2003, H.O. Baral (ex H.B. 7382, M-0276592, holotype).

Latin diagnosis: *Similis* Orbiliae clavuliformi *sed ascosporae angustiores, subcylindricae, cauda basaliter saepe inflata, processi vitrei excipuli marginalis breves vel saepe absentes. Habitat ad lignum et corticem putridum ramorum siccorum fruticum vel arborum angiospermarum vel coniferarum in zona thermo- ad mesosubmediterranea vel temperata atlantica ad subcontinentale Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.15–0.5(–0.7) mm diam., 0.08–0.17 mm high (receptacle 0.08–0.11 mm), (pale to) light (to bright) (pinkish-)rose, orange-rose or orange, translucent, round (rarely elliptical), scattered to (sub)gregarious; disc flat, sometimes slightly convex, margin thin, sometimes indistinct, 0(–10) µm protruding, smooth, rarely very finely rough; broadly sessile or with a distinct stipe up to 0.05–0.06 × 0.1–0.18 mm, superficial; dry light to bright pinkish-rose or orange(-red). **Asci** *(35–)40–55(–58) × 6–7.2((–8)) µm {9}, †34–55(–60) × (5–)5.5–6.5(–6.8) µm {10}, 8-spored, spores 2–4-seriate, ((0–))(1–)2–3(–4)((–5)) lower spores inversely oriented {11} (mostly not mixed), pars sporifera *23–32 µm long; **apex** (†) hemispherical (rarely slightly truncate), dome †1–1.8 → 0.8–1.2 µm thick {10}, with distinct apical chamber; **base** with short to (very) long (rarely absent), thin to medium thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *((11–))(13–)14–18(–19)((–20.5)) {19} or (17–)18–21.5(–23) {3} × (2.2–)2.3–2.7(–3) µm {22}, †(12–)13–17(–18) × (2–)2.2–2.6 µm {10}, with cylindric(-ellipsoid) head *(7.5–)8.5–11(–12.5) µm long and a ± sharply differentiated tail *(4–)5–8(–11) µm long, tail shorter than head (rarely of equal length), apex rounded or obtuse, tail straight or slightly to medium curved, base not or often slightly, sometimes medium inflated, *((0.5–))0.8–1.2(–1.5)((–2)) µm wide; **SBs** *(3.5–)4–6 × (0.6–)0.7–1.2(–1.3) µm {13}, rod-shaped to subulate, sometimes slightly pyriform, ampulliform, or dumbbell-shaped, apically narrowed to a small to mostly wide point; overmature *2.5–3 × 1.4–1.5 µm. **Paraphyses** apically uninflated to often slightly (rarely medium) clavate-capitate, rarely spathulate, terminal cells *(7.5–)9–20(–23) × 2–3.5(–4) µm {7}, †6–15 × 1.8–3 µm {1}, lower cells *(3–)5–10(–12) × (1.5–)1.8–2.5(–3.7) µm {5}; sometimes branched at upper septum. **Medullary excipulum** subhyaline to pale rose, 10–30 µm thick, of dense textura intricata with many inflated cells, not or medium sharply delimited. **Ectal excipulum** pale rose, of thin-walled (†slightly gelatinized), ambiguously or ± vertically oriented t. globulosa-angularis from base to mid flanks, 25–150 µm thick near base, cells */†(8–)10–17(–21) × (6–)8–14(–17) µm {3}; 15–25 µm thick at flanks and margin, at margin of t. prismatica-porrecta oriented at a 30–60 or often 70–90° angle to the surface (including outer cells), marginal cortical cells */†6–11 × (2.3–)3–4(–5) µm {6} (at submargin *5–8 × 4–5 µm), **glassy processes** absent {25}, sometimes present on some or most cells, 1–5(–7.5) × 2.8–4 µm {8}, refractive, somewhat stratified. **Anchoring hyphae** sparse, †(1.7–)2–3(–4) µm wide, walls 0.2–0.3(–0.7) µm thick {2}, forming a medium dense, hyaline t. intricata 20–50 µm thick at base, covering apothecia at flanks as a thin layer. **SCBs** globose, in paraphyses 1–3 µm diam., in marginal excipulum 2–3.3 µm. **Exudate** over paraphyses (0.3–)1–2.5(–4) µm thick; over margin (0.3–)1–4(–5) µm, ± continuous to cloddy, externally coarsely rough, loosely attached, subhyaline to pale yellowish. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {3}). **Conidiophores** not seen. **Conidia** Y-shaped, total size *36–50 × 46–48 µm (†60–62 × 43–73 µm), stipe *24–31 × (2.6–)3.5–4 µm (†24.5–33 × 2.5 µm), 4–5-septate, arms slightly tapering or cylindrical, *(19–)23–29 × (2.8–)3.5–4.2 µm {H.B. 8106}, †37.5–44 × 2.5–3 µm {H.B. 5226a}, 4–9-septate {2}.

Habitat: collected (0–)0.2–5 m above the ground, corticated, more rarely ± decorticated, (2–)5–25(–40) mm thick twigs and branches, rarely cones, of *Anagyris foetida* {1}, *Buxus sempervirens* {1}, *Cedrus atlantica* {1}, *Cercis siliquastrum* {3}, *Clematis* (?)*flammea* {1}, *Cornus sanguinea* {1}, *Cytisus scoparius* {6}, *Eucalyptus* sp. {1}, *Euonymus europaeus* {1}, *Frangula alnus* {1}, *Lonicera implexa* {1}, *L. xylosteum* {1}, *Olea europaea* {1}, *Petteria ramentacea* {1}, *Pinus* sp. {1}, *P.* ?*contorta* {1}, *P. sylvestris* {3}, *Punica granatum* {1}, *Quercus ilex* {4}, *Q. suber* {1}, *Rosa* sp. {2}, *Rosmarinus officinalis* {1}, *Salix* sp. {1}, *S.* ?*aurita* × *caprea* {1}, *Ulex europaeus* {8}, *Vitis vinifera* {1}, stems of *Rubus armeniacus* {1}, *R.* (?)*bifrons* {1}, *R. fruticosus* agg. {1}, *R. grandifolius* {1}, on 0.1–0.2 mm deep (slightly to) medium to strongly decayed wood {23} or bark {23} (on periderm {2} or bast {9}), on cut, splitted, or eroded wood, sometimes in beetle galleries, in small to large cracks or large periderm-free areas when on bast, sometimes on inner surface of detaching bark, sometimes at border of resinous wounds, on herbaceous stem of *Melilotus* sp.{1}, on textile (rope) {1}, slightly to strongly greyed, green algae very sparse to abundant. **Associated**: *Baggea* sp. {1}, *B. pachyascus* {1}, *Bionectria ralfsii* {1}, *Bulbillomyces* sp. {1}, ?*Calloria* sp. {1}, *Caloplaca* sp. {1}, *C. holocarpa* {1}, *Capronia* sp. {1}, '*Chlorosplenium*' *viridulum* {1}, *Claussenomyces* spp. {2}, *C. atrovirens* {1}, *Coniochaeta* sp. {1}, *Corticiaceae* {1}, *Dacrymyces* sp. {1}, *Didymosphaeria futilis* {1}, *Hyalorbilia erythrostigma* {2}, *H. fusispora* {1}, *H. inflatula* {1}, *H. juliae* {1}, *H. subfusispora* {1}, *Hyaloscypha minuta* {1}, *Hysterium angustatum* {1}, *Hysterographium fraxini* {1}, *Karstenia idaei* {1}, *K. rhopaloides* {1}, *Lecanora* sp. {1}, *Lophiostoma caulium* {1}, *L.* ?*macrostomum* {1}, *Mellitiosporiella pulchella* {3}, *Mollisia* spp. {3}, *M.* ?*discolor* {1}, *M. ligni* {2}, *M. rosae* {1}, *Neodasyscypha cerina* {2}, *Nitschkia broomeana* {1/1}, *Olla scrupulosa* {1}, *Orbilia aristata* {3}, *O. aurantiorubra* {2}, *O. breviaristata* {2}, *O.* ?*caulicola* {1}, *O. cercidicola* {2}, *O. corculispora* {3}, *O. eucalypti* {2}, *O. filiformis* {1}, *O. flagellispora* {3}, *O. flavida* {2}, *O. gambelii* {5}, *O. microserpens* {1}, *O. myriolentiformis* {1}, *O. myriosphaera* {3}, *O. pleiogambelii* {4}, *O. polyspora* {3}, *O. quaestiformis* {2}, *O. rosicola* {1}, *O. sarothamni* {1}, *O. serpentina* {1}, *O. spermoides* {1}, *O. subaristata* {5}, *O. subocellata* {1}, *O. subovoidea* {3}, *O. trapeziformis* {1}, *O. vinosa* {2/1}, *O. vitalbae* {2}, *O. xanthoguttulata* {1}, *Orthotrichum* sp. {1}, *Patellaria atrata* {2}, *Patellariopsis dennisii* {1}, *Phyllactinia guttata* {1}, *Physcia* sp. {1}, *Pirottaea* ?*imbricata* {1}, *Propolis farinosa* {1}, *Pseudolachnea hispidula* {1}, *Pyrenopeziza rubi* {1}, *Rutstroemia fruticeti* {1}, *Sarea resinae* {1}, *Schizoxylon* sp. {1}, *Stereum hirsutum* {1}, *Unguiculariopsis* sp. {1}, *U. ilicincola* {1}, *Unguiculella eurotioides* {1}, fruticose lichen {1}. **Desiccation tolerance**: fully viable for at least 3 months, some spores after 5 months. **Altitude**: 2–1530 m a.s.l. **Geology**: Cambrian & Ordovician sand- & siltstone, quartzitic wacke, Keuper (marl & sandstone), Lower to Upper Jurassic and Cretaceous to Tertiary sand-, marl- & limestone, Minette & shale, dolomite, Pleistocene sand & loess; granite, migmatite, gneiss, mica schist. **Phenology**: throughout the year (long-lived).

Phenology of *O. subclavuliformis*

Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
3	4	3	1	3	8	3	4	7	6	3	5

Taxonomic remarks. *Orbilia subclavuliformis* differs from *O. clavuliformis* in the narrower and more cylindrical instead of ellipsoid ascospore heads, also in often slightly inflated tail bases. Concerning the long heads and inflated tail bases the species rather closely approaches *O. flagellispora*, in the first feature also *O. clavuliaristata*, but both species differ in more ellipsoid-fusoid spore heads and in often longer tails with a mostly thinner middle part (almost always > 0.7 µm wide). *O. flagellispora* differs also in mostly more strongly inflated tail bases. *O. subclavuliformis* differs from both *O. clavuliformis* and *O. flagellispora* in the glassy processes being often absent or at least very short. *O. breviclava* deviates in shorter spores and the presence of crystalloid SCBs.

Variation. *O. subclavuliformis* is somewhat variable in spore size and shape. Three atlantic collections (Pls 324: 3–4; 326: 4) have conspicuously longer spores, though the other features are quite the same as in typical specimens. Likewise, spore width (and also ascus width) varies somewhat among the populations. In many collections the spore heads are strikingly cylindrical (e. g., Pl. 325: 5), but this feature often varies to some extent towards subcylindrical or sometimes narrowly ellipsoid. The spore tails vary somewhat in length, thickness, and basal inflation. As an exception, they can be less than 0.8 µm thick in their middle part (Pls 325: 4; 326: 1i), thus obscuring the limits to *O. flagellispora*.

Not included collections. A sparse unpreserved sample on wood of *Pinus* from Bretagne deviated in exceptionally short spore heads (Pl. 325: 6). A sketchily documented collection on *Chamelaucium* from southwestern Australia did not clearly differ from European specimens (spores *15 × 2.2 µm, SBs 4.5 × 1 µm, glassy processes absent), but the single minute apothecium showed only a few living spores. A sample on *Arbutus* from southwestern Canada studied by O. & A. Ceska (pers. comm.) matches well *O. subclavuliformis* in the spores (*15–20 × 2–2.5 µm), but differs in apothecia with a minutely toothed margin.

Anamorph. The trinacrium subtile-like conidia observed on the natural substrate closely match those reported for *O. clavuliformis*. In the sample from Luxembourg (Pl. 325: 2e) the conidial arms were longer and narrower than in the Spanish collection (Pl. 326: 2h).

Phylogeny. A sequence from apothecia of *O. subclavuliformis* on *Eucalyptus* comprises SSU (with S1506 intron), ITS, and LSU. In our phylogenetic analyses (Phyls 9, 12, S13), the species clustered in the *aristata-clavuliformis* clade. When analysing LSU (D1–D2), S13), it clustered with medium support with *O. clavuliformis* in a clade, with a minimum distance of 0.8 %, the next close being *O. aristata* (KT222395) with 1.3 %. In the ITS region *O. subclavuliformis* shows a distance of 6.5 % to *O. clavuliformis*, but a similar distance to *O. aristata*, *O. fimbriata*, and other species of the *aristata-clavuliformis* clade can be noted. When analysing the intron (S12), *O. subclavuliformis* surprisingly clustered moderately supported with *O. spermoides*, though with a distance of 21 %.

An environmental sequence from northern Alaska (Toolik lake, arctic tundra soil, KJ827497), comprising only partial 5.8S and entire ITS2, clustered in a strongly supported clade with *O. subclavuliformis*, but deviates from it by 15 nt and 1 gap in the ITS2 (Phyl. 12).

Ecology. *O. subclavuliformis* grows on ± rotten wood and bark of xeric twigs and branches of various trees and shrubs of angio- but also gymnosperms, including stems of *Rosa* and *Rubus*. In the many records from western France the host was mostly *Ulex* (or *Cytisus*).

The rather numerous collections indicate occurrence from supra- or meso- to thermotemperate (rarely orotemperate and

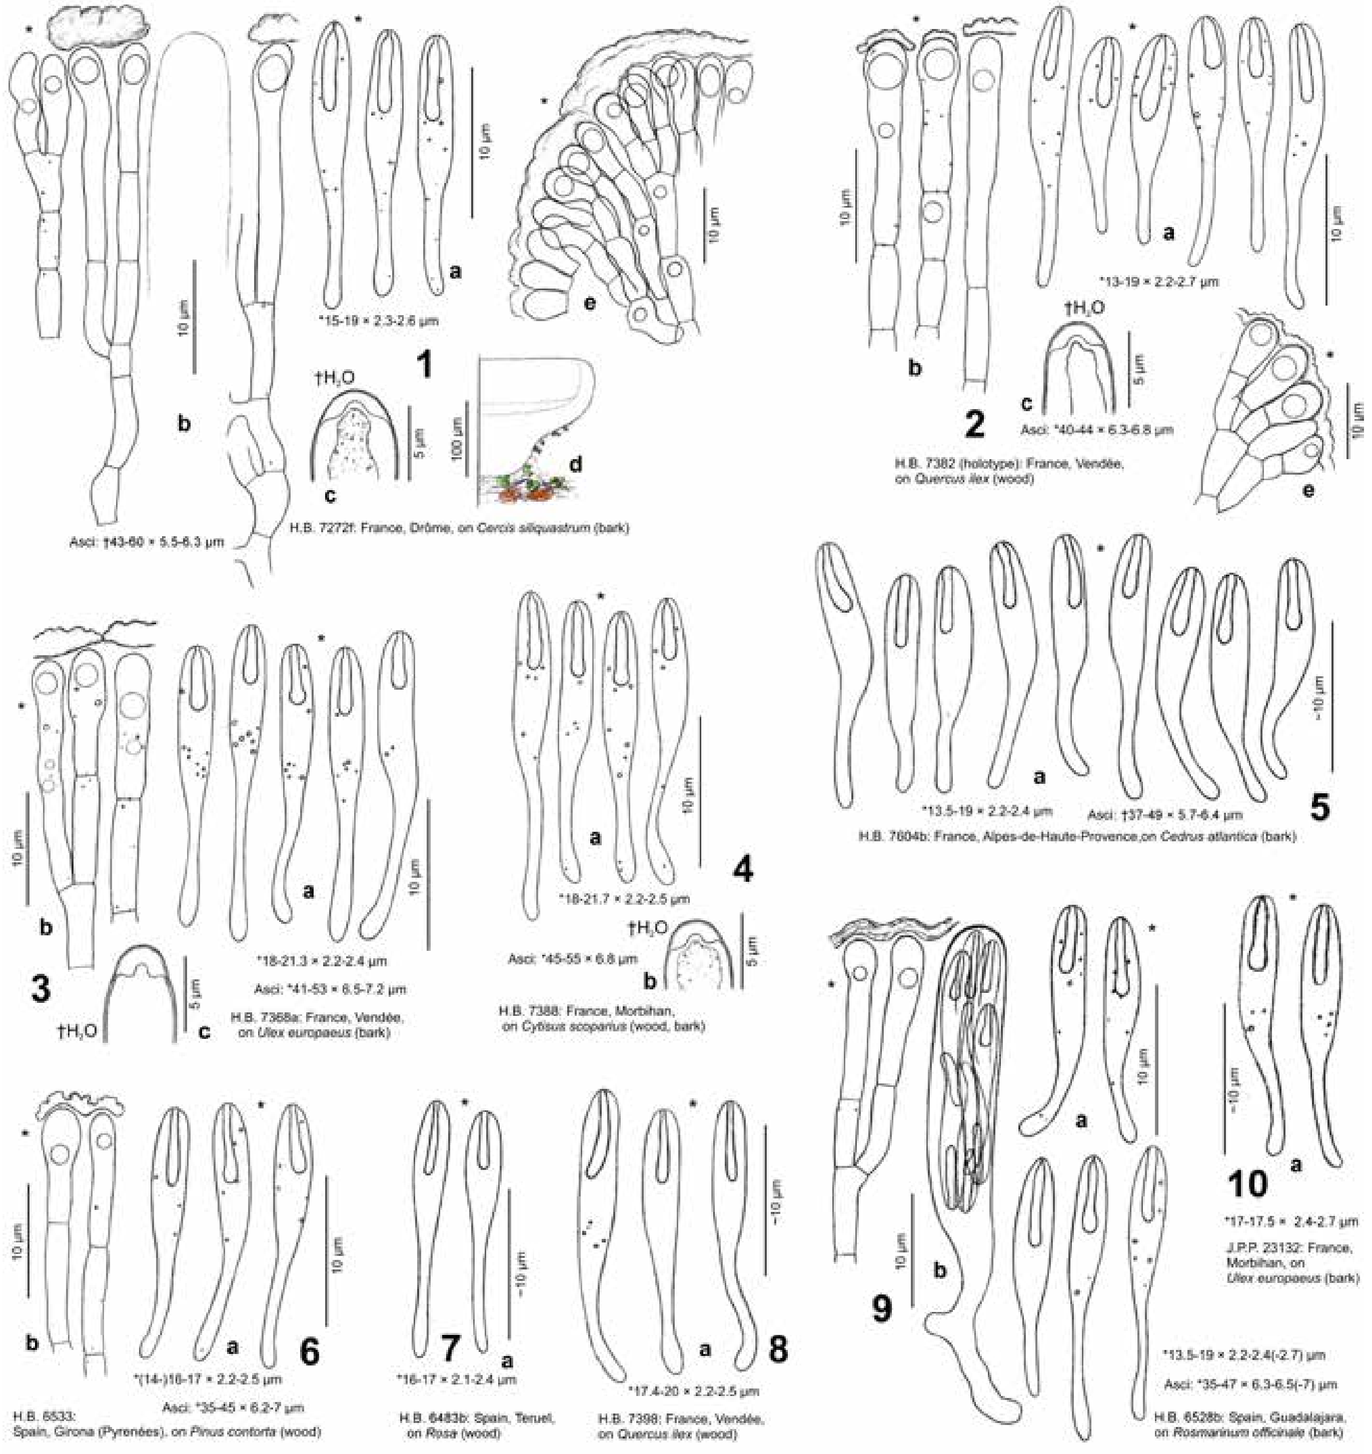

Plate 324. **1–9**: *Orbilia subclavuliformis*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium in median section; **e**. id., marginal ectal excipulum.

orosubmediterranean) humid, suprasub- to mesosub- and even supra- to thermomediterranean semihumid areas in atlantic to subcontinental central, western, and southern Europe.

On Madeira (Macaronesia) *O. subclavuliformis* occurred in the supramediterranean humid ridge-crest laurel forest (*Ilici canariensis-Ericetum platycodonis*). The not included collections comprise a mild-maritime humid mixed evergreen forest with *Arbutus* in western Canada, a subtropical semihumid eucalypt low open forest (karri-tingle) in southwestern Australia, and an arctic tundra for the DNA-isolate from Alaska.

Orbilia flagellispora (Raitv. & R. Galán) Baral & G. Marson, **comb. nov.**, MB 813607 — Pls 327–330, Map 57

Basionym: *Hyalinia flagellispora* Raitv. & R. Galán in Galán et al., Mycol. Res. 98: 1142 (1994)

?= *Orbilia herbarum* Velen., Monogr. Discom. Bohem.: 102, pl. 11 fig. 19 (1934)

Etymology: *flagellispora*: referring to the very long and narrow tails of the ascospores; *herbarum*: growing on herbaceous substrate.

Typification: Mexico, Baja California, El Sauzal, leaf of *Rhus laurina*, 14.III.1990, R. Galán (AH 6780, holotype of ***Hyalinia flagellispora***). — Czechia, Mnichovice, 'stem of *Lotus corniculatus*' (?leaf of *Carex*), 21.XI.1929, J. Velenovský (PRM 152431, holotype of ***Orbilia herbarum***).

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.7(–0.9)((–1.2)) mm diam., 0.11–0.18(–0.23)((–0.36)) mm high (receptacle 0.09–0.15 mm), light to bright orange to rose, not or slightly translucent, ± round; scattered or often subgregarious to gregarious in small groups; disc flat, margin distinct, 0–30 µm protruding, finely crenulate or with prominent whitish teeth, sometimes smooth; broadly sessile or mostly with ± distinct obconical stipe 0.04–0.1(–0.24) × 0.1–0.2 mm, superficial or slightly immersed in biofilm or furrows; dry bright to deep rose-orange or orange-red, somewhat contracted. **Asci** *(47–)50–73 × 6–7.7(–8) µm {7}, †(40–)45–65(–70) × (5–)5.3–6.5(–7) µm {8}, 8-spored, spores 2(–4)-seriate, 1–3(–4) lower spores inversely oriented {12} (not mixed), pars sporifera *30–40 µm long; **apex** (†) hemispherical to slightly truncate, dome †1–2(–3) → 0.7–1.5 µm thick {10}, with distinct, small apical chamber; **base** with short to long, medium thick stalk, L- or h-shaped. **Ascospores** *(14–)16–26.5(–28.5) × (2.3–)2.6–3.3(–3.6) µm {18}, †16–26(–29.5) × (2–)2.3–3(–3.3) µm {11}, sperm-shaped: with ellipsoid-fusoid head and sharply differentiated filiform tail, apex obtuse to subacute (rarely rounded or acute), head *(9–)9.5–12(–12.5) µm long, straight or sometimes slightly inequilateral, tail */†(7.5–)9.5–15(–18) × (0.2–)0.3–0.6(–0.9) µm {8}, base nearly always slightly to strongly swollen to *0.9–1.7(–2.3) µm thick {8}, †0.7–1.8(–2.3) {3}, ± bulbous, rarely in all spores only †0.2–1 µm thick {1 Canada}, straight or slightly to medium (rarely very strongly) curved at base or above; **SBs** *(3–)3.3–5(–5.3) × 0.8–1.3(–1.5) µm {11}, rod-shaped, subulate, pear-shaped to ampulliform, apically narrowed to a small or wide point, overmature *3–4 × 1.4–1.7 µm. **Paraphyses** apically uninflated or slightly to medium clavate-capitate, terminal cells *(7–)12–18(–24) × (1.8–)2.2–3.5(–4.5) µm {8}, †13–18 × 2–2.7 µm {T}, lower cells *((3.5–))(6–)8–13(–17) × 1.5–2.5(–3)((–3.7)) µm {7}; not or sometimes branched near apex, sometimes flexuous; hymenium very pale rose. **Medullary excipulum** hyaline to very pale rose, 30–85 µm thick, of medium dense textura intricata with many inflated cells, very sharply delimited at flanks. **Ectal excipulum** pale rose, of (†) thin-walled to slightly gelatinized, vertically oriented t. (globulosa-)angularis(-prismatica) from base to mid flanks, 20–100 µm thick near base, cells *(8–)10–20(–24) × (5–)7–14(–16.5) µm {6}; 20–40 µm thick on lower flanks, cells *8–12 × 5–8 µm, oriented at a 70–80° angle to the surface, 15–30(–40) µm near margin, inner part of t. prismatica-angularis oriented at 45–80°, outer part of t. prismatica-porrecta oriented at 20–50°, marginal cortical cells *(5–)6–11(–14) × (2–)2.3–4 µm {5}, or outer part of t. prismatica oriented at 60–80°, then cortical cells *5–10 × 3–5 µm {5}, **glassy processes** 0–12 {8} or 10–40 {8} or up to 40–60 {5} × (2–)2.5–4(–4.5) ((–6)) µm, refractive, sometimes stratified, ± straight, sometimes curved outwards or inwards, coherent to form indistinct small squamules or very prominent teeth 40–60 × 50–100 µm. **Anchoring hyphae** sparse to medium abundant, */†2–3(–4) µm wide, walls 0.2–0.4(–0.8) µm thick {6}. **SCBs** in paraphyses and ectal excipulum absent {1} or globose {7}, 1–2.5 µm diam., rarely some needle-shaped {1}; excipular cells at base and lower flanks with globose, pale yellowish(-orange) **LBs** 1.3–3 µm diam. {2} (carotenoids). **Exudate** over paraphyses hyaline, 0.5–2.5(–3) µm thick; over marginal excipulum 1–3 µm thick, granular to cloddy, mostly loosely, sometimes firmly attached. — **ANAMORPH**: trinacrium- {5} (Y), descalsia- {5} (┼), and dwayaangam-like {1} (dw) (presumed, from natural substrate {11}). **Conidiophores** not seen. **Conidia** variable in shape: 2-armed, Y-shaped (trinacrium subtile-like): total size †36–40 × 39–40 µm, stipe †15–17 × 2.5–4 µm, 2–4-septate, arms †25–27 × 3.5–4.8 µm, 6-septate {2}; 3-armed (┼-shaped, descalsia-like): total size †/*40–55 × (25–)35–53 µm, stipe †/*18–21(–35) × 2–4 µm, 3–4-septate, arms †/*11–26 × 2.5–3.5 µm, 3–5-septate {3}; 4-armed or 6–7-armed (dwayaangam-like): total size *64–65 × 68 µm, stipe *13–15 × 2.4–3.2 µm, 2–3-septate, arms *20–42 × 2.7–3.6 µm, 3–7-septate {1}.

Habitat: collected (0–)0.5–5 m above the ground, on corticated to decorticated, 3.5–27 mm thick twigs and branches, also 10–15 cm thick trunks, of *Alnus alnobetula* {5}, *Crataegus* sp. {1}, *Cedrus atlantica* {1}, *Cercis siliquastrum* {1}, *Cornus sanguinea* {4}, *Crataegus* sp. {1}, *Juniperus communis* {3}, *Larix* sp. {1}, *Picea* sp. {1}, *P. abies* {4}, *Pinus* ?*contorta* {1}, *P. sylvestris* {3}, *Salix* sp. {1}, *S. appendiculata* {1}, *S. aurita* {1}, *S. caprea* {2}, *S.* (?) *cinerea* {1}, *S. glauca* {1}, *S. phylicifolia* {1}, sometimes on slightly resinous wounds, on bark (periderm and mainly bast) {26}, also on wood {7} or blackened resin {4}, often on edges of bark or in small cracks, slightly to medium decayed; on stem of *Rubus fruticosus* {1}, rotten, non-sceletonized leaf of *Rhus laurina* {T}; greyed or blackened, with a few to many green algae (sometimes included within the basal excipulum: Pl. 328: 1e), **Associated**: *Amphosoma*

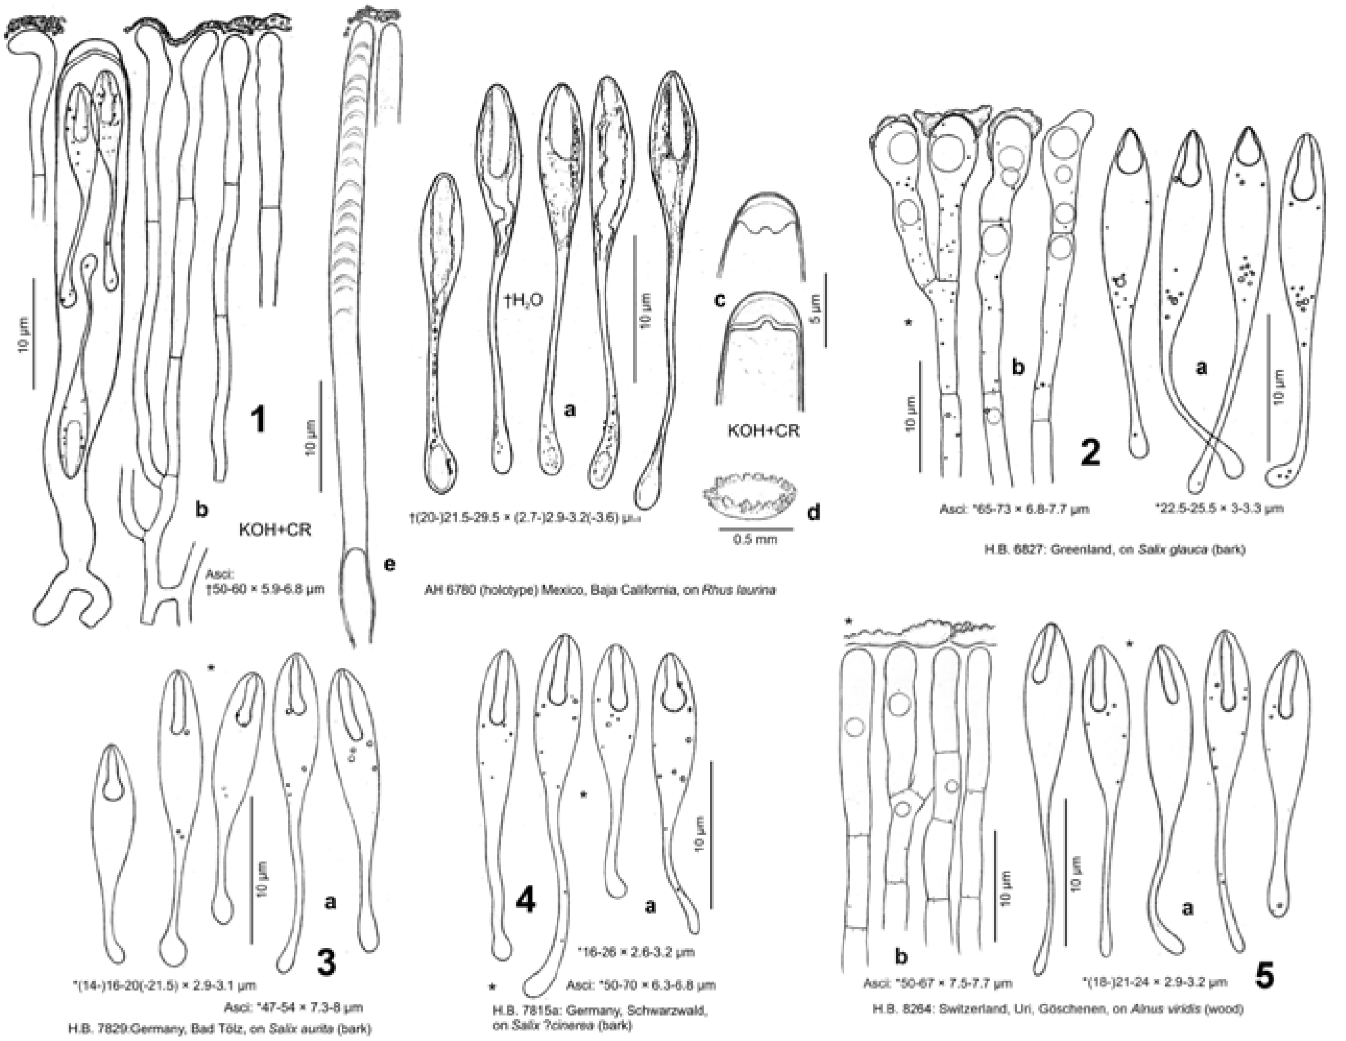

Plate 327. **1–5**: *Orbilia flagellispora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium with dentate margin (rehydrated); **e**. marginal cortical cell with long glassy process.

(central Europe), 460–1800 m (southern Europe). **Geology**: Greenland: Precambrian sediment, Canada: Devonian-Mississippian sedimentary rock; Europe: Buntsandstein, Keuper (marl- & sandstone), Triassic dolomite, Lower to Upper Jurassic Minette, marl- & limestone, Cretaceous sand- & limestone, Eocene flysch; granite, quartzite, phyllite, mica schist, wacke, ophiolite, biotite-amphibole. **Phenology**: III–X (but certainly throughout the year, long-lived).

Taxonomic remarks. *Orbilia flagellispora* differs from *O. aristata* and *O. subaristata* mainly in longer spore heads (9–12 instead of 7–10 µm). The width of the spore heads and the middle parts of tails is very similar in the three taxa, but the tail bases are always slightly to strongly bulbous in *O. flagellispora* and mostly also in *O. subaristata*, but not or only very slightly so in *O. aristata*. The tails in *O. flagellispora* and *O. subaristata* are sometimes strongly bent just above the bulbous base, reminiscent of golf clubs. However, such curved tail bases did not occur in the holotype of *O. flagellispora* (Pl. 327: 1a, see also Galán et al. 1994). For the similar *O. asturiensis* see p. 686. Confusion is easily possible with the rare Australian *O. pseudoflagellispora* (series *Albovinosae*, section *Aurantiorubrae*), which differs from *O. flagellispora* mainly in truncate thin-walled ascus apices (dead state) and in wider SBs.

A very sparse, unpreserved Australian collection on bark of *Eucalyptus*, mentioned under *O. pseudoflagellispora* (Pl. 526: 2, section *Aurantiorubrae*), differs in slightly narrower spores (*19–22 × 2.2–2.6 µm) being frequently 1-septate (apparently when overmature). It is possibly more closely related to *O. clavuliaristata* or *O. angustoaristata* which, however, both differ in spores with uninflated tail bases, the latter also in

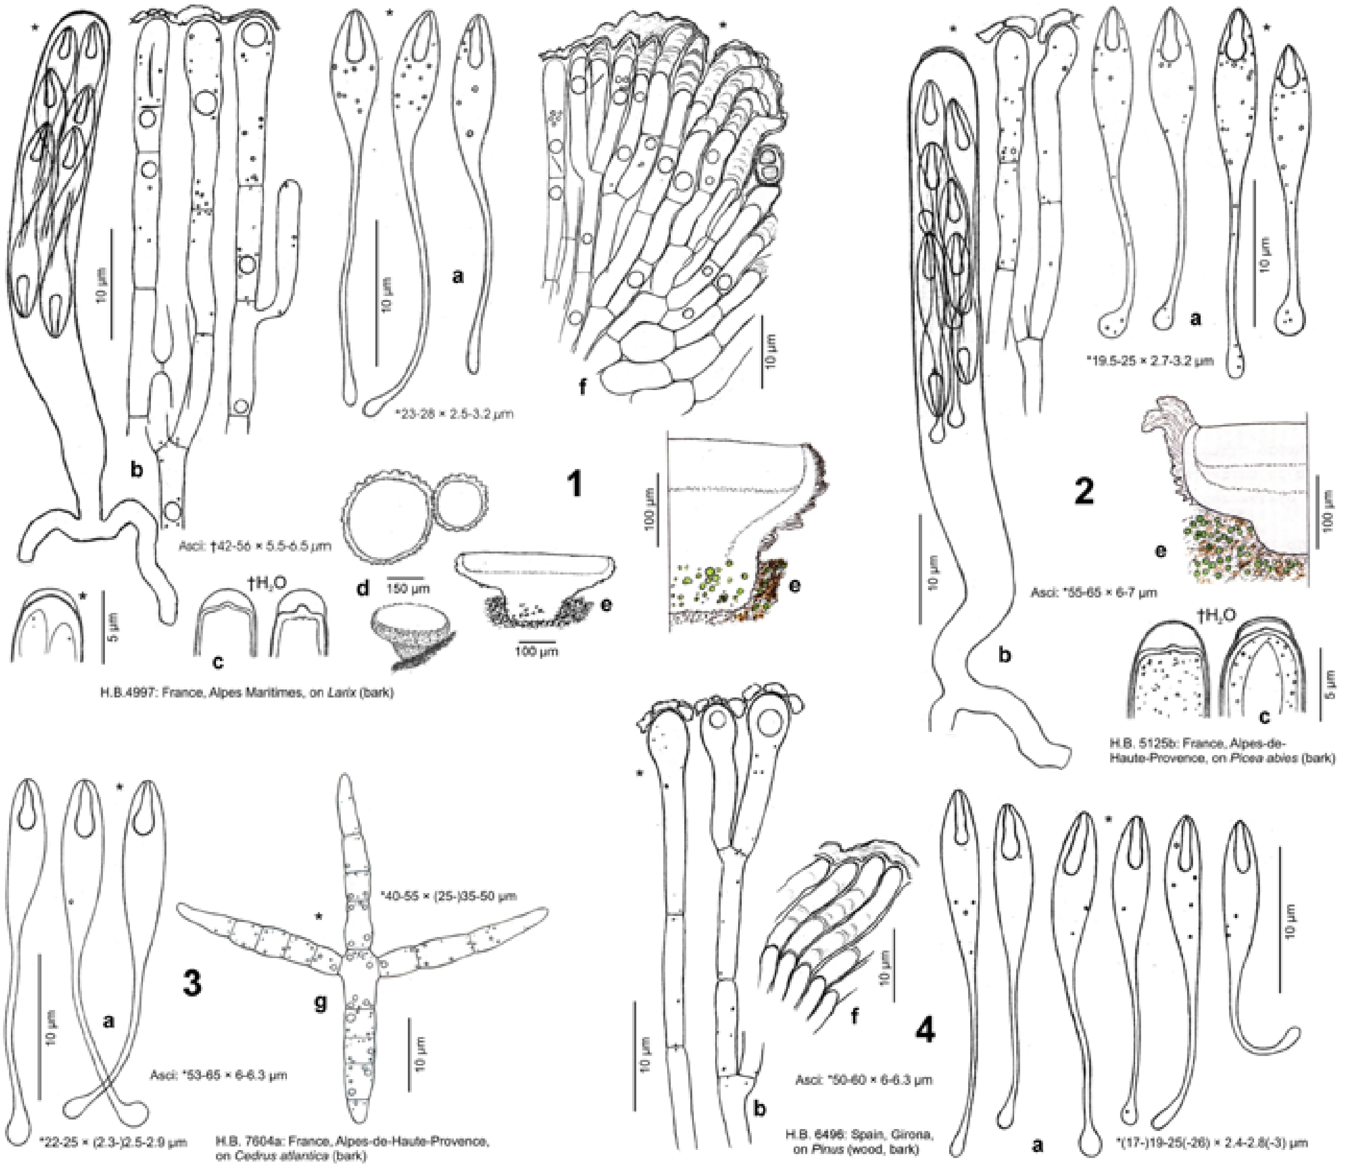

Plate 328. **1–4**: *Orbilia flagellispora*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia with crenulate margin (rehydrated); **e**. apothecia in median section; **f**. id., marginal cortical cells with glassy processes; **g**. conidium from substrate.

much narrower SBs and in the presence of crystalloid SCBs. Because of the tear-shaped SBs the specimen might be related to *O. pseudoflagellispora*, but whether it was devoid of an apical thickening was not clarified.

Variation. Considerable variation in the maximum length of the glassy processes and consequently the length of the teeth at the apothecial margin was found among the collections but also within a collection. A length of up to 40–60 µm was noted in the holotype (on leaves of *Rhus*, Mexico) but also in some bark-inhabiting central and southern European specimens, without showing any further morphological deviations that would allow separation from specimens with inconspicuous teeth, i. e., with glassy processes 2–20 µm long. The only feature that was more or less correlated with such short or nearly absent glassy processes was found in the somewhat wider and shorter marginal cortical cells which run under a higher angle to the surface. Possibly, long glassy processes require longer cortical cells from which they emerge. Also the curvature of the glassy processes in specimens with distinct teeth is not consistent. Sometimes they are curved outwards (e. g., Pls 328: 2e; 329: 5c–d), sometimes inwards (e. g., H.B. 6827), and apparently rather straight in the holotype and some other collections. In those samples with short teeth, the processes were also either ± straight or inwards or outwards curved, even within a single apothecium. The observed differences in length and curvature of glassy processes did not correlate with the substrate.

Two collections (H.B. 7815a, H.B. 9163a) showed large, yellowish LBs in the cells of the basal ectal excipulum (Pl. 329: 6e), a feature not seen in other specimens, and in H.B. 9163a only in the largest of the five apothecia examined, showing the deepest pigmentation.

In a few collections on *Cornus sanguinea* from Luxembourg, *O. aristata* grew in more or less close association with both *O. flagellispora* and *O. subaristata*. The apothecia of *O. aristata* were here recognizable by their very short marginal teeth, whereas the other two appear to be macroscopically indistinguishable. In a mixed collection on *Alnus* (H.B. 8269) both *O. aristata* and *O. flagellispora* had very short processes and, therefore, looked macroscopically almost identical.

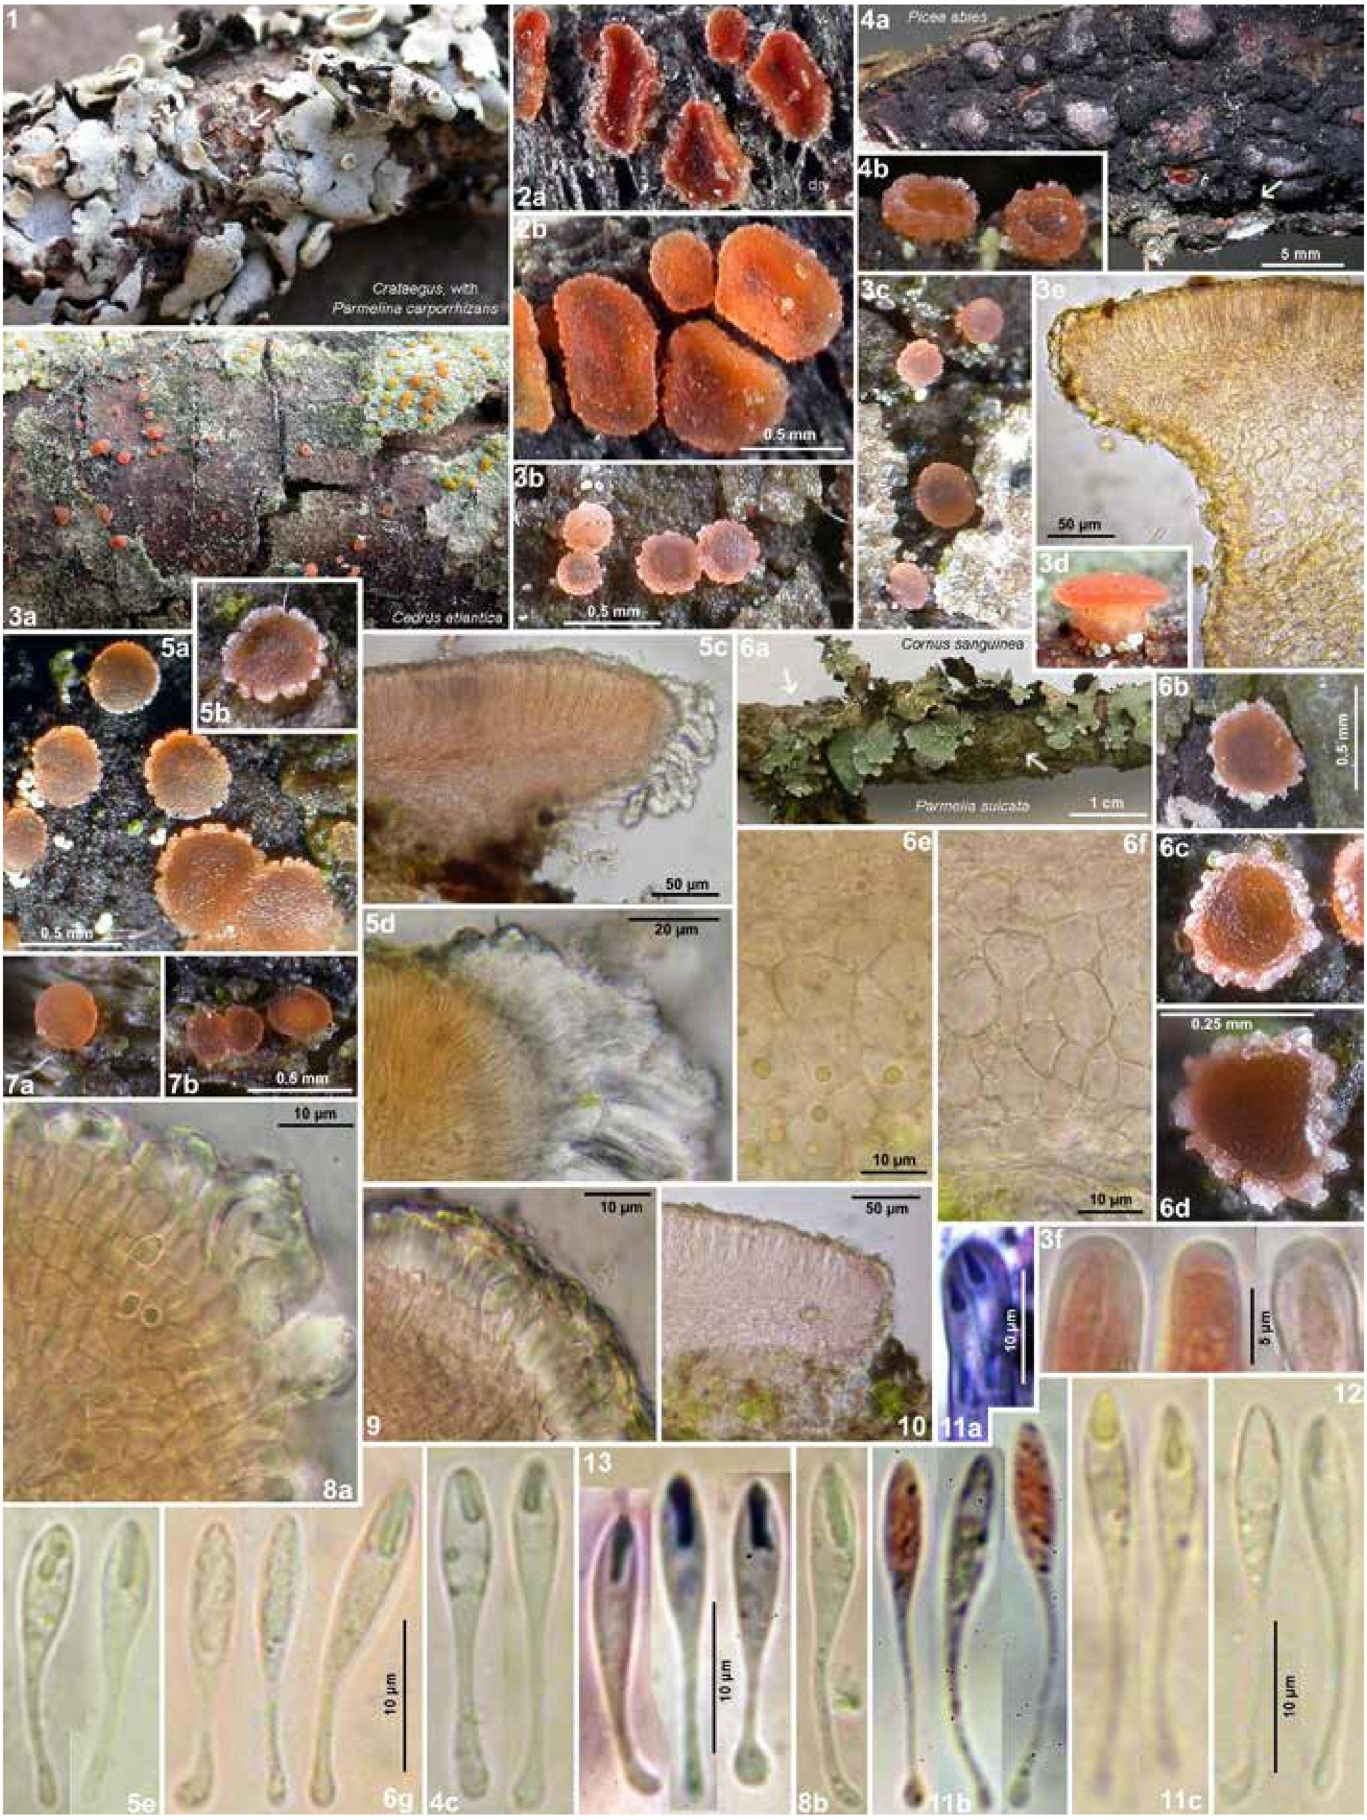

Plate 329. **1–13**: *Orbilia flagellispora*. – **1**, **3a**, **6a**. dead corticated xeric branches (**3a** with *Caloplaca holocarpa*); **4a**. living branch of *Picea abies*, with blackened resinous wound; **2b**, **3a–d**, **4b**, **5a–b**, **6b–d**, **7a–b**. rehydrated apothecia; **2a**. dry apothecia; **3e**, **5c**, **10**. apothecia in median section; **5d**, **8a**, **9**. id., marginal ectal excipulum; **6e–f**. id., basal ectal excipulum (**6e** cells with yellowish LBs); **3f**, **11a**. ascus apices; **4c**, **5e**, **6g**, **8b**, **11b–c**, **12**, **13**. ascospores. – Living state (spores in **11a** & **13** with SBs stained deep blue in CRB), except for **6g** left, **12** left (in H_2O), **11b** (in CR), **5d** (in KOH), **3f** (in KOH+CR), ascus in **11a** (in CRB). – **1**: phot. Plate 330. **1–3**: *Orbilia flagellispora*. – Conidia from substrate (living state, except for some cells). — **1**. H.B. 7829: Germany, Lenggries, on *Salix*; **2**. H.B. 8264: Switzerland, Uri, on *Cornus*; **3**. H.B. 8272b: Switzerland, Obwalden, on *Picea*.

Spore length varies strikingly among the collections of *O. flagellispora*, but often also within a single apothecium. The holotype showed the longest spores (Galán et al. 1994: 20–30 × 2.5–3.5 µm), but also in some European specimens the spores measured 24–28 µm (Pls 328: 1a; 329: 12, H.B. 9151f). This variation is mainly due to a variable tail length, but also the length of the spore head varies to some extent. In some collections the head measured 10–13 µm (e.g., Pl. 327: 2a; 328: 3a) but in others only 9–11 µm (Pl. 328: 1a, H.B. 8248c), so that the delimitation from *O. subaristata* with 7–10 µm long spore heads may become obscure, if only a few spores are available for comparison. The width of the bulbous tail bases may also vary rather considerably, even within a collection. In the only North American collection the tail bases were exceptionally narrow, varying from uninflated to medium bulbous (†0.2–1 µm thick, unillustrated).

Type studies. In the type of ***O. flagellispora***, Galán et al. (l.c.) apparently saw a few living spores with SBs as they stated 'sometimes with 1 large oil inclusion'. In any case, their photos of dead spores in MLZ clearly show the transparent region of the SBs (see Fig. 67g). In the present reexamination (Pl. 327: 1a) the SBs of some spores were visible when mounted in water, measuring ~5–6 µm in length, whereas in all collections on bark referred to *O. flagellispora* the SBs of living spores measured 3–5.3 µm. Future collections on leaves should, therefore, be explored for SB length, also for spore length and basal curvature.

The description of ***Orbilia herbarum*** Velen. (1934: 102, pl. 11 fig. 19) somewhat resembles *O. flagellispora*. The holotype (PRM 152431) contains a minute plant fragment which looks like a leaf tip of possibly *Carex*, not like a stem of *Lotus corniculatus* as stated by Velenovský. No apothecia could be found by Svrček (1954) and in the present study. Based on the description, Svrček considered *O. herbarum* to be very close to *O. aristata* (as '*O. occulta*'). The rather narrow and elongated spore heads resemble *O. flagellispora*, from which *O. herbarum* differs, besides the substrate, in basally uninflated tails. *O. herbarum* could perhaps also be close to *O. subclavuliformis*, although Velenovský's drawing shows very narrow spore tails, or to the mainly extra-European *O. angustoaristata* or *O. clavuliaristata*.

Not included collection. A sample on bark of *Fraxinus* from Switzerland studied in the dead state (IVV: H.B. 9242b) differs in rather short spores (†13.3–19 × 2.3–2.6 µm) with not or hardly inflated tail bases, also in short asci (†31–38 × 5–5.5 µm) and might be more related to *O. clavuliaristata*.

Anamorph. Conidia with a different number of arms were detected on the substrate near apothecia of 11 collections. These were mostly Y-shaped trinacrium-like or ┼-shaped descalsia-like conidia. Two times dwayaangam-like conidia were seen, either 6–7-armed (Pl. 330: 3) or 4-armed (H.B. 4997). No pure culture was available, but the different conidial types from substrate are similar to the anamorphs of the closely related *O. aristata* and *O. subaristata*.

Phylogeny. A sequence of a sample from southern France (on *Picea*, G.M. 2010-09-03.3, from apothecia) comprises S1506 intron, ITS, and LSU. When analysing ITS+LSU (Phyl. 9), *O. flagellispora* clustered in a strongly supported clade with *O. subaristata* (3 strains) and *O. aristata* (H.B. 6713) with a distance of 2.8–3 % and 3.5 % in the ITS (0.7–0.9 and 0.2 % in LSU), respectively. When analysing the intron, *O. flagellispora* clustered unresolved within section *Hemiorbilia* by showing a very high distance (~23–28 %) to any other species of *Orbilia*.

Five environmental sequences from *Picea* shoots and needles in Lithuania and one from *Pinus heldreichii* needles in Montenegro comprise partial 5.8S and entire ITS2. The *Pinus* isolate (Lazarević & Menkis 2020, GenBank MT242053) fully coincides with *O. flagellispora*, whereas those from *Picea* (A. Menkis pers. comm., Menkis et al. 2015, KP897776) differ by 3(–4) nt in the ITS2. The medium support of the *O. flagellispora* clade in Phyl. 12 is due to the missing ITS1 in KP897776; the clade is strongly supported when restricting the analysis to the ITS2 region (not shown).

3a–g. H.B. 7604a: France, Sisteron, on *Cedrus*; **4a–c**. H.B. 9162d: France, Le Labouret, on *Picea*; **5a–e**. H.B. 8359a: Luxembourg, Differdange, on *Cornus*; **6a–g**. Ecology. Within Europe, *O. flagellispora* grows on slightly to medium decayed bark, exceptionally wood, of xeric twigs, branches or trunks of gymno- and angiosperm trees and shrubs. It mainly occurs at higher altitudes in orotemperate (montane to subalpine) and orosubmediterranean humid forests, but it was sometimes also recorded at colline altitude in cold-temperate humid (Luxembourg, Steiermark) or hemiboreal (Lithuania, DNA-extract) or supra- to mesosubmediterranean semihumid areas. When growing on resin of conifers, some branches or trunks were still alive. The five DNA isolates of Menkis et al. (2015) were from *Picea* shoots and needles damaged by the spruce bud scale (*Physokermes piceae*), whereas trees with undamaged needles at the same locality were without the fungus, suggesting that it does not occur as an endophyte in living plant tissue.

Two records from northern Europe are from the supraboreal (on *Salix*) and hemiboreal zone (DNA isolate from *Picea* needles), one sample is from a subarctic humid tundra vegetation in western Greenland (on the dwarf shrub *Salix glauca*), and one from a boreal humid Douglas fir mixed conifer forest of northwestern North America (Northern Rocky Mountains, on *Picea*). The type collection was on a dry coriaceous leaf of *Rhus laurina* in a subtropical semiarid chaparral with *Quercus agrifolia* in Baja California (Sonoran Desert, Middle America).

Specimens included. **NORWAY**: **Sør-Trøndelag**, 33 km S of Oppdal, SW of Kongsvoll, Botanical Garden, 900 m, twig of *Salix phylicifolia*, on bark, 18.VII.2012, S. Orbilia angustoaristata Baral & G. Marson, **sp. nov.**, MB 813608 — Pls 331–332

Etymology: referring to the ascospores which are much narrower than in the otherwise similar *O. aristata*.
Typification: Australia, Northern Territories, Curtin Springs Roadhouse, twigs of *Acacia jennerae*, 10.X.1998, G. Marson (ex H.B. 6277f, MEL 2389201, holotype).

Latin diagnosis: *Apothecia rehydratata 0.18–0.8 mm diam., vivide rosea, sessilia vel substipitata, margine subtiliter crenulata vel distincte albido-dentata. Asci 8-spori. Ascosporae *12–17 × 1.6–2.4 µm, anguste ellipsoideo-fusoideae, cauda basali 3.5–7.5 × 0.3–0.7 µm, basi non inflata praeditae, in statu vivo* *corpusculum refringens bacilliformem vel subulatum, ad apicem affixum continentes. Cellulae vivae excipuli marginalis et paraphysium corpuscula globosa et crystalloidea continentes, excipulum marginale saepe processis vitreis, dentes minutos formantibus praeditum. Habitat ad lignum vel corticem putridum ramulorum vel ramorum siccorum* Acaciae *et* Pittospori phillyreoidis *in zona subtropica arida ad temperata subhumida Australiae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.18–)0.25–0.45(–0.8) mm diam., 0.09–0.2 mm high (receptacle 0.08–0.15 mm), (pale to) light to bright rose-pink to rose-red, round, scattered to subgregarious; disc flat, margin rising 0–5 µm above disc, finely whitish crenulate or with distinct small teeth (10–20 × 15–30 µm), rarely smooth; sessile to (sub)stipitate, stipe 0.08 × 0.2 mm, superficial or half immersed in biofilm. **Asci** *(40–)48–56(–68) × 5–6 µm {2}, †39–58 × 4.5–5.6 µm {2}, 8-spored, spores 3–4-seriate, (0–)1–3 lower spores inversely oriented {2} (not mixed), pars sporifera *26–28 µm long; **apex** (†) hemispherical to slightly truncate, dome 1.2–1.6 → 0.5–1 µm thick, with or without apical chamber; **base** with short to very long, ± thin, flexuous stalk, L- to Y-shaped. **Ascospores** *12–15(–17) × 1.6–2.4 µm {2}, †12–15(–18.5) × 1.7–2 µm {2}, with (subcylindrical to) narrowly ellipsoid-fusoid, *8–10 µm long head and medium sharply differentiated narrow tail of *3.5–7.5 × 0.3–0.7 µm, apex rounded to obtuse, tail straight to slightly curved, never widened at the base; **SBs** *(2–)2.5–3.5 × 0.4–0.5 µm {2}, rod-shaped to subulate, more overmature *0.8(–1) µm wide, ampulliform, apically narrowed to a small or often wide point, with a few minute LBs. **Paraphyses** apically uninflated to slightly clavate-capitate, terminal cells *9–24 × (2–)2.3–3.5(–4) µm {2}, lower cells *8–12 × 1.8–2.2(–3.5) µm {2}; unbranched near apex, hymenium light rose. **Medullary excipulum** hyaline to pale rose, 20–130 µm thick, of medium dense textura intricata-globulosa, sharply delimited. **Ectal excipulum** hyaline to pale rose, of medium gelatinized {2}, vertically oriented t. angularis(-prismatica) at base and flanks, 20–50 µm thick near base, cells */†10–21 × 7–14 µm {2}, common walls †1–1.3(–2) µm thick; 15–30 µm thick near margin, inner part of t. prismatica-angularis oriented at a 30–50° angle to the surface, outer part abruptly of t. prismatica(-porrecta) oriented at 20–45°, marginal cortical cells *5–16 × 3–4 µm {2}, **glassy processes** absent {1} or present {2}, 10–20 × 3.5–4(–4.5) µm, stratified, ± coherent to form teeth. **Anchoring hyphae** sparse, */†2–4 µm wide, walls 0.2–0.7 µm thick {2}, sometimes covering lower flanks by a 10 µm thick layer. **SCBs** in paraphyses and ectal excipulum globose, 1–2.7 µm diam., also crystalloid {2}. **Exudate** over paraphyses 0.5–1 µm thick, continuous to granular-cloddy, loosely attached; over margin and flanks rough-cloddy, 0.5–1 µm thick. — **ANAMORPH**: unknown.

Habitat: collected 0–1.5 m above the ground, ± decorticated, 1.5–9 mm thick twigs & branches of *Acacia jennerae* {1}, *Pittosporum phillyreoides* {1}, on wood {1} or remnants of bast {2} (outer layers of bark removed), outer 0.3 mm deep medium to strongly decayed, greyed, green algae sparse or absent. **Associated**: *Baggea* sp. {1}, *Claussenomyces* sp. {1}, *Coccomycetella* sp. {1}, *Dacrymyces* sp. {1}, *Dothideomycetes* {1}, *Exidia* sp. {1}, *Gloniopsis* sp. {1}, *Orbilia austropleiomicrosoma* {1}, *O. coronohesperidea* {1}, *O. ?livistonae* {1}, *O. megahesperidea* {1}, *O. multiaustraliensis* {1}, *O. multiserpens* {2}, *O. myriella* {1}, *O. myrionamibica* {1}, *O. ?myrioolneyae* {1}, *O. pleioaustraliensis* {2}, *O. pleiocoronohesperidea* {1}, *Peniophora* sp. {1}, *Symbiotaphrina desertorum* {2}, *?Triblidium* sp. {1}, *Xylobolus* sp. {1}. **Desiccation tolerance**: fully viable for at least 2 months. **Altitude**: 248–480 m a.s.l. **Geology**: Cenozoic regolith. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia angustoaristata* is characterized by rather elongate and narrow spore heads which gradually attenuate into a comparatively short tail. *O. herbarum* Velen. (1934: 102) was described with similar spores, but the holotype is now empty and the substrate (herbaceous) and geographical origin is different. The northern hemispheric *O. aristata*, *O. clavuliaristata*, *O. clavuliformis*, *O. frullaniae*, and *O. subclavuliformis* differ in mostly wider spores, wider SBs, and in the absence of crystalloid SCBs, *O. aristata* also in much shorter spore heads and longer, more abrupt tails. For the similar *O. brevicauda* see p. 705.

Variation. The two collections of *O. angustoaristata* closely resemble each other in their micromorphology. Variation was mainly observed in the length of the glassy processes and consequently in the length of the margin teeth. This variation occurred within both collections, the margin being either distinctly crenulate to denticulate or almost to entirely smooth.

Not included collections. Two European samples on leaves of *Dryas* (Pl. 331: 4), with minute (0.2 mm diam.), whitish to pale cream apothecia, were only studied in the dead state and might represent a separate species. They were among the specimens published by Nograsek & Matzer (1991: 460) from Sweden and Austria under the provisional name *O. inconspicua* which turned out to be a mixture (see p. 1674). The fungus of Pl. 331: 4 was probably not studied by the authors who only reported spores without a tail. Besides typical *O. angustoaristata*, this fungus resembles also *O. frullaniae*, *O. brevicauda*, and *O. clavuliaristata* in spore shape, but consistently deviates in rather short tails (†2.5–3.5 × 0.3–0.4 µm). The glassy processes have a size of 1–9 × 3–3.5 µm.

A collection from southwestern Australia on bark of *Dodonaea viscosa* subsp. *angustissima* (Pls 331: 3; 332: 2) is not included because it differs in slightly wider asci and spores, slightly larger, especially wider SBs (3–3.8 × 0.6–0.8 µm) with an often narrow attachment, and longer glassy processes (15–50 × 2.5–3.5 µm) forming much larger teeth (40–75 × 40–160 µm). Though studied in the living state, crystalloid SCBs were only seen in some of the apothecia examined. This collection showed a drought tolerance of 20 months.

Phylogeny. A sequence comprising S1506 intron, ITS, and LSU was gained from two different apothecial extracts of the not included sample on *Dodonaea* (H.B. 8838b). In the combined analysis (Phyl. 9) it clustered unexpectedly with *O. velutina* in a moderately supported clade within the strongly supported *vinosa-velutina* clade in spite of its close similarity with species of series *Hemiorbilia*. A medium supported association with *O. velutina* was also observed when analysing LSU (Phyl. S13).

In the ITS region *O.* cf. *angustoaristata* shows a distance of 11.5–15 % to other members of the *vinosa-velutina* clade. In the LSU the distance to *O. velutina* is 1.5 %, to *O. multicurvula* 3 %, to *O. nothoaprilis* 3.5 %, and to members of the *aristata-clavuliformis* clade 5–8.3 %. This raises the question whether the sequence might originate from another, macroscopically similar *Orbilia* that grew in association. However, none of the five *Orbilia* species that were recorded in association with it on the same branches, including *O. fimbriata*, show a micromorphology similar to *O. velutina*. We retained *O. angustoaristata* in series *Hemiorbilia* because of its morphology which is reminiscent of, e. g., *O. flagellispora*.

Ecology. *O. angustoaristata* was found on ± rotten bark and wood of xeric twigs and branches of *Acacia* and *Pittosporum*. In the holotype most apothecia grew on decorticated wood, while in the paratype they equally grew on bark and wood. The holotype was from a subtropical arid acacia open shrubland in central Australia (south of MacDonnell Ranges), the paratype from a warm-temperate subhumid eucalypt woodland in eastern Australia west of the Great Dividing Range. The not included collection on *Dodonaea* was in a subtropical semiarid acacia open shrubland on Cretaceous sedimentary rock in southwestern Australia, while those on *Dryas* were from a calcareous humid shrubland and pasture (*Dryadetum*) in the (sub)alpine, cryorotemperate eastern Alps of central Europe.

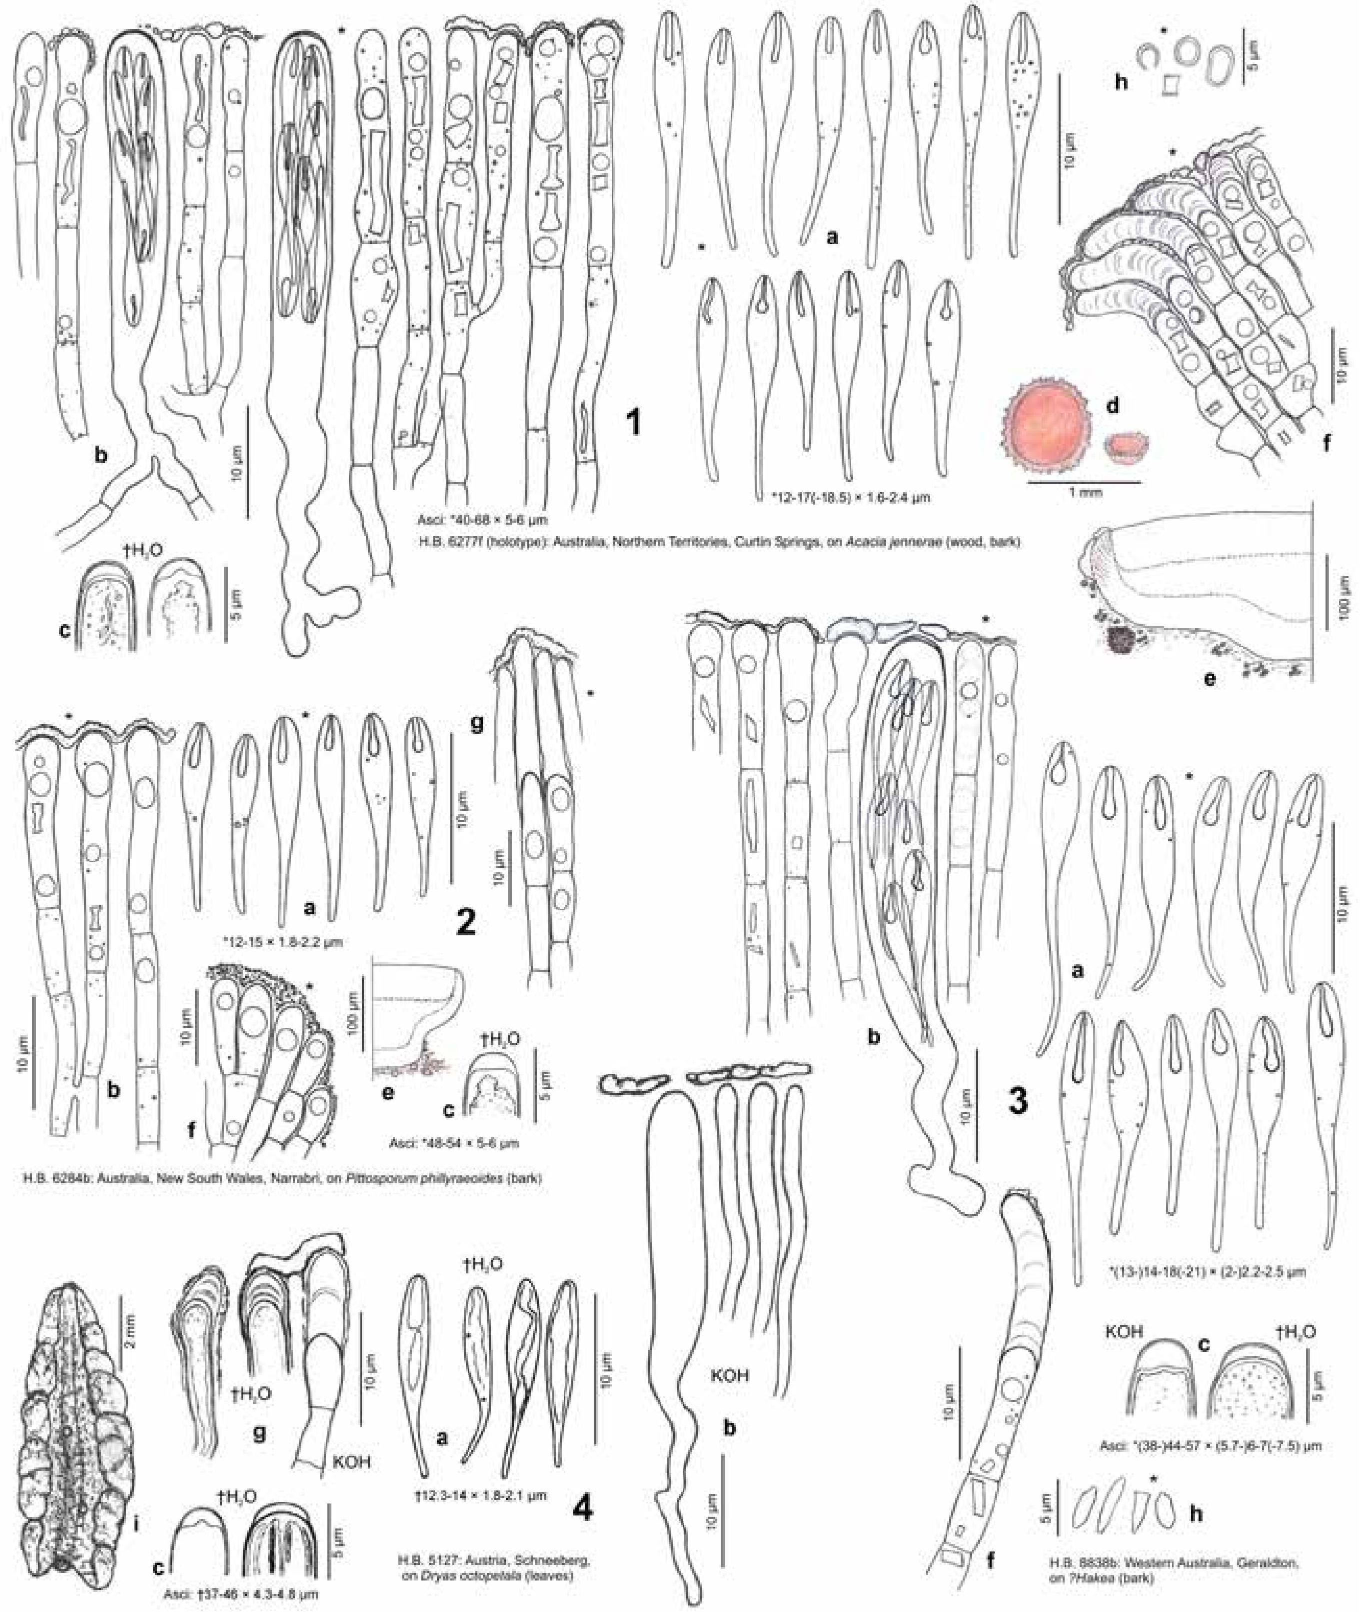

Plate 331. **1–2**: *Orbilia angustoaristata*; **3–4**: *O.* cf. *angustoaristata*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecia with dentate margin (rehydrated); **e**. apothecia in median section; **f**. id., marginal ectal excipulum, cortical cells with or without glassy processes; **g**. id., external view; **h**. crystalloid SCBs in ectal excipular cells (lower flanks); **i**. leaf of *Dryas* (underside, with two apothecia).

Specimens included. **AUSTRALIA**: **Northern Territories**, Finke, 100 km E of Yulara, 24 km ENE of Curtin Springs Roadhouse, 28 km NNE of Mt. Connor, 480 m, twigs of *Acacia jennerae*, on wood & bark, 10.X.1998, G. Marson (ex H.B. 6277f, MEL 2389201, **holotype**; MEL 2389203B, **isotype** [in type of *O. multiaustraliensis* MEL 2389203A]). – **New South Wales**, Brigalow Belt South, 20 km SW of Narrabri, 248 m, branches of *Pittosporum phillyreoides*, on bark, 24.X.1998, G. Marson (H.B. 6284b).

Not included. **AUSTRIA**: **Niederösterreich**, 6.7 km WSW of Puchberg, 2.2 km ESE of Hochschneeberg, between Waxriegel and train station, ~1840 m, leaves of *Dryas octopetala*, 19.VIII.1990, A. Nograsek, W. Pongratz & K. Waltl (H.B. 5127 ø, GZU 63-92, as *O. inconspicua*). – **Steiermark**, 13 km NE of Schladming, 4.3 km N of Aich, Stoderzinken, 2010 m, leaf of *Dryas octopetala*, 21.VII.1987, J. Hafellner & A. Nograsek (GZU 37-92, as *O. inconspicua*). — **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, Nerren Nerren, W of Toolonga 190 m, trunk of *Dodonaea viscosa* subsp. *angustissima*, on bark, 8.XI.2007, G. Marson (H.B. 8838b; sq.: KT222396).

Plate 332. **1**: *Orbilia angustoaristata*; **2**: *O.* cf. *angustoaristata*. – **2a**. semiarid acacia shrubland; **1a**. dead, partially decorticated xeric branches of *Pittosporum phillyreoides*; **2b**. detached xeric bark of *Dodonaea viscosa*; **1b–g**, **2c–i**. rehydrated apothecia; **1h**, **2m**. apothecia in median section; **2l**. id., marginal ectal excipulum; **2j**. id., basal ectal excipulum; **1i**, **2k**. ascus apices; **2n**. ascospores. – Living state, except for **1h** (in KOH), **1i** (in KOH+IKI), ascus in **2k**. — **1a–i**. H.B. 6284b: Australia, New South Wales, on *Pittosporum*; **2a–n**. H.B. 8838b: Western Australia, Yalgoo, on *Dodonaea*.

Orbilia frullaniae Baral & Priou, **sp. nov.**, MB 813609 — Pls 333–334

Etymology: named after the substrate, *Frullania dilatata*.

Typification: France, Besançon, leaves of *Frullania dilatata*, 3.II.2008, J.M. Moingeon & G. Moyne (ex H.B. 8760, M-0276487, holotype).

Latin diagnosis: *Similis* Orbiliae angustoaristatae *sed cellulae vivae excipuli et paraphysium absque corpusculis crystalloideis, capites ascosporarum breviora, corpuscula refringentia latius, asci apice leniter crassitunicati, ab* O. brevicauda *ascosporis majoribus, corpusculis refringentibus et processis vitreis longioribus differt. Habitat ad folia senescentia vel emortua sicca* Frullaniae dilatatae *in zona temperata humida subatlantica Europae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** fresh 0.25–0.65 mm diam., 0.19–0.4 mm high (receptacle 0.11–0.16 → 0.07–0.1 mm), light to bright orange-rose, non-translucent, round, scattered; disc slightly concave, margin 10–80 µm protruding (incl. teeth), with white incurved teeth 40–80 × 40–70 µm; sessile on a broad obconical base or mostly with a distinct stipe 0.12–0.25 × 0.2–0.25 mm; dry somewhat contracted, bright pink-red with whitish marginal teeth. **Asci** *44–54 × 5.5–6 µm, †33–43 × 4.5–5.3 µm, 8-spored, spores *4-seriate, (1–)2(–4) lower spores inverted (not mixed), pars sporifera *22–25 µm long; **apex** (†) slightly to medium truncate, hemispherical in profile view, dome †0.6–0.8 → 0.5–0.6 µm thick, without apical chamber; **base** with short to medium long, thick, flexuous stalk, L- to h-shaped. **Ascospores** *(11.5–)14–16(–17.5) × 2.1–2.4 µm, †13.5–15.5 × 2–2.2 µm, head fusoid, apex obtuse (to subacute), *7–8 µm long, tail *7–8(–9) × 0.4–0.7 µm (towards head 0.5–0.8 µm), straight to slightly flexuous; **SBs** *2–2.8 × 0.7–0.9(–1) µm, subcylindrical (to tear-shaped), apically narrowed to a small or medium wide point, ± straight. **Paraphyses** apically uninflated or mostly slightly capitate, terminal cells *(12–)15–19 × 2.7–3.3 µm, lower cells *7.5–11 × 1.7–2.4 µm. unbranched at upper septum, hymenium pale rose. **Medullary excipulum** pale rose-orange, 70 µm thick, of dense textura globulosa-intricata, indistinctly delimited. **Ectal excipulum** very pale rose, of thin-walled, indistinctly oriented t. globulosa from base to mid flanks, 70–90 µm thick at lower flanks, cells *10–20(–23) × (6–)9–12(–14) µm; 20–25 µm thick near margin, inner part of t. (prismatica-)angularis oriented at a 60–80° angle to the surface, outer part of t. porrecta oriented at 20–40°, marginal cortical cells *8–12 × 2.5–3.5(–4) µm; **glassy processes** (5–)20–60 × 2.5–3.5(–4.5) µm, high-refractive, indistinctly stratified, at margin strongly inwards curved, coherent to form distinct teeth. **Anchoring hyphae** very abundant, */†1.7–3.5(–5) µm wide, walls 0.2–0.3(–0.8) µm thick, forming a medium dense, hyaline, slightly gelatinized t. intricata up to 90 µm thick at base, covering flanks as a 5–10 µm thick layer, intergrading with glassy processes. **SCBs** globose, in paraphyses 1.3–2 µm diam., in ectal excipulum (near margin) 1.5–2.5 µm. **Exudate** over paraphyses 0.2–0.5 µm thick, granular, hyaline, loosely lying over gel, on glassy processes 1–3 µm thick, cloddy-continuous. — **ANAMORPH**: unknown.

Habitat: collected 1.6 m above the ground, corticated, 15 cm thick living trunk of *Prunus mahaleb*, on necrobiotic or dead, darkened leaflets of *Frullania dilatata*. **Associated**: ?*Brachythecium* sp., *Lepraria* sp., *Metzgeria furcata*, *Normandia pulchella*, *Orthotrichum* sp., *Rhytidium rugosum*. **Desiccation tolerance**: ectal excipular cells still viable after 2 weeks. **Altitude**: 370 m a.s.l. **Geology**: Middle Jurassic limestone (marble). **Phenology**: II.

Taxonomic remarks. *Orbilia frullaniae* is similar to the Australian *O. angustoaristata*, from which it is tentatively separated by the absence of crystalloid SCBs, also by slightly shorter spore heads, wider SBs, and thinner ascus apical thickenings. However, in one of the collections mentioned under *O. angustoaristata* (H.B. 8838b) crystalloid SCBs were also often absent. Another close relative of *O. frullaniae* is the Chinese *O. brevicauda* which is tentatively separated by smaller ascospores and shorter SBs, also by shorter glassy processes. The North American *O. clavuliaristata* differs in slightly wider spores and larger SBs, also in slightly thicker domes and much shorter glassy processes. *O. subclavuliformis* distinctly differs in thicker spore tails, longer SBs, and in very short or absent glassy processes. A collection on *Hedera* in remote association with *Frullania* (Pl. 339: 11, atlantic Europe) differs in much longer SBs and almost smooth apothecia and is, therefore, considered as an aberrant form of *O. aristata*.

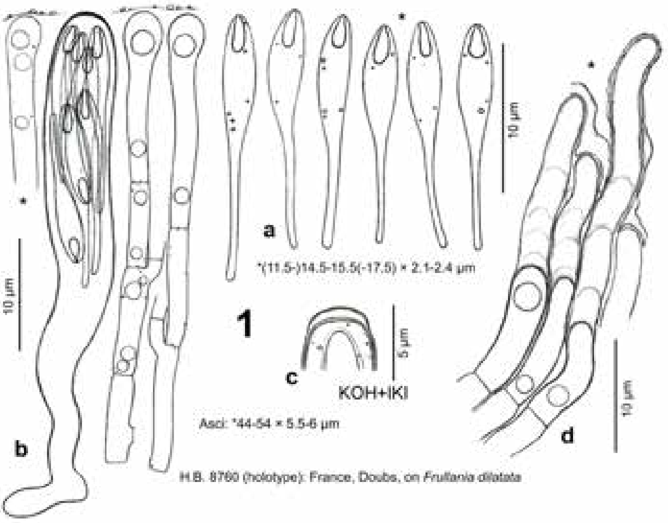

Plate 333. **1**: *Orbilia frullaniae*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apex; **d**. marginal cortical cells with glassy processes (median section).

Not included collection. A sample on a 5 mm thick corticated xeric twig of *Cornus* (on periderm, closely associated with an acrocarpous moss and lichens, Pl. 334: 2) showed a similar spore size [*14–16.5 × 2.3–2.5(–2.7) µm] but has spores with longer, more cylindrical heads and shorter tails, and much wider, tear-shaped SBs 2.4–3 × 1.3–1.6 µm (only a few living spores could be seen). The shorter glassy processes (10–20 µm) and particularly the presence of rod-shaped SCBs 3.5–4 × 0.8–1 µm in the ectal excipular cells at mid flanks are further diagnostic features. This sample seems to be intermediate to *O. clavuliaristata*, which was also recorded on *Cornus*, but deviates in, e. g., more dumbbell-shaped SBs, more distinct spore tails, and the absence of crystalloid SCBs.

Ecology. *O. frullaniae* grew on old but still-living leaflets of *Frullania dilatata* on a standing trunk of *Prunus* in a cold-temperate humid, subatlantic, medium shady *Prunus mahaleb*-*Buxus sempervirens* forest on calcareous Jurassic soil in southwestern central Europe. The species is probably rare or is not confined to *Frullania*, otherwise it would have been encountered earlier on this thoroughly investigated bryophyte. The not included collection was on rotten bark of a xeric twig of *Cornus* from the northern foothills of central Pyrenees in a warm-temperate humid, atlantic forest with *Robinia* and *Cornus sanguinea* on calcareous soil (Cretaceous).

Specimens included. **FRANCE**: **Franche-Comté**, **Doubs**, 15.5 km SSW of Besançon, 1 km N of Courcelles-Les-Quingey, 370 m, trunk of *Prunus mahaleb*, on leaves of *Frullania dilatata*, 3.II.2008, J.M. Moingeon & G. Moyne (ex H.B. 8760, M-0276487, **holotype**; J.P.P. 28020, **isotype**).

Not included. **FRANCE**: **Midi-Pyrénées**, **Ariège**, 16.5 km ENE of St.-Girons, 0.7 km NE of Castelnau-Durban, les Mouns, 450 m, twig of *Cornus sanguinea*, on bark, 30.X.2011, J.P. Priou (H.B. 9622a).

Plate 334. **1**. *Orbilia frullaniae*; **2**. *O.* cf. *frullaniae*. – **1a**. subatlantic forest with *Buxus sempervirens* and *Prunus mahaleb*; **1b**. living *Prunus mahaleb* tree after pieces of bark were harvested; **1c–d**. apothecia on *Frullania dilatata*, with *Metzgeria*; **1e**, **g**. fresh apothecia; **1f**, **h–j**, **2a–c**. rehydrated apothecia (**2a–c** with acrocarpous moss & foliose lichen), **1k**. dry apothecia; **1l–n**. apothecium in median section; **1o–p**. id., ectal excipulum and anchoring hyphae near base; **1q**, **2d–e**. ascospores. – Living state (**1q** right in CRB), except for **2d** (in H_2O). – **1a–b**: phot. G. Moyne; **1e**, **g**, **l–o**, **1q** right: phot. J.P. Priou. — **1a–p**. H.B. 8760 (holotype): France, Doubs, on *Frullania* (on *Prunus*); **2a–e**. H.B. 9622a: France, Ariège, on *Cornus*.

Orbilia brevicauda Ying Zhang, Baral & K.Q. Zhang, in Zhang et al., Fungal Diversity 36: 143 (2009) — Pls 335–336

Etymology: named after the short-tailed ascospores.

Typification: China, Yunnan, Yimen, branch of indet. angiosperm, 1.VII.2006, Z.F. Yu (ex YMFT1.01851 & ex H.B. 8715, M-0140891, holotype).

Description: — **TELEOMORPH**: **Apothecia** fresh or rehydrated 0.4–1 mm diam., 0.1–0.12 mm high (receptacle 0.09 → 0.06 mm), light cream-yellow-orange, medium translucent, round, scattered; disc flat, margin distinctly crenulate by small whitish, hardly protruding teeth; sessile, superficial. **Asci** *36–50 × 5.2–5.4 µm, †(30–)35–40 × (4.2–)4.5–5(–5.3) µm, 8-spored, spores (*) biseriate, 1–2 lower spores inverted, pars sporifera *22–25 µm long; **apex** (†) hemispherical to very slightly truncate, dome †1 → 0.3–0.8 µm thick, with slight apical chamber; **base** with short to medium long, ± thin, flexuous stalk, L-, T- or Y-shaped. **Ascospores** *11.5–13.5 × 2–2.2 µm, †10.8–12.5 × 1.7–1.9 µm, with a narrowly ellipsoid-fusoid head *7–8 µm long (†6–7 µm) and an abrupt thin tail *4.5–5.5 × 0.6–

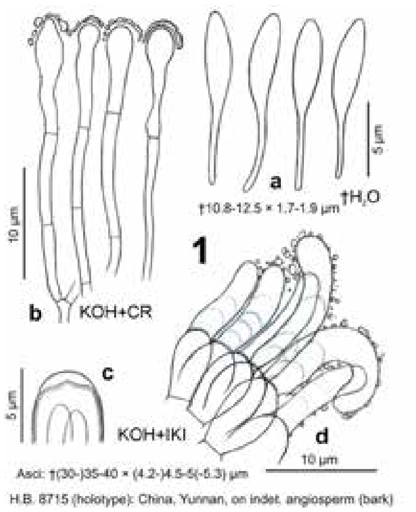

Plate 335. **1**: *Orbilia brevicauda*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apex; **d**. marginal cortical cells with glassy processes (median section).

0.7(–0.9) µm (†4–5 × 0.3–0.5 µm), apex obtuse, head straight to slightly inequilateral, tail straight to slightly curved, rarely basally slightly inflated; **SBs** *1.6–2.2 × 0.7–0.9 µm, tear-shaped to almost cylindrical, apically narrowed to a ± wide point, straight. **Paraphyses** apically slightly to medium clavate-capitate, sometimes spathulate, terminal cells *12 × 2–4 µm, †8–11 × (1.7–)2–2.5(–3) µm, lower cells *9.5–11 × 1.4–2.2 µm, †7–11 × 1–1.7 µm; unbranched at upper septum. **Medullary excipulum** 15–30 µm thick, of dense textura intricata-porrecta, ± horizontally oriented, with many inflated cells, sharply delimited. **Ectal excipulum** of (†) thin-walled, indistinctly oriented t. globulosa-angularis from base to mid flanks, 20–45 µm thick near base, cells †6–11 × 5–10 µm; 20 µm thick near margin, of t. prismatica-angularis oriented at a 40–80° angle to the surface, marginal cortical cells †6–8 × 4–5.5 µm; **glassy processes** absent or usually present, 6–16 × 2.5–3.5 µm, medium refractive, hardly stratified, ± coherent to form small teeth. **Anchoring hyphae** medium abundant, †1.5–2.5 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses globose, 1.3–2.7 µm diam., in ectal excipulum not examined. **Exudate** over paraphyses 0.3–1.3 µm thick, granular-cloddy, ± loosely attached, over margin 0.3–1 µm thick, granular. **— ANAMORPH**: unknown.

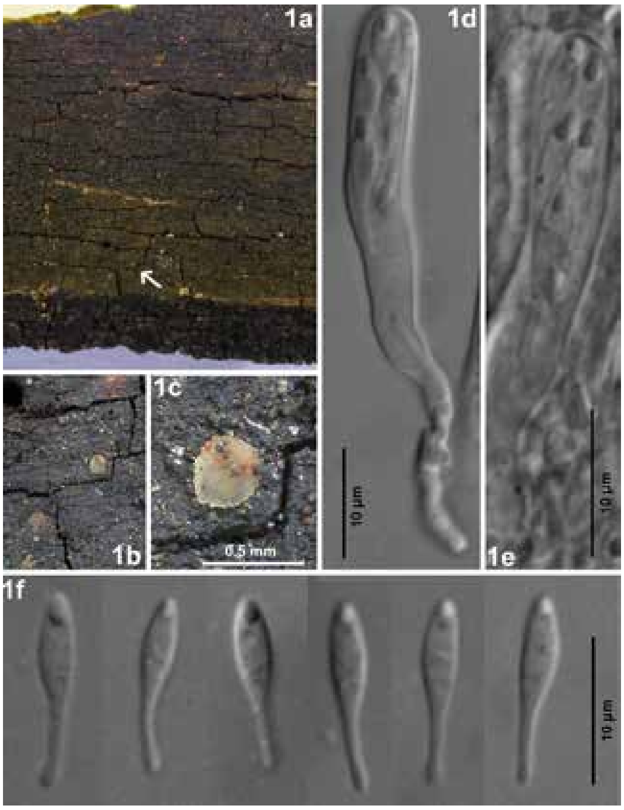

Plate 336. **1**: *Orbilia brevicauda*. – **1a**. blackened underside of detached bark of indet. angiosperm; **1b–c**. rehydrated apothecium; **1d–e**. mature asci; **1f**. ascospores (perhaps overmature because SBs smaller than in **1d–e**); — Living state. – **1b–f**: phot.Zhang et al. (2009b, DIC). — **1a–f**. H.B. 8715 (holo-/isotype): China, Yunnan, on indet. angiosperm.

Habitat: collected on moist ground on detached bark of ~10 cm thick branch or trunk of unidentified angiosperm tree, on medium decayed inner surface of bark, strongly blackened, no algae. **Associated**: none observed. **Desiccation tolerance**: not tested. **Altitude**: 2000 m a.s.l. **Geology**: Jurassic-Cretaceous-Paleogene sedimentary rock. **Phenology**: VII.

Taxonomic remarks. *Orbilia brevicauda* is similar to the Australian *O. angustoaristata*, from which it differs in shorter ascospores and spore heads, shorter and wider SBs, thinner apical domes, and apparently also in the absence of crystalloid SCBs. The Australian *O. parviclava* and the North American *O. clavuliaristata* differ in distinctly wider spore heads, the latter also in a tendency to longer spores. Also *O. frullaniae* is similar (for the differences see p. 704).

Ecology. The very sparse, apparently only two apothecia in the single collection of *O. brevicauda* grew on rotten, detached bark of an unidentified angiosperm tree in a shady subtropical humid (winter-dry) evergreen mountain forest in southeastern Asia. Considering the relationship within series *Hemiorbilia*, *O. brevicauda* is probably a desiccation-tolerant species that grows on exposed, attached branches. In fact, the bark fragment in the holotype shows a xeric appearance, which permits to assume that the branch recently fell to ground.

Specimens included. **CHINA**: **Yunnan**, **Yuxi**, Yimen, 75 km SW of Kunming, 53 km NW of Yuxi, Longkou Forest Park, 2000 m, branch of indet. angiosperm, on bark, 1.VII.2006, Z.F. Yu (ex YMFT1.01851, ex H.B. 8715, M-0140891, **holotype**).

Orbilia clavuliaristata Baral & E. Weber, **sp. nov.**, MB 813610 — Pls 337–338

Etymology: named after the ascospores that resemble *O. clavuliformis*, though having narrow tails similar as in *O. aristata*.

Typification: Germany, Traunreut, branch of *Frangula alnus*, 18.VIII.2010, T.R. Lohmeyer (ex H.B. 9419, M-0276456, holotype).

Latin diagnosis: *Similis* Orbiliae clavuliformi *sed ascosporae caudis longioribus et multo angustioribus*, *corpusculis refringentibus multo brevioribus differt. Habitat ad corticem putridum ramulis siccis* Corni *vel* Frangulae *in zona temperata humida Americae septentrionalis et Europae centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.3–0.5(–0.7) mm diam., 0.09–0.17 mm high, (pale to) light rose-orange, medium translucent, round, scattered; disc flat (to slightly convex), margin indistinct, 0–5 µm protruding, smooth to finely crenulate; broadly sessile, superficial but sometimes ± immersed in cracks of periderm; dry light to bright orange-rose. **Asci** *(31–)40–60(–70) × 6–6.5(–7.2) µm {2}, †(32–)35–48(–55) × (4–)4.3–5.5(–6) µm {4}, 8-spored, spores *3-seriate, (1–)2–3(–4) lower spores inverted {4} (not mixed); **apex** (†) hemispherical to slightly truncate, dome †1–1.3(–1.5) → 0.7–1 µm thick {4}, apical chamber distinct or not; **base** with very short to very long, thin ot thick, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *(11–)12–16.5(–18) × (2.3–)2.4–2.6(–2.7) µm {4}, †10–15 × 2–2.4 µm {1}, with ellipsoid-fusoid head and sharply differentiated thin tail, head *7–10(–11) µm long (1/2–2/3 of spore length), straight or sometimes slightly inequilateral, apex obtuse (to subacute), tail *4–7(–8) × 0.3–0.6 µm, not swollen at base, straight to slightly curved or flexuous; **SBs** *(2.2–)2.5–3.5(–4.2) × (0.8–)1–1.2(–1.4) µm {4},

pyriform to dumbbell-shaped, also rod-shaped, apically narrowed to a ± wide point, straight, overmature 2–2.5 × 1.2–1.3 µm {1}. **Paraphyses** apically slightly (rarely medium) clavate-capitate, terminal cells *(5.5–)7–17(–19) × (1.8–)2.2–2.7(–3.3) µm {3}, lower cells *(5.3–)6.5–11(–12) × 1.5–2.5(–3.3) µm {3}; sometimes branched at upper septum. **Medullary excipulum** 15–50 µm thick, of dense textura intricata with some or many inflated cells, sharply delimited. **Ectal excipulum** of thin-walled, irregularly or vertically oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 25–60 µm thick near base, cells *8–20(–24) × 6–12 µm {2}; 15–20 µm thick near margin, pale rose, inner part of t. prismatica-angularis oriented at a 50–80° angle to the surface, outer part of t. prismatica-porrecta oriented at 20–50°, marginal cortical cells */†(4–)6–11(–13) × 2.5–3.5(–4) µm {4}; **glassy processes** absent {2} or present, 1–4 {3} or 4–10(–20) {3} × 2.5–4 µm {4}, high-refractive, ± stratified or not, sometimes outwards curved. **Anchoring hyphae** very sparse to medium abundant, †1.7–3 µm wide, walls 0.2–0.3 µm thick {2}, sometimes forming a 30 µm thick, slightly gelatinized, rather dense t. intricata. **SCBs** in paraphyses and ectal excipulum (near margin) globose, (0.8–)1.2–2(–2.7) µm diam. {3}. **Exudate** over paraphyses and exterior 0.2–1(–2) µm thick, cloddy-continuous, hyaline, loosely or firmly attached. **— ANAMORPH**: trinacrium-like (presumed, from natural substrate {2}). **Conidiophores** not seen. **Conidia** Y-shaped, total size */†(29–)44–50 × (23–)40–55 µm, stipe †(17–)21–31 × 2.2–3 µm, 3–5-septate, arms slightly (also strongly) tapering, */†(12–)20–33 × 2–3 µm, 2–6-septate {2}.

Habitat: collected 0.1–1 m above the ground, corticated, 2–9 mm thick twigs and branches of *Cornus* sp. {1}, *C. florida* {2}, *Frangula alnus* {1}, on medium decayed bark {4} (periderm {3} and bast {4}), along or in holes and cross fissures of periderm, sometimes on inner surface of detaching periderm, slightly greyed, also blackened and close to old pyrenomycete, green algae sparse or abundant. **Associated**: *Caloplaca* sp. {1}, *Graphis scripta* {1}, *Physcia* sp. {1}, various discocarpous lichens. **Desiccation tolerance**: fully viable for at least 2 months, paraphyses still alive after 11 months. **Altitude**: 2–570 m a.s.l. **Geology**: USA: Late Proterozoic sedimentary rock, Quaternary sediments; Germany: Pleistocene calcareous till. **Phenology**: V, VIII (but rather long-lived).

Taxonomic remarks. *Orbilia clavuliaristata* resembles *O. clavuliformis* in its ellipsoid-fusoid ascospore heads, but differs in longer and much narrower spore tails and much shorter SBs. From *O. angustoaristata* it differs in wider spores and SBs, and in the absence of crystalloid SCBs. However, in one of the Australian collections mentioned under *O. angustoaristata* (Pl. 331: 3) crystalloid SCBs were often also absent. That collection, but also the similar *O. frullaniae*, are actually very similar to *O. clavuliaristata* but differ in much longer glassy processes forming prominent teeth, also in narrower SBs and slightly narrower spores. A European collection on *Cornus* mentioned under *O. frullaniae* deviates by crystalloid SCBs.

O. clavuliaristata is segregated from *O. aristata* by narrower spore heads and shorter tails. A European collection on *Hedera* (Pl. 339: 11) mentioned under *O. aristata* differs from *O. clavuliaristata* in slightly longer, sometimes basally a bit swollen spore tails, somewhat longer SBs, and in shorter asci with thinner apical domes.

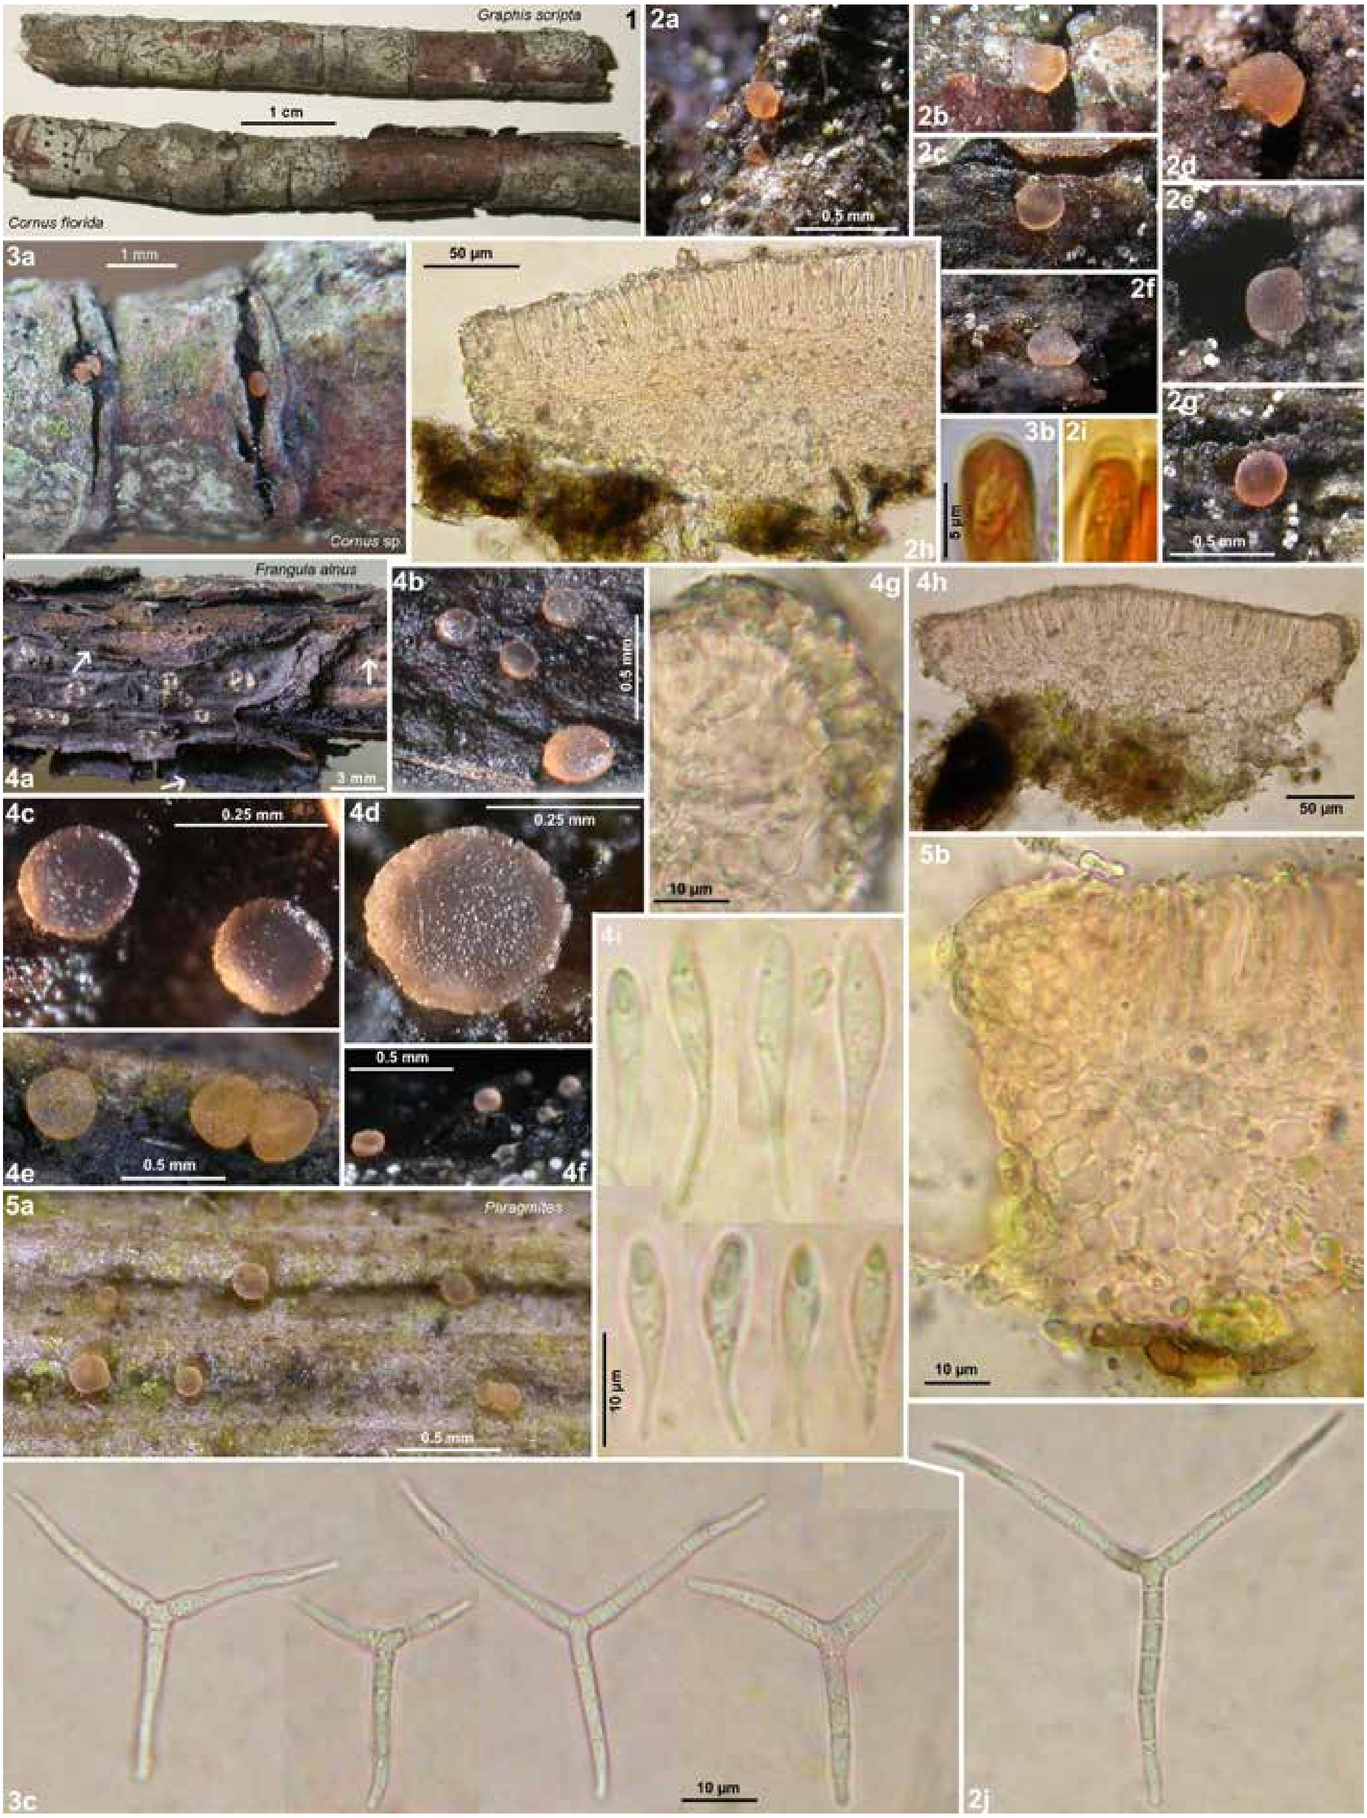

Plate 338. **1–4**: *Orbilia clavuliaristata*; **5**: *Orbilia* cf. *clavuliaristata*. – **1**, **3a**, **4a**. dead corticated xeric branches; **4b–f**. fresh apothecia; **2a–g**, **3a**, **5a**. rehydrated apothecia; **2h**, **4h**. apothecia in median section; **4g**, **5b**. id., marginal region; **2i**, **3b**. ascus apices; **4i**. ascospores; **2j**, **3c**. conidia from substrate. – Living state, except for **2h** (in KOH), **2j** (in H_2O), **3c** (3 left conidia, in H_2O), **4i** (2 spores on upper right). — **1**. H.B. 7403: USA, Tennessee, on *Cornus*; **2a–j**. H.B. 7404: ibid., on *Cornus*; **3a–c**. H.B. 7401: USA, North Carolina, on *Cornus*; **4a–i**. H.B. 9419 (holotype): Germany, Traunreut, on *Frangula*; **5a–b**. H.B. 7737: Luxembourg, Mersch, on *Phragmites*.

O. breviaristata differs in shorter and thicker spore heads and apothecia with prominent marginal teeth. The spore heads of *O. clavuliaristata* resemble those of *O. flagellispora* but that species sharply differs in mostly longer tails with always swollen bases.

Variation. Within the three North American specimens some variation can be noted. The one from North Carolina (18 m a.s.l., *Cornus* sp.) has distinctly shorter spores and SBs whereas those from Tennessee (500–540 m a.s.l., *Cornus florida*), tend to have inequilateral spores. Despite the short spores, the sample from North Carolina showed the longest asci. The European sample on *Frangula* fits quite well these specimens. Also here the ascus length is at the lower end of the range, while the spores attain the highest length (18 µm), also the heads of the spores are a bit longer compared to the North American specimens.

Not included collections. A sample on *Euphorbia* from Madeira (J.P. Priou, IVV: J.P.P. 15165, spores *13–17 × 2.1–2.5 µm, SBs 2.5–4 × 0.8–1.2 µm) fits quite well *O. clavuliaristata*, but is not included because of its different ecology. A collection from Boston Harbor Islands is intermediate to *O. subclavuliformis* in having wider spore tails and less fusoid heads but an SB length that fits *O. clavuliaristata* (IVV: bhi-F665). A central European collection on *Phragmites* (Pl. 337: 5) is not included because of the unusual substrate, rather thin (70–80 µm), pale rose apothecia, comparatively short asci, and slightly wider spores with rather short and wide SBs (SB size could be a result of overmaturity). *O. herbarum* Velen. differs from the latter collection in longer tails, according to the protologue (see p. 699).

Anamorph. The conidia observed on the substrate near apothecia of *O. clavuliaristata* are hardly different from those trinacrium-like conidia found in *O. clavuliformis* and related species.

Ecology. *O. clavuliaristata* was collected on medium decayed bark of xeric twigs and branches of angiosperms. Three samples on *Cornus* derive from warm-temperate humid forests of the southern Appalachian Mountains and coastal lowlands of eastern North America, while the type collection was on *Frangula* in a cold-temperate humid colline high moor (*Salici-Franguletum* among *Vaccinio-Pinetum*) in central Europe. The not included collection from cold-temperate humid central Europe was on a xeric culm of *Phragmites* in a *Phragmitetum* along a rivulet within a mixed forest, that from Macaronesia on *Euphorbia* in thermosubmediterranean semihumid southern Madeira, and that from Boston in cold-temperate humid northeastern North America.

Specimens included. **GERMANY**: **Bayern**, **Oberbayern**, 6.7 km NE of Traunreut, 2.8 km ESE of Palling, W of Lampertsheim, Harpfetshamer Filz, 570 m, branch of *Frangula alnus*, on bark, 18.VIII.2010, T.R. Lohmeyer (ex H.B. 9419, M-0276456, **holotype**). — **USA**: **North Carolina**, 33 km SE of Franklin, 6 km NE of Gatesville, Merchants Millpond State Park, Cypress Point Trail, 2 m, twigs of *Cornus*, on bark, 16.V.2003, W. Jaklitsch (H.B. 7401, W.J. 2134 ø, anam. substr.). – **Tennessee**, Appalachian Mts., Blue Ridge Mts., Great Smoky Mts., 23 km SE of Maryville, 9 km SSW of Townsend, Cades Cove, 540 m, twigs of *Cornus florida*, on bark, 22.V.2003, W. Jaklitsch (H.B. 7404, W.J. 2190 ø, anam. substr.). – Great Smoky Mts., 40 km ESE of Maryville, ~5 km SSW of Gatlinburg, Old Sugarlands Trail, 520 m, branch of *Cornus florida*, on bark, 24.V.2003, W. Jaklitsch (H.B. 7403, W.J. 2215 ø).

Not included. **LUXEMBOURG**: **Gutland**, **Mersch**, Luxembourg Plateau, 4.3 km S of Larochette, 1.2 km N of Koedange, below Folkend, Mäschpesch, 300 m, culm of *Phragmites australis*, 1.IV.2005, G. Marson (H.B. 7737). — **MACARONESIA**: **Madeira**, 2 km NW of Funchal, Jardín Botánico, twig of *Euphorbia balsamifera*, 265 m, 19.IX.2015, J.P. Priou (J.P.P. 15165, doc. vid.). — **USA**: **Massachusetts**, 16 km SE of Boston, 3.5 km NNE of Hingham, Slate Island, 2 m, branch of indet. angiosperm, on wood, 21.III.2017, A.C. Dirks & L.A. Kappler, vid. L. Quijada (bhi-F665, doc. vid.).

Orbilia aristata (Velen.) Velen., Opera Bot. Čech. 4: 104 (1947) — Pls 339–343, Map 58

≡ *Orbilia occulta* (Rehm) Sacc. var. *aristata* Velen., Monogr. Discom. Bohem.: 102 (1934)

(?) = *Radotinea caudata* Velen., Monogr. Discom. Bohem.: 298, pl. 17 figs 57, 58, 70 (1934) [non *Orbilia caudata* Starbäck]

Etymology: *aristata*: referring to the long and thin, awn-shaped ascospore tails; *caudata*: likewise from the spores having prominent basal tails.

Typification: Czechia, Mnichovice, branch of *Salix aurita*, 7.XII.1927, J. Velenovský (PRM 152468, holotype of ***Orbilia occulta* var. *aristata***); Germany, Stuttgart, Weilimdorf, branch of *Salix eleagnos*, 23.VI.2000, H.O. Baral & E. Weber (ex H.B. 6713, M-0291760, epitype, designated here, MBT385115, CBS 140834; sq.: KT596782, genotype 1) — Czechia, Radotín, branch of *Cornus mas*, 31.III.1927, J. Velenovský (PRM 151698, holotype of ***Radotinea caudata***, without apothecia).

Misapplied name: Rehm (1891: 459), Velenovský (1934: 102), Kirschstein (1936: 204), Svrček (1954: 10, 1960: 16), Ellis & Ellis (1985: 12), Beyer (1998: 191), as *O. occulta*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.2–0.6(–1) mm diam., (0.09–)0.1–0.2(–0.38) mm high (receptacle 0.075–0.13 mm), pale to bright rose or (ochraceous-)orange(-apricot), rarely reddish-cream, ± translucent, round, rarely elliptical, very scattered to densely gregarious; disc (slightly concave) flat to slightly (rarely medium) convex, margin thin, 0–15 µm protruding (5–25 µm incl. glassy processes), smooth or often finely powdered, or crenulate by small whitish teeth up to 20–30 × 30–40 µm; sessile or sometimes with an obconical or cylindrical stipe 0.06–0.08 or up to 0.15–0.2 × 0.12–0.2 mm, superficial but slightly immersed in biofilm; dry bright to deep orange-red(-apricot), somewhat contracted. **Asci** *(40–)45–62(–70) × (6–)6.2–7.5(–8) µm {18}, †(34–)38–55(–58) × (5–)5.5–6.5(–7) {11}, 8-spored, spores 2–4-seriate, 1–**2**–3(–4)((–5)) lower spores inversely oriented {49} (never mixed), pars sporifera *(29–)30–35(–40) µm long; **apex** (†) hemispherical to slightly truncate, dome †(1.1–)1.3–1.8(–2)((–2.3)) → 0.8–1 µm thick {14}, with or without apical chamber, endotunica bright red in $\mathrm{CR}_{\mathrm{SDS}}$; **base** with short to very long, thin to thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *((11.5–))(13–)14–22(–23)((–26)) × (2.5–)2.7–3.3(–3.5)((–4)) µm {77}, †(12–)14–20(–22) × (2.2–)2.5–3(–3.2) µm {18}, sperm-shaped: with ellipsoid-fusoid (rarely clavate) head and sharply differentiated filiform tail, head *(6–)7–9(–10) µm long, apex obtuse, sometimes subacute, rarely rounded, tail *(6–)8–12(–13)((–15)) × (0.25–)0.3–0.6(–0.8) µm, base usually not or only slightly inflated to *0.8(–1) µm wide {~160}, exceptionally bulbous, 0.8–1(–1.3) µm wide {6}, †0.2–0.6(–0.9) µm) wide, tail straight to slightly flexuous, exceptionally strongly bent; **SBs** *(2.5–)3–4(–4.5)((–4.8)) × (0.8–)0.9–1.3(–1.5) µm {25}, pyriform, also rod-shaped to subulate, apically narrowed to a small to ± wide point, overmature *2–3 × 1.2–1.7 µm, tear-shaped to ampulliform. **Paraphyses** apically (cylindrical to) slightly to medium (rarely strongly) clavate-capitate, rarely spathulate, terminal cells *(6–)10–25(–32) × (2–)2.3–3.5(–5.5) µm {7}, †10–22 × 1.8–2.7 µm {3}, lower cells *6–14(–16) × 1.5–2.5 µm {6}; sometimes branched at upper septum; hymenium very pale rose to light rose-orange. **Medullary excipulum** very pale to light rose, 30–80(–100) µm thick, of medium loose or dense textura intricata with many inflated cells, or t. globulosa-angularis, sharply or very indistinctly delimited. **Ectal excipulum** hyaline to pale rose, pale to light orange-rose near margin, of (†) thin-walled, vertically oriented t. angularis-prismatica from base to mid flanks, 20–80(–100) µm thick near base, cells *8–26 × (4–)7–16(–20) µm {9}; 15–40(–50) µm thick near margin, of t. prismatica-angularis oriented at a 50–90° angle to the surface, outer cells of t. porrecta oriented at 10–30°, marginal cortical cells *(6–)7–12(–16) × 1.8–4 µm {5}, **glassy processes** always present {> 80}, attaining a length of 1–5 {23}, 5–10 {19}, 10–15 {16}, 15–20 {12}, 20–30 {14}, or 30–40 {2} µm, (2–)2.5–4(–5) µm wide, refractive, sometimes ± stratified, straight or slightly curved up- or downwards, often forming ± distinct coherent teeth. **Anchoring hyphae** sparse to abundant, */†(1.5–)2–3(–5) µm wide, walls 0.2–0.4 µm thick {5}. **SCBs** in paraphyses and sometimes in ectal excipulum globose, 1–2.5 µm diam. {16}, rarely absent {3}.

Large pale yellowish **LBs** (carotenoids) in basal excipular cells usually absent, rarely present {3}, 1.5–3.5 µm diam. **Exudate** over paraphyses 1–3.5 µm thick, hyaline to pale yellowish-chlorinaceous, continuous to mostly cloddy-granular, loosely attached; on margin and flanks among glassy processes ± scattered, cloddy, 0.5–2 µm thick. — **ANAMORPH**: trinacrium- {–/9} (Y), descalsia- {1/9} (┼), and dwayaangam-like {2/10} (dw) (from ascospore or conidial isolate {3}/natural substrate {23}). **Conidiophores** not seen. **Conidia** variable in shape: 2-armed (Y-shaped, trinacrium subtile-like), total size †/*42–80 × 48–100 µm, stipe †/*22.5–55 × 2.2–3.5 µm, 3–6-septate, arms †/*27–51 × 2.2–3.5 µm, 4–7-septate {3}; 3-armed (┼-shaped, descalsia-like, tetraradiate in 3 dimensions when floating), total size †/*33–73 × 30–63 µm, stipe †/*13–31 × 2.1–3.5 µm, 2–5-septate, arms †/*12–41 × 2.3–3.5 µm, (1–)3–6-septate {6}; 4(–7)-armed (dwayaangam-like), total size *37–75 × 29–70 µm, stipe *12–20 × 2.8–3.8 µm, 2–4-septate, arms *13–42 × 3–3.5 µm, (1–)2–6-septate, 4–7-armed {4}; very rarely unbranched.

Habitat: collected (0–)0.2–3(–8) m above the ground, corticated (to partly, rarely entirely decorticated), dead or sometimes still-living, (2.5–)5–25 mm, rarely 30–50 mm thick branches or up to 20 cm thick trunks of *Abies alba* {3}, *Acer campestre* {1}, *A. glabrum* {1}, *A. pseudoplatanus* {2/1}, *Alnus alnobetula* {4}, *Amelanchier lamarckii* {1/1}, *Aronia melanocarpa* {1}, *Betula pendula* {1}, *Cornus* sp. {2}, *C. alternifolia* {1}, *C. sanguinea* {16}, *Corylus cornuta* {1}, *Cotinus coggygria* {1}, *Crataegus* sp. {1}, *Cytisus scoparius* {1}, *Fagus sylvatica* {13}, *Frangula alnus* {4}, *Fraxinus excelsior* {5}, *Ilex aquifolium* {2}, *Larix decidua* {1}, *Laburnum alpinum* {1}, *Ligustrum vulgare* {1}, *Lonicera periclymenum* {1}, *L. xylosteum* {1}, *Malus domestica* {5/1}, *Picea* sp. {1}, *P. abies* {5}, *Pinus* sp. {2}, *P. sylvestris* {4}, *Prunus domestica* {1}, *P. padus* {1}, *P. spinosa* {6}, *Punica granatum* {1}, *Pyrus communis* {1}, *Quercus rubra* {2}, *Rhus typhina* {2}, *Robinia pseudoacacia* {1}, *Rosa* sp. {5}, *Rubus* (?)*bifrons* {1}, *R. fruticosus* {9}, *R. idaeus* {1/1}, *R.* (?)*silesiacus* {1}, *Salix* sp. {22/1}, *S. alba* {1}, *S. aurita* {2}, *S.* ?*aurita* × *caprea* {1}, *S. caprea* {12/1}, *S. cinerea* {1/1}, *S. eleagnos* {1}, *S.* ?*fragilis* {1}, *S. rhamnifolia* {1}, *Sorbus* sp. {1}, *S. aria* {1}, *S. aucuparia* {3}, *Syringa vulgaris* {3}, *Taxus baccata* {1}, *Thuja plicata* {1}, *Tilia tomentosa* {1}, *Ulmus* sp. {1}, *U. minor* {1}, *Viburnum lantana* {1}, *Vitis vinifera* {2}, indet. angiosperm {1}, on 0.1–0.5(–1) mm deep (slightly to) medium (to strongly) decayed bark {146} (bast {69} or periderm {24}), more rarely wood {39}, often in small cracks of bark, or on detaching bark (on edges and inner surface), frequently along old wounds, sometimes on blackened resin {3}, also on largely decorticated wood, rarely on boring dust of bark beetles; Phenology of *O. aristata*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
12	17	12	18	21	19	16	31	11	11	18	6

Taxonomic remarks. *Orbilia aristata* is characterized by sperm-shaped ascospores composed of an ellipsoid-fusoid head and an abrupt, long and thin tail which is usually not inflated at the base, also in short to medium long glassy processes that may form small whitish teeth at the margin. For the very similar *O. subaristata*, *O. breviaristata*, *O. flagellispora*, *O. clavuliaristata*, and *O. fimbriata* see there. The North American *O. occulta* and *O. spermoides* and Australian *O. austroocculta* are sharply separated from all these species by much shorter though equally wide spore heads, the former two also by the presence of crystalloid SCBs. Confusion with the much more rare *O. pseudoaristata* (series *Albovinosae*, section *Aurantiorubrae*) is easily possible. This species sharply differs in truncate thin-walled ascus apices in the dead state, also in wider, more tear-shaped SBs.

Variation. *O. aristata* is somewhat variable in length and width of the ascospores, also in shape of spore heads, length and occasional basal inflation of spore tails, and in SB length.

P. Perz; **21**: phot. M. Bemmann. —

Spore length varies from *13–17 to 18–23 µm, spore width from *2.5–2.8 to 3–3.5 µm, with exceptionally values of 26 µm in length or 3.8–4 µm in width. Variation in spore length is mainly due to a variable tail length, but also to a different length of the head. SB length varies from *3–3.5 to 3.5–4.5 µm. A specimen from Mongolia had extraordinarily long spore tails (11–15 µm, J.P. Priou pers. comm.), whereas the spores in a collection from Altay Republic (E.S. Popov pers. comm.) were with (7–)9–11 µm long tails quite typical (the other Mongolian sample had hardly any developed spores; all three samples were on *Salix*).

The tail bases are usually not thicker than their middle part, but in some collections a bulbous basal inflation was seen in a few spores. In *O. subaristata* and *O. flagellispora* this bulbous inflation is more frequently present, but due to an often great variability within each population, the taxonomic importance of the feature should not be overestimated.

A German collection on *Pinus* needles (Pl. 339: 9) seems to belong to *O. aristata*, although the spore tails had sometimes a bulbous base reminiscent of *O. subaristata*. However, Beyer (1998: 191, fig. 59) did not notice such inflation in the same specimen, and also in another collection on pine needles (I. Wagner, IVV: 16.II.2012) no distinctly inflated tail bases were seen. Probably this is only a matter of how many free spores were available for study. Inflated tail bases were rarely seen in a few spores of some other collections of *O. aristata*, e.g., on *Malus* (Poland, IVV: 9.VIII.2006), *Salix* (Luxembourg, 8.V.1997, unillustrated), and *Rubus* (Germany, 9.VIII.1999, unillustrated).

The length of the glassy processes varied rather strongly among the populations, but often also within them. Usually they did not exceed a length of 15–20 µm, but in a number of samples they attained 25, 30, 35, or even 40 µm. For instance, a length of 20–35 µm was noted on *Picea* from Poland (P.P. 20060625-4), and 5–25 µm on *Sorbus* from Lapland (H.B. 9406a). In a sample on the inner surface of bark of a standing trunk of *Fagus* from Luxembourg (Pl. 340: 3), the processes varied between 10–20 and 15–35 µm. A correlation to the substrate or geographical origin could so far not be seen within European records. Also a North American collection (on *Acer glabrum*, IVV: H.B. 5672a) had extraordinarily long glassy processes (up to 20–40 µm), but another (on *Corylus cornuta* IVV: H.B. 6030) only 2–8 µm. Both were from Colorado, and their consistently uninflated spore tails appear to forbid placement in *O. subaristata*. Rather short glassy processes (up to 5 or 10 µm) were noted in quite a lot of European collections, but also in specimens from central Asia, and intermediate cases were also frequent. This variation in length of glassy processes results in striking macroscopical differences in the apothecial margin (see Pl. 340). But even if some or all apothecia of a population had smooth margins, they always possessed at least very short processes.

Apothecial size varied among the populations between (0.1–)0.15–0.25 and 0.3–0.7(–1) mm, and colour from pale to bright and between rose and orange. Also the thickness of the apothecia differed between 0.1–0.12 and 0.15–0.2 mm, exceptionally 0.38 mm, especially depending on the occasional presence of a stalk which was characteristic of some collections.

In three collections (P.P. 20060809-3, P.P. 20070303, H.B. 9226a), large hyaline to pale yellowish LBs in the basal cells of the ectal excipulum were seen. This feature was not observed in any other collection of *O. aristata*, whenever the ectal excipulum was studied (a similar variation was noted in *O. flagellispora*).

Nomenclature and type studies. The first report of *O. aristata* (under the name *O. occulta*) appears to be that of Rehm (1891), who believed that his European collections fit exactly the North American type material of *O. occulta*. Also later authors have adopted the name *O. occulta* for European specimens with spores with ovoid-ellipsoid heads and long, thin tails. However, *O. occulta* differs in several points from *O. aristata* (see below) and is so far only known from the east of North America.

Velenovský (1934: 102, Pl. XI fig. 5) reported and figured under the name *O. occulta* [var. *occulta*] several Bohemian collections (on dry, sun-exposed branches of *Populus tremula*, *Frangula alnus*, *Crataegus*, *Carpinus*, Pl. 341: a, see also Fig. 154), with apothecia 0.3–0.6 mm diam., fire-red or rose, asci 25–30 × 5 µm, and spores up to 20 µm, with heads 6–10 µm and tails of same length. From these samples he separated in a note under this species in a few words a sample on bark of *Salix aurita* as a new variety *O. occulta* var. *aristata* (Pl. 341: b), based on smaller (0.2–0.3 mm), amber-coloured apothecia, much larger asci (50 × 8–10 µm, only shown in unpublished manuscript), and shorter spores (total length 12–15 µm, spore heads ~6–7 µm long according to sketch). The author compared both varieties with the South American *O. caudata*. Although Velenovský's diagnoses are very brief, his illustrations leave little doubt that he was dealing in both cases with *O. aristata* as circumscribed in the present study.

Reexamination of the holotype of ***O. occulta* var. *aristata*** confirms identity with our concept of this species. Contrary to Svrček's (1954) statement, the type specimen is not empty: it contains about 20 apothecia growing on bark (rehydrated ~0.13–0.25 mm diam., now pale cream). The abundant glassy processes measure 8–15 × 3–4 µm and form only very indistinct teeth at the margin. The asci concur in their length with the original data but are much narrower (Pl. 339: 1) which better meets the length/width ratio in Velenovskýs sketch. The material does not show any clear microscopic differences to Velenovský's description under the name *O. occulta* [var. *occulta*]. Two larger, whitish, *Orbilia*-like fructifications grew in association. They contained only narrowly cylindrical phialides with rod-shaped conidia ~4–5 × 1 µm, and certainly do not belong to the *Orbilia*.

Later, Velenovský (1947: 104) attributed his var. *aristata* species rank on the basis of two further collections, on bark of *Salix aurita* and *S. caprea*. Svrček named one of them (the *S. aurita* collection) 'holotypus speciei', but could not detect any apothecia also here. No material of the other sample seems to exist. Since Velenovský (1947) did not provide a description, but clearly referred to his monograph as '*Orbilia aristata* Vel. Mon. 102', this name has to be considered as a status novum for *O. occulta* var. *aristata*, not a new species, and the 'holotypus speciei' is only authentic material. On the ± detached bark of this material a single minute apothecium could be detected, with fully

---

mature asci and glassy processes of 15–25 × 2.5–3 µm which form agglutinated teeth at the margin (Pl. 339: 4). Also here numerous discoid yellowish fructifications of an imperfect fungus grew in association, with rod-shaped conidia 3.5–5 × 1 µm.

Because *O. aristata* turned out to be genetically heterogeneous (see below), though being rather invariable in the morphology of the teleomorph, a solution must be found which fixes the name. We here designate a sample from Germany (Stuttgart-Weilimdorf, on *Salix*, ex H.B. 6713, CBS 140834) as **epitype** of *O. aristata*, because it is on the type substrate and in the clade with the majority of available sequences.

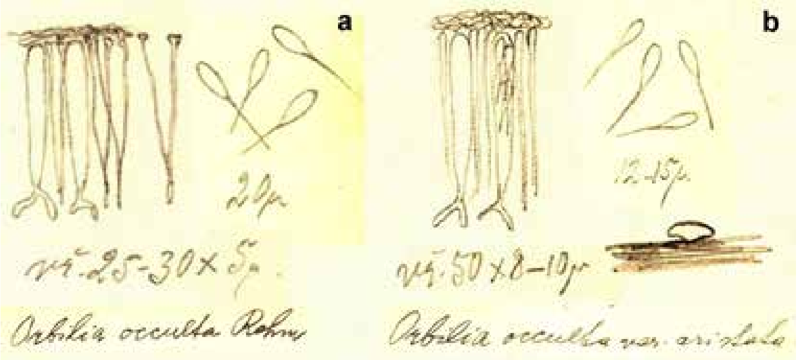

Plate 341. **a**. *Orbilia occulta* var. *occulta*, **b**. *O. occulta* var. *aristata* (holotype); both from Velenovský's unpublished manuscript (= *O. aristata*), with ascus and spore size.

In the holotype of ***Radotinea caudata*** (Czechia, Radotín, on corticated branch of *Cornus mas*, 31.III.1927, J. Velenovský, PRM 151698) no apothecia could be found, neither by Svrček (in sched.) nor in the present study, although it contains fairly many fragments of bark. The presence of a crustose lichen with black apothecia and a *Lophiostomataceae* indicate that the branch protruded in the air, which is also evident from the protologue (sun-exposed, dry, thermophilous slope). As already suspected by Svrček (1960, as *O. occulta*), the detailed original description appears to refer to *O. aristata* or perhaps *O. subaristata*, judging from the drawn 15–20 µm long ascospores and 15–35 µm long glassy processes (see Fig. 173). Velenovský depicted rather long glassy processes for *Radotinea caudata* reminiscent of *O. subaristata*, but this species seems improbable because he did not figure the least inflation at the tail bases, although his sketch on the manuscript plate shows 16 free spores. We also cannot exclude with certainty *O. pseudoaristata* (series *Albovinosae*), a species which differs from *O. aristata* mainly in truncate thin-walled ascus apices. Velenovský considered *Radotinea* to be intermediate between the hyaloscyphaceous genus *Olla* Velen. (because of solid hairs with a lumen only at the very base) and *Orbilia* (because of asci with a 'pedicello flexuoso, basi bilobo').

Since Velenovský attributed his variety *aristata* species rank not until 1947, *Radotinea caudata* has priority over *Orbilia aristata*. However, a new combination for *R. caudata* is blocked by *Orbilia caudata* Starbäck, therefore, the name *O. aristata* has to be chosen for the present taxon (Art. 53.1, Turland et al. 2018).

Not included collections. Two collections from northwestern France (Pl. 339: 11–12, on *Hedera* and *Populus*) somewhat resemble *O. clavuliaristata* in their more elongate spore heads. Spore heads similar to that on *Hedera* occurred also in other collections of *O. aristata* (e.g., Pl. 339: 6), but on *Hedera* the asci were extraordinarily short, and the apical domes thinner than usual (†0.8 → 0.5 µm). From *O. frullaniae* the *Hedera* specimen differs in wider spores and longer SBs, and in short glassy processes. In the collection on *Populus* the spore heads seem too large when compared with typical *O. aristata*. The associated conidia (Y-shaped on *Hedera*, Y- and ┼-shaped on *Populus*) do not differ from those of *O. aristata*. Also in this relationship appears to belong a very recent sample from Denmark on *Cryptomeria* (T. Læssøe, IVV: 24.I.2020).

In a sparse sample on *Salix* from northern Germany (Pl. 339: 10) only a single mature ascus was seen; it contained spores with rather thick spore tails, but the heads are too short to refer it to *O. clavuliformis*. A sample on *Acacia* from Réunion (Mascarene Islands, IVV: H.B. 9722e) includes a single, pale cream apothecium which was only studied in the dead state; it deviates from *O. aristata* in smaller, especially narrower spores (†11.5–15 × 2–2.2 µm). For *Radotinea caudata* from Czechia see above.

Anamorph. The anamorph of *O. aristata*, like that of the similar *O. subaristata* and *O. flagellispora*, is characterized by the occurrence of different conidial types: Y-shaped conidia with long arms and stipes similar to *Trinacrium subtile*, ┼-shaped descalsia-like conidia (3-dimensional), and 4- to more-armed dwayaangam-like conidia (probably also 3-dimensional).

One conidial and two ascospore isolates were available. In pure culture conidial production was stimulated by flooding with water. In one ascospore isolate (H.B. 6713: Stuttgart, on *Salix* bark) only tetraradiate (descalsia-like) conidia were seen, whereas in the two other isolates (G.M. 2014-06-21.1: Luxembourg, on *Rubus*, from ascospores; 20.V.2011: on *Fraxinus* bark, from conidia) only dwayaangam-like conidia were obtained. In the *Rubus* sample also a curucispora-like conidium was seen on the natural substrate besides many dwayaangam-like ones. This result, which is supported by deviating molecular data (see below), suggests that different species are involved which cannot be recognized by the teleomorph alone.

However, Ando (1992) reported in a Japanese isolate identified as *Trinacrium subtile* besides typical 2-armed conidia, which occurred in a frequency of more than 90%, five further conidial types, which are mostly comparable to those observed by us. He named them *Sigmoidea* (unbranched), *Lambdasporium* (2-armed), *Articulospora* (3-armed), and *Retiarius* or *Dwayaangam* (4-armed).

On the natural substrate we frequently observed trinacrium-, descalsia-, or dwayaangam-like conidia in association with apothecia, sometimes two together in a given population, e.g., *Trinacrium* & *Descalsia*, *Descalsia* & *Dwayaangam*, rarely *Trinacrium* & *Dwayaangam*, or all three together. Several transitional conidial forms were sometimes observed, similar as in *O. subaristata*. *O. aristata* sometimes grew in association with *O. subaristata* and *O. flagellispora* on the same branch, therefore, the observed mixture of conidial types might be due to the presence of different species. In two not included collections being intermediate to *O. clavuliformis* (Pl. 339: 11–12) we found similar trinacrium- and descalsia-like conidia: in H.B. 7386 predominantly descalsia-like, in H.B. 7387 solely trinacrium-like.

Phylogeny. Two different genotypes were observed within *O. aristata*. Sequences of genotype 1 were taken from an

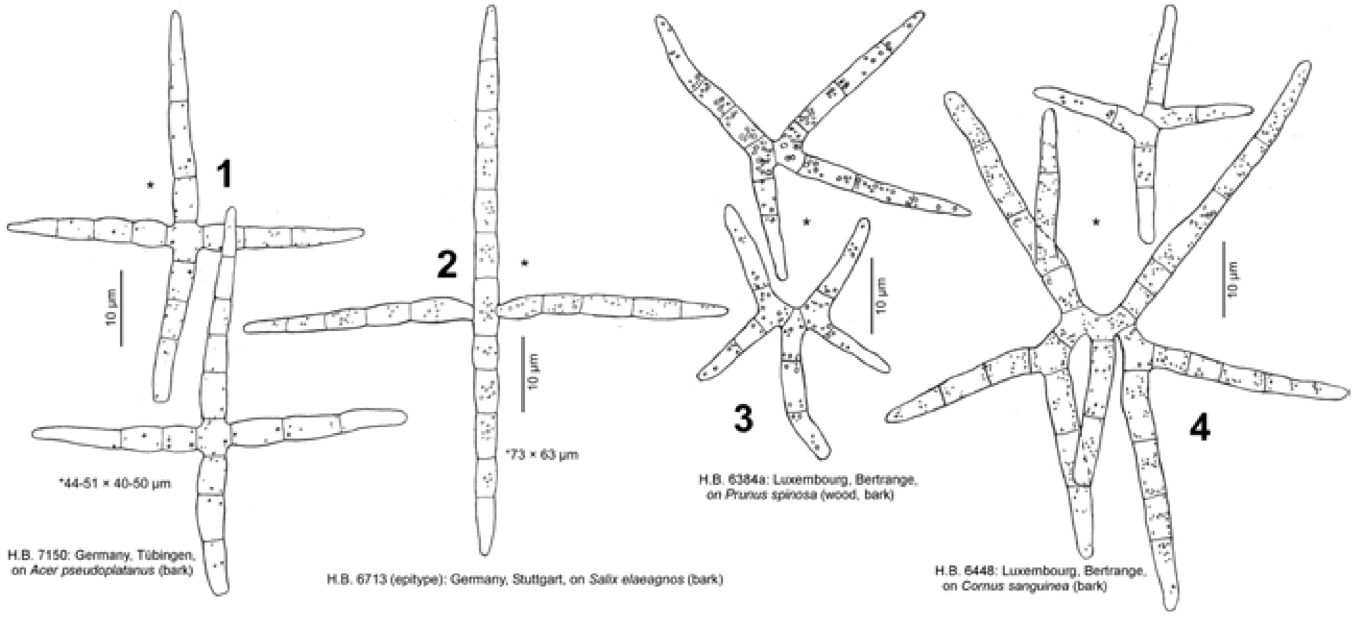

Plate 342. **1–4**: *Orbilia aristata*: conidia from culture (**2**) and substrate (**1**, **3–4**).

ascospore isolate of H.B. 6713 (Stuttgart-Weilimdorf, *Salix*, conidia descalsia-like, Pl. 342: 2) and from apothecia of three samples in which no conidia were observed: G.M. 2014-11-30.1 (Luxembourg, Roeser, *Rubus*, IVV), G.M. 2018-09-11.5 (France, Gap, *Fagus*, IVV) and G.M. 2014-12-30.1 (Luxembourg, Walferdange, *Fagus*, unillustrated).

Sequences of genotype 2 (conidia dwayaangam-like, Pl. 343: 5) derive from an ascospore isolate of G.M. 2014-06-21.1 (Luxembourg, Roeser, *Rubus*) and a conidial isolate of G.M. 2011-05-20.1 (Itzig, Luxembourg, *Fraxinus*). Sequences of type 1 comprise SSU+ITS+LSU, those of type 2 ITS+LSU or ITS, respectively. All are without S1506 intron (in the sample from Itzig the intron region is not covered).

In the ITS region the two strains with dwayaangam-like conidia (genotype 2) are identical, and likewise the strains with descalsia-like or without observed conidia (genotype 1) concur with 1 nt deviation in the ITS1 (A in Germany & France, G in Luxembourg). In the available parts of SSU (V8–V9) and LSU (D1–D2/D3) the strains of genotype 1 are identical. However, the two genotypes show a distance of 5 % in ITS (22–23 nt and 6 gaps) and 1.5 % in LSU D1–D2. This distance in the ITS/LSU exceeds that between *O. aristata* genotype 1 and *O. flagellispora* (3.5–3.8/0.2 %) or *O. subaristata* (3.5–3.8/0.8–1 %), while the distance between *O. aristata* genotype 2 and *O. flagellispora* or *O. subaristata* lies around 4.5–5/1.8–2.3 %. The two genotypes of *O. aristata* do not even form a clade of their own in our analyses of the ITS and/or LSU region (Phyls 9, 12, S12).

This preliminary result strongly suggests that two species are involved which might turn out to be characterized by different types of predominantly formed conidia. In the teleomorph no differences could be detected regarding ascospore and SB size. The length of the glassy processes varied within genotype 1 between 1–3 µm (*Salix*), and 18–35 µm (*Rubus* and *Fagus*), while no data were available for genotype 2.

A Chinese environmental strain (LN910274, almost entire ITS2) clustered unsupported with *O. aristata* s.str. and with a 7 % distance (Phyl. 12). Since the relationship of most of our collections and also the holotype of *O. aristata* remains unclear due to an uncertain or unknown connection to a conidial type, we feel unable at present to split *O. aristata* into two taxa.

Ecology. *O. aristata* occurs on ± rotten bark (rarely wood) of xeric branches and trunks of various gymno- or predominantly angiosperm trees and shrubs, rarely on coniferous leaves. The most favourite substrates were *Salix* {44}, *Cornus* {19}, *Fagus* {13}, *Rubus* {12}, *Prunus* {8}, *Malus* {6}, *Rosa* {5}, and *Sorbus* {5}, but also on different conifers {17}. Only a single record on *Quercus* and none on *Carpinus* came to our notice. Exceptional collections were on herbaceous substrates (*Humulus*, *Heracleum*). *O. aristata* has been reported in the literature under the name *O. occulta* on bark of *Malus* (Rehm 1891) and *Pyrus* (Kirschstein 1936), also on wood of *Populus*, *Frangula*, *Crataegus*, *Carpinus* (Velenovský 1934), *Prunus spinosa* (Svrček 1960), and *Salix* (Ellis & Ellis 1985). Especially Velenovský and Kirschstein emphasized the sun-exposed xeric habitat.

O. aristata is a very common species in cold-temperate humid areas of central Europe, where it occurs in moist or dry, ± thermophilous forests, especially at sun-exposed borders or in hedges, also in plantations and ruderal places. A few collections are from hemi- to oroboreal forests in Scandinavia, orotemperate (subalpine) alder bushes (*Alnetum viridis*) in the Alps, and mesotemperate atlantic lowland forests. Some other records are from orotemperate to orosubmediterranean humid forests in southern France and a mesosubmediterranean (semi)humid site in Montenegro. A few records indicate that the species also occurs in western North America and in central Asia: in the cold-temperate humid ponderosa pine and Douglas fir mixed forests of Southern Rocky Mountains and Colorado Plateau, in a continental, orotemperate subhumid, montane *Picea-Betula* mountain taiga in the Sayan mountains of Altay and a willow steppe in the altimontane (sub)humid (winter-dry) highland forests of central Mongolia. *O. aristata* was only exceptionally found in the summer-dry semihumid eumediterranean belt, where the very similar *O. subaristata* occurs.

The not included sample on bark of *Acacia* from Mascarene Islands east of Madagascar was from a warm-temperate subhumid (winter-dry) angiosperm woodland.

Orbilia subaristata Baral, G. Marson & Matočec, **sp. nov.**, MB 813611 — Pls 344–347, Map 59

Etymology: named according to the close similarity with *O. aristata*.

Typification: Luxembourg, Esch-sur-Alzette, Kayl, twigs and branches of *Cornus sanguinea*, 17.VII.2001, G. Marson (ex H.B. 7005a, M-0276591, holotype).

Latin diagnosis: *Similis* Orbiliae aristatae *sed excipulum marginale processis vitreis longioribus*, *dentes albidos exiguos formantibus praeditum*, *ascosporae cauda paulo longiore*, *basi saepe inflata et curvata*, *asci paulo longiores. Habitat ad corticem putridum*, *raro lignum*, *ramulorum et ramorum siccorum fruticum vel arborum angiospermarum, raro coniferarum, in zona thermo-ad submediterranea semihumida, etiam (oro)temperata humida Europae meridionalis et occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.9(–1.4) mm diam., (0.11–)0.16–0.25(–0.38) mm high (receptacle 0.12–0.17 mm), light to bright orange(-rose) or orange(-ochraceous), round, very scattered to gregarious; disc flat, rarely slightly convex with age, margin 0–60 µm protruding (incl. teeth), usually with prominent whitish teeth, rarely smooth; broadly sessile or with distinct stipe 0.1–0.2 × 0.15–0.4 mm, superficial; dry deep orange-red. **Asci** *(45–)50–75(–94) × (6–)6.3–7.5(–8.3) µm {15}, †45–70 × 5.5–6.5 µm {2}, 8-spored, spores 2(–4)-seriate, (0–)1–3(–4) lower spores inversely oriented {22} (not mixed), pars sporifera *26–40 µm long; **apex** (†) hemispherical, dome †1.2–2.3 → 0.8–1.5 µm thick {8}, with apical chamber; **base** with short to medium long, ± thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *((13.5–))(16–)18.5–24.5(–27) × (2.5–)3–3.5(–3.8) µm {26}, †(15.5–)17–24(–25)((–29)) × 2.6–3.4(–3.6) µm {12}, sperm-shaped: with ellipsoid-fusoid (to fusiform) head and sharply differentiated filiform tail, head *7–10 µm long, apex obtuse to acute, tail *(10–)11–15(–16.5) × 0.3–0.6(–0.8) µm, base of tail in the majority of spores slightly to ± strongly inflated (bulbous), in some collections not or only slightly so, *(0.4–)0.7–1.3(–1.8) µm thick {13}, †0.5–1.2 µm {4}, head in profile view sometimes somewhat inequilateral, tail straight or slightly to medium curved (often only at base); **SBs** *(3–)3.5–4.2(–4.7) × (1–)1.1–1.3(–1.4) µm {12}, rod-shaped, subulate, pyriform to ampulliform, apically narrowed to a small or wide point. **Paraphyses** apically uninflated to medium (rarely strongly) clavate-capitate (rarely spathulate), sometimes flexuous, terminal cells *8–20(–24) × 2–4(–5.5) µm {5}, lower cells *9–13.5(–16) × 1.7–2.5 µm {3}; rarely or infrequently branched near apex, hymenium light orange. **Medullary excipulum** pale rose, 30–80(–100) µm thick, of medium dense textura intricata with many inflated cells, or t. globulosa, very indistinctly to rather sharply delimited. **Ectal excipulum** pale to light rose-orange, of (†) slightly gelatinized, vertically oriented t. angularis(-prismatica) from base to mid flanks, 30–150 µm thick near base, cells *8–20 × 6–12 µm {3}, common walls †0.5–1.3 µm thick; 20–30 µm thick at flanks, cells *4–9 × 3.5–6 µm, near margin 20–30 µm, of t. prismatica-porrecta oriented at a 45–90° angle to the surface, outer layer of narrower hyphae oriented at 20–30°, marginal cortical cells *(4–)6–11(–16) × 2–4 µm {4} (12–18 µm long at mid flanks), **glassy processes** present {47}, (8–)15–50(–80) × 2–3.5(–3.8) µm {14}, refractive, faintly stratified, coherent to form small to mostly large teeth (10–)20–60(–80) × (10–)20–60 µm. **Anchoring hyphae** sparse to abundant, *2–3 µm wide, walls 0.2(–0.3) ((–0.5)) µm thick {3}, forming an up to 50 µm thick dense t. intricata at base. **SCBs** globose, in paraphyses 1–2.5 µm diam., in excipular cells 1–3 µm diam. **Exudate** over paraphyses 1.5–4 µm thick, cloddy, loosely attached, hyaline to scarcely yellowish; over margin and flanks absent. — **ANAMORPH**: trinacrium- {1/4} (Y), descalsia- {1/12} (┼), and dwayaangam-like {-/4} (dw) (from ascospore isolate {1}/ natural substrate {12}). **Conidiophores** not seen. **Conidia** variable in shape: 2-armed (Y-shaped, trinacrium-like): total size *23–70 × 23–87 µm, stipe *10–45 × 2.8–3 µm, 1–7-septate, arms *15–64 × 2–3.5 µm, 3–9-septate {2}; 3-armed (┼-shaped, descalsia-like, tetraradiate in 3 dimensions when floating): total size */†52–70 × 50–85 µm, stipe */†17–25 × 2.7–3.5 µm, 2–3-septate, arms */†22–41 × 2.7–3.5 µm, 3–6-septate {5}; 4(–5)-armed (dwayaangam-like): total size */†27–95 × 34–115 µm, stipe */†15–30 × 2–3.5 µm, 2–4-septate, arms */†7–60 × 2–2.7 µm, 1–6-septate, 4–5-armed {3}; very rarely unbranched.

Habitat: collected 0.1–3 m above the ground, corticated to partially decorticated, 3–27(–70) mm thick twigs and branches of *Acer campestre* {1}, *Aeonium arboreum* {1}, *Arbutus unedo* {1}, *Carpinus* sp. {1}, *C. betulus* {1}, *Crataegus* sp. {1}, *C. monogyna* {2}, *Ceratonia siliqua* {1}, *Cercis siliquastrum* {5}, *Cistus* sp. {1}, *Cornus sanguinea* {6/1}, *Crataegus monogyna* {1}, *Echium leucophaeum* {1}, *Fraxinus* sp. {2}, *Juniperus communis* {1}, *Olea europaea* {2}, *Pistacia lentiscus* {1}, *Pinus brutia* {3}, *P. halepensis* {1}, *Punica granatum* {2}, *Pyrus spinosa* {2}, *Quercus* sp. {1}, *Q. coccifera* {1}, *Q. ilex* {2}, *Q. rotundifolia* {1}, *Q. pyrenaica* {1}, *Rhamnus alaternus* {1}, *Rosa* sp. {7}, *R. ?canina* {1}, *Rubus fruticosus* {1}, *Salix* sp. {2}, *S. caprea* {1}, *Spartium junceum* {1}, *Vitis vinifera* {1}, on 0.1–0.5 mm deep (slightly or) medium to strongly decayed bark {48} (bast, rarely periderm), rarely wood {10} or resin {1}, sometimes close to or on old pyrenomycetes, ± greyed, covered by sparse to abundant green algae. **Associated**: *Baggea* sp. {2}, *B. pachyascus* {1}, *Candelariella lutella* {1}, ?*Calloria* sp. {3}, ‘*Chlorosplenium*’ *viridulum* {1}, *Claussenomyces* sp. {1}, *Cryptodiscus* sp. {1}, *C. foveolaris* {1}, *C. pallidus* {1}, *Dacrymyces* sp. {1}, *Durella atrocyanea* {1}, *D. ?compressa* {1}, *D. connivens* {1}, *Hyalorbilia erythrostigma* {1}, *H. orbiliicola* (parasitic on *O. subaristata*) {1}, *Hyphodiscus theiodeus* {1}, *Hysterobrevium mori* {1}, *Hysteropatella* sp. {1}, *H. elliptica* {1}, *Ionomidotis fulvotingens* {1}, *Karstenia* sp. {2}, *K. idaei* {1}, *K. rhopaloides* {1}, *Lecidella elaeochroma* {1}, *Melanelia glabratula* {1}, *Mellitiosporiella pulchella* {3}, *Mollisia ligni* {1}, *M. rosae* {1}, *Nitschkia broomeana* {2/1}, *Orbilia aristata* {2}, *O. carpoboloides* {2}, *O. ?cejpii* {1}, *O. cercidicola* {3}, *O. clavuliformis* {1}, *O. delphinus* {3}, *O. eucalypti* {1}, *O. euonymi* {1}, *O. flagellispora* {3},

(central Europe), 1–1320 m (southern Europe). **Geology**: Lower Jurassic sandstone & Minette, marl & slate, Cretaceous limestone, dolomite, flysch, Miocene sandstone, Tertiary molasse, Pleistocene sand & loess; granite, basaltic and trachybasaltic flows and pyroclasts. **Phenology**: throughout the year (long-lived).

Phenology of *O. subaristata*											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
2	4	7	2	5	8	2	8	7	8	7	2

Taxonomic remarks. *Orbilia subaristata* differs from *O. aristata* in consistently longer glassy processes forming distinct whitish teeth, in slightly longer asci and spore tails, the latter being often basally swollen and more or less curved, also in sometimes somewhat inequilateral spore heads, finally in the occurrence in more thermophilous and (oro)mediterranean sites. The similar *O. flagellispora* differs from both species in distinctly more elongate spore heads.

Variation. *O. subaristata* varied mainly in the spore tails which, even within a collection, often showed a very different strength of curvature and basal inflation. In some collections the tail bases were consistently only slightly swollen, and in some spores or specimens even not at all. Although matching *O. aristata* in spore shape, these collections are included in *O. subaristata* because of the presence of rather long glassy processes and a mediterranean provenance. A collection on *Pinus brutia* from southeastern Turkey was reported by Kaya et al. (2018) under the name *O. aristata*, but the slightly bulbous base of the spore tails and the large apothecia with often distinct white teeth clearly refer it to *O. subaristata*.

Anamorph. The conidia of *O. subaristata* are very similar to those of *O. aristata* and comprise the same types: Y- and ┼-shaped, and dwayaangam-like with 4–5-arms. The ┼-shaped conidia (tetraradiate, descalsia-like) occurred in almost every collection in which conidia were observed, but the other types were only seen in some of them. However, usually only a few conidia were found on the natural substrate. As in *O. aristata*, conidia in pure culture were only formed when flooded with water. Descalsia-like conidia predominated in culture, while less often trinacrium- and no dwayaangam-like conidia could

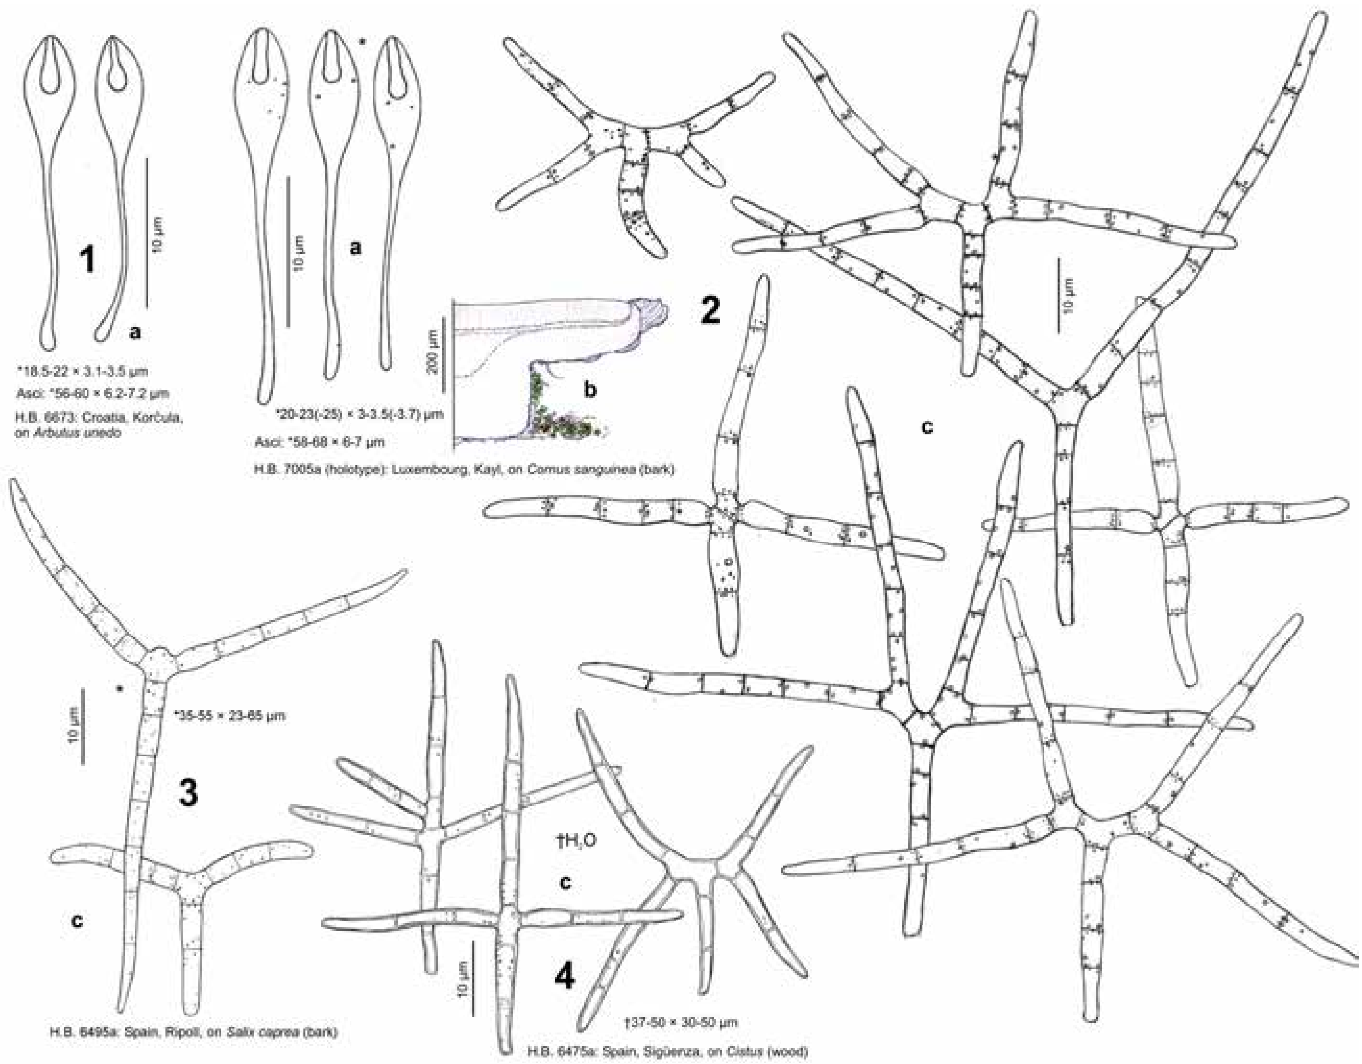

Plate 345. **1–4**: *Orbilia subaristata*. – **a**. ascospores; **b**. apothecium in median section; **c**. conidia from substrate.

be found. As a rule, descalsia-like conidia are in the majority also on the natural substrate, but sometimes spots with dwayaangam-like conidia occurred. The length of the arms varied rather strongly in all these conidial types.

Phylogeny. Sequences were taken from an ascospore isolate of a Croatian sample (H.B. 6685a, on *Punica*) comprising SSU, ITS, and LSU, and from apothecia of four samples comprising ITS and mostly also LSU, two from southern France (H.B. 9076 from Aix-en-Provence, H.B. 9151d from Nyons, both on *Cercis*) and three from Luxembourg (G.M. 2014-01-29.1, 2014-01-31.1, 2014-11-08.1, all from Kayl on *Cornus*). The S1506 intron is absent in all of them (G.M. 2014-01-31.1 includes only ITS2 and LSU). The six sequences are almost identical in the ITS region: the Croatian strain differs from all other samples by 2 nt in the ITS2, and that from Aix differs from all others by 1 nt. Between the strains from Nyons and Kayl no differences occur (a few positions are ambiguous).

The distance to *O. aristata* s.l. lies in the range of 3.5–5%, and to the other members of the *aristata-clavuliformis* clade at 2.8–3% (*O. flagellispora*), 4–5.5% to *O. clavuliformis*, 6% (*O. fimbriata*), and 6–7.5% to *O. subclavuliformis* (but 11–11.5% to *O. spermoides*/*occulta*). In the LSU (637 nt) the *O. subaristata* strains are identical and differ from *O. aristata* and *O. flagellispora* by 0.8–1% and from other species (including *O. aristata* with dwayaangam-like conidia) by min. 2–2.5%.

An unpreserved sample on *Cornus* from Luxembourg with unknown morphology (G.M. 2015-02-22.1), misidentified as *O. subaristata*, shows to *O. subaristata* a 6–6.5% distance in the ITS region (2% in the LSU D1–D2, no difference in D3), also it differs in possessing the S1506 intron. It clustered unresolved in the *aristata-clavuliformis* clade (Phyls 9, 12, S13), with a high distance to other species (*O. clavuliformis* ITS 5%, LSU 1%; *O. subclavuliformis* and *O. aristata* s.l. ITS 6–6.5%, LSU 1–1.5%; *O. fimbriata* ITS 6%, LSU 2%).

Ecology. *O. subaristata* was found on ± rotten bark (rarely wood) of xeric twigs and branches of various angiosperm trees and shrubs, exceptionally on gymnosperms (*Pinus brutia*, *P. halepensis*). Although *O. subaristata* sometimes grew in association with both *O. aristata* and *O. flagellispora*, it shows a rather different distribution area, being predominantly collected in the thermo- to supramediterranean phrygana or maquis, in supra- to mesosubmediterranean woodlands and orotemperate forests of southern Europe. However, *O. subaristata* was also repeatedly found in supratemperate humid subcontinental Europe, mainly at two sites in Luxembourg in thermophilous open woodlands with *Quercus*, *Salix*, *Cornus sanguinea*, *Crataegus*, *Prunus spinosa*, and *Sambucus nigra*. One of them represents the type locality, at which the *Cornus* bushes are scattered in a dry southeast-exposed grassland belt adjacent to a forest on a hill at the border of Lower and

Orbilia breviaristata Baral, Priou & G. Marson, **sp. nov.**, MB 813612 — Pls 348–350, Map 60

Etymology: referring to the tail of the ascospores which is much shorter than in *O. aristata*.

Typification: Germany, Tübingen, stem of *Rubus fruticosus*, 24.VII.2002, H.O. Baral (ex H.B. 7171a, M-0276444, holotype).

Latin diagnosis: *Similis* Orbiliae aristatae *sed ascosporae cauda multo breviore, asci paulo breviores. Habitat ad corticem vel lignum putridum ramulorum siccorum* Rubi, Euphorbiae *et fruticum* angiospermarum *in zona atlantica ad subcontinentale temperata locis thermophilis Europae occidentalis et centralis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.15–0.4(–0.5) mm diam., 0.06–0.12 mm high, pale to light rose or rose(-orange), medium to strongly translucent, round, subgregarious in small groups; disc flat, margin 5 µm protruding, with minute to often distinct whitish teeth; broadly sessile to subsessile, superficial; dry light to bright orange-rose, only slightly contracted. **Asci** *32–50 × (5.6–)6–7.3 µm {3}, †32–43 × 5.3–6.5 µm {3}, 8-spored, spores (*) biseriate, ((0–))1–2(–3)((–4)) lower spores inverted {4} (not mixed), pars sporifera *(21–)25–26(–31) µm long; **apex** (†) hemispherical, dome †1–1.8(–2) → 0.7–1 µm thick {3}, with slight to distinct apical chamber; **base** with short to long, medium thick, flexuous stalk, L-, T- or Y-shaped. **Ascospores** *(9.7–)10–13(–14) × 2.8–3.4(–3.6)((–3.8)) µm {10}, †(8–)9–12.5 × (2.5–)2.7–3 µm {5}, sperm-shaped: with ellipsoid-fusoid, *6.5–7.5(–8) µm long head and sharply differentiated filiform tail *(2–)3–5.3(–6) × 0.2–0.6 µm, apex obtuse to subacute, tail not swollen at base, straight to slightly (exceptionally strongly) geniculate towards head, ~½–¾ as long as head; **SBs** *2.8–3.8 × 1.1–1.3 µm {4}, pyriform to dumbbell-shaped, apically narrowed to a ± small point, overmature *2.5–2.8 × 1.4–1.5 µm. **Paraphyses** apically uninflated or often slightly (rarely strongly) clavate-capitate, terminal cells *(8.5–)12–20 × 1.8–3.5(–4.5) µm {3}, lower cells *4–9 × 1.7–2.3 µm {3}; not or rarely branched at upper septum. **Medullary excipulum** subhyaline, 15–40 µm thick, of dense textura intricata-globulosa with many inflated cells, very indistinctly to very sharply delimited. **Ectal excipulum** of light orange-rose, thin-walled t. globulosa(-prismatica) from base to mid flanks, 15–70 µm thick near base, cells *(5–)9–22 × (4–)7–19 µm {2}; 20–30 µm thick near margin, of t. prismatica oriented at a 50–70° angle to the surface, outer part of t. prismatica-porrecta oriented at 20–40°, marginal cortical cells *6–12 × 2.7–4 µm {1}, †7–12 × 2.2–3.2 µm {1}; **glassy processes** (3–)8–30(–40) × 2.5–3.5 µm {6}, high-refractive, sparsely stratified, coherent to form distinct teeth, predominantly curved inwards {3}. **Anchoring hyphae** medium sparse to abundant, */†1.5–3.2 µm wide, walls 0.2–0.3 µm thick {2}. **SCBs** in paraphyses and marginal excipular cells globose (to elongate), 1.8–3(–4) µm diam. **Exudate** over paraphyses 1–2.5(–3) µm thick, cloddy, coarsely rough, loosely attached, hyaline; over margin 0.2–0.3(–1) µm thick, continuous, rough. — **ANAMORPH**: descalsia-like (presumed, from natural substrate {1}). **Conidiophores** not seen. **Conidia** ┼-shaped, total size *62–66 × 47–50 µm, stipe *30–31 × 3.5–4 µm, 3–4-septate, arms *30–38 × 3.5–4 µm, 4–5-septate.

Habitat: collected 0.7–2 m above the ground, on partially to entirely decorticated stems of *Euphorbia characias* {1}, *Rubus fruticosus* agg. {3}, *Rubus* (?)*bifrons* {1}, 8–15 mm thick branches of *Cytisus scoparius* {2}, *Frangula alnus* {1}, *Pinus* ?*nigra* {1}, *Ulex europaeus* {4}, on very decayed wood {9} or bark {3} (periderm-free bast), also on splitted bark, along deep clefts, or in beetle galleries (sometimes on boring dust), sometimes on wounds, medium greyed, often with many green algae. **Associated**: *Hyalorbilia latispora* {1}, *H. multiguttulata* {1}, *H. subfusispora* {1}, *Hyaloscypha minuta* {1}, *Karstenia rhopaloides* {2}, *Lophiostoma compressum* {1}, *Orbilia aristata* {1}, *O. aurantiorubra* {2}, *O. clavuliformis* {3}, *O. corculispora* {2}, *O. eucalypti* {2}, *O. filiformis* {1}, *O. subclavuliformis* {2}, *O. vinosa*

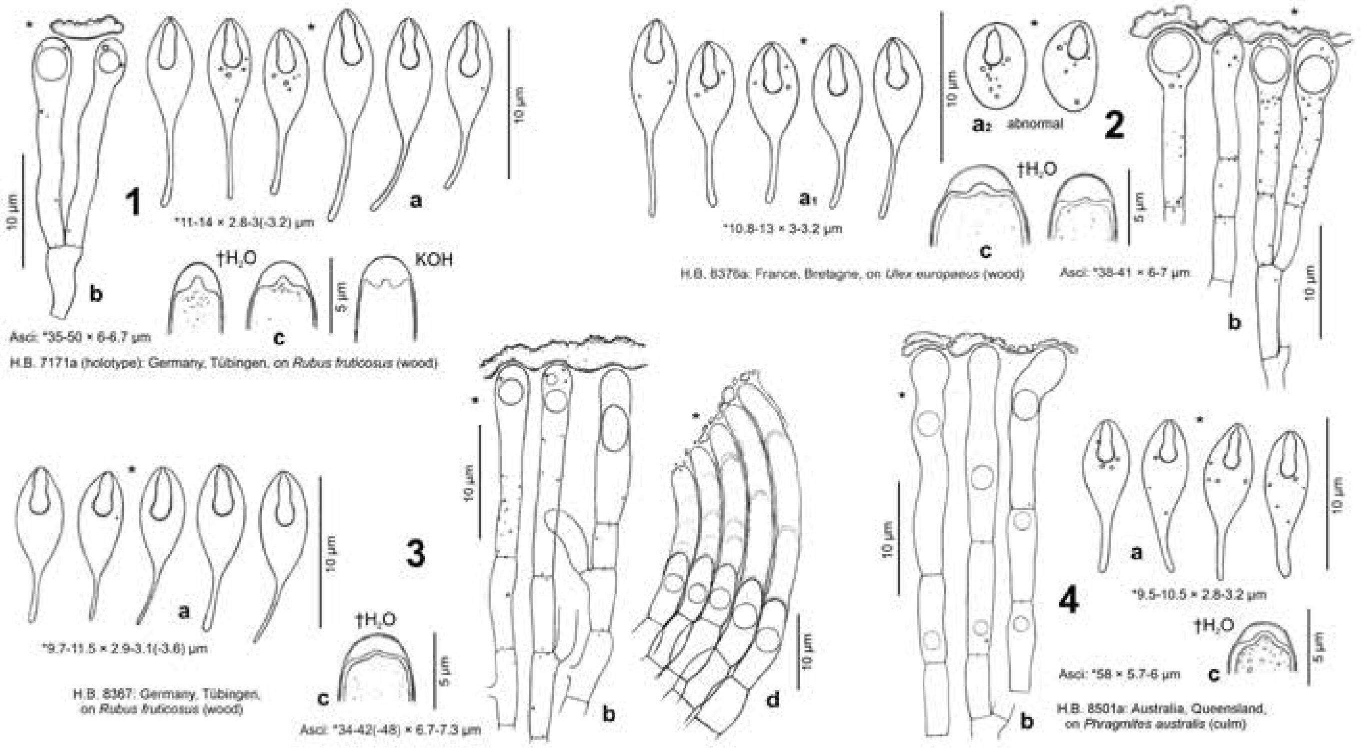

Plate 348. **1–3**: *O. breviaristata*; **4**. *O.* cf. *breviaristata*. – **a**. ascospores (**2a$_2$** 2 abnormal spores); **b**. paraphyses; **c**. ascus apices; **d**. marginal ectal excipulum in median section, cortical cells with glassy processes.

{1}, *O. vitalbae* {2/1}, *Pirottaea ?imbricata* {1}, *Pyrenopeziza rubi* {2}, *Sporidesmium* sp. {1}. *Unguiculariopsis* sp. {1}. **Desiccation tolerance**: excipular cells, paraphyses and immature asci still viable after 1 month, ascospores after 2 months. **Altitude**: 1–390 m a.s.l. **Geology**: Cambrian silt & wacke, Keuper (Knollenmergel etc.), Lower Jurassic & Cretaceous sand- & limestone, Quaternary sand & gravel; granite, gneiss. **Phenology**: II–IV, VI–VII, X–XII (throughout the year).

Taxonomic remarks. *Orbilia breviaristata* is very similar to *O. aristata*, except for the ascospore tails which are consistently and considerably shorter in all examined apothecia from all so far known collection sites. The asci are only slightly shorter than in *O. aristata*. If no free spores are found in a preparation, *O. breviaristata* is easily confused with *O. aristata* since the tails are often difficult to see in full length within the living asci. That this taxon is not an immature stage of *O. aristata* is indicated by the presence of fully developed SBs in the ascospores. Furthermore, the tails of immature ascospores (with not yet developed SBs) of both taxa are not shorter than those of mature spores, i. e., the tails attain their final length at an early stage of spore formation. Macroscopically, the apothecia of *O. breviaristata* tend to be smaller, paler and more translucent in comparison to *O. aristata*, and to have more distinct marginal teeth.

Also the spores of *O. occulta* and *O. spermoides* strongly resemble those of *O. breviaristata*, but their spore heads and SBs are shorter and slightly wider, and the excipular cells contain crystalloid SCBs. *O. multiaustraliensis* (series *Hesperidea*) resembles *O. breviaristata* in the spores, but differs, besides 32-spored asci, in the presence of crystalloid SCBs and absence of glassy processes. The Australian *O. megaocculta* differs in much wider asci and spores, much thicker spore tails, and much wider SBs.

Variation. In the collections on *Cytisus* and *Ulex* some of the glassy processes were very short (e. g., 3–12 µm in J.P.P. 29039, J.P. Priou pers. comm.) and, therefore, the margin was only finely denticulate or almost smooth (Pl. 349: 3a–b). In one collection of *O. breviaristata* a single aberrant ascus contained broader spores 5.7–6 × 3.7–4 µm, without any trace of a tail (Pl. 348: 2a$_2$).

Not included collections. In a Spanish sample on *Rubus* the apothecia entirely lack glassy processes and the spores tend to be more clavate (IVV: E.R.D. 7961). An Australian sample on culms of *Phragmites australis* (Pls 348: 4; 350, for a site photo see Pl. 620: 1a) differs merely in slightly thinner apical domes. The spore tails are comparatively short and thick. The specimen might be conspecific with European *O. breviaristata* but is not included mainly because of the deviating substrate

Map 60. Known distribution of *O. breviaristata* in Europe (yellow = not included collection).

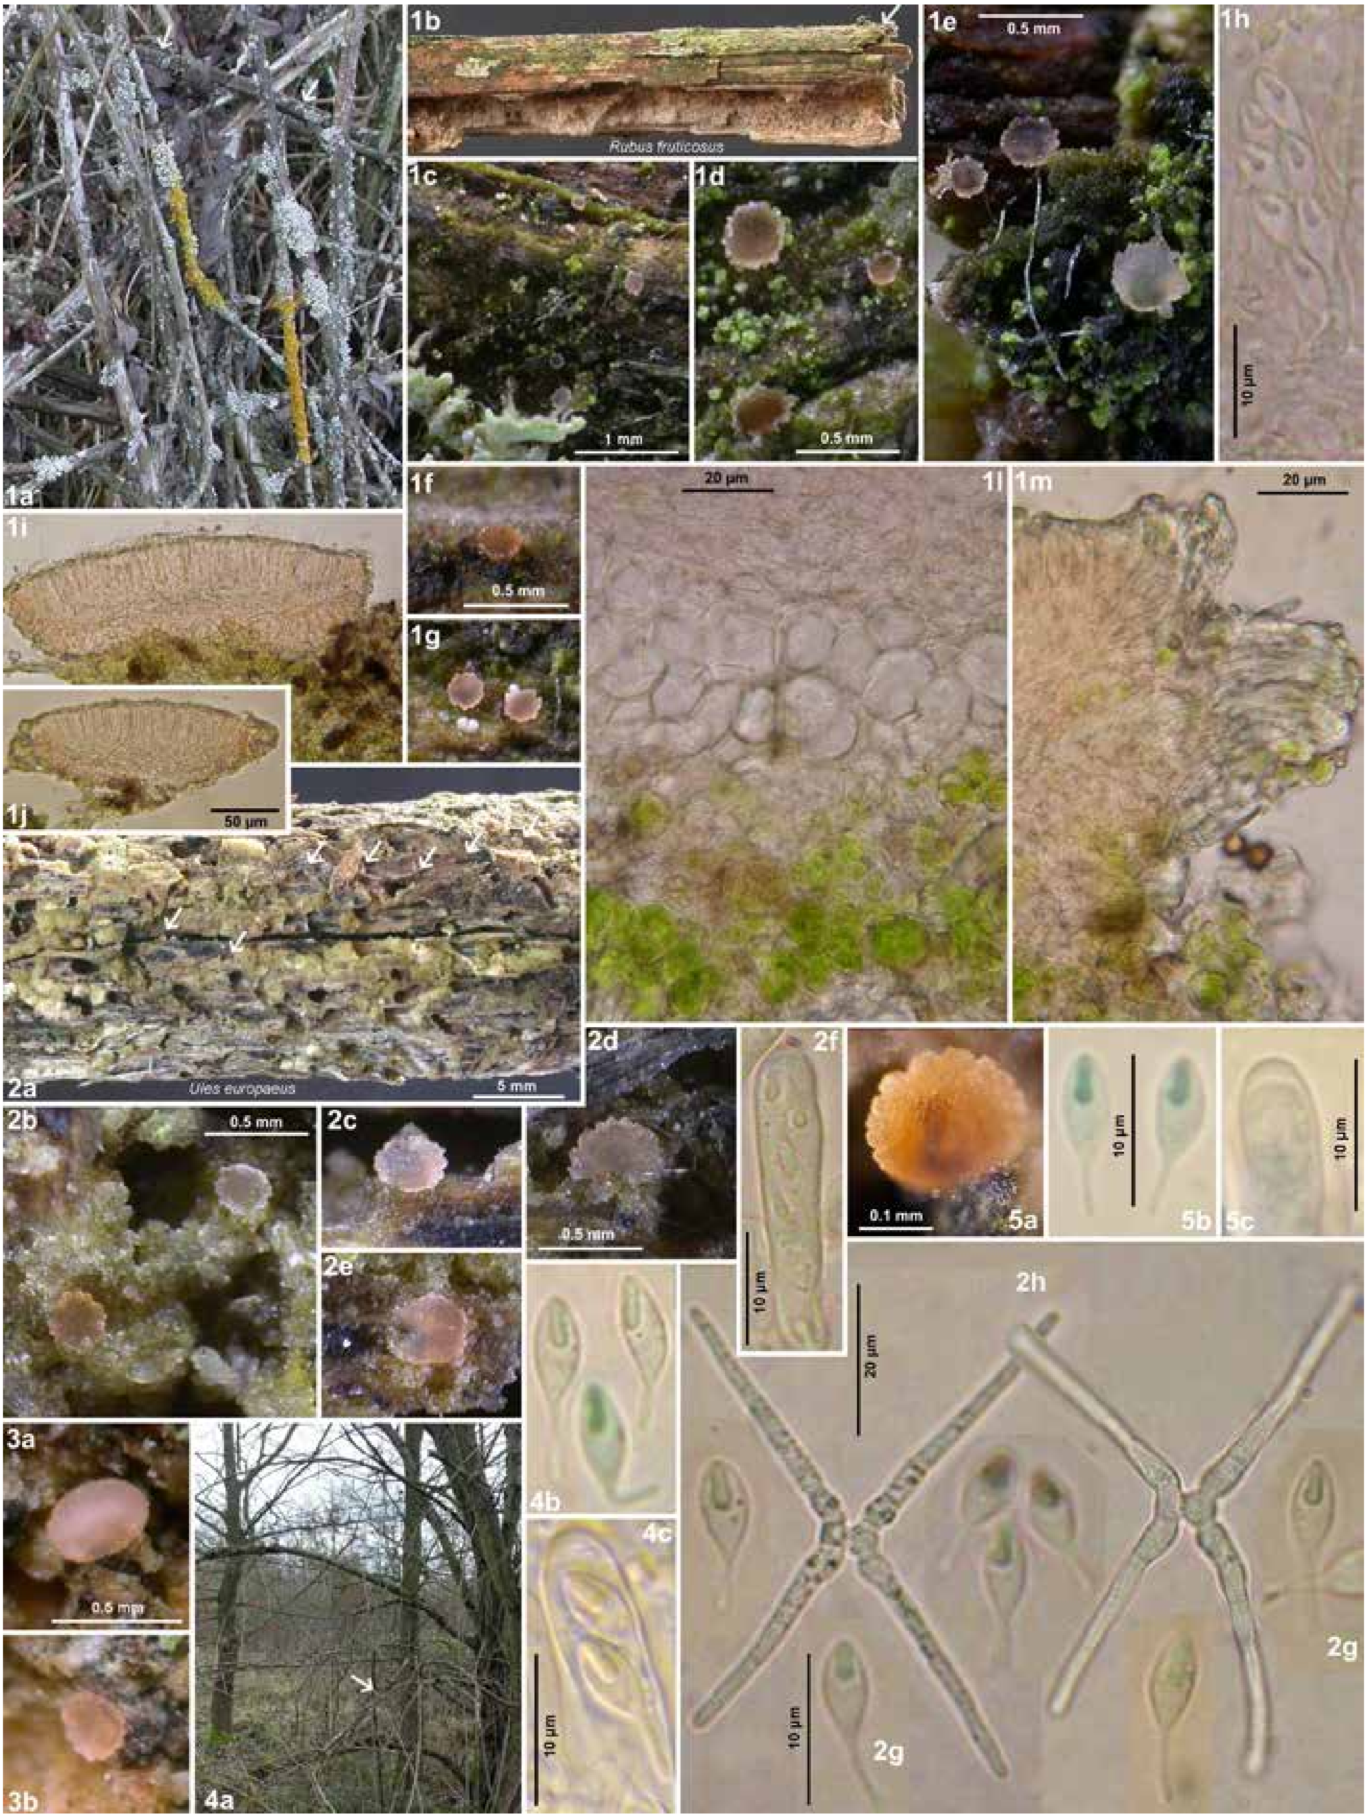

Plate 349. **1–5**: *Orbilia breviaristata*. – **1a**, **4a**. old stems of *Rubus fruticosus* ~ 1 m above the ground; **1b**. rotten stem of *Rubus fruticosus*; **2a**. decorticated xeric branch of *Ulex europaeus* with beetle galleries; **1c–g**, **2b–e**, **3a–b**, **5a**. rehydrated apothecia; **1i–j**. apothecia in median section; **1m**. id., marginal ectal excipulum with glassy processes; **1l**. id., basal ectal excipulum; **1h**, **2f**, **4c**. mature asci with spores; **5c**. apex of immature ascus; **2g**, **4b**, **5b**. ascospores; **2h**. conidia from substrate. – Living state (**4c**: oblique illumination) except for asci in **1h**, **2f**, **4c**, **5c** (in H_2O). – **3a–b**: phot. Plate 350. **1**: *Orbilia* cf. *breviaristata*. – **1a**. dead xeric culm of *Phragmites australis* blackened by *Arthrinium arundinis*; **1b–d**. rehydrated apothecia; **1e**. apothecium in median section (with dark brown conidia of *Arthrinium*); **1f**. apothecium in top view; **1g**. marginal ectal excipulum in median section; **1h**. id., basal ectal excipulum; **1i**. mature ascospores inside asci. – Living state, except for asci in **1i**. — **1a–i**. H.B. 8501a: Australia, Queensland, on *Phragmites*.

and geographical origin. Also here one apothecium contained broader spores without any trace of a tail.

Anamorph. The descalsia-like conidia observed on the natural substrate near apothecia of *O. breviaristata* resemble those of the similar *O. aristata* (Pl. 349: 2h). In two collections (IVV: H.B. 7171a, 8367) K-shaped, curucispora-like conidia were observed which might instead belong to the (presumed) anamorph of *Hyalorbilia subfusispora*.

Phylogeny. Two sequences comprising ITS and LSU were available of the two samples from Luxembourg. The S1506 intron is absent in both. No unequivocal differences could be observed between them in the regions without ambiguities. The ITS region was very badly sequenced but in combination of both a rather useful sequence resulted which clustered with low support sister to *O. clavuliformis* (Phyl. 12), to which it showed the lowest distance (4–4.5%), followed by *O. subaristata*, *O. aristata*, *O. subclavuliformis*, and *O. flagellispora* with 6–8% (data approximate because of ambiguous positions in *O. breviaristata*). When analysing LSU D1–D2 (not shown), *O. breviaristata* clustered strongly supported and with a 0.8% distance with *O. clavuliformis*, followed by *O. subclavuliformis* (1.5%), *O.* aff. *subaristata* (1.7%), *O. aristata* with dwayaangam-like conidia (2%), and *O. aristata* with curucispora-like conidia (2.4%).

Ecology. *O. breviaristata* was found on rotten bark and wood of xeric branches of *Ulex*, *Frangula* and *Cytisus*, somewhat woody stems of *Euphorbia*, and stems of *Rubus fruticosus* agg. The species shows an atlantic to subcontinental, cold- to warm-temperate humid distribution in western and central Europa, where it seems to prefer thermophilous hedges with *Rubus*, *Ulex* or *Cytisus*. The type locality is a rather extensively used garden in which also *O. aristata* was found at the same place, but on separate stems of *Rubus*. A collection from Spain (on *Frangula*) was from a meso-submediterranean semihumid river bank. The not included collection from northeastern Australia was in a tropical (sub)humid floodplain between savannah and rainforest on Devonian sedimentary rock, on standing, dead, xeric *Phragmites* culms being covered over large areas by a black conidial layer of *Arthrinium arundinis*.

Specimens included. **NORWAY**: **Hedmark**, 10 km NW of Hamar, 1.7 km SSE of Brumunddal, 140 m, branch of *Pinus ?nigra*, on bark, 16.VII.2012, S. Orbilia megaocculta Baral, **sp. nov.**, MB 813613 — Pl. 351

Etymology: named after the large ascospores similar as in species related to *O. occulta*.

Typification: Australia, New South Wales, Lithgow, branch of *Eucalyptus*, 26.X.1998, G. Marson (ex H.B. 6775, MEL 2389216, holotype).

Latin diagnosis: *Similis* Orbiliae breviaristatae *sed asci, ascosporae et cauda ascosporarum multo latiores, corpuscula refringentia multo latiora. Habitat ad corticem putridum rami sicci* Eucalypti *in zona temperata humida Australiae meridio-orientalis.*

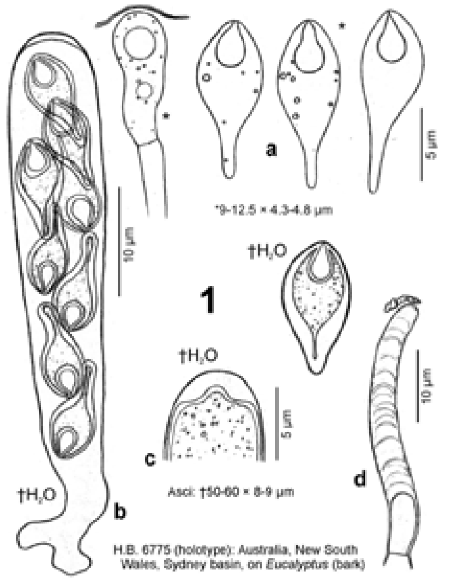

Plate 351. **1**: *Orbilia megaocculta*. – **a**. ascospores; **b**. ascus and paraphysis; **c**. ascus apex; **d**. marginal cortical cell with glassy process.

Description: — **TELEOMORPH**: **Apothecia** rehydrated ~0.2 mm diam., light orange; disc flat, margin finely crenulate. **Asci** †50–60 × 8–9 µm, 8-spored, spores ± biseriate, 3–6 lower spores inversely oriented (sometimes mixed); **apex** (†) hemispherical, dome 1.7–2.2 µm thick, with apical chamber; **base** with very short stalk, Y-shaped. **Ascospores** *9–12.5 × 4.3–4.8 µm, broadly fusoid, apex obtuse, base mostly with a short tail 2.5–4 × 0.7–0.8 µm, straight; **SBs** *3–3.5 × 2–2.2 µm, tear- to pear-shaped, apically narrowed to a small point; with some small LBs. **Paraphyses** apically uninflated to medium clavate, terminal cells */†~ 12–15 × 2.5–4.8 µm. **Medullary excipulum** not examined. **Ectal excipulum** of medium gelatinized textura globulosa (common walls †1–1.5 µm thick), cells near base †12–23 × 10–20 µm; **glassy processes** at margin 20–30 × 2.7–4 µm, stratified, coherent to form short and broad teeth. **Anchoring hyphae** not seen. **SCBs** in paraphyses globose. **Exudate** over paraphyses and glassy processes 0.3–1.5 µm thick, continuous, loosely attached. **— ANAMORPH**: unknown.

Habitat: ± corticated, 8 mm thick xeric branch of *Eucalyptus* sp., on medium decayed edge of bark in a cleft. **Associated**: none observed. **Desiccation tolerance**: some paraphyses and spores still viable after 2 years. **Altitude**: 1073 m a.s.l. **Geology**: Permian-Triassic sedimentary rock. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia megaocculta* is characterized by rather large, broadly ellipsoid-fusoid ascospores with large, tear-shaped SBs and a short, medium thick tail, also by medium long glassy processes. The European *O. breviaristata* differs in much narrower asci and spores, much thinner spore tails, and much narrower SBs. *O. megaocculta* resembles also taxa around *O. multiaustraliensis* and *O. arizonensis* (series *Hesperidea*) in spore shape and also in the higher number of inverted spores, but these species are without glassy processes and possess crystalloid SCBs, *O. multiaustraliensis* also differs in 32-spored asci.

Ecology. *O. megaocculta* is only known from the holotype on rotten bark of a dead xeric branch of *Eucalyptus* in a warm-temperate humid eucalypt woodland at the top of a mountain in the Great Dividing Range of southeastern Australia. Only two apothecia were detected in the sample which were used up during examination.

Specimens included. **AUSTRALIA**: **New South Wales**, Sydney Basin, 95 km WNW of Sydney, 11.5 km SE of Lithgow, 1.6 km SE of Mt. York, 1073 m, branch of *Eucalyptus*, on bark, 26.X.1998, G. Marson (ex H.B. 6775, MEL 2389216, **holotype**).

Orbilia fimbriata Baral & G. Marson, **sp. nov.**, MB 813614 — Pls 352–353

Etymology: named after the long-haired apothecial margin.

Typification: Western Australia, Toolonga, trunk of *Dodonaea viscosa* subsp. *angustissima*, 8.XI.2007, G. Marson (ex H.B. 8838a, MEL 2389261, holotype; sq.: KT222369).

Latin diagnosis: *Apothecia rehydratata 0.4–1.5 mm diam., vivide (ochraceo-) aurantiaca, sessilia vel subsessilia, margine longissime albopilosa. Asci 8-spori. Ascosporae *19–21 × 3.9–4.7 µm, ellipsoideo-fusoideae, cauda basali 10–11 × 0.9–1.1 µm, basi leniter inflata praeditae, in statu vivo corpusculum refringens magnum, pyri- ad moniliformem, ad apicem affixum continentes. Cellulae vivae paraphysium corpuscula globosa continentes. Excipulum marginale pilis perlongis, copiosis, hyalinis, crassitunicatis, pauciseptatis praeditum. Exsudato nullo. Habitat ad corticem putridum siccum trunci emortui* Dodonaeae *in zona subtropica semiarida Australiae occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.4–)0.5–1(–1.5) × 0.35–0.7(–1) mm diam., 0.1–0.22 mm high (receptacle near margin 0.1–0.15 mm), light to bright (yellowish-)orange(-ochraceous), non-translucent, round to often elliptical, scattered to subgregarious in small groups; disc strongly concave to finally flat, margin 70–150 µm protruding by the long, white hairs which are often somewhat teeth-like agglutinated; broadly sessile or with a broad stipe-like base, superficial; disc dry completely closed by the incurved hairs. **Asci** *65–75(–90) × 7.5–8.7 µm, †50–68 × 6–7(–8) µm, 8-spored, spores (*) biseriate, 0(–1) lower spores inverted (sometimes mixed), pars sporifera *47–55 µm long; **apex** (†) hemispherical to very slightly

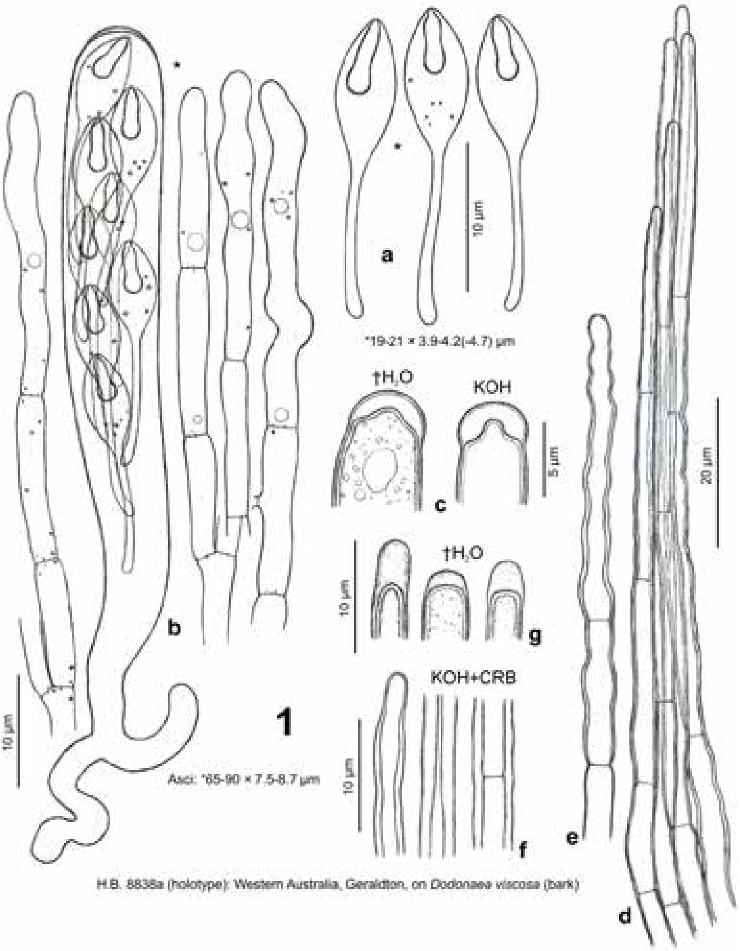

Plate 352. **1**: *Orbilia fimbriata*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. agglutinated marginal hairs; **e**. non-agglutinated hair at uppermost margin; **f**. detail of hairs (tip and middle part); **g**. some hair tips with glassy caps.

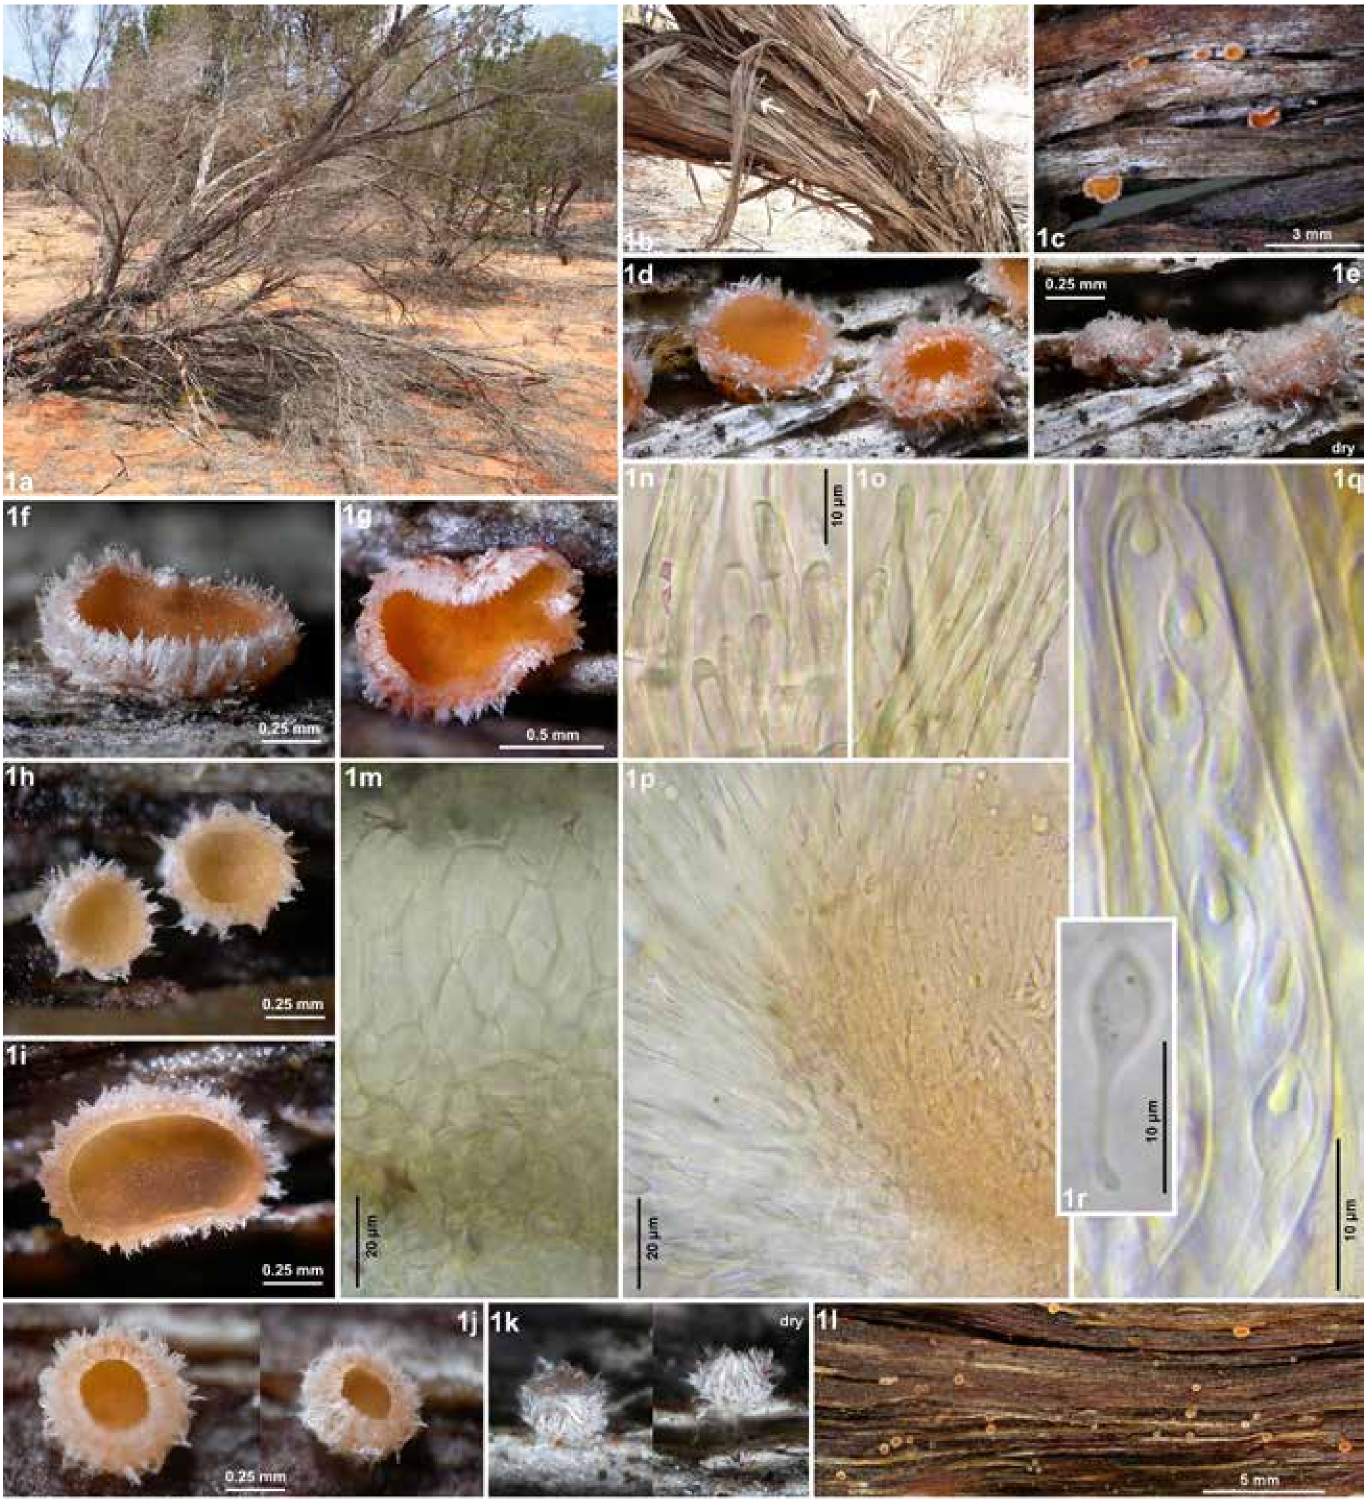

Plate 353. **1**: *Orbilia fimbriata*. – **1a**. semiarid acacia shrubland with dead *Dodonaea* shrub in front; **1b**. dead standing trunk of *Dodonaea* with detaching outer bark; **1c–d**, **f–j**, **l**. rehydrated apothecia; **1e**, **k**. dry apothecia; **1m**. median section of basal ectal excipulum; **1p**. id., marginal ectal excipulum with hairs; **1n–o**. detail of hairs; **1q**. ascus with ascospores; **1r**. ascospore. – Living state, except for **1r** (in KOH). — **1a–r**. H.B. 8838a (holotype): Western Australia, Yalgoo, on *Dodonaea*.

truncate, dome immature †1.2–1.4 µm thick (KOH 1.5–1.7 → 0.7–1.3 µm), with slight to distinct apical chamber; **base** with short to long, thin or thick, flexuous stalk, T-, L-, Y- or h-shaped. **Ascospores** *19–21 × 3.9–4.2(–4.7) µm, †(16–)17–19.5 × (3.5–)3.8–4.1 µm, sperm-shaped: with ellipsoid-fusoid, *9–9.5(–10) µm long head and sharply differentiated filiform tail *10–11 × 0.9–1.1 µm, apex subacute, tail slightly and gradually swollen at base, straight to slightly curved; **SBs** *4–4.5(–5) × 1.3–1.7 µm, pyriform to dumbbell-shaped, apically narrowed to a ± small point. **Paraphyses** apically uninflated to often slightly lageniform, terminal cells *16–31 × 2.2–3.5 µm, often slightly to strongly flexuous, lower cells *11–15(–20) × 1.8–3 µm; never branched at upper septum. **Medullary excipulum** subhyaline to pale orange, 25–70 µm thick, of medium dense textura intricata with some inflated cells, sharply delimited. **Ectal excipulum** hyaline to pale rose-orange, of (†) thin-walled to slightly gelatinized, vertically oriented t. globulosa-prismatica from base to mid flanks, 20–70 µm thick near base, cells *10–31 × 7–14 µm, †8–15 × 6–12 µm; 20–30 µm thick at flanks, 20–50 µm near margin, of t. porrecta oriented at a 0–10° angle to the surface, marginal cortical cells *7–15 × 3–4 µm, giving rise to hairs; **hairs** *60–210(–300) × 3–4.5 µm, ± straight, with hyaline, smooth, glassy walls *0.5–1 µm thick (in KOH 0.5–1.5 µm), gradually more thin-walled towards apex and base, here walls 0.2–0.3 µm thick, with somewhat undulating surface, sparsely septate, ± agglutinated in small groups to form very narrow teeth, towards hymenium non-agglutinated hairs *60–100 × 3.5–5 µm; wall surface CRB deep lilac; **glassy processes** mostly absent, in some apothecia present at tip of short inner hairs of upper margin, 2–4 × 3–4 µm. **Anchoring hyphae** (very) abundant, †2–4 µm wide, walls 0.2–0.4(–1) µm thick, forming a medium dense, pale yellowish t. intricata 50–80 µm thick. **SCBs** in paraphyses globose, 1–1.5 µm diam., in ectal excipulum not observed. **Exudate** over paraphyses and hairs absent, among anchoring hyphae present, thin, pale yellowish **— ANAMORPH**: unknown.

Habitat: collected 0.5–2 m above the ground, corticated, ~10–20 cm thick standing, almost dead branches and trunks of *Dodonaea viscosa* subsp. *angustissima*., on exterior of strongly detached and decayed bark, greyed, no algae. **Associated**: *Acanthostigma ?minutum*, *Mycocalicium* sp., *Orbilia ?angustoaristata*, *O. australiensis*, *O. austrocylindrica*, *O. pleiovirgula*, *O. ?pubescens*. **Desiccation tolerance**: fully viable for at least 6 months, many submature asci still alive after 20 months. **Altitude**: 190 m a.s.l. **Geology**: Cretaceous sedimentary rock (red-brown sandy soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia fimbriata* resembles *O. aristata* and related species in ascospore shape. It differs by rather broad spore heads, paraphyses often slightly lageniform and not covered by exudate, and particularly by the very long hairs which are not agglutinated to form thick teeth but only in thin fascicles. The hairs are not solid but show a lumen up to the mostly thin-walled apex. The rather large apothecia with their orange disc and long white hairs may easily be mistaken in the field for a member of the *Helotiales*, e.g., of the family *Arachnopezizaceae*.

Phylogeny. Two sequences of almost equal length, comprising ITS and LSU, one also a short part of SSU, were obtained from apothecia of the holotype. They fully concur, and in both the S1506 intron is absent. Only the longer version was uploaded in GenBank. *O. fimbriata* clustered in the *aristata-clavuliformis* clade when analysing ITS, LSU, or both regions (Phyls 9, 12, S13). In the ITS the distance to other members of the clade lies in the range of 6–8 %, and in the LSU D1–D2 at 2.5–3.5 %, the closest taxa being *O. flagellispora* and *O. subaristata*.

Ecology. *O. fimbriata* was found on rotten, detaching bark of a dead, xeric trunk of *Dodonaea* and its branches in a subtropical semiarid acacia open shrubland in the Yalgoo ecoregion of western Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Yalgoo, 187 km N of Geraldton, W of Toolonga, Nerren Nerren, 190 m, branches and trunk of *Dodonaea viscosa* subsp. *angustissima*, on bark, 8.XI.2007, G. Marson (MEL 2389261, **holotype**; H.B. 8838a, **isotype**; sq.: KT222369).

Orbilia occulta (Rehm) Sacc., Syll. Fung. 8: 623 (1889) — Pls 354–355

≡ *Calloria occulta* Rehm, Hedwigia 24: 14 (1885)

Etymology: apparently referring to the apothecia growing hidden in clefts of periderm.

Typification: USA, New Jersey, Newfield, unlocalized, branch of *Vitis vinifera*, I.1882, J.B. Ellis (Rehm 770, M-0206545, lectotype, designated here, MBT382101). Georgia, Tifton, Black Shank Farm, branch of indet. angiosperm, 8.V.2015, Y.Y. Shao (GXU 1467, epitype, designated here, MBT385116, ex-epitype culture: TF018; sq.: MG742398, MG742399).

Misapplied name: J.B. Ellis (N. Amer. F. 438), as *Peziza regalis*.

Misinterpretation of *O. occulta*: Korf (1992: 510), CUP-MM-002694 = *Orbilia euphorbiae*, CUP-MM-002555 = *O. pisciformis*; Rehm (1891: 459), Velenovský (1934: 102), Kirschstein (1936: 204), Svrček (1954: 10, 1960: 16), Ellis & Ellis (1985: 12), Beyer (1998: 191), = *Orbilia aristata*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.3–)0.4–0.7(–0.9) mm diam., (0.12–)0.17–0.2 mm high (receptacle 0.12–0.14 mm), light orange-rose, round, scattered, sometimes gregarious; disc flat to slightly convex, margin thin, 0–30 µm protruding, smooth or usually distinctly crenulate due to small teeth up to 30–40 × 30–50 µm; with a very short stipe 0.05 × 0.15 mm, superficial; dry bright orange. **Asci** *50–76 × (5.7–)6–6.7 µm {1}, †(37–)40–60 × (4–)4.3–5.8(–6.3) µm {4}, 8-spored, spores (*/†) subbiseriate, 1–3 lower spores inverted {2} (sometimes mixed), pars sporifera *28–38 µm long; **apex** (†) hemispherical to slightly truncate, dome †1–1.5 → 0.5–1.3 µm thick {4}, with or without apical chamber; **base** with short to medium long, thick, flexuous stalk, L-, h- (or H-)shaped. **Ascospores** *(9.5–)10–12(–13) × (2.8–)3–3.4(–3.6) µm {1}, †(7–)8–11.5(–12) × 2.7–3.3 µm {4}, sperm-shaped: with broadly ellipsoid(-fusoid) head 5–6(–7) µm long and sharply differentiated filiform tail of *(2–)2.5–6(–7) µm long × 0.3–0.4 µm thick (†0.2–0.3 µm wide), apex obtuse (to subacute), also rounded, tail not swollen at base, straight to slightly flexuous; **SBs** *1.8–2.2(–2.5) × 1.1–1.2 µm, tear- to pear-shaped, apically narrowed to a small to wide point, overmature *1.5 × 1.2 µm. **Paraphyses** apically slightly to strongly clavate-capitate (exceptionally spathulate), terminal cells *12–23 × 2.2–3.2 µm {1}, †1.5–3 {T} or 2–4.7 {1} µm wide, lower cells *6–12 × 1.5–2.4 µm {1}, †1.2–1.5 µm wide {T}; branched only towards base. **Medullary excipulum** pale orange, 30–40 µm thick, of dense or loose textura intricata with some or many inflated cells, sharply delimited. **Ectal excipulum** pale rose-orange, of (†) thin-walled to slightly gelatinized, vertically oriented t. globulosa-angularis-prismatica at base and flanks, (20–)30–70(–100) µm thick near base, cells *7–17(–21) × 7–13(–15) µm {1}, †5–11 × 3–6 µm {2}; 15–20 µm thick near margin, inner layer of t. prismatica oriented at a 40–70° angle to the surface, outer layer of t. porrecta oriented at 10–40°, marginal cortical cells †4–9 × 2–5 µm {2}; **glassy processes** (3–)10–50 × (2–)2.5–4 µm {4}, medium to high-refractive, partly stratified, ± coherent to form ± distinct small teeth. **Anchoring hyphae** abundant, */†2–3.3 µm wide, walls 0.2–0.5 µm thick {2}, sometimes forming a strongly gelatinized t. oblita up to 60 µm thick. **SCBs** in paraphyses small, globose; in ectal excipulum at flanks crystalloid, very pale yellowish-reddish, 1.8–6 × 1–2 µm {1}. **Exudate** over paraphyses (0.2–)0.5–1.5(–3) µm thick, forming a continuous layer or cloddy caps, hyaline, smooth to rough, ± firmly attached, over hairs only as small scattered granules. **— ANAMORPH**: trinacrium-like (from ascospore isolate {1}, Shao et al. 2018). **Conidiophores** forming reduced, integrated nodules or short hyphal cells of 0.5–4 × 1–1.2 µm. **Conidia** triradiate, *24–40 × 21–32 µm, stipe *14–20 × 1.5–2 µm, ~3–4-septate, arms ± straight, *13–24×1.8–2.3 µm, ~3–5-septate, gradually slightly tapered towards ends {1}.

Habitat: collected ~1 m above the ground, corticated, 3–20 mm thick, sometimes still viable twigs and branches of *Cornus* sp. {1}, *Malus domestica* {2}, *Vitis vinifera* {T}, indet. angiosperm {1}, on slightly to medium decayed bark {5} (bast), in holes or cross clefts of periderm or on periderm-free areas and on inner surface of detached bark, rarely on wood {1}, strongly greyed or not, green algae abundant or sparse. **Associated**: *Hysterographium fraxini* {1}, *Lecanora* sp. {1}, *Orbilia ?clavuliformis* {1}, *O. regalis* {1}, *Pertusaria* sp. {1}, fruticose lichen {1}. **Desiccation tolerance**: fully viable for at least 2 months. **Altitude**: 35–1200 m a.s.l. **Geology**: Miocene sedimentary rock; granite. **Phenology**: I, V (but certainly long-lived).

Taxonomic remarks. *Orbilia occulta* is characterized by sperm-like ascospores composed of a short, broadly ellipsoid head and an abrupt, thin tail of about the length of the head or slightly shorter, also by medium long glassy processes forming small teeth at the margin, and by the presence of crystalloid SCBs in the ectal excipulum. Earlier authors made no distinction between North American *O. occulta* and European *O. aristata*, which is separated here based on longer spore heads and the absence of crystalloid SCBs. Our studies revealed, however, that even within North America four

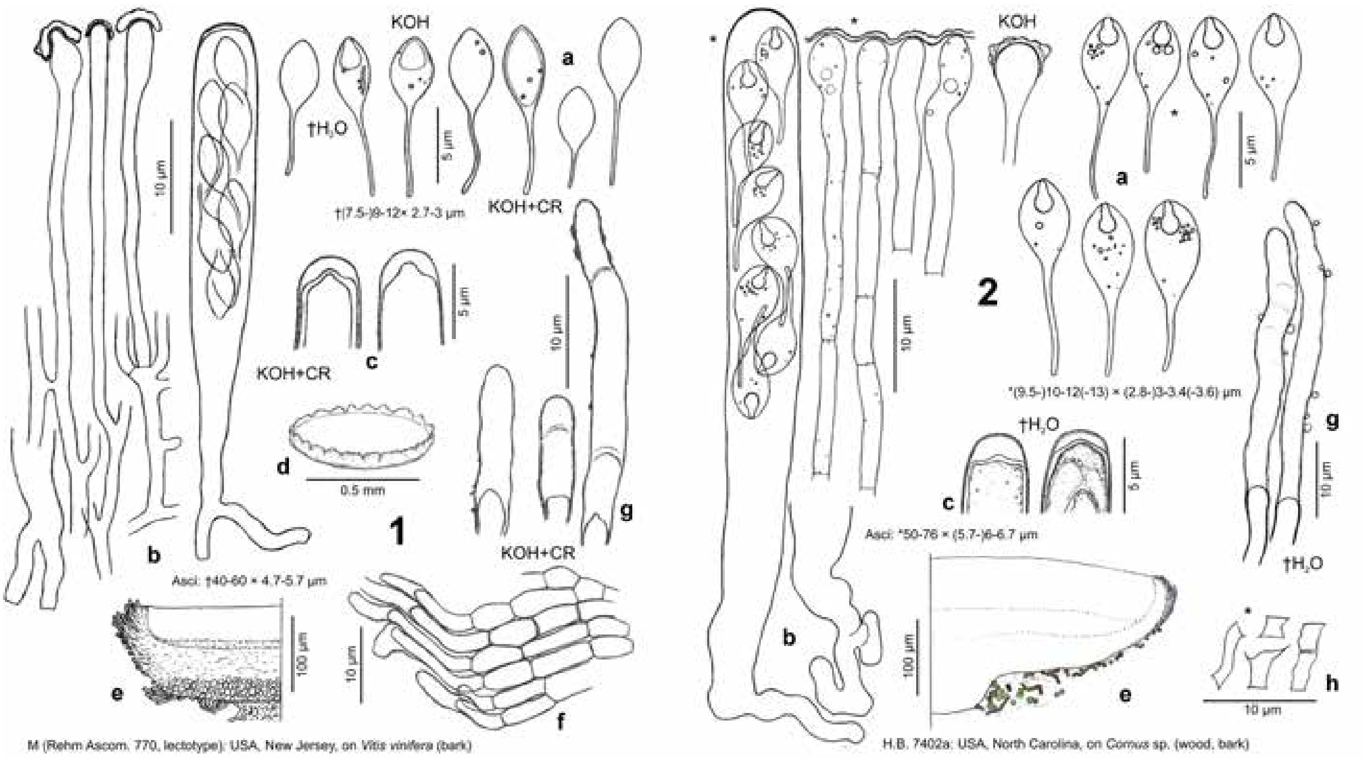

Plate 354. **1–2**: *Orbilia occulta*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium with dentate margin (rehydrated); **e**. apothecia in median section; **f**. id., ectal excipulum at mid flanks, cortical cells with glassy processes; **g**. marginal glassy processes; **h**. crystalloid SCBs in ectal excipulum at flanks.

different species with thin, basally uninflated spore tails need to be distinguished: *O. aristata*, *O. clavuliaristata*, *O. occulta*, and *O. spermoides*. The rather short spores of *O. occulta* strongly resemble those of the European (and Australian) *O. breviaristata*, which differs in slightly longer and narrower spore heads and SBs, in the absence of crystalloid SCBs, and in smaller apothecia.

To the closest relatives of *O. occulta* appear to belong the mainly North American conifericolous *O. spermoides* and the Australian *O. austroocculta*. The three species much resemble each other in spore shape, also in the comparatively short and broad SBs. *O. occulta* and *O. spermoides* further share the presence of crystalloid SCBs, which are present in noticeable abundance within series *Hemiorbilia* only here and in *O. angustoaristata* and *O. breviclava*. *O. occulta* differs from *O. spermoides* in shorter spore tails, the presence of distinct exudate over the ± swollen paraphysis apices, and in a thinner marginal excipulum composed of a less developed textura porrecta, the cortical cells of which do not form hyphoid agglutinated hairs, also in a flat hymenium. For the differences to *O. austroocculta* see p. 735.

Variation in *O. occulta* was observed in the paraphysis apices, some of which were medium to strongly inflated, but in other apothecia of the same population only slightly so. Also the length of glassy processes and the thickness of apothecia and basal ectal excipulum varied considerably. One of the two specimens on *Malus* was immature and grew as a mixture with the lectotype of *O. regalis* (M.C. Cooke 2778, see under *O. regalis*, p. 775, and IVV: H.B. 5343). In the mature specimen on *Malus* (J.B. Ellis NAF 438) and the sample from Georgia the spores were shorter (†7–10 × 2.7–3.2 µm) than in those on *Vitis* and *Cornus*.

Type studies. In the protologue of *Calloria occulta*, Rehm (1885) mentioned two collections: J.B. Ellis NAF 142 and 848, both 'on outer bark of living grape vine'. Two duplicate series of one of them (Ellis 848, Jan. 1882) were distributed as Rehm Ascomyc. 770 and J. Kunze Fungi Sel. Exs. 282. Specimens of these two series exist at M. Although Rehm mentioned besides Rehm 770 also Kunze 282 and Ellis 142, it must be assumed that his description is solely based on Rehm 770. In the present study, Rehm's specimen Ascomyc. 770 was thoroughly investigated from a specimen in M (M-0206545, Pl. 354: 1). This is designated here as **lectotype** of *O. occulta*. The specimen from Georgia (on indet. angiosperm, TF018, GXU 1467), from which a sequence was gained, is designated here as **epitype** of *O. occulta* (Pl. 355: 4).

Duplicate specimens of Rehm 770 in M-0206544, S-F9973, and S-F9974 were not studied, but a duplicate in HBG (Pl. 355: 1). This was later labelled '*Orbilia cruenta*', probably based on Seaver's (1951) opinion of a synonymy between these two taxa. Rehm (1885) described the spores as oval, with a long filiform lower part, 15 × 3 µm, whereas in the present reexamination distinctly shorter spores were found. The apothecial size stated in the protologue ('0.3–7 mm') is clearly an error for 0.3–0.7 mm.

Also NAF 142 was studied from a duplicate in M (as '*Peziza vinosa*'). This remained unidentified because no spores could be found. The strongly truncate, thin-walled ascus apex suggests that it does not belong in section *Hemiorbilia*. The asci are narrower [†47–50(–65) × 3.5–4.5 µm], the paraphyses apically hardly inflated and covered by a 1 µm thick exudate, and the glassy processes up to 20 µm long. The substrate is decorticated angiosperm wood, while the label suggests 'decaying bark and wood'.

Misapplication. Because of a strong macroscopical resemblance, J.B. Ellis (NAF 438), M.C. Cooke (nr. 2778), and later authors confused *O. occulta* and *O. regalis*, although these species have very differently shaped ascospores and paraphyses. In the two specimens preserved at K and issued as *Peziza regalis*, both species grew in association in Cooke 2778 (lectotype of *O.*

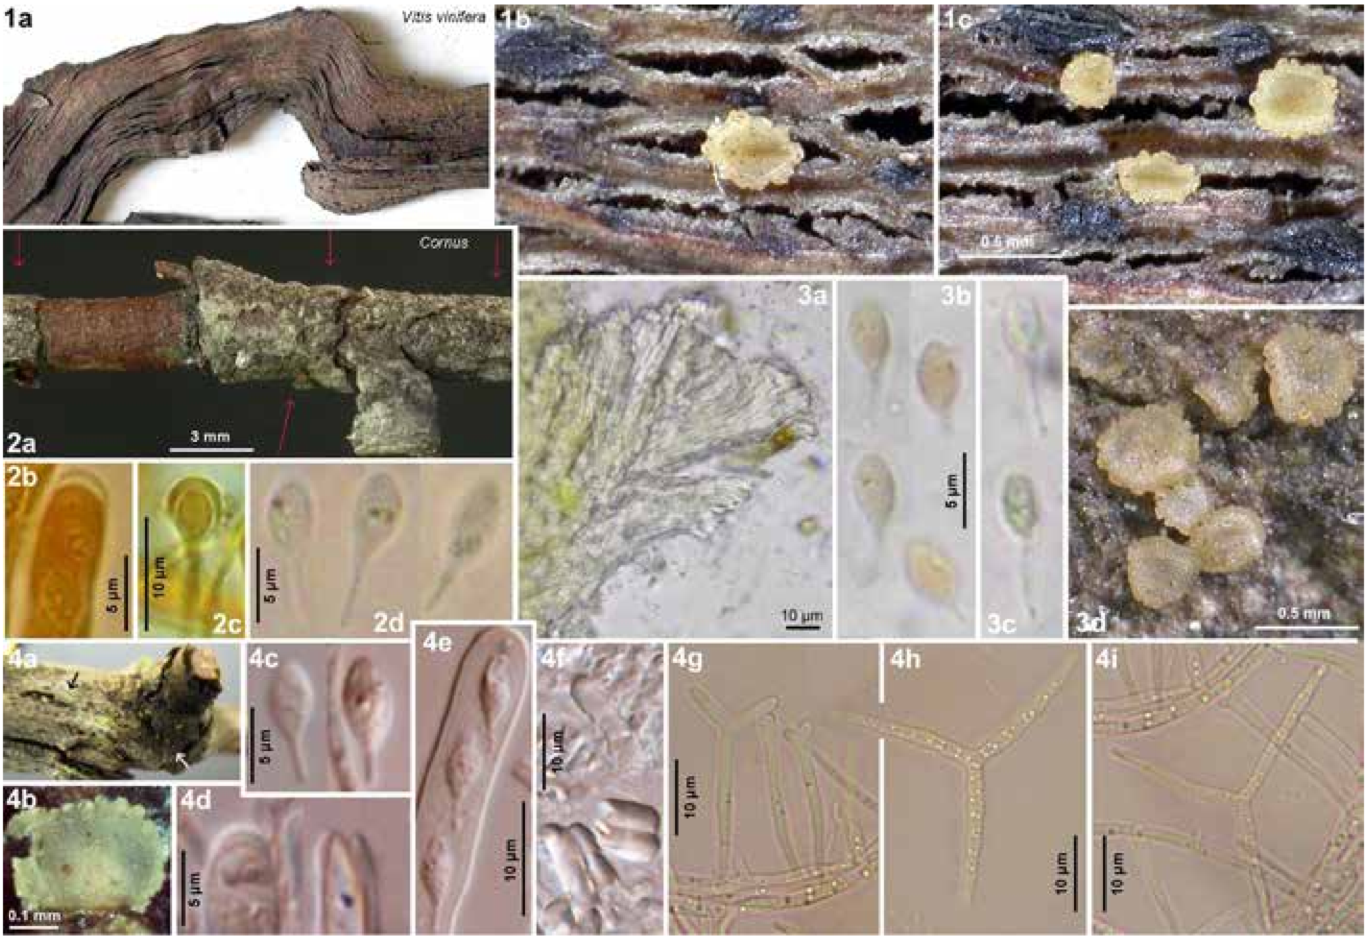

Plate 355. **1–4**: *Orbilia occulta*. – **1a**. detached bark of *Vitis vinifera* (inner surface); **2a**. dead corticated xeric branch of *Cornus*; **4a**. corticated twig of indet. angiosperm; **1b–c**, **3d**, **4b**. rehydrated apothecia; **3a**. marginal ectal excipulum in median section; **4f**. glassy processes; **2b**, **4d**. ascus apices; **4d** right: apex of emptied ascus with slit-like opening; **2c**. paraphysis apex; **2d**, **3b–c**, **4c**, **e**. ascospores; **4g–i**. conidia on reduced conidiophores (from culture). – Dead state (**2b–c** in KOH+IKI, **2d**, **3a** in KOH, **3b** in KOH+CR, **3c**, **4c–f** in H_2O). – **4**: phot. Y.Y. Shao. — **1a–c**. Rehm 770 (isolectotype, HBG): USA, New Jersey, on *Vitis*; **2a–d**. H.B. 7402a: North Carolina, on *Cornus*; **3a–d**. N. Amer. F. 438 (K(M) 180561): unlocalized (?New Jersey), on *Malus*; **4a–i**. GXU 1467 (epitype): Georgia, Tifton, on indet. angiosperm.

regalis), while only *O. occulta* could be detected in Ellis NAF 438. In Cooke 2778 the identity of the *O. occulta* population is somewhat uncertain because no spores could be found, but its affiliation in section *Hemiorbilia* is beyond doubt.

Rehm (1891: 459) referred German collections from Mittelfranken and Thüringen on detaching bark of *Malus* to *O. occulta*. Two from Mittelfranken exist in S (VIII.1866, Neuhof and Sugenheim, S-F9975, 9976, as *O. cruenta*) and carry the note '*Calloria occulta* mihi, spec. nov.', but were not cited in the protologue and were not examined by us. Several later authors used the name *O. occulta* for European collections which possibly all represent *O. aristata*. Seaver (1951: 158) referred *O. occulta* to synonymy with *O. cruenta* Schwein., however, the identity of *O. cruenta* is unclear (see p. 1668), as is the origin of Seaver's description of *O. cruenta* which does not mention any spore tails.

Reexamination of the two Macaronesian collections reported by Korf (1992) under the name *O. occulta* revealed distinct differences in spore shape between them, which is already obvious from his sketches. Ascus apical thickenings are absent in both collections, which are treated here as members of two different series of section *Aurantiorubrae*: *O. euphorbiae* in series *Regales* (Pl. 401: 3) and *O. pisciformis* in series *Commatoideae* (Pl. 419: 2).

Anamorph. The conidia obtained by Y.Y. Shao in pure culture resemble those of *Trinacrium subtile* but are smaller and with narrower stipe and arms (Shao et al. 2018; Pl. 355: 4g–i). In this culture also small, subglobose, light brown conidia-like structures developed singly on short hyaline side branches, which where tentatively classified in Shao et al. (l.c.: fig. 1: 4c) as chlamydospore-like bodies. Although brown-walled cells have so far never been seen in pure culture of *Orbiliomycetes*, it appears from the single available photo that these structures emerged from the hyphae of the *Orbilia*.

Phylogeny. An ITS sequence was gained by Y.Y. Shao (Shao et al. 2018) from pure culture of the sample from Georgia. In our phylogenetic analysis it clustered strongly (ITS) or medium supported (ITS+LSU) in a clade with *O. spermoides* (Phyls 9, 13), here called *occulta-spermoides* clade, though with an ITS distance of 9%. A short piece of LSU (~150 nt) comprising the partial D1 region shows a 4.5% distance (7 deviating nt). No chromatograms were available for this isolate to verify the two sequences.

The *occulta-spermoides* clade consistently clustered as a sister group of the *aristata-clavuliformis* clade. This placement received strong support in our ITS analysis (Phyl. 12) or the combined analysis of SSU+ITS+LSU in Baral et al. (2017b), medium support in the present combined analysis of ITS+LSU (Phyl. 9), or no support based on LSU (S13).

Ecology. *O. occulta* is so far only known from three sites in eastern North America, growing on slightly to medium decayed bark (also wood) of xeric twigs and branches of *Cornus*, *Malus*, and *Vitis*. Two sites are located in the warm-temperate humid lowlands of New Jersey and cold-temperate humid highlands of southern Appalachian Mountains, and one in the subtropical humid lowlands of Georgia.

Specimens included. **USA**: **New Jersey**, Newfield, unlocalized, branch of *Vitis vinifera*, on bark, I.1882, J.B. Ellis (NAF 848, Rehm 770, M-0206545, **lectotype**; H.B. 5054a ø; M-0206544, HBG, **isolectotypes**). – ibid., branch of *Malus domestica*, on bark, undated, J.B. Ellis (Cooke 2778, K(M), immature [mixture with *O. regalis*], H.B. 5344 ø). – Unlocalized, branch of *M. domestica*, on bark, undated, J.B. Ellis (N. Amer. F. 438, as *Peziza regalis*; K(M) 180561, as *Orbilia regalis*; H.B. 9769 ø). – **North Carolina**, Appalachian Mts., Blue Ridge Mts., 31 km E of Franklin, 8 km NE of Cashiers, Big Green Mt., Panthertown Valley, 1200 m, twig of *Cornus*, on bark & wood, 20.V.2003, W. Jaklitsch (W.J. 2174 ø, H.B. 7402a). – **Georgia**, 7 km NNW of Tifton, Black Shank Farm, 105 m, branch of indet. angiosperm, on bark, 8.V.2015, Y.Y. Shao (GXU 1467, **epitype**, TF018, anam. cult., doc. vid., sq.: MG742398, MG742399).

Orbilia austroocculta Baral & G. Marson, **sp. nov.**, MB 813615 — Pls 356–357

Etymology: named after the occurrence in Australia and the similarity with *O. occulta*.

Typification: Western Australia, Wannamal, branch of *Acacia*, 4.IX.2006, G. Marson (ex H.B. 8582a, MEL 2389241, holotype).

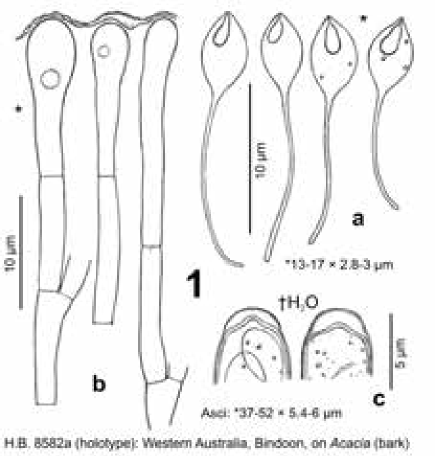

Plate 356. **1**: *Orbilia austroocculta*. – **a**. ascospores; **b**. paraphyses; **c**. ascus apices.

Latin diagnosis: *Similis* Orbiliae occultae *sed ascosporae apice magis acutae, cauda multo longiore, cellulae vivae excipuli marginalis absque corpusculis crystalloideis. Habitat ad corticem putridum rami sicci* Acaciae *in zona subtropica semihumida Australiae meridio-occidentalis.*

Plate 357. **1**: *Orbilia austroocculta*. – **1a**. semihumid Eucalypt open woodland, fallen *Acacia* tree; **1b**. dead corticated xeric branch of *Acacia* (rehydrated); **1c–f**. rehydrated apothecia; **1g**. median section of ectal excipulum near margin; **1h**. id., marginal glassy processes agglutinated as teeth; **1i–k**. mature asci; **1l**. ascus apex; **1m**. ascospores; **1n**. conidium from substrate. – Living state, except for **1j–k** (in KOH+IKI), **1l** (in H_2O), right ascus in **1i**, upper spore in **1m**. — **1a–n**. H.B. 8582a (holotype): Western Australia, Bindoon, on *Acacia*.

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.28–0.75(–1) mm diam., 0.15–0.2 mm high (receptacle 0.09–0.11 mm), bright orange, hardly translucent, round to elliptical, scattered; disc slightly concave to flat, margin distinct, 0–40 µm protruding (including teeth), with prominent white teeth; with a hidden stipe 0.1 × 0.1 mm, erumpent from holes or cracks in periderm; dry ± hysterioid. **Asci** *37–52 × 5.4–6 µm, †33–40 or 46–60 × 4.5–5.3 µm, 8-spored, spores *1–2-seriate, 1(–2) lower spores inverted (not mixed), pars sporifera *27 µm long; **apex** (†) ± hemispherical, dome †1.1–1.4 → 0.7–0.8 µm thick, with small apical chamber; **base** with short to medium long, ± thick, flexuous stalk, L-shaped. **Ascospores** */†13–17 × 2.8–3 µm, with 5–5.5 µm long, broadly fusoid head and sharply differentiated, long and very narrow, basally uninflated tail *(6–)7.5–11.5(–12.5) × 0.3 µm (†0.2 µm), apex subacute to acute or almost acuminate († acute to acuminate), tail straight to often slightly or medium curved; **SBs** *2–2.5 × 0.7–1.1 µm, tear- to pear-shaped, apically narrowed to a small point, with or without very short filum. **Paraphyses** apically slightly to medium clavate, terminal cells *12–20 × 2.5–4.3 µm, lower cells *10–14 × 1.7–2.1 µm; unbranched at upper septum, hymenium pale orange. **Medullary excipulum** hyaline to light orange, 40 µm thick, of dense, horizontally oriented textura intricata with many inflated cells, medium sharply delimited. **Ectal excipulum** hyaline, light orange towards margin, of thin-walled, vertically oriented t. angularis-globulosa from base to submargin, 50 µm thick near base, cells *(7–)10–16(–25) × (6–)8–13(–16.5) µm; 15–20 µm thick near margin, outer part of t. prismatica-porrecta oriented at a 10–20° angle to the surface, marginal cortical cells *6–13 × 2.5–4 µm; **glassy processes** 30–100 × 2–3 µm, high-refractive, stratified, curved inwards, coherent to form distinct teeth. **Anchoring hyphae** sparse, ~2 µm wide. **SCBs** in paraphyses globose, inconspicuous, 1–1.5 µm diam., in ectal excipulum 2–2.5 µm diam. **Exudate** over paraphyses and glassy processes 0.3–1(–1.7) µm thick, granular-cloddy to continuous, subhyaline, ± firmly attached. — **ANAMORPH**: unknown (but see below).

Habitat: collected 0.5–1.5 m above the ground, ± corticated, 10–11 mm thick branch of *Acacia* sp., on very decayed bark (bast), strongly greyed, quite many green algae. **Associated**: *Orbilia albidorosea*, *O. austroregalis*, *O. pleiocrescens*, crustose lichens. **Desiccation tolerance**: fully viable for at least 2 months, some immature asci and many paraphysis and excipular cells still alive after 11 months. **Altitude**: 272 m a.s.l. **Geology**: Archean granulite with granitic gneiss (red-brown soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia austroocculta* closely resembles the North American *O. occulta* and *O. spermoides* in the ascospores having short and broad heads and abrupt, very narrow tails. From *O. occulta* it differs in more acute spore apices and much longer tails, and from *O. spermoides* in clavate paraphyses covered by exudate and in narrower spore heads. From both species *O. austroocculta* further differs in the absence of crystalloid SCBs.

Anamorph. On the substrate three different kinds of conidia were observed: a trinacrium-like conidium with slightly upwards curved arms, a multiarmed dicranidion-like conidium, and K-shaped, curucispora-like conidia with curved arms (the latter probably belonging to a *Hyalorbilia*). The trinacrium-like conidium would best fit the known anamorphs of series *Hemiorbilia*.

Ecology. *O. austroocculta* is only known from a single collection on rotten bark of a xeric branch of *Acacia* in a subtropical semihumid eucalypt woodland (with *Macrozamia*) in southwestern Australia (Jarrah Forest ecoregion).

Specimens included. **AUSTRALIA**: **Western Australia**, Jarrah Forest, 25 km NNE of Bindoon, 12 km ESE of Wannamal, 271 m, branch of *Acacia*, on bark, 4.IX.2006, G. Marson (ex H.B. 8582a, MEL 2389241, **holotype**, anam. substr.)

Orbilia spermoides Baral & G. Marson, **sp. nov.**, MB 813616 — Pls 358–359, Map 61

Etymology: named according to the sperm-shaped ascospores.

Typification: USA, Arizona, Grand Canyon, Tusayan, branch of *Pinus edulis*, 28.VIII.1994, G. Marson (ex H.B. 5227a, M-0276588, holotype).

Latin diagnosis: *Similis* Orbiliae occultae *sed exsudato paraphysium absente vel minute granuloso, cellulae vivae paraphysium corpuscula crystalloidea continentes, ascosporae cauda longiore, corpuscula refringentia majora, apothecia majora. Habitat ad corticem leniter vel valde putridum ramorum siccorum coniferarum in zona temperata ad boreale subhumida ad humida Americae septentrionalis et orosubmediterranea Europae.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.5–1.5(–2.8) × (0.35–)0.5–1 mm, (0.15–)0.2–0.25(–0.3) mm high (receptacle 0.12–0.14 mm), (pale to) light to bright orange-rose, round or broadly to narrowly elliptical if growing in clefts, scattered to ± gregarious; disc strongly concave to flat, margin with prominent, white, pubescent teeth 50–130 × 50–100 µm, rising 30–120 µm above disc, rarely smooth; stipe absent or ± distinct, obconical, 0.1–0.2 × 0.2–0.35 mm, superficial or often distinctly erumpent from outer layers of bark; disc dry nearly closed, large apothecia then ± hysteriform, bright to deep orange. **Asci** *(58–)65–80(–103) × (5–)5.5–6.7(–7.3) µm {5}, †(46–)50–70(–74) × (4.2–)5–5.5(–6.5) µm {2}, 8-spored, spores (*) subbiseriate, (0–)1–2(–3) lower spores inversely oriented {5} (not or sometimes mixed), pars sporifera *30–35(–45) µm long; **apex** (†) hemispherical to slightly truncate, dome †0.7–1.3 → 0.4–0.8 µm thick {4}, with ± indistinct apical chamber; **base** with short to long, medium thick, flexuous stalk, T-, L- or h-shaped. **Ascospores** *(9–)12–17(–18.5) × 3.2–3.8(–4) µm {4}, *15–18.5 × 3.2–3.5 µm {France}, †10–13 × 2.8–3.2 µm wide {2}, sperm-shaped: with broadly ellipsoid-fusoid head 5–6(–7) {4} or 6–7(–8) {France} µm long and sharply diffenentiated filiform tail ((3–))(5–)7–9.5(–11) × 0.2–0.5 µm (†0.2–0.3 µm), apex obtuse, also rounded or subacute, base of tail not or only slightly inflated to *0.5(–0.7) µm, head sometimes slightly inequilateral, tail straight or slightly curved; **SBs** *(1.8–)2–2.5(–2.8) × 1.2–1.6(–1.7) µm {5}, broadly tear- to pear-shaped, apically narrowed to a ± small point. **Paraphyses** apically uninflated, also slightly to medium clavate or spathulate-lageniform, straight or often slightly to strongly flexuous, terminal cells *(11–)13–25(–28) × (1.7–)2–3(–3.5) µm {4}, lower cells *8–15.5(–17.5) × 1.7–2.6 µm {4}, †1.2–1.6 µm wide; not or rarely branched at upper septum (exceptionally below apex); hymenium light orange-rose. **Medullary excipulum** in total 50–130 µm thick, usually 2-layered: upper layer 20–40 µm thick, of light orange-rose, ± horizontally oriented, dense textura porrecta-intricata with a few inflated cells; lower layer 30–100 µm thick, of hyaline, dense to rather loose t. intricata with many inflated cells, medium to very sharply delimited. **Ectal excipulum** towards margin pale to light orange-rose, from base to mid flanks of thin-walled († slightly gelatinized), vertically oriented t. angularis(-prismatica), (35–)50–70 µm thick near base, cells *9–24 × 7.5–16 µm {4}; 20–40 µm thick at mid flanks, 20–70 µm at margin, at mid flanks or margin of a thick t. porrecta oriented at a 0–45° angle to the surface {5}, forming fascicles of agglutinated cell rows or sometimes free **hairs** ~30–60 µm long, 1–4-septate, individual cells *(9–)12–20(–25) × 3–4.5(–6) µm {3}, **glassy processes** 10–70 × (2.5–)3–4(–5) µm {5}, rarely only 3–6 µm long (exceptionally absent), high-refractive, stratified or not, slightly to strongly outwards curved, sometimes hooked, cell rows and glassy processes coherent to form hairy teeth at mid flanks and margin. **Anchoring hyphae** sparse to abundant, */†2–3.7 µm wide, walls 0.2–0.3(–0.5) µm thick {2}, gelatinized or not. **SCBs** in paraphyses and excipular cells from base to margin crystalloid, hyaline to pale orange, 2.8–7 × (1.5–)2–3(–4) µm {5}, also globose. **Exudate** absent or finely granular, 0.1–0.3 µm thick {5}. — **ANAMORPH**: trinacrium-like (from ascospore isolate {1} and natural substrate {5}). **Conidiophores** not seen. **Conidia** 2-armed (T-shaped), total size *20.5–32 × 18–33 µm (†21–23 × 19.5–26.5 µm) {4}, stipe *16–26 × 3.1–4.5 µm (†14–17.5 × 3.5–4 µm), (3–)4–5(–6)-septate, arms ± tapering, distinctly bent downwards, */†8–15 × 3.5–4.2 µm, (1–)2–3(–4)-septate, 1 unbranched phragmoconidium seen in pure culture: *30 × 4 µm, 5-septate.

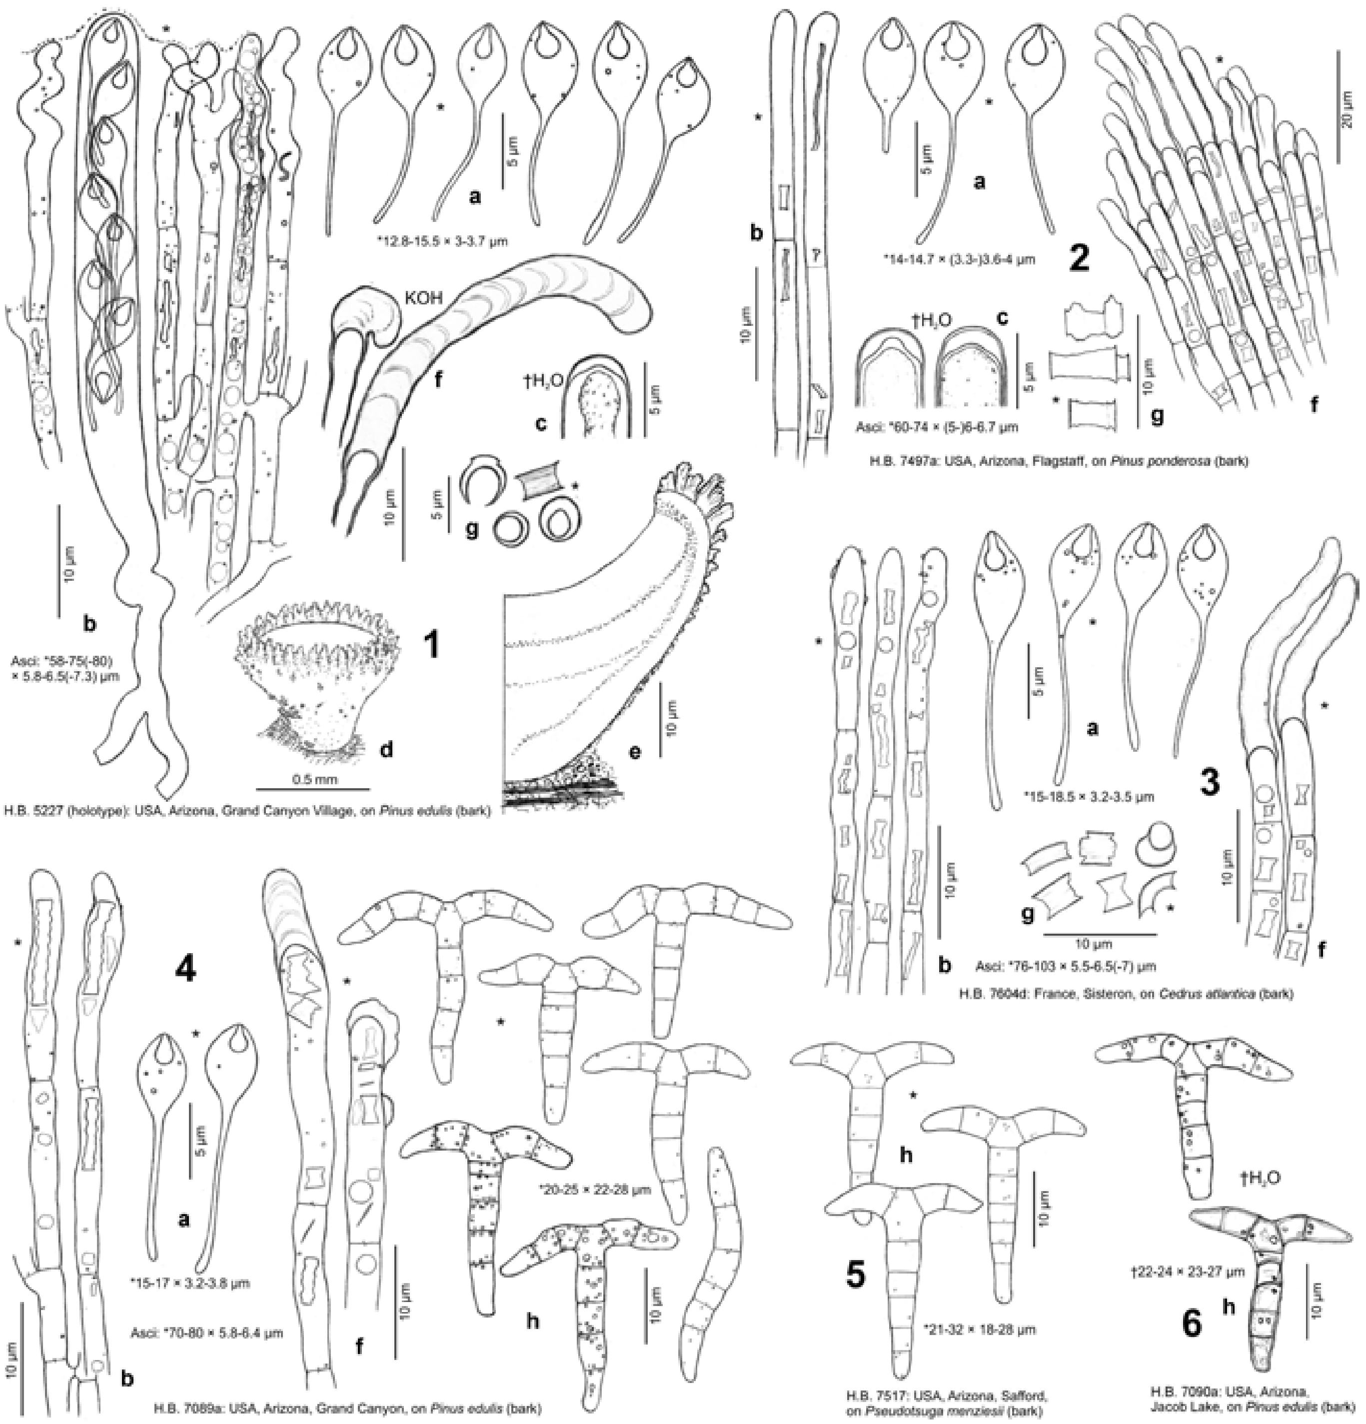

Plate 358. **1–6**: *Orbilia spermoides*. – **a**. ascospores; **b**. asci and paraphyses; **c**. ascus apices; **d**. apothecium (rehydrated); **e**. apothecium in median section; **f**. id., marginal ectal excipulum, cortical cells with glassy processes; **g**. crystalloid SCBs in lower parts of ectal excipulum; **h**. conidia from substrate (**4h**, **6h**) and pure culture (**5h**).

Habitat: collected 0.5–5 m above the ground on still-attached, corticated or sometimes nearly decorticated, 6–23 mm thick twigs and branches of living or recently dead young or old trees of *Cedrus atlantica* {1}, *Pinus edulis* {3}, *P. ponderosa* {2}, *Pseudotsuga menziesii* {2}, branches often curved down towards ground, on slightly to strongly decayed, partly loosely attached bark {8} (periderm & bast), usually growing in cross clefts of bark, often in large numbers, exceptionally a few apothecia on wood {2} in cracks through bark, more or less greyed, sometimes covered by green algae. **Associated**: *Caloplaca holocarpa* {1}, *Carestiella ?schizoxyloides* {1}, *Claussenomyces pseudotsugae* {1}, *Cryptodiscus muriformis* {1}, ?*Flavoparmelia* {1}, *Hyalorbilia orbilicola* (parasitic on *O. flagellispora*) {1}, ?*Lecidea* sp. {3}, *Melanohalea* sp. {1}, *Orbilia ?clavuliformis* {1}, *O. flagellispora* {1}, *O. multimacroasca* {1}, *O. phanosoma* {1}, *O. subclavuliformis* {1}, *Parmelia sulcata* {1}, '*Patinella*' *abietina* {1}, *Propolis ?strobilina* {1}, *Pseudevernia intensa* {1}, *Sclerococcum* sp. {4}, *Usnea ?parvula* {2}. **Desiccation tolerance**: fully viable for 19 months, conidia still alive after 2 years. **Altitude**: 2068–2820 m a.s.l. (North America), 1447 m (Europe). **Geology**: Permian lime- & sandstone; granite, andesite, rhyolite, gneiss, basalt. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia spermoides* strongly resembles the angiosperm-inhabiting *O. occulta* in spore shape and glassy processes, but is readily separated by the paucity of exudate, the uninflated paraphysis apices, the hyphoid agglutinated cell rows at the margin, larger and thicker apothecia, longer spore tails, larger SBs, and particularly by the presence of crystalloid SCBs in paraphyses and excipular cells. For the delimitation from *O.*

Plate 359. **1–3**: *Orbilia spermoides*. – **2a**. Douglas fir mixed forest in Pinaleno Mts.; **1a–b**, **2b**, **d**, **3a–b**. rehydrated apothecia; **1c–d**, **2c**. dry apothecia; **1e**. apothecium in median section; **3d**, f. id., marginal region with glassy processes; **3c**. id., basal ectal excipulum, cells with crystalloid SCBs; **1f**, **3e**. asci with mature ascospores; **1g**. conidia from substrate. – Living state, except for ascus in **3e**. — **1a–g**. H.B. 7497a: USA, Arizona, Flagstaff, on *Pinus*; **2a–d**. H.B. 7517: ibid., Safford, on *Pseudotsuga*; **3a–f**. H.B. 7604d: France, Sisteron, on *Cedrus*.

aristata (p. 709) and *O. austroocculta* (p. 733) see under these species. In the hyphoid cell rows forming a thick t. porrecta at the margin the species resembles *O. fimbriata*, while other members of series *Hemiorbilia* show usually only a thin outer layer of t. porrecta.

Variation. In *O. spermoides* the glassy processes are remarkably variable in length. They are sometimes completely absent on most of the marginal cortical cells, or form very short caps on the agglutinated marginal cell rows. Possibly the processes got lost as they easily break at their base. The single

Map 61. Known distribution of *O. spermoides* in North America.

European collection differs from the North American merely in slightly longer spore heads and slightly longer asci.

Anamorph. *O. spermoides* formed trinacrium incurvum-like conidia in pure culture and on the natural substrate, in contrast to species related to *O. aristata* which have larger trinacrium subtile-like conidia and higher-branched conidial types.

Phylogeny. Two sequences obtained from the same sample from Pinaleno Mts. on *Pseudotsuga*, one from an ascospore isolate and one from apothecia, comprise the S1506 intron, ITS, and LSU, one also SSU. The two sequences surprisingly differ in the ITS region by 4 nt, in the intron by 1 nt, and in the LSU by 1 nt.

In our phylogenetic analyses, *O. spermoides* formed with *O. occulta* with rather high distance a supported clade (for details see under *O. occulta*, p. 732). The species is rather distant from the *aristata-clavuliformis* clade (11–15 % in ITS, 3.3–4.7 % in LSU D1–D2), also the intron shows a very high distance to all other members of section *Hemiorbilia* which have it (> 20 %).

Ecology. *O. spermoides* inhabits slightly to strongly rotten bark of xeric twigs and branches of gymnosperms. In western North America it was found on *Pinus* and *Pseudotsuga* in cold-temperate subhumid pinyon-juniper woodlands and cold-temperate to boreal humid ponderosa pine, Douglas fir, and Engelmann spruce forests of the Colorado Plateau (Grand Canyon, Mogollon Rim) and Chihuahuan Desert (Pinaleno Mountains). The single record from southern Europe on *Cedrus* was in an orosubmediterranean humid open mixed forest on the south-exposed slope of the Lure mountain range in calcarean Southern French Prealps.

Specimens included. **USA**: **Arizona**, Grand Canyon, Kaibab Plateau, 28 km ESE of Fredonia, 13 km NNW of Jacob Lake, 2115 m, branch of *Pinus edulis*, on bark, 17.V.1995, G. Marson (H.B. 7090a, anam. substr.). – Coconino Plateau, 8.5 km NNE of Tusayan, Mather Point, 2177 m, branch of *P. edulis*, on bark, 13.VI.2000, G. Marson (H.B. 7604d, anam. substr.).

Orbilia nanosperma Baral & G. Marson, **sp. nov.**, MB 813617 — Pls 360–361

Etymology: named after the small sperm-shaped spores.

Typification: Western Australia, Northcliffe, bark of *Eucalyptus jacksonii*, 16.XII.2001, G. Marson (ex H.B. 7201b, MEL 2389220, holotype).

Latin diagnosis: *Apothecia rehydratata 0.15–0.5 mm diam. (sine dentibus), aurantiaca, sessilia, margine exigue albido-dentata. Asci 8-spori. Ascosporae *5.5–7 × 1.6–1.9 µm, ellipsoideo-fusoideae, cauda basali 2–3.2 × 0.2–0.3 µm praeditae, in statu vivo corpusculum refringens lacrimiformem, ad apicem affixum continentes. Excipulum marginale processis vitreis perlongis, dentes conspicuos formantibus praeditum. Habitat ad corticem separatum, leniter putridum rami sicci* Eucalypti jacksonii *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.15–)0.2–0.4(–0.5) mm diam. (excl. teeth), 0.06–0.16 mm high (receptacle 0.06–0.09 mm), pale to light orange(-rose), round, scattered; disc flat, margin not or scarcely protruding, with 6–13 very prominent whitish teeth (20–)50–100 × (20–)30–70(–100) µm; sessile, superficial; dry with strongly incurved teeth partially or entirely covering the disc. **Asci** *~25–33 × 3.5–4.3 µm, †22–33 × 3–3.7 µm, 8-spored, spores (*) biseriate, 1(–2) lower spores inverted (not mixed), pars sporifera *12–16 µm long (†10–12 µm); **apex** (†) conico-hemispherical, dome †0.8–1 → 0.6 µm thick, in KOH mature 1–1.9 µm, without or sometimes with apical chamber; **base** with short to long, thin, flexuous stalk, L-shaped. **Ascospores** *5.5–7 × 1.6–1.7(–1.9) µm, †5–6.5(–7) × 1.4–1.6 µm, sperm-shaped: with ellipsoid-fusoid head and sharply differentiated filiform tail, head 3.3–4 µm long, apex obtuse to subacute, tail *2–3.2 × 0.2–0.3 µm, not swollen at base, straight or sometimes flexuous, often slightly to strongly geniculate near head; **SBs** *1.3–1.5 × 0.5–0.7 µm, tear- to pear-shaped, apically narrowed to a small point. **Paraphyses** apically uninflated or slightly to medium capitate, terminal cells †(3.5–)8–15 × 1.8–3.5 µm, lower cells †4–7 × 1.8–2.2 µm; unbranched at upper septum. **Medullary excipulum** hyaline, 10–40 µm thick, of medium dense textura globulosa forming horizontal chains, indistinctly to sharply delimited. **Ectal excipulum** of (†) distinctly thick-walled, ± vertically oriented t. globulosa-angularis from base to margin, 20–70 µm thick near base, cells †8–24 × 6–19 µm; 15 µm thick near margin, outermost margin of t. porrecta oriented at a 70–80° angle to the surface, marginal cortical cells †5–9 × 2–2.5 µm; **glassy processes** 10–100 × 2.5–4 µm, high-refractive, brittle, frequently stratified, ends curved inwards, agglutinated to form very prominent teeth. **Anchoring hyphae** medium abundant, †1.7–3.3 µm wide, walls 0.2–0.8 µm thick. **SCBs** in paraphyses globose, ~0.7–1.5 µm diam. **LBs** light yellow-orange

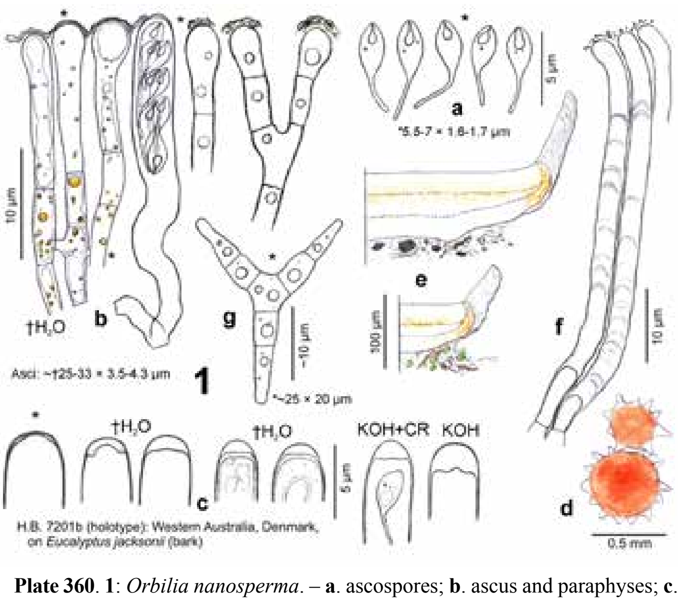

Plate 360. **1**: *Orbilia nanosperma*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecia in median section; **f**. glassy processes on marginal cortical cells; **g**. conidium from substrate.

Plate 361. **1**: *Orbilia nanosperma*. – **1a**. Eucalypt tall open forest (karri tingle), hanging xeric bark of *Eucalyptus jacksonii*; **1b**. outer surface of bark; **1d**, **f**, **h–k**. rehydrated apothecia; **1c**, **e**. dry apothecia; 1l. apothecium in external view; **1g**. asci and paraphyses (in KOH+IKI). — **1a–l**. H.B. 7201b (holotype): Western Australia, Warren, on *Eucalyptus*.

(carotenoids), abundant in lower part of paraphyses and in marginal excipulum, (†) up to 2 µm diam., IKI pale blue-green. **Exudate** over paraphyses 0.2–0.8 µm thick, continuous, finely rough, hyaline, firmly attached; over teeth granular. **— ANAMORPH**: trinacrium-like (presumed, from natural substrate). **Conidiophores** not seen. **Conidia** *~25 × 20 µm, stipe *13 × 3.3 µm, 2-septate, arms *12 × 3.5 µm, 2-septate, straight, distinctly tapering.

Habitat: collected 2–4 m above the ground, on large thin pieces of bark detached from ~60 m tall trees of *Eucalyptus jacksonii*, fallen from high above the canopy, on slightly decayed bast, on outer surface (very exceptionally on inner surface), slightly greyed, covered by a few algae (?*Gloeocapsa*). **Associated**: *Lachnum eucalypticola*, *Orbilia aviaristata, O. lilacina*, *O.* ?*pseudoflagellispora*. **Desiccation tolerance**: mature asci viable after 3 months (a few still after 9 months), ascospores survived for 9 months. **Altitude**: 195 m a.s.l. **Geology**: granite with alkali feldspar, migmatite, diorite, gabbro. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia nanosperma* is easily recognized by its small sperm-shaped ascospores and long triangular marginal teeth, also by comparatively small apothecia. The spores are similar as in *O. aristata* or *O. breviaristata* but much smaller. They also resemble those of *O. saccharifera* (section *Aurantiorubrae*) even in size, but that species differs in lacking an apical dome, longer asci (†33–47 µm), different paraphyses, and in much shorter glassy processes which emerge from thicker, septate cortical cells and which do not form teeth.

Anamorph. Only two rather small trinacrium-like conidia were seen on the natural substrate.

Ecology. *O. nanosperma* was collected on detached, slightly decayed, xeric bark of *Eucalyptus jacksonii* (Red Tingle) in a subtropical semihumid (summer-dry) open (though rather dense) eucalypt (karri-tingle) forest in the Warren ecoregion at the southern end of Darling Range in southwestern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Warren, 30 km SE of Pemberton, 14 km ENE of Northcliffe, W of Shannon, Middleton Road, 195 m, *Eucalyptus jacksonii*, on bark detached from branches, 16.XII.2001, G. Marson (ex H.B. 7201b, MEL 2389220, **holotype**; MEL 2389282, **isotype**, anam. substr.).

Orbilia aviflagellata Baral & G. Marson, **sp. nov.**, MB 813618 — Pls 362–363

Etymology: named after the ascospores having an inflated apex like a bird's head, but otherwise similar to *O. flagellispora*.

Typification: Western Australia, Mt. Singleton, twig and branch of *Acacia*, 24.XI.2001, G. Marson (ex H.B. 7204b, MEL 2389223, holotype).

Latin diagnosis: *Apothecia rehydratata 0.2–1 mm diam.*, *roseo-aurantiaca*, *sessilia*, *margine exigue albido-dentata. Asci 8-spori. Ascosporae *18.5–25 × 2.8–3.6 µm*, *triangulare-fusoideae*, *asymmetricae*, *cauda basali 13–17 × 0.3–0.4 µm*, *basi valde inflata praeditae*, *in statu vivo corpusculum refringens lacrimiformem*, *ad apicem affixum continentes. Excipulum marginale processis vitreis*, *dentes conspicuos formantibus praeditum. Habitat ad corticem vel lignum putridum ramuli et rami sicci* Acaciae *in zona subtropica semiarida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.25–0.6(–1) mm diam., 0.12–0.17 mm high, pale to light dirty orange-rose, slightly translucent, round, medium to very scattered; disc flat, margin 0–10 µm protruding, with ~15–22 prominent whitish teeth 30–90 × 20–80 µm, these sometimes short or absent; broadly sessile, superficial, dry ± contracted, disc partly closed by the incurved hairs. **Asci** *58–75 × 6.5–7.5 µm, †49–67 × 6–6.6 µm, 8-spored, spores (*) biseriate, 0–2(–3) lower spores inverted (± not mixed), pars sporifera *30–38 µm long; **apex** (†) hemispherical to slightly truncate, dome †1.5–1.8 → 1–1.2 µm thick (KOH 2.5–3 → 1.5–2 µm), with distinct apical chamber; **base** with short to medium long, ± thick, flexuous stalk, L- to Y-shaped. **Ascospores** *(18.5–)20–25 × 2.8–3.3(–3.6) µm, †20–25 × 3–3.4 µm, sperm-shaped: with fusoid to fusiform head and sharply edifferentiated filiform tail, head 5.5–7 µm long, apex obtuse to subacute-acuminate, tail 13–17 × 0.3–0.4 µm, always with distinctly swollen, bulbous base */†1.1–1.5 µm thick, head in profile view strongly inequilateral (triangular), tail straight to slightly (sometimes medium) curved; **SBs** *(2.2–)2.7–3.2(–3.5) × 1.3–1.5(–1.7) µm, tear- to pear-shaped, apically narrowed to a ± small point. **Paraphyses** apically uninflated to slightly clavate-capitate, rarely lageniform, terminal cells *(6–)11–20(–25) × 2.2–3(–3.5) µm, lower cells *10–18 × 1.6–2 µm (up to 2.5 µm wide near base); branched only near base. **Medullary excipulum** ± hyaline, 30–50 µm thick, of dense textura intricata with many inflated cells, sharply delimited from ectal excipulum by a 5–8 µm thick layer of t. porrecta. **Ectal excipulum** hyaline, towards margin pale orange, of (†) thin-walled to slightly gelatinized, vertically oriented t. globulosa-angularis from base to mid flanks, 30–60 µm thick near base, cells *8–24 × 6–16 µm; 20–35 µm thick at flanks and margin, at margin inner part of t. prismatica-angularis oriented at a 45–90° angle to the surface, outer part of t. porrecta oriented at 30–70°, marginal cortical cells *10–15 × 2.7–3.2 µm, †8–13 × 2–3 µm; **glassy processes** (5–)10–60(–100) × (2–)2.5–3(–3.5) µm, high-refractive, often stratified, straight or partly curved inwards towards end, easily breaking, coherent to form distinct teeth. **Anchoring hyphae** sparse to abundant, *1.8–3.5 µm wide, walls 0.2 µm thick. **SCBs** in paraphyses and ectal excipulum (near margin) globose, (0.7–)1.5–2.5 µm diam. **Exudate** over paraphyses (0.5–)1–3(–4) µm thick, cloddy, hyaline to very pale chlorinaceous, loosely attached; over margin and flanks 1–3 µm thick. — **ANAMORPH**: unknown.

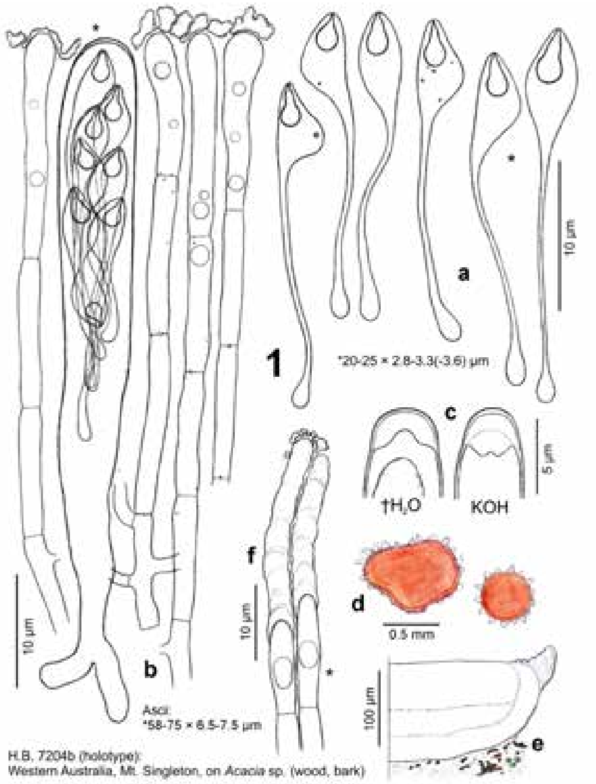

Plate 362. **1**: *Orbilia aviflagellata*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. rehydrated apothecia; **e**. apothecium in median section; **f**. glassy processes on marginal cortical cells.

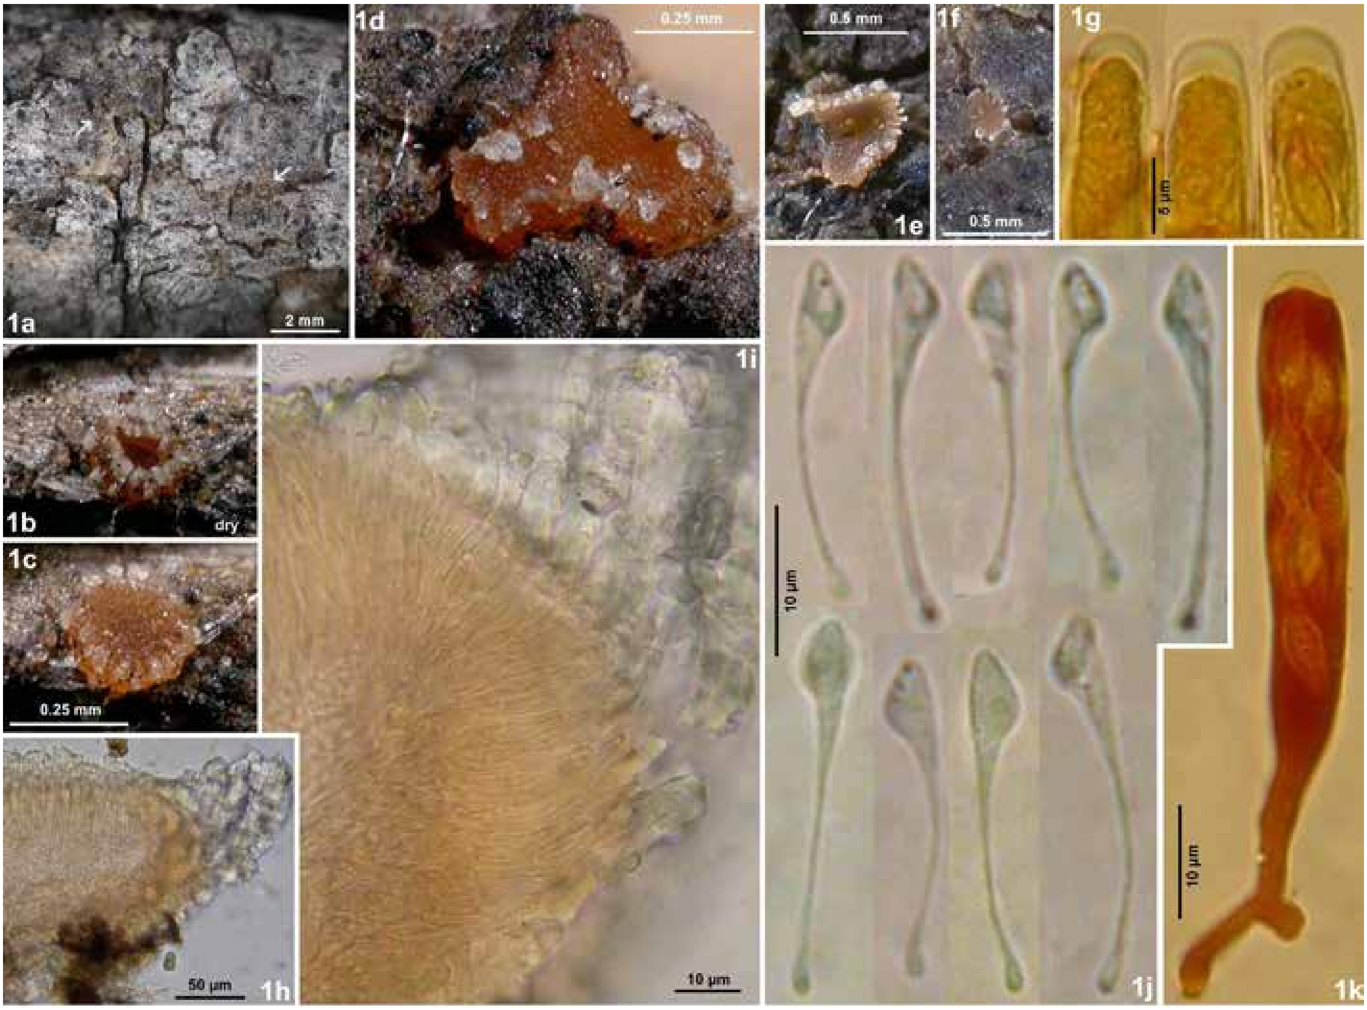

Plate 363. **1**: *Orbilia aviflagellata*. – **1a**. dead corticated xeric branch of *Acacia*; **1b**. dry apothecium; **1c–f**. rehydrated apothecia; **1h**. apothecium in median section; **1i**. id., marginal ectal excipulum with glassy processes; **1g**. ascus apices; **1k**. ascus; **1j**. ascospores. – Dead state (**1g**, **k** in KOH+IKI; **1h–j** in H_2O, lower left 3 spores in KOH). — **1a–k**. H.B. 7204b (holotype): Western Australia, Mt. Singleton.

Habitat: collected 0.5–2 m above the ground, partially to almost entirely decorticated, 2 and 11 mm thick twig and branch of *Acacia* sp., on bark (bast), more rarely on wood, medium to strongly decayed, greyed, algae absent or sparse. **Associated**: *Caloplaca* sp., *Orbilia amberina*, *O. australiensis*, *O. austroobtusispora*, *O. helicoobliqua*, *O. hesperidea*, *O. microserpens*, *O. multiserpens*, *O. myriolilacina*, *O. myriooblique*, *O. nothovinosa*, *O. paraobliqua*, *O. pleioaustraliensis*, *O. pleioaustrocylindrica*, *Ostropales*, ?*Parmelia* sp., *Patellaria* ?*andina*, *Symbiotaphrina* ?*desertorum*, ?*Triblidium* sp. **Desiccation tolerance**: fully viable for at least 18 months. **Altitude**: 380 m a.s.l. **Geology**: Archean sedimentary rock (light ochre soil). **Phenology**: long-lived.

Taxonomic remarks. *Orbilia aviflagellata* closely resembles the predominantly mediterranean *O. subaristata*, from which it differs in the ascospores having consistently asymmetrical heads. The strongly inequilateral shape of the spore heads is only visible in profile view, whereas in front view the spores perfectly fit those of *O. subaristata*. This peculiar 3-dimensional spore shape was observed in all ~12 apothecia tested. Likewise, the spore length of 19–25 µm was found to be rather constant within the holotype collection. For the similar *O. aviaristata* see below.

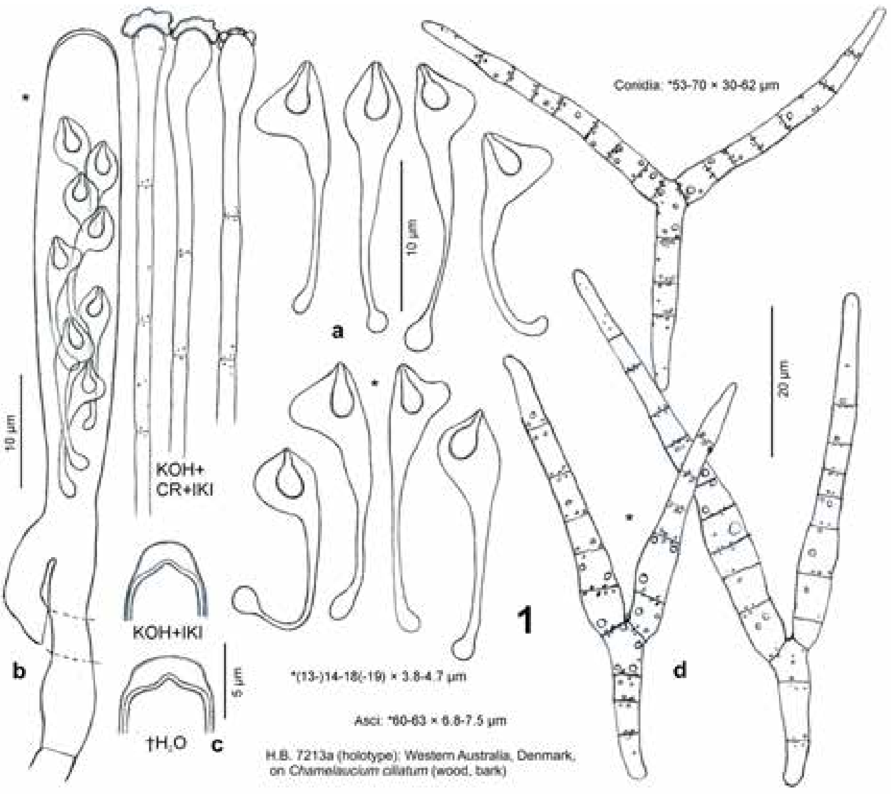

Plate 364. **1**: *Orbilia aviaristata*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. conidia from substrate.

Ecology. *O. aviflagellata* grew on ± rotten bark and wood of xeric twigs and branches of *Acacia* in a subtropical semiarid eucalypt open woodland in the Darling Plateau of southwestern Australia, at the border between Avon Wheatbelt and Yalgoo ecoregion.

Specimens included. **AUSTRALIA**: **Western Australia**, Avon Wheatbelt, 78 km NE of Wubin, 18 km SW of Mt. Singleton, W of Lake Moore, 380 m, twig & branch of *Acacia*, on bark & wood, 24.XI.2001, G. Marson (ex H.B. 7204b, MEL 2389223, **holotype**).

Orbilia aviaristata Baral & G. Marson, **sp. nov.**, MB 813619 — Pls 364–365

Etymology: named after the ascospores being similar as in *O. aristata* but with the inflated apex resembling a bird's head.

Typification: Western Australia, Denmark, branch of *Chamelaucium ciliatum*, 15.XII.2001, G. Marson (H.B. 7213a, MEL 2389228, holotype).

Latin diagnosis: *Similis* Orbiliae aviflagellatae *sed ascosporae distincte breviores*, *capitibus magis triangularibus*, *distincte latioribus*, *caudis subapicaliter saepe inflatis*, *dentes apotheciorum pauces*, *latiores*. *Habitat ad corticem vel lignum putridum ramorum siccorum* Chamelaucii *et* Eucalypti *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.3–0.6 mm diam. (0.2–0.45 mm excl. teeth), 0.15 mm high (receptacle 0.09–0.1 mm), light orange-rose, not or slightly translucent, ± round, medium to very scattered; disc flat, margin 10 µm protruding, with ~7–10 prominent whitish, ± triangular teeth 60–100 × 60–100 µm; sessile on a stalk-like base 0.05 × 0.22 mm, superficial; disc dry deep orange-red, somewhat contracted but teeth still projecting outwards. **Asci** *60–63 × 6.8–7.5 µm {T}, †38–55(–60) × 5.5–6.8(–7.5) µm {2}, 8-spored, spores (*) biseriate, 0–2 lower spores inverted (not mixed) {2}, pars sporifera *35 µm long, †27–32 µm; **apex** (†) hemispherical to slightly conico-truncate, dome †1.5–2 → 0.7–1.5 µm thick (H_2O or KOH) {2}, with small apical chamber; **base** with short to medium long, ± thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(13–)14–18(–19) × 3.8–4.7 µm (3.5–3.8 µm in front view) {T}, †(11.5–)12.5–16.5 × 3.4–4(–4.3) µm (2.8–3.2 µm in front view) {2}, sperm-shaped: with broadly fusiform head and sharply edifferentiated, filiform to subulate tail, head 4.5–5.5 µm long, apex obtuse to subacute-acuminate, tail 10–14 µm long, upper half or third usually ± widened, base always distinctly swollen (bulbous), */†(1–)1.3–1.6(–1.9) µm thick, head in profile view very strongly inequilateral (triangular), tail straight to often slightly to medium (rarely strongly) curved, 0.3–0.6 µm thick at narrowest part; **SBs** *3–3.5 × 1.3–1.6 µm {T}, tear- (to pear-)shaped, apically narrowed to a small to wide point. **Paraphyses** apically slightly to medium clavate(-capitate), terminal cells †12–19(–23) × (2–)2.5–3(–3.5) µm {T}, lower cells †8–13 × 1.3–1.8 µm {T}; unbranched. **Medullary excipulum** hyaline, 30 µm thick, of medium dense, horizontally oriented textura intricata with many large inflated cells (t. globulosa), medium sharply delimited. **Ectal excipulum** hyaline, of (†) slightly to medium gelatinized (common walls 1–1.5 µm), indistinctly vertically oriented t. globulosa-angularis(-prismatica) from base to mid flanks, 50–60 µm thick near base, cells †9–15 × 7–10 µm {T}; 15–20 µm thick at margin, inner part of t. angularis oriented at a high angle to the surface, outer part of t. prismatica-porrecta oriented at 70–80° (submargin) or 40–60° (upper margin), marginal cortical cells †6–10 × 2.5–3.5 µm {T}; **glassy processes** 10–100 × 2–3.7 µm {T}, high-refractive, stratified or not, ± straight but curved inwards at the end, coherent to form distinct teeth. **Anchoring hyphae** sparse, †1.5–3 µm wide, walls 0.2–0.5 µm thick. **SCBs**: no data available. **Exudate** over paraphyses (0.2–)1–2(–4) µm thick, cloddy, hyaline, firmly attached; over marginal teeth 2–3 µm thick. — **ANAMORPH**: trinacrium-like (presumed, from natural substrate {T}). **Conidiophores** not seen. **Conidia** Y-shaped, total size *53–70 × 30–62 µm, stipe *17.5–25 × 3.5–4.5 µm, 2–3-septate, arms *35–57 × 4–5.5 µm, 6–10 septate, tapering, slightly to strongly diverging, ± straight {T}.

Habitat: collected 0–4 m above the ground, corticated to partially decorticated, 5–12 mm thick branches of *Chamelaucium ciliatum* {T}, trunk of *Eucalyptus jacksonii* {1}, on bark (bast) {2} and wood {T}, at edges of detaching bark {T} or on outer surface of entirely detached

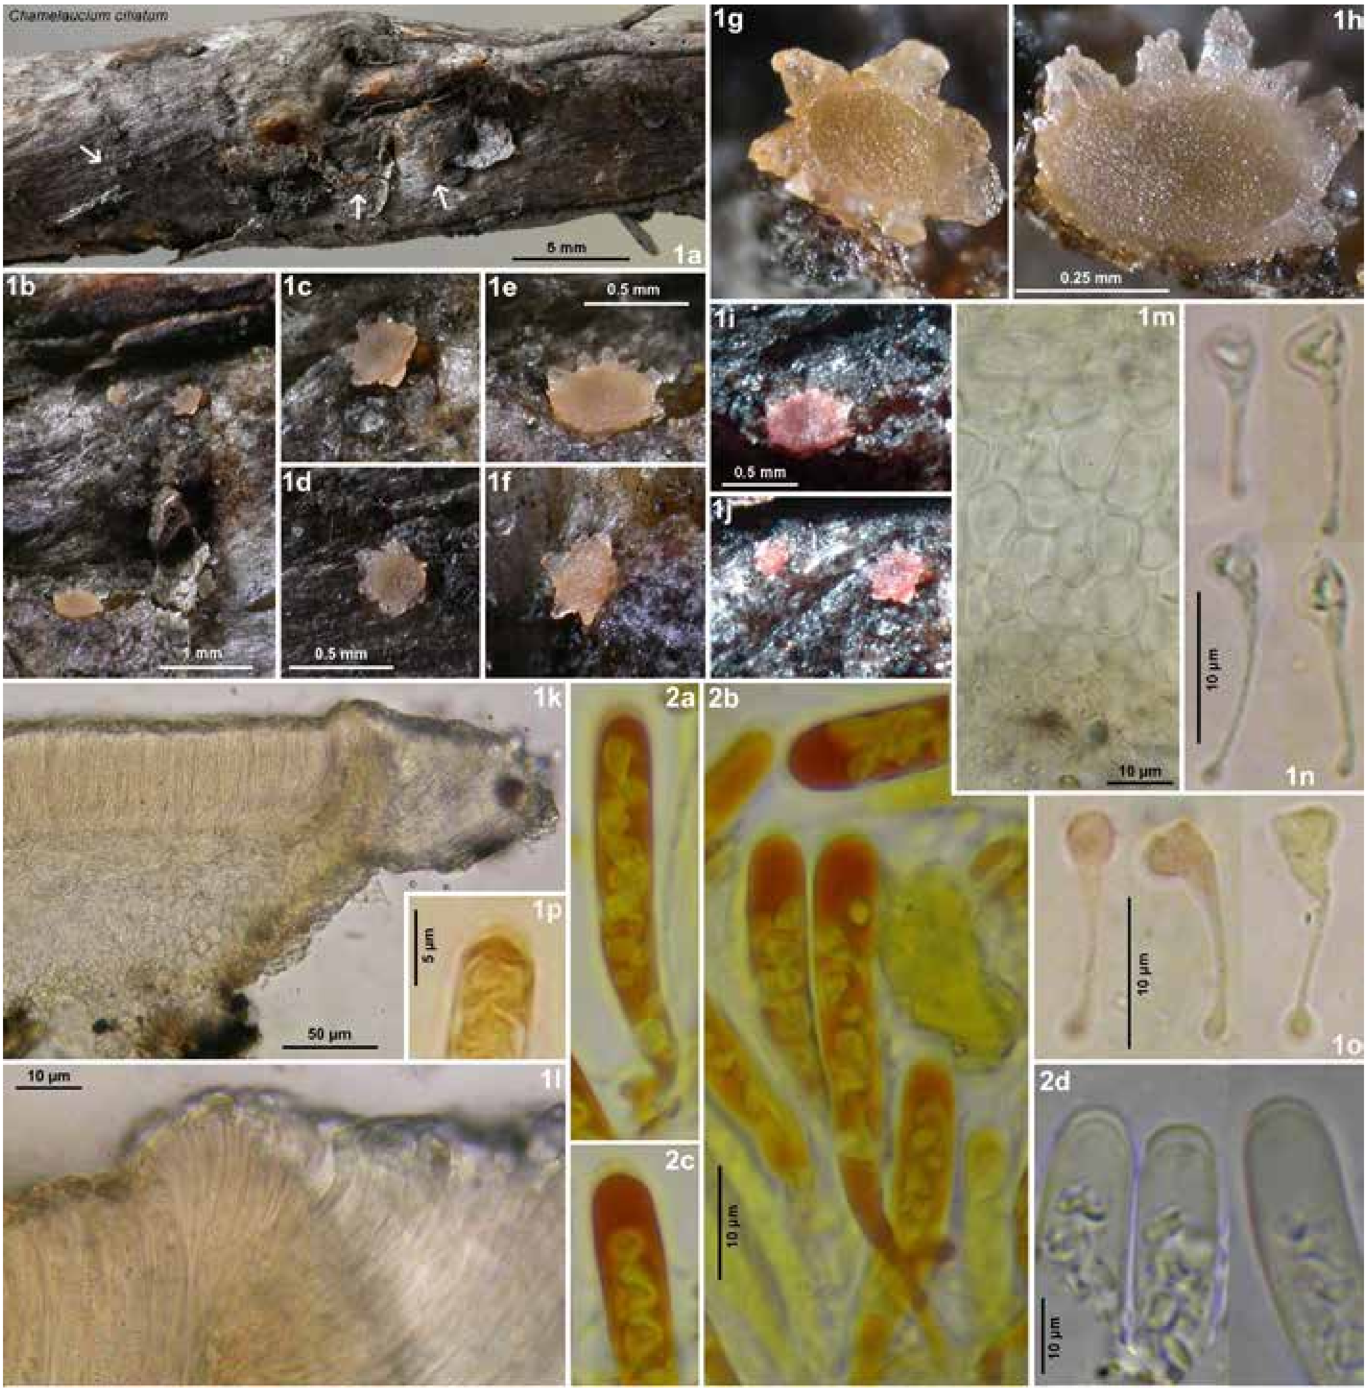

Plate 365. **1–2**: *Orbilia aviaristata*. – **1a**. dead, partially decorticated, xeric branch of *Chamelaucium ciliatum*; **1b–j**. rehydrated apothecia (**i–j**: phot. 2002, **b–h**: phot. 2006); **1k**. apothecium in median section; **1l**. id., marginal ectal excipulum with glassy processes; **1m**. id., basal ectal excipulum; **1n–o**. ascospores; **1p**, **2c–d**. ascus apices; **2a–b**. asci. – Dead state (**1n**, **2d** in H_2O; **1k–m** in KOH; **1o** in KOH+CR, **1p**, **2a–c** in KOH+IKI). — **1a–p**. H.B. 7213a (holotype): Western Australia, Denmark, on *Chamelaucium*; **2a–d**. H.B. 7201e: ibid., Northcliffe, on *Eucalyptus*.

trunk bark fallen from high above (1), 0.1 mm deep slightly to strongly rotten, partly over cracks of periderm, ± greyed, green algae absent or abundant (?*Gloeocapsa*). **Associated**: *Orbilia ?multiaustrocylindrica* {1}, *O. ?subclavuliformis* {1}, *O. triangulispora* {1}. **Desiccation tolerance**: fully viable for at least some weeks, dead in all parts after 9.5 months. **Altitude**: 75–195 m a.s.l. **Geology**: felsic granitic rocks with alkali feldspar, diorite, migmatite, gabbro. **Phenology**: long-lived.

Taxonomic remarks. *Orbilia aviaristata* closely resembles *O. aviflagellata*, from which it is tentatively separated by much shorter ascospores with distinctly wider, more triangular and asymmetrical heads, which often show a craw-like swelling at the transition to the spore tails, also by fewer and more triangular marginal teeth.

Anamorph. Only three conidia were detected on the natural substrate (Pl. 364: 1d). One of them resembles the type of *Trinacrium subtile* but the other two had less divergent arms.

Ecology. *O. aviaristata* was found on rotten bark and wood of xeric branches of *Chamelaucium ciliatum* and on detached fallen bark of *Eucalyptus jacksonii* (Red Tingle) at two distant (100 km) sites in subtropical semihumid eucalypt (karri-tingle) tall and low open forests in the Jarrah Forest and Warren ecoregions in the southern Darling Range and Plateau of southwestern Australia.

Specimens included. **AUSTRALIA**: **Western Australia**, Jarrah Forest, 47 km WNW of Albany, 13 km NNE of Denmark, NE of Mt. Lindesay, 75 m, branch of *Chamelaucium ciliatum*, on bark & wood, 15.XII.2001, G. Marson

Habitat ad corticem putridum siccum ramorum partim vivorum plerumque* Banksiae *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.2–)0.3–0.7(–0.9) mm diam. (incl. teeth), 0.1–0.21 mm high (receptacle 0.1–0.15 mm), light to bright orange or rose, ± translucent, round, very scattered or subgregarious in small groups; disc flat, margin 0–10 µm protruding (excl. teeth, 10–100 µm incl. teeth), with 5–16 prominent whitish teeth 20–100 × 30–120 µm; ± broadly sessile or with a distinct stipe 0.07–0.1 × 0.16 mm, superficial to slightly erumpent; disc dry partially to entirely covered by the incurved teeth, bright orange(-rose). **Asci** *(42–)48–56(–63) × 5.4–6.5 µm {2}, †38–50 × 4.5–5.5 µm {3}, 8-spored, spores *1–2-seriate, (0–)1–3(–4) lower spores inverted {2} (rarely mixed), pars sporifera *30–33 µm long; **apex** (†) hemispherical to very slightly truncate, dome †0.8–1 → 0.5–0.8 {1} or 1.2–1.7 → 0.8–1 {1} µm thick, with or without distinct apical chamber; **base** with short to medium long, thick, flexuous stalk, L- to Y-shaped. **Ascospores** *(6–)7–8(–9) × 2.8–3.3(–3.8) µm {3}, †5.5–7 × 2.3–3.2 µm {2}, strongly clavate, rarely fusoid, with slight to distinct, obtuse to subacute lateral protrusion, apical end rounded to obtuse, base strongly attenuated, tail-like or often with a distinct short tail 1–1.5 × 0.3–0.5 µm, head slightly to strongly inequilateral, tail straight or slightly curved; **SBs** attached at the lateral protrusion, *1.8–2.6 × 1.2–1.5 µm {2}, (broadly) tear-shaped, apically narrowed to a small point, pointing with the acute end laterally or obliquely downwards. **Paraphyses** apically uninflated to slightly (rarely medium) capitate-clavate, terminal cells *(8.5–)11–20(–23) × (2–)2.5–3.5(–4)((–4.5)) µm {3}, lower cells *(6.5–)7.5–11 × 1.8–2.7 µm {3}; unbranched at upper septum. **Medullary excipulum** hyaline to pale rose, 20–70 µm thick, of medium dense textura intricata with many inflated cells, rather sharply delimited from ectal excipulum, at flanks by a t. porrecta. **Ectal excipulum** hyaline, pale reddish towards margin, of (†) slightly to medium gelatinized, vertically oriented t. (globulosa-)angularis(-prismatica) from base to margin, 25–110 µm thick near base, cells *10–25 × 9–17 µm {2}, †10–17 × 8–11 µm {1}, common walls †0.3–1(–1.5) µm thick; 20–30 µm thick near margin, inner part of t. prismatica oriented at a 60–90° angle to the surface, outer part of t. porrecta oriented at 10–40°, marginal cortical cells *8–12 × 3–3.5 µm {1}, †7–10 × 2–3 µm {1}; **glassy processes** 10–100 × 2–3.5 µm {2} (2–10 µm long at innermost margin), high-refractive, slightly stratified, brittle, straight or inwards curved, coherent to form compact teeth. **Anchoring hyphae** medium to very abundant, */†(1.7–)2–3(–4) µm wide, walls 0.2–0.5(–1) µm thick {2}. **SCBs** in paraphyses and ectal excipulum (near margin) globose, 1–2.2 µm diam. **Exudate** over paraphyses (0.5–)1–2(–3) µm thick, cloddy, hyaline to pale yellowish, loosely attached; on glassy processes absent or sparse and thin. **— ANAMORPH**: unknown.

Habitat: collected (0–)1–3 m above the ground, on corticated, (4–)7–16 mm thick still-attached branches (especially towards their ends) or on up to 15–20 cm thick standing, partly still-living trunks, of *Acacia* sp. {1}, *Banksia grandis* {3}, *B. menziesii* {2}, on attached or partially detached, medium to strongly decayed bark {5} (periderm {3} and bast {2}), partly on scars where leaves or fruits were attached, slightly to strongly greyed, green algae sparse or abundant. **Associated**: *Cosmospora* sp. {1}, *Gloniopsis* sp. {1}, *G. praelonga* {3}, *Mellitiosporiella* sp. {1}, *Nitschkia* cf. *broomeana* {1}, *Orbilia amberina* {1}, *O. austrocylindrica* {1}, *O. curvatinavajoana* {2}, *O. eucalypti* {3}, *O. microserpens* {1}, *O.* ?*nothovinosa* {1}, *O. pleioserpens* {1}, *Patellaria* '*andina*' {1}, *Proliferodiscus griseoviolaceus* {1}, ?*Stilbella* sp. {1}, ?*Teichospora* sp. {1}. **Desiccation tolerance**: fully viable for at least 16 months. **Altitude**: 65–370 m a.s.l. **Geology**: Cretaceous sedimentary rock; Archean granite, granulite, feldspar, migmatite. **Phenology**: long-lived.

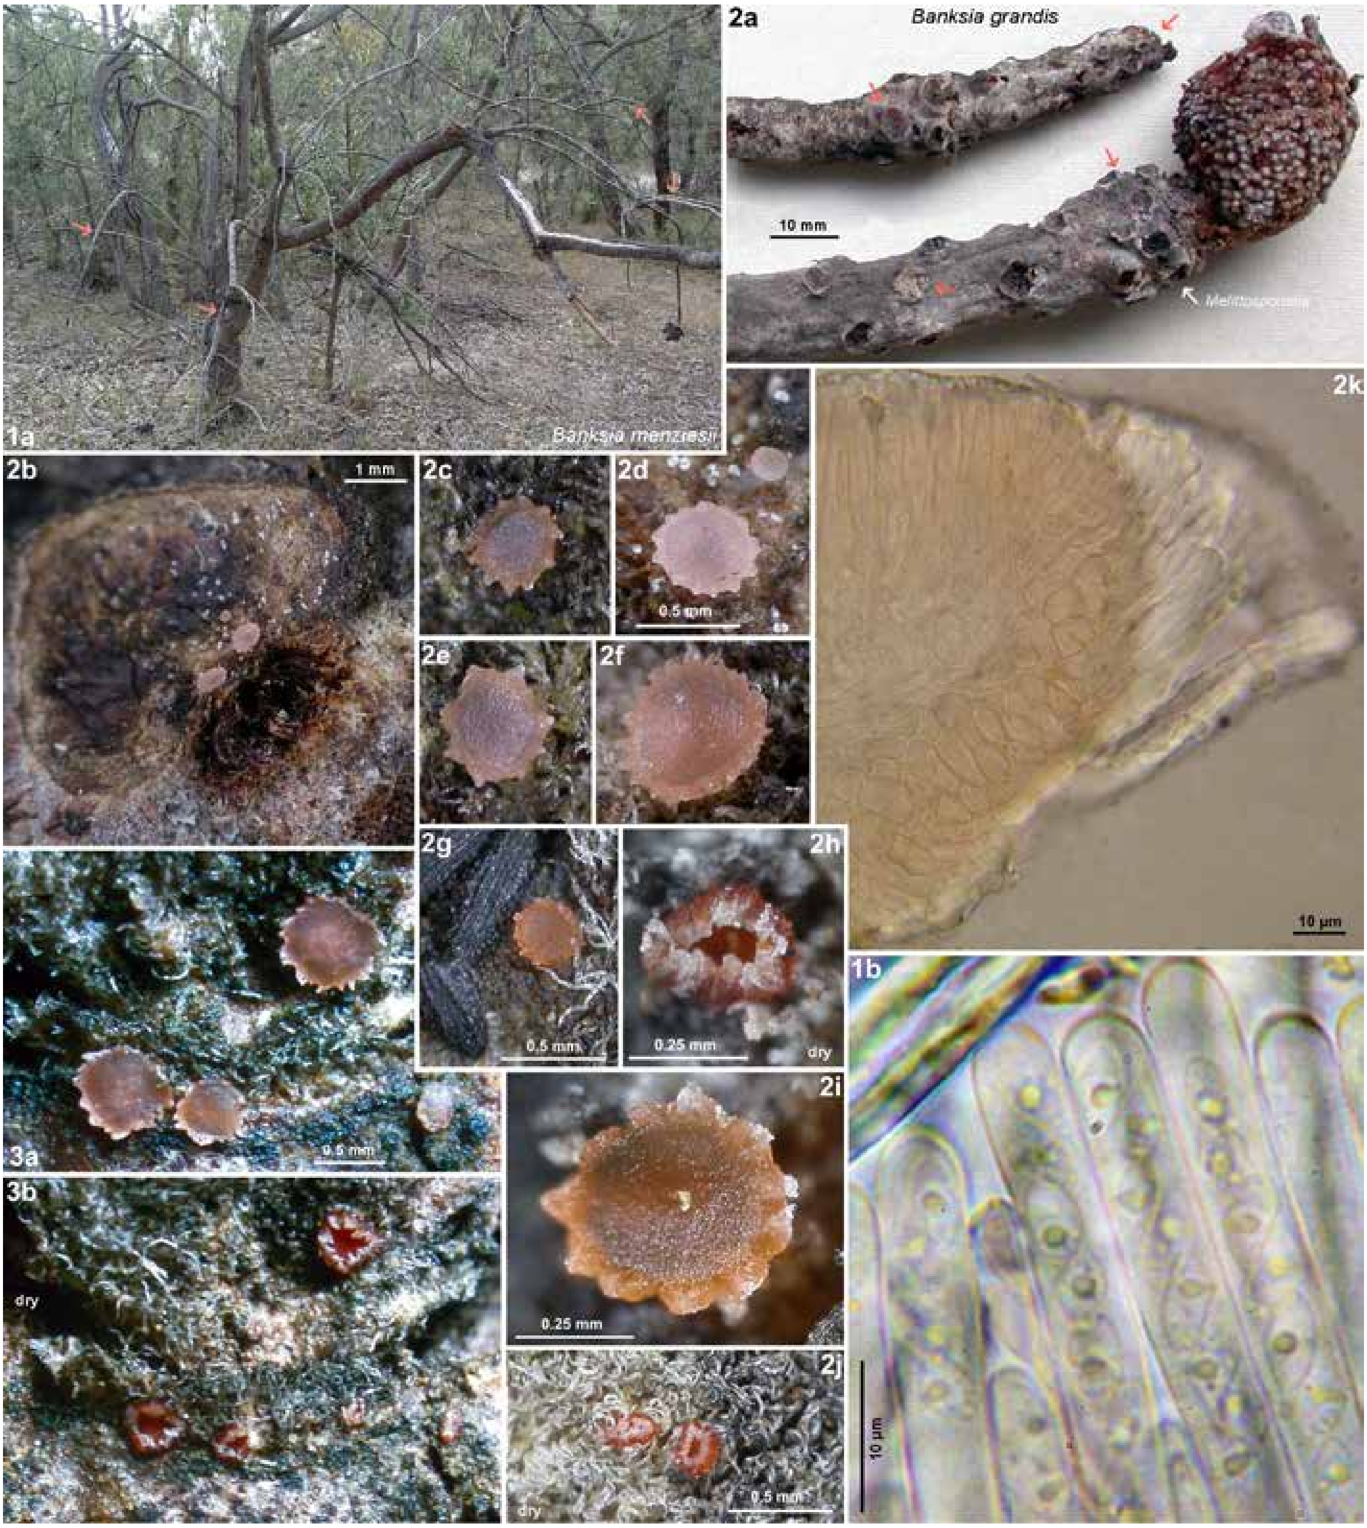

Plate 367. **1–3**: *Orbilia aviceps*. – **1a**. *Banksia menziesii* in semihumid banksia-eucalypt open woodland; **2a**. dead corticated xeric branches of *B. grandis*; **2b–g**, **i**, **3a**. rehydrated apothecia (**2g** with *Gloniopsis praelonga*); **2h**, **j**, **3b**. dry apothecia; **2k**. marginal ectal excipulum in median section, with glassy processes; **1b**. mature asci with ascospores. – Living state. — **1a–b**. H.B. 7209a: Western Australia, Muchea, on *Banksia*; **2a–k**. H.B. 8659a: ibid., Kalamunda, on *Banksia*; **3a–b**. H.B. 7322a (holotype): ibid., on *Banksia*.

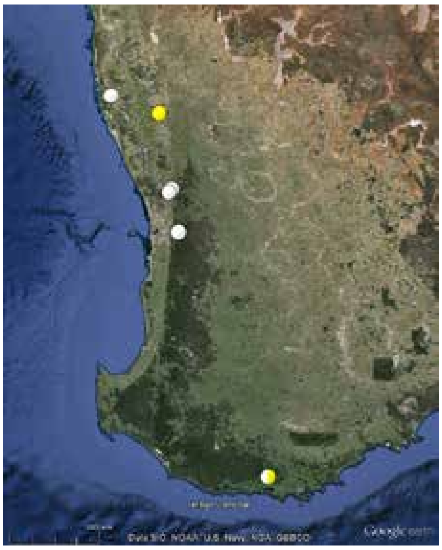
Taxonomic remarks. *Orbilia aviceps* is well characterized by its strongly asymmetrical ascospores with a lateral protrusion and a short basal tail, somewhat resembling a bird's head, or the flowers of *Aconitum*. The tear-shaped spored body is attached to the lateral protrusion, similar as in *O. corculispora* (concerning the peculiar feature of lateral insertion of SBs see also p. 72). For the similar *O. triangulispora* see below.

Although the spores resemble those of *O. corculispora*, *O. aviceps* is placed in series *Hemiorbilia* because of the similarity with the two preceding species regarding spore shape, long glassy processes, and paucity of inverted lower spores. Molecular data were not available from this and the very similar *O. triangulispora*.

Variation. The apothecia varied in size from 0.2–0.3 up to 0.3–0.9 mm, including their teeth, also in the number of teeth. The distinct though short spore tails, which are the main difference to *O. triangulispora*, were only very exceptionally absent.

Ecology. *O. aviceps* was found on ± rotten bark of xeric branches of two species of *Banksia*, once also on *Acacia*, in



Map 62. Known distribution of *O. aviceps* (white) and *O. triangulispora* (yellow) in southwestern Australia.

subtropical semihumid southwestern Australia: in banksia-eucalypt open woodlands in the coastal Geraldton Sandplains and at the northern end of Darling Range, here also in a eucalypt open forest (jarrah-marri), and at the southern end of Darling Range/Plateau in a eucalypt low open forest (karri-tingle).

Specimens included. **AUSTRALIA**: **Western Australia**, Geraldton Sandplains, 20 km SE of Jurien Bay, 18 km NE of Cervantes, Cervantes Rd, 65 m, branch of *Acacia*, on bark, 11.XI.2007, G. Marson (H.B. 8954e). – Swan Coastal Plain, 48 km NNE of Perth, 4.5 km NE of Muchea, Reserve Road, 800m 97 m, branch of *Banksia menziesii*, 3.IX.2006, G. Marson (G.M. 2006-09-03.1 ø). – Jarrah Forest, 54 km NNE of Perth, 11 km NE of Muchea, 187 m, trunk of *B. menziesii*, on bark, 23.XI.2001, G. Marson (H.B. 7209a). – 28 km E of Perth, 8 km ESE of Kalamunda, 4 km E of Bickley, junction of Lockwood and Gunjin Road, 370 m, branches of *B. grandis*, on bark, 13.XII.2001, G. Marson (ex H.B. 7322a, MEL 2389235, **holotype**). – ibid., 7.IX.2006, G. Marson (H.B. 8659a). – 7 km WNW of Albany, 13 km NNE of Denmark, NE of Mt. Lindesay, 75 m, branch of *B. grandis*, on bark, 15.XII.2001, G. Marson (ø).

Orbilia triangulispora Baral, **sp. nov.**, MB 813621 — Pls 368–369, Map 62

Etymology: referring to the nearly triangular shape of the ascospores.

Typification: Western Australia, Denmark, branch of *Chamelaucium ciliatum*, 15.XII.2001, G. Marson (ex H.B. 7213b, MEL 2389229, holotype).

Latin diagnosis: *Similis* Orbiliae avicipiti *sed ascosporae distincte breviores et latiores, absque cauda. Habitat ad corticem et lignum putridum siccum ramorum* Chamelaucii *et* Verreauxiae *in zona subtropica semihumida Australiae meridio-occidentalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.2–0.6 mm diam., 0.1–0.2 mm high (receptacle 0.1–0.15 mm), bright orange to (rose-)orange, slightly translucent, round, scattered to subgregarious; disc flat, margin distinct, 5–15 µm protruding (30–100 µm incl. teeth), with prominent ± whitish teeth of 40–120 × 30–100 µm (varying in size between apothecia); sessile or with distinct, 0.05 mm high stipe, superficial; dry deep apricot-red. **Asci** *50–58 × 5.3–6 µm {1}, †(37–)42–53 × 4.5–5.3 µm {2}, 8-spored, spores (†) uniseriate, orientation irregular {T} or basal 2–5 spores inverted {1}, pars sporifera *29–33 µm; **apex** (†) hemispherical to slightly truncate, dome †1–1.3 → 0.8–1 µm thick {2}, apical chamber partly distinct; **base** with short to medium long, thick, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(3.5–)4–4.7 {T} or 5–6(–7) {1} × (3.3–)3.5–4 {2} µm, triangular in profile view (in front view probably ellipsoid-fusoid), with ± pronounced, obtuse to subacute lateral protrusion, apical end mostly obtuse, basal end ± attenuated, rarely tail-like; **SBs** attached at lateral protrusion, *(1.8–)2–2.5(–3) × (1–)1.2–1.4(–1.6) µm {2}, tear- to pear-shaped, also subglobose, apically narrowed to a small point, with or without a very short filum, acute end pointing laterally or sometimes slightly downwards. **Paraphyses** apically slightly clavate-capitate, terminal cells *12–20 × (2–)2.5–3.5 µm {1}, †12–19 × 2.2–3 µm {T}, lower cells *8–12.5(–14) × 1.8–2.4 µm {1}, †6–9 × 1.3–1.7 µm {T}; frequently branched in middle and lower part. **Medullary excipulum** very pale to light orange, 30–60 µm thick, of medium dense textura intricata or t. globulosa, with some or many inflated cells, indistinctly to sharply delimited. **Ectal excipulum** pale to light orange, of (†) not or slightly to medium gelatinized, ± vertically oriented t. globulosa-angularis-prismatica from base to mid flanks, 25–60 µm thick near base (up to 100 µm in stipe), cells *10–24(–28) × 8–16(–18) µm {1}, †8–15 × 6–8 µm {T}, common walls up to †0.5–1 µm thick; 20–30 µm thick near margin, inner layer of t. angularis, outer layer of t. prismatica-porrecta oriented at a 20–45° angle to the surface, marginal cortical cells *10–12 × 4–5 µm {1}, †8–11 × 2.5–3.5 µm {T}; **glassy processes** 5–100 × 2–3 µm {T}, high-refractive, not stratified (in KOH slightly so), brittle, partly curved inwards near apex (sometimes uncinate), coherent to form large distinct teeth. **Anchoring hyphae** abundant, †1.5–3 µm wide, walls 0.2–0.4(–1) µm thick {2}, forming a 5–10 µm thick hyaline layer on flanks. **SCBs** in paraphyses and marginal excipulum globose, (0.8–)1.5–2 µm diam. {1}. **Exudate** over paraphyses (0.3–)1–2.5(–3) µm thick, thin and rough or large and cloddy, loosely attached; over teeth absent or 1–2 µm thick, firmly attached. **— ANAMORPH**: unknown.

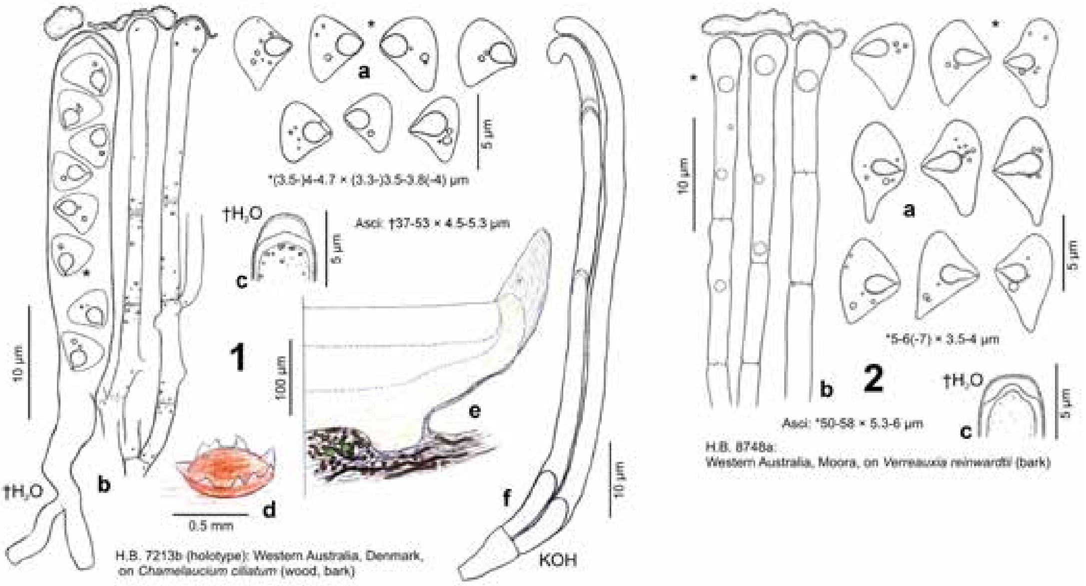


Plate 368. **1–2**: *Orbilia triangulispora*. – **a**. ascospores; **b**. ascus and paraphyses; **c**. ascus apices; **d**. apothecium (rehydrated); **e**. apothecium in median section; **f**. id., marginal cortical cells with long agglutinated glassy processes.

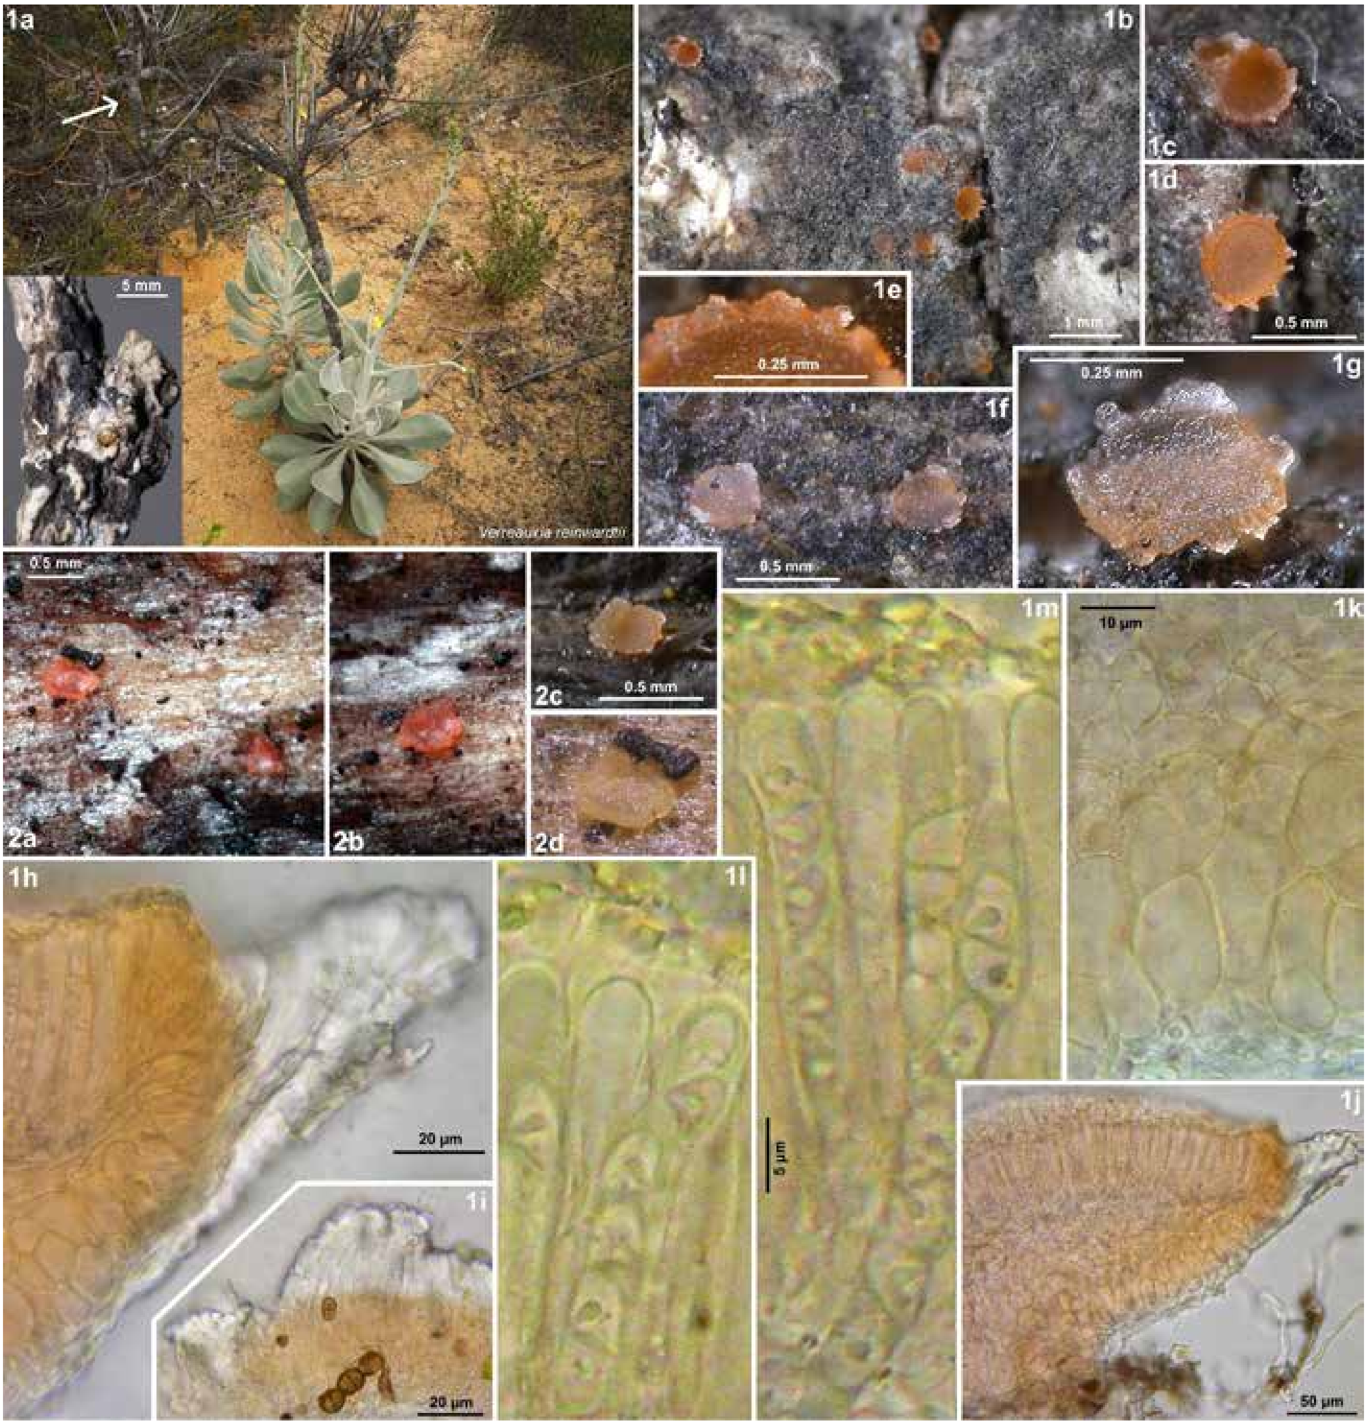

Plate 369. **1–2**: *Orbilia triangulispora*. – **1a**. acacia shrubland, *Verreauxia reinwardtii* with dead, corticated, xeric branch (arrow); **1b–g**, **2a–d**. rehydrated apothecia (phot. **2a–b** after 10 months, **2c** after 4.5 years, **2d** after 10 years); **1j**. apothecium in median section; **1h**. id., marginal ectal excipulum with glassy processes; **1i**, marginal teeth in top view; **1k**. basal ectal excipulum in median section; **1l–m**. mature asci with ascospores. – Living state (except for mature asci in **1l–m**). — **1a–m**. H.B. 8748a: Western Australia, Moora, on *Verreauxia*; **2a–d**. H.B. 7213b (holotype): ibid., Denmark, on *Chamelaucium*.

Habitat: collected 0–1 m above the ground, partially to entirely decorticated, 8–11 mm thick branches of *Chamelaucium ciliatum* {1}, *Verreauxia reinwardtii* {1}, on 0.1 mm deep strongly decayed bark {2} and wood {1}, slightly to strongly greyed, green algae sparse. **Associated**: *Orbilia amberina* {1}, *O. aviaristata* {1}, *O. curvativitalbae* {1}, *O. lilacina* {1}, *O. ?multiaustrocylindrica* {1}, *O. plurililacina* {1}, *O. ?subclavuliformis* {1}, *Ostropales* {1}, ?*Parmelia* sp. {1}, *Proliferodiscus olivaceoviridis* {1}. **Desiccation tolerance**: viable in all parts after 3 months, some spores still alive after 9.5 months. **Altitude**: 75–235 m a.s.l. **Geology**: Cretaceous sedimentary rock (ochre sandy soil); granite. **Phenology**: long-lived.

Taxonomic remarks. The ascospores of *O. triangulispora* resemble *O. aviceps* in shape, but are shorter and wider and never possess a distinct tail. The basal spore end is only sometimes tail-like, otherwise it is still recognizable in being often more attenuated than the upper end. In combination with the occurrence on different host plants, *O. triangulispora* is believed to represent a species of its own.

Variation. The spores and SBs in the paratype are longer than in the holotype and some spores resemble *O. aviceps* in their attenuated base.

Ecology. *O. triangulispora* grew on rotten wood and bark of xeric branches of *Verreauxia* and *Chamelaucium* at two very distant (500 km) sites in southwestern Australia: in a subtropical semihumid eucalypt open woodland in the Swan Coastal

Plain ecoregion at the northern part of Darling Plateau and in a eucalypt low open forest (karri-tingle) in the Jarrah Forest ecoregion at the southern end of Darling Range.

Specimens included. **AUSTRALIA**: **Western Australia**, Swan Coastal Plain, 150 km N of Perth, 13 km WNW of Moora, Dandaragan Road, 235 m, branch of *Verreauxia reinwardtii*, on bark, 24.X.2007, G. Marson (H.B. 8748a). – Jarrah Forest, 47 km WNW of Albany, 13 km NNE of Denmark, NE of Mt. Lindesay, 75 m, branch of *Chamelaucium ciliatum*, on wood & bark, 15.XII.2001, G. Marson (ex H.B. 7213b, MEL 2389229, **holotype**).

Series *Vibrioides*

Orbilia subgenus ***Hemiorbilia*** section ***Hemiorbilia*** series ***Vibrioides*** Baral, E.Weber & G. Marson, **ser. nov.**, MB 829071 – Type species: *Orbilia vibrioides* Baral, Priou & G. Marson

Etymology: named according to the ascospores resembling bacteria of the genus *Vibrio* in some of the species, including the type.

Latin diagnosis: *Apothecia sessilia, disciformia, aurantio-ochracea vel roseo-rubra, disco et margine glabro vel saepe albido- ad luteo-pulveraceo, margine parum crenulato vel costato. Asci 8- ad 128-spori, apice in statu emortuo hemisphaerico, valde crassitunicato. Ascosporae ovoideae, cylindricae vel clavatae, apice rotundato vel obtuso, rectae vel valde curvatae, in statu vivo corpusculum refringens bacilliformem, lacrimiformem vel globosum, ad apicem vel subapicem affixum continentes. Paraphyses ad apicem non vel parum inflatae, exsudato crasso, hyalino vel fortiter sulphureo tectae. Excipulum marginale absque processis vitreis. Habitat ad lignum vel plerumque corticem putridum ramorum in aere prominentium,* etiam ad culmos vel folios Poacearum, *in zona temperata vel subtropica ad tropica, humida ad arida.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated (0.1–)0.15–0.5(–0.9) mm diam., pale to bright ochraceous- to rose-orange, rarely pale cream, disc and exterior smooth or slightly to strongly pruinose to warted by whitish to mostly yellow exudate, margin in some taxa crenulate or ribbed, sessile. **Asci** *27–60 × 4.7–6.8 µm when 8-spored, *(46–)55–80(–120) × (8.5–)9.5–13(–15) µm when 32–128-spored, ± half of spores inverted (strongly mixed); **apex** (†) hemispherical, with very thick dome: immature 1.5–2.5(–3.5) µm when 8-spored, (2–)3–4(–6) µm when 32–128-spored, often with small apical chamber; **base** T-, L-, Y- or h-shaped. **Ascospores** *(3.4–)3.8–5(–5.3) µm long when 8-spored, *(4.3–)5–15(–17) µm when 32–128-spored, (1.4–)1.6–2.6(–3.2) µm wide, cylindrical to clavate, apex rounded to obtuse, base rarely with a tail, straight to ± strongly curved (cashew- to L-shaped or helicoid); **SBs** attached to apical or subapical (to lateral) spore wall, (1–)1.5–3.5(–4.5) × (0.2–)0.3–1.3 µm, rod-shaped to ampulliform or tear-shaped to globose, straight, sometimes geniculate, apically narrowed to a wide or sometimes very narrow point. **Paraphyses** uninflated or slightly clavate-capitate at the apex, terminal cells 0.6–1.3(–2.2)× as long as lower cells, unbranched or sometimes branched near apex. **Ectal excipulum** cells near base *(5–)7–15(–18) × (4–)5–13(–16) µm, near margin of t. angularis to mostly t. prismatica-porrecta, outer part oriented at a high to often medium or low angle, without **glassy processes**. **SCBs** globose or absent; **VBs** consistently absent; **carotenoids** in LBs not observed. **Exudate** (0.2–)1–3(–8) µm thick, coarsely cloddy, loosely to firmly attached, hyaline to bright sulphur-yellow. **— ANAMORPH**: unknown.

Habitat: on bark and wood of corticated to decorticated, dead, still-attached twigs and branches of angio- rarely gymnosperms, rarely on *Poaceae*; temperate humid or subtropical to tropical semihumid to arid; all species desiccation-tolerant.

Recognized species: 10.

Taxonomic remarks. Series *Vibrioides* represents a somewhat isolated lineage characterized by a series of partly plesiomorphic traits, including a strong wall thickening of the hemispherical apex of the predominantly multispored asci, straight to strongly curved ascospores with apically or obliquely attached spore bodies, ± uninflated paraphyses with short terminal cells, and abundant external exudate.

The multispored members of this series are already macroscopically rather easily recognizable by apothecia with a pruinose to prominently warted hymenium. The rough to cloddy, pale to bright sulphur-yellow exudate covers the tips of paraphyses and the often ribbed margin. It is predominantly firmly attached to the paraphyses, at least its innermost part, for the case that it consists of several layers. The exudate shows a striking autofluorescence under UV-illumination (365 nm, yellow to orange, Fig. 97), in contrast to other members of section *Hemiorbilia* in which the fluorescence is comparatively weak. Because the autofluorescence of the surrounding substrate is usually low, the mostly scattered apothecia can easily be detected under UV, even in the dry state. The paraphyses project either singly or in fascicles about 5–15 µm beyond the hymenium and provoke a warted surface, reminiscent of a crumble cake.

The very thick apical domes of the asci are characteristic of the whole group, also the rod-shaped to ampulliform to globose SBs which are subapically inserted in some of the multispored species and then partly geniculate. A faintly yellowish-reddish (dextrinoid) iodine reaction of the thick inner part of the apical dome was inconsistently obtained in *O. vibrioides*, *O. junci*, *O. myrioobliqua*, *O. helicoobliqua*, *O. angustoobliqua*, and *O. paraobliqua* (in IKI or MLZ, with or without KOH-treatment). This inner part stains distinctly pinkish-red in CR_{SDS}, but this congophilous reaction is also observed in other members of section *Hemiorbilia*. *O. junci* is tentatively placed in series *Vibrioides* here because of its strongly thickened apical dome, but otherwise it shares also characteristics of series *Hesperideae*.

Species delimitation. Some infraspecific variability was noted in most of the included species, sometimes within a population or even a single apothecium. Due to this variation and the often only slight interspecific differences, together with the frequently observed coexistence of two or up to five of the multispored taxa of series *Vibrioides* within the same collection, the present species concept needs further investigation. Particularly three species were problematic: *O. anguliobliqua*, *O. helicoobliqua*, and *O. curvatiobliqua*. They are only known from a single mixed collection on *Acacia*, in which they grew in separate populations on different twig fragments, though in close association with two further species of this series, *O. myrioobliqua* and *O. pleistoobliqua*. During documentation, the three populations were thought at first to belong to a single species, but finally we preferred to separate them as different species.

Anamorph. We have rarely seen conidia on the natural substrate in association with members of series *Vibrioides*: tridentaria-like in *O. vibrioides* and *O. graminis*, dwayaangam-like and trinacrium-like in the multispored Australian species. However, their connection to a teleomorph remained uncertain. *O. junci* possesses a dwayaangam-like anamorph, but its affiliation in series *Vibrioides* is uncertain because DNA data were unavailable.

Phylogeny. Sequences comprising ITS and LSU were available for *O. myrioobliqua*, *O. helicoobliqua*, *O. graminis*, and two different genotypes of *O. vibrioides*. When analysing ITS+LSU (Phyl. 9), ITS (Phyl. 10), or LSU (Phyl. S13), the four species clustered in a strongly (ITS+LSU, ITS, LSU)

Table 67. Positions in the LSU (D1–D2) found to be more or less specific to series *Vibrioides* (yellow), in comparison with series *Hesperideae* (green) and series *Hemiorbilia* (blue). Y = C/T, R = A/G. Position numbers starting with TGACCT by omitting predominant gaps in alignment of all groups of *Orbiliomycetes*.

supported clade that stands rather isolated from other groups of section *Hemiorbilia*. A distance of 16.5–23.5 % (S1506 intron), 12–13.5 % (ITS), and 2–3 % (LSU D1–D2) is noted between the 64-spored and the 8-spored taxa, but between *O. vibrioides* s.l. and *O. graminis* the distance is even higher (21 % in intron, 16.5–19 % in ITS, 4 % in LSU), while between *O. myrioobliqua* and *O. helicoobliqua* it is only 1.3 % (ITS) and 0.2–0.4 % (LSU).

Further DNA data from multispored members of series *Vibrioides* are required to substantiate the above result which places the multispored Australian taxa with strongly fluorescent exudate in close relationship with 8-spored taxa from outside Australasia in which the exudate is less fluorescent. The morphological similarity in spore shape between *O. vibrioides*/*graminis* and *O. curvatiobliqua* and the thick-walled ascus apex in all members of this group support the close relationship between 8- and multispored taxa.

Specific nucleotide positions. The entire series *Vibrioides* shares a few positions with two members of the *cryptogena-sarothamni* clade: at pos. 162 and 254 of LSU D1 with *O. corculispora* and at pos. 524 and 562 of LSU D2 with *O. sarothamni* (Tab. 67). However, it differs from the *cryptogena-sarothamni* clade in the motif ATTA (vs. ATTG) at the 5'-end of ITS2 (Tab. 20) and also lacks the large gap region downstream of it, mentioned under series *Hesperideae*.

The two available sequences of *O. vibrioides* s.l. differ in the SSU V8 at pos. 66 by CGA**A**AG (as in the *Lecophagus* and *Hyalorbilia* clade and some *Dactylellina* spp.) from all other *Orbilia* spp. which here have CGA**G**AG. Only short parts of SSU were available for *O. graminis*, *O. myrioobliqua*, and *O. helicoobliqua* which do not cover this region.

Ecology. The three species with 8–16-spored asci occur in temperate humid to subtropical semihumid areas of Europe, North America, and Macaronesia. Two inhabit xeric culms and leaves of monocots whereas *O. vibrioides* s.l. was found on both angio- and gymnosperm wood and bark. The as yet known distribution of the eight multispored species is confined to the west and southwest of Australia, where the sites extend from subtropical semihumid at the northern border of Darling Range to tropical arid at the Pilbara semidesert. The inhabited hosts include *Fabales*, *Myrtales*, *Proteales*, and *Santalales*. Most of the collections were on *Acacia*, and the majority of apothecia grew on bark of corticated branches, often in association with other species of *Orbilia*, mainly of section *Hemiorbilia*, but also with *Hysteriales*, *Ostropales*, *Patellariales*, and lichens.

Orbilia vibrioides Baral, Priou & G. Marson, **sp. nov.**, MB 813536 — Pls 370–371, Map 63

Etymology: named after the ascospores which resemble bacteria of the genus *Vibrio*.

Typification: USA, Arizona, Sedona, branch of *Arctostaphylos patula*, 8.V.1995, G. Marson (ex H.B. 5733c, M-0276606, holotype).

Latin diagnosis: *Apothecia rehydratata 0.14–0.9 mm diam., aurantiaca vel roseo-rubra, sessilia, margine laevi. Asci 8-spori, apice in statu emortuo valde crassitunicati. Ascosporae *3.5–5.3 × 1.8–3.3 µm, valde curvatae (botuliformes), apice rotundatae vel obtusae, basi leniter attenuatae, in statu vivo corpusculum refringens magnum, globosum vel lacrimiformem, ad apicem cuspide brevi affixum continentes. Cellulae vivae excipuli marginalis et paraphysium corpuscula globosa continentes. Habitat ad lignum vel corticem modice vel valde putridum ramulorum et ramorum siccorum fruticum et arborum angiospermarum vel coniferarum in zona temperate humida ad subtropica sub- vel semihumida Europae, Macaronesiae et Americae septentrionalis.*

Description: — **TELEOMORPH**: **Apothecia** rehydrated 0.14–0.2 up to 0.2–0.5(–0.9) mm diam., 0.07–0.18 mm high (receptacle 0.07–0.13 mm), pale to bright orange to rose-red, translucent, round, slightly undulating when large, scattered to densely gregarious in small groups; disc flat, margin ± distinct, 0–5 µm rising above disc, smooth; sessile, rarely with hidden stipe 0.09 × 0.1 mm, slightly immersed in algal layer; dry bright to deep (pink-)orange to brick-red. **Asci** *33–35 {1} or 42–45 {1} or 57–60 {1} × (5.2–)5.5–6(–6.8) {3} µm, †(20–)26–57 × (4–)4.5–5.5(–6.7) µm {7}, 8-spored, orientation irregular, pars sporifera *20–22 µm; **apex** (†) hemispherical to very slightly conical or truncate, dome †1.5–2.5(–3.5) → 1–2.5 µm thick {9} (in KOH thicker than in H_2O), with small apical chamber, endotunica in CR_{SDS} light rose-red, IKI very pale reddish-grey (dextrinoid); **base** with short to long, thick to thin, flexuous stalk, L-, Y- or h-shaped. **Ascospores** *(3.5–)3.8–5(–5.3) × (1.8–)2–2.5(–3.3) µm {11}, †3.5–5.5 × 1.8–2.7 µm {3}, cashew-shaped, apex rounded to obtuse, base partly slightly

attenuated, (very) strongly curved by (90–)120–180°, sometimes very slightly helicoid; **SBs** apically attached to spore wall, *1–2(–2.2) × 0.7–1.3 µm {5}, broadly tear-shaped to globose {11}, apically narrowed to small point, mostly with a very short filum; with a few minute LBs. **Paraphyses** apically uninflated to slightly clavate-capitate, terminal cells *(6–)8–12(–15) × (1.7–)2–3(–3.3) µm {3}, †1.5–3 µm wide {2}, straight, sometimes ± flexuous, lower cells *(4–)5–12 × 1.8–3.2 µm {4}; never or sometimes branched at upper septum. **Medullary excipulum** (very) pale rose, ~10–50 µm thick, of dense textura angularis(-intricata), medium sharply delimited. **Ectal excipulum** very pale rose, sometimes pale orange near margin, of thin-walled, ± vertically oriented t. angularis-globulosa from base to mid flanks or margin, 30–40(–80) µm thick near base, cells *5–15(–18) × 5–13(–16) µm {4}; 15–25 µm thick near margin, of t. prismatica-porrecta oriented at a 30–80° angle to the surface, outer part also at 10–30°, marginal cortical cells cylindric-clavate, (†) somewhat thick-walled, */†(5–)6–12(–16) × 2.5–3.5(–5) µm {3}, **glassy processes** absent. **Anchoring hyphae** ± abundant, *1.8–3 µm wide (up to 5 µm near insertion), walls 0.2(–0.3) µm thick {3}. **SCBs** in paraphyses and excipulum absent or often present, globose. **Exudate** very pale to light chlorinaceous- or sulphur-yellow, over paraphyses (0.3–)1–2(–4) µm thick, continuous to coarsely cloddy, ± loosely attached; over margin rough-cloddy, (0–)1–5(–8) µm thick. **— ANAMORPH**: unknown (but see below).

Habitat: collected 0.1–3 m above the ground, corticated to decorticated, 2.5–45 mm thick twigs and branches of *Arbutus andrachne A. menziesii* {1}, *Arctostaphylos patula* {1}, *Buxus sempervirens* {1}, *Corylus avellana* {1}, *Erica* sp. {1}, *E. scoparia* {1}, *Ilex aquifolium* {1}, *Laurus novocanariensis* {1}, *Mahonia dictyota* {1}, *Malus × scheideckeri* {1}, *Picea abies* {4}, *Pinus halepensis* {1}, *Quercus ilex* {1}, *Salix* sp. {1}, *Sambucus* sp. {1}, *Taxus baccata* {1}, *Ulex europaeus* {3}, partly on or close to long decorticated old wounds, on 0.1–1 mm deep slightly to strongly decayed wood {20} and bark {4}, greyed, covered by green algae. **Associated**: *Claussenomyces* sp. {1}, *Chrysodisca peziculoides* {1}, *Cryptodiscus foveolaris* {1}, *C. tabularum* {1}, *Dacrymyces* sp. {1}, *Diplolaeviopsis* sp. {1}, *Durella* sp. {2/1}, *D. ?connivens* {1}, *Gloniella* sp. {1}, *Hysterium* sp. {1}, *?Hysteropatella* sp. {1}, *Mellitiosporiella pulchella* {1}, *M. macrospora* {1}, *Mollisia ?melaleuca* {1}, *M. obscura* {1}, *Neodasyscypha cerina* {1}, *Orbilia aprilis* {1}, *O. cylindrospora* {4}, *O. ?dixiensis* {1}, *O. eucalypti* {1}, *O. euonymi* {2}, *O. flavida* {1}, *O. hesperidea* {1}, *O. pleionavajoana* {1}, *O. vinosa* {2}, *O. ?subulivinosa* {1}, *Parmelia sulcata* {1}, *Perrotia flammea* {1}, *Phragmiticola* sp. {1}, *Pragmopora* sp. {1}, *Propolis viridis* {2}, *Sarea difformis* {1}, *Stictis friabilis* {1}, *Trentepohlia* sp. {1}, *Triblidium calyciiforme* {1}, *Usnea* sp. {1}. **Desiccation tolerance**: fully viable for at least 6 weeks, paraphyses and excipular cells still alive after 22 months. **Altitude**: 3–510 m a.s.l. (central and atlantic Europe), 12–1275 m (southern Europe), 90–180 m (northern North America), 1320 m (southern North America). **Geology**: Cambrian, Ordovician, Silurian & Devonian silt- & sandstone, Pennsylvanian-Permian red sandstone, Muschelkalk, Cretaceous sand-, silt- & limestone, dolomite, Pleistocene sand; granite, diorite, gabbro, basalt, mica schist & gneiss. **Phenology**: V–VI, VIII–III (throughout the year, long-lived).

Taxonomic remarks. *Orbilia vibrioides* is well characterized by its small, strongly curved (cashew-shaped) ascospores and thick apical domes. The inner part of the apical dome reacts very pale reddish-grey (dextrinoid) in IKI (KOH-pretreated, negative in MLZ, observed in H.B. 5961b and 6696b). In those species of section *Orbilia* with similar cashew-shaped spores the dead asci have thin-walled truncate apices.

For the very closely related *O. graminis* on herbaceous monocots see p. 750. Two samples on *Pinus sylvestris* from southern France (Pl. 372: 5) are intermediate to *O. graminis* in having subulate SBs and are mentioned under that species.

Variation. There is considerable variation in spore and ascus size, and especially in the size of the spore body, but without apparent ecological correlation. The collections from Madeira and Arizona showed the largest dimensions (ascus length, apical thickening, spore length and width). The exudate on the apothecial margin is often rather thick and layered, resembling stratified glassy caps. However, its yellow colour in water and the lilac stain in CRB suggest that there is only exudate present.

Anamorph. Tridentaria-like conidia emerged in great number from the hymenium of a mature apothecium of *O. vibrioides* (Pl. 370: 1g). However, a parasitic infestation is imaginable since we found two times very similar conidia emerging from the apothecia of *O. cylindrospora* (section *Orbilia*; Pls 370: 4g; 371: 5b). Yet, in these two collections *O. vibrioides* grew in association. It remains open whether the tridentaria-like conidia belong to any of the two species (see also under *Hyalorbilia hergiswiliana*, p. 433, for which a parasitic growth in hymenia of *Orbilia vinosa* and perhaps *O. montigena* is considered). The conidia in the three samples associated with *O. vibrioides* were 3–4-armed, total size †/*19–38 × (5–)13–33 µm, stipe 8–12.5 × 2–3.3 µm, 0–1-septate, arms (6.5–)10–27(–36) × 2.3–4 µm, 1–2 or (2–)3–4(–6)-septate, slightly to strongly tapering, ± diverging; conidiophores short, */†~2–10 × 1.5–2.2 µm. In a further collection of *O. vibrioides* (H.B. 9822b), a similar 3-armed conidium was seen on the natural substrate. Comparable conidia but with more than 3–4 arms were observed in association with *O. pleiomicrosoma* (Pls 813–814), partly also ermerging from the apothecia.

In two further collections of *O. vibrioides* trinacrium-like (Y-shaped) conidia were observed on the natural substrate near the apothecia (see IVV): in H.B. 7376 with two arms, total size †27–36(–51) × 27–48 µm, stipe 13–15 × 2–2.6 µm, 1–3-septate, arms only slightly tapering, 16–27 × 2–3 µm, 2–4(–7)-septate; in J.P.P. 11207 with larger conidia, one of the two conidia with one arm branched again (similar as in *H. hergiswiliana*).

Phylogeny. Sequences gained from apothecia collected in the departments Ardèche (on *Picea*) and Var (on *Arbutus*) comprise SSU, ITS, and LSU. The S943 and S1506 introns are present in the former but absent in the latter sample. In addition, a distance of 8 % in the ITS is observed between the two samples, but only 0.8 % (5 nt) in the LSU D1–D2, and 0 % in LSU D3–D5 and SSU V8–V9.

An uncultured DNA isolate from *Picea* shoots and needles in Lithuania (KP897546, clone 2168_426, Menkis et al. 2015), comprising partial 5.8S and entire ITS2, shows in the ITS2 region a perfect match to *O. vibrioides* on *Picea* (except for 2 inserts), though differing by 4 nt in the 5.8S, probably by mistake. A total of nine sequences of *O. vibrioides* from two remote sites in Lithuania were obtained by Menkis et al., all from shoots of *Picea* damaged by the spruce bud scale, showing a variation of 0–2.5 % in the ITS2 region (A. Menkis pers. comm.). No doubt, all these conifericolous strains are conspecific, and it might be interpreted as a hint that samples on coniferous substrate here referred to *O. vibrioides* belong to a species of their own.

Our analyses place *O. vibrioides* and *O. graminis* in a strongly (ITS+LSU, LSU) or medium (SSU+ITS+LSU, ITS, S1506 intron) supported clade (Phyls 7, 9–10, S12, S13), but with a distance of 15.5–17 % in the ITS, 21.5 % in the intron, and 4 % in the LSU D1–D2. This clade, which also includes *O. myrioobliqua* and *O. helicoobliqua* (shown in Phyls 9–10), clustered in all these analyses unresolved among the other clades of section *Hemiorbilia*. BLAST searches in GenBank for LSU D1–D2 yielded species of series *Hesperideae* and *Hemiorbilia* with a 95 % similarity. Also the ITS region best matches members of section *Hemiorbilia*, though with high distance and ambiguous alignment. BLAST searches for the intron yielded members of various groups of *Orbilia* with a distance of ~22–25 %, and for the SSU V8–V9 region members of section *Hemiorbilia*.

Ecology. Contrary to the similar *O. graminis*, *O. vibrioides* was so far only found on woody substrates: slightly to strongly decayed wood and bark of xeric twigs and branches of both coniferous and angiosperm trees and shrubs. The collections are mainly from humid to semihumid regions of Europe, especially from the supra- to mesotemperate or supra- to mesosubmediterranean atlantic west (Great Britain, France, Spain), also from subcontinental central Europe (Thüringen), orotemperate southern France (Massif central), hemiboreal Lithuania (DNA extract), and mesomediterranean France and Dalmatia. One record was from mesosubmediterranean (sub)humid laurel forests in Madeira (Macaronesia). Three samples from western North America include the mild-maritime humid Pacific northwest (southern end of Coast Mountains) and warm-continental subhumid west (manzanita chaparral scrubland at Mogollon Rim adjacent to Sonoran Desert). The vegetation includes different laurel forests (*Lauro novocanariensis-Perseetum indicae*, *Ilici canariensis-Ericetum platycodonis*), *Ulex* shrubs, a *Quercus*-*Castanea* forest, and a submediterranean *Quercus ilex* forest, and in Thüringen a cold-temperate montane *Picea* plantation.

Map 63. Known distribution of *O. vibrioides* in Europe and Macaronesia.
